To determine whether there is any difference in diagnosing interstitial lung disease (ILD) using volume high-resolution CT (VHRCT) compared with conventional high-resolution CT (CHRCT).*Methods and Materials A retrospective study was carried out in 31 patients who were diagnosed with ILD between December 2017 and March 2018. The CT scans were all performed using a 256-row detector CT (Revolution CT, GE Healthcare). All patients underwent VHRCT (120kVp, SmartmA, 80mm, Helical, 50% pre- Asir-V) and conventional high-resolution CT (CHRCT) scan. Two experienced radiologists independently assessed the subjective image quality. Both were blinded to scanning parameters of patients. Multiple radiographic patterns include interstitial interlobular septa thickening, intralobular interstitial thickening, ground glass opacity, honey combing and cyst, subpleural line, bronchiolectasis, micro nodules, bronchovascular bundles, respiratory artefact were assessed. CT values and image noise of the left ventricle, musculus erector spinae and thoracic spine were measured by a single observer.*Results CHRCT and VHRCT had no significant difference in recognising interstitial interlobular septa thickening, ground glass opacity, honey combing and cyst, subpleural line, bronchiolectasis, micro nodules and bronchovascular bundles (P=0.831, 0.209, 0.265, 0.133, 0.576, 0.148, 0.082). The subjective image quality of intralobular interstitial thickening was higher in VHRCT scan mode than CHRCT mode (4.56±0.51; 3.88±0.89, P=0.019). VHRCT imaging revealed higher subjective image quality of respiratory artefact (4.42±0.96; 3.68±0.87;P=0.000). CT value of the left ventricle, musculus erector spinae and thoracic spine were not significantly different between the two groups(P=0.668,0.327,0.479,P>0.05).Significant differences in noise of left ventricular (36.47±4.93; 31.46±7.83, P=0.000), musculus erector spinae (38.72±5.66; 32.07±6.40, P=0.000) and vertebral (65.51±21.57;49.53±13.45, P=0.001) between VHRCT and CHRCT.*Conclusions There was no significant differences in subjective image quality between VHRCT and CHRCT. VHRCT scans were considered to be significantly better than CHRCT scans for interstitial interlobular septa thickening and respiratory artefact*Clinical Relevance/Application VHRCT has a comparable diagnostic capability with CHRCT. It is potentially feasible to replace a separate CHRCT with VHRCT.

RESULTS

CHRCT and VHRCT had no significant difference in recognising interstitial interlobular septa thickening, ground glass opacity, honey combing and cyst, subpleural line, bronchiolectasis, micro nodules and bronchovascular bundles (P=0.831, 0.209, 0.265, 0.133, 0.576, 0.148, 0.082). The subjective image quality of intralobular interstitial thickening was higher in VHRCT scan mode than CHRCT mode (4.56±0.51; 3.88±0.89, P=0.019). VHRCT imaging revealed higher subjective image quality of respiratory artefact (4.42±0.96; 3.68±0.87;P=0.000). CT value of the left ventricle, musculus erector spinae and thoracic spine were not significantly different between the two groups(P=0.668,0.327,0.479,P>0.05).Significant differences in noise of left ventricular (36.47±4.93; 31.46±7.83, P=0.000), musculus erector spinae (38.72±5.66; 32.07±6.40, P=0.000) and vertebral (65.51±21.57;49.53±13.45, P=0.001) between

VHRCT and CHRCT.

CLINICAL RELEVANCE/APPLICATION

VHRCT has a comparable diagnostic capability with CHRCT. It is potentially feasible to replace a separate CHRCT with VHRCT.

SDP-PH-79   Evaluation Of Various Non-Gaussian Diffusion Models For The Classification Of Peripheral Nerve Sheath Tumors In Patients With Neurofibromatosis Type 1

Participants
Michael G. Kaul, Hamburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Diffusion weighted imaging (DWI) can classify peripheral nerve sheath tumors (PNST) in patients with neurofibromatosis type 1 (NF1). The analysis of perfusion/diffusion effects maybe als of interest for therapy monitoring. The intravoxel incoherent motion (IVIM) model is known to model perfusion but also for its less numerical robustness. Therefore we evaluated six non-Gaussian models regarding the numerical stability and their feasibility of distinguishing between benign and malignant PNST using small and middle ranged b-values that are commonly scanned for an IVIM-analysis.*Methods and Materials In a retrospective study 29 examinations of 26 patients were examined in a 3T MRI scanner. DWI-data was fitted to a monoexponential apparent-diffusion-coefficient (ADC) model using b-values of 0,300,400,600,800s/mm². Aditional b-values 10,20,30,50,70,100 were included to be sensitiv for perfusion when fitting six non-Gaussian models (IVIM, kurtosis, stretched-exponential, and the statistical models based on truncated Gaussian, gamma, and beta distributions). Tests for significance and receiver-operating-characteristic (ROC) analysis were performed. Numerical aspects of the fitting processes were evaluated.*Results All fitted models provided at least one parameter that showed significant difference between the two entities. Diffusion coefficients were generally significantly higher in benign than in malignant tumors. Malignant tumors showed a stronger deviation from a monoexponential behavior than in benign tumors as the stretch-exponent of the stretched-exponential model was smaller. The non-Gaussian model with the lowest values for AIC and BIC using all eleven b-values was the stretched exponential model. Except of the IVIM model R² values and the analyzable area of the other models were on a similar high level but the ADC model performed the best. The ADC model provided an area-under-the-curve (AUC) of 0.91 with sensitivity of 94% and specificity of 74%. The AUC values for the multi-variant regressions of the statistical models exceed the AUC of the ADC model, but their ROC curves differed not significantly.*Conclusions Non-Gaussian models did not perform significantly better in differentiation than the ADC model with a reduced number of b-values. The IVIM model performed worst. The other non-Gaussian models provide with the kurtosis and stretch exponent additional parameters, which are sensitive to the perfusion effects imaged by small b-values.*Clinical Relevance/Application As PET/CT comes with a radiation burden it is of interest to improve the diagnostic value of MRI. This is to importance especially in children and young adults where a PET examination is only given after a strong indication.

RESULTS

All fitted models provided at least one parameter that showed significant difference between the two entities. Diffusion coefficients were generally significantly higher in benign than in malignant tumors. Malignant tumors showed a stronger deviation from a monoexponential behavior than in benign tumors as the stretch-exponent of the stretched-exponential model was smaller. The non-Gaussian model with the lowest values for AIC and BIC using all eleven b-values was the stretched exponential model. Except of the IVIM model R² values and the analyzable area of the other models were on a similar high level but the ADC model performed the best. The ADC model provided an area-under-the-curve (AUC) of 0.91 with sensitivity of 94% and specificity of 74%. The AUC values for the multi-variant regressions of the statistical models exceed the AUC of the ADC model, but their ROC curves differed not significantly.

CLINICAL RELEVANCE/APPLICATION

As PET/CT comes with a radiation burden it is of interest to improve the diagnostic value of MRI. This is to importance especially in children and young adults where a PET examination is only given after a strong indication.

SDP-PH-8   Robustness Of CT Radiomics Features: Did SECT And DECT Match To Each Other?

Participants
Jingyu Zhong, MD, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To identify the robust radiomics features (RFs) for single-energy (SE) CT and dual-energy (DE) CT.*Methods and Materials A standardized phantom with sixteen rods of different density was used to test the RF robustness by using test-retest analysis, by using intra-scanner analysis of different scan modes, and by comparing ten different scanners. The acquisition parameters were selected to present classical abdomen-pelvic examination with fixed field of view, reconstruction matrix, slice thickness. Images of SE scan at 120 kV, DE scan at mixed energy 120 kV and virtual monoenergetic imaging (VMI) at 70 keV were used for analysis. Sixteen ROIs for according rods were drawn with a rigid registration was made to avoid variations in segmentation. RFs were extracted via Pyradiomics platform. RFs repeatability was assessed by Bland-Altman analysis. Robust RFs were selected by using the intraclass correlation coefficient (ICC), concordance correlation coefficient (CCC), both with a cutoff of 0.90, and coefficient of variation (CV) with a cutoff of 10%.*Results A total of 94 RFs including 19 first order RFs and 75 texture RFs were assessed. The test-retest analysis presented that 91.5% of the RFs are repeatable. The intra-scanner analysis within sixteen rods demonstrated that only 15.9%, 11.8%, and 9.6% of the RFs were with ICC > 0.90, while 14.8%, 10.8%, and 9.6% were with CCC > 0.90 for SE 120 kV vs. DE mixed 120 kV, DE mixed 120 kV vs DE VMI 70 keV, and SE 120 kV vs. DE VMI 70 keV comparison, respectively. The inter-scanner analysis showed that percentage of RFs with CV < 10% extracted from each of sixteen rods were from 5.3% to 23.4%, from 10.6% to 31.9%, and from 8.5% to 26.6%, on SE 120 kV, DE mixed 120 kV, and DE VMI 70 keV, respectively.*Conclusions The majority of RFs from the same CT scanner with different scan modes were not reproducible. The RFs extracted from SE 120 kV, DE mixed 120 kV, and DE VMI 70 keV did not matched to each other, even multiple acquisition parameters were fixed. RFs involving multiple CT scanners with the same scan mode were of low reproducibility, and indicated large material differences.*Clinical Relevance/Application Radiomics results from multiple CT scanners with various scan modes must be interpreted with caution because of potential for nonreproducible data.

RESULTS

A total of 94 RFs including 19 first order RFs and 75 texture RFs were assessed. The test-retest analysis presented that 91.5% of the RFs are repeatable. The intra-scanner analysis within sixteen rods demonstrated that only 15.9%, 11.8%, and 9.6% of the RFs were with ICC > 0.90, while 14.8%, 10.8%, and 9.6% were with CCC > 0.90 for SE 120 kV vs. DE mixed 120 kV, DE mixed 120 kV vs

DE VMI 70 keV, and SE 120 kV vs. DE VMI 70 keV comparison, respectively. The inter-scanner analysis showed that percentage of RFs with CV < 10% extracted from each of sixteen rods were from 5.3% to 23.4%, from 10.6% to 31.9%, and from 8.5% to 26.6%, on SE 120 kV, DE mixed 120 kV, and DE VMI 70 keV, respectively.

CLINICAL RELEVANCE/APPLICATION

Radiomics results from multiple CT scanners with various scan modes must be interpreted with caution because of potential for nonreproducible data.

SDP-PH-80 Non-contrast Lung Functional Imaging: T2*, Ventilation, And Perfusion

Participants
Mitsue Miyazaki, PhD, La Jolla, California (*Presenter*) Research Grant, Canon Medical Systems Corporation

PURPOSE

Ultra-short TE (UTE) imaging with TE of less than 0.1 ms allows visualization of lungs despite low proton density and short T2* [1]. To demonstrate the ability to measure lung volumes at both inspiration and expiration, estimate T2* maps in lungs, and visualize pulmonary vessels using free breathing 3D UTE.*Methods and Materials The study was carried out on a clinical 3T (Vantage Galan, version 6, Canon Medical, Japan) scanner on 4 healthy volunteers (46 ± 23 years) after obtaining IRB approved written informed consent. Images were acquired using a body SPEEDER coil. The scanning protocol included the following series: i) 3D UTE without fat suppression (TE/TR = 96 μ s/3.7 ms, NEX = 1, FA = 5°, in the coronal orientation FOV = 40× 40 cm, matrix size 256× 256); ii) 3D UTE same as in i) but with fat suppression: five SPectral Adiabatic Inversion Recovery (SPAIR) pulses per 64 segments were applied, resulting in approximately one SPAIR per 50 UTE lines. Both series used respiratory bellows and were scanned during the inspiratory period. Non-fat suppressed data were also acquired during expiration. For each series, 64 segments with approximately 250 lines per respiratory cycle were collected resulting in over 16000 lines and about 8% of k-space filled; and iii) multi-echo UTE (four TEs = 96 μ microseconds / 2.3/4.5/6.7 ms, TR = 12.5ms, NEX = 1, FA = 4°, in the coronal orientation FOV = 50× 50 cm, matrix size 256× 256) with the respiratory bellows set for the expiratory phase of the cycle.*Results The fat signal around the heart is suppressed demonstrating better visualization of myocardium and blood. In addition, proximal pulmonary vessels are unambiguously defined with fat suppression. Average lung volumes measured from the segmentation of the UTEs images obtained at inspiration and expiration phase were 3.25 ± 0.13 / 2.68 ± 0.08 liters respectively. The average T2* for lung was 0.90 ± 0.08 ms; an example of the colormap superimposed over first echo (TE = 0.1 ms) image is shown in Figure 1. Calculated mean specific ventilation was 0.11 ± 0.02.*Conclusions Under free breathing, lung studies of T2*, expiratory/inspiratory volume, specific ventilation and the pulmonary vasculature, are reported. These may provide useful information in patients with lung diseases.References [1] Bergin CJ, et al. Radiology. 1991; 179: 777-81. [2] Pell GS, et al. JMRI. 2006; 23: 248-252. [3] Dante PI, et al. [7] Theilmann, RJ, et al. JMRI 2009; 30: 527-534. *Clinical Relevance/Application Lung health study including lung ventilation, T2*, and perfusion can be possible under non-radiation, non-contrast, and free-breathing MRI.

RESULTS

The fat signal around the heart is suppressed demonstrating better visualization of myocardium and blood. In addition, proximal pulmonary vessels are unambiguously defined with fat suppression. Average lung volumes measured from the segmentation of the UTEs images obtained at inspiration and expiration phase were 3.25 ± 0.13 / 2.68 ± 0.08 liters respectively. The average T2* for lung was 0.90 ± 0.08 ms; an example of the colormap superimposed over first echo (TE = 0.1 ms) image is shown in Figure 1. Calculated mean specific ventilation was 0.11 ± 0.02.

CLINICAL RELEVANCE/APPLICATION

Lung health study including lung ventilation, T2*, and perfusion can be possible under non-radiation, non-contrast, and free-breathing MRI.

SDP-PH-81 Identification Of The Optimal Adaptive Statistical Iterative Algorithm Reconstruction-v Blending Level For Low Dose Chest Ct

Participants
Yanhong Zhao, MMed,MMed, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To assess the image quality of chest CT on with different blending levels of adaptive statistical iterative reconstruction V (ASiR-V) algorithm, and investigate the optimal blending level of ASiR-V algorithm for low dose chest CT.*Methods and Materials Thirty patients suspected thoracic disease were enrolled. All patients underwent chest CT on a 256 row wide-coverage volumetric CT (Revolution CT, GE healthcare, Milwaukee, WI). The Tube voltage was 80 kV, the automatic tube current modulation technique was used with noise index of 22. For each patient, 11 image sets were reconstructed by using lung algorithm and standard algorithm with ASiR-V blending level from 0 to 100% with 10% increasement. Two radiologists independently evaluated the image quality subjective score with 5-point scale for the image noise, artifacts and the capacity of the tiny structures of bronchovascular bundles. The image noise of aorta, lung tissue and muscle was measured. Measurement data among different groups was compared with two-way ANOVA.*Results With ASiR-V blending level increase, the image noise of aorta, lung tissue and muscle decreased gradually (p<0.05). At 70% and 80% blending levels of ASiR-V, the image scores of lung algorithm were found the highest(4.88±0.31 and 4.72±0.52), and images scores of these two image sets were found no statistical difference(P=0.102). At 60% and 70% blending levels of ASiR-V, the image scores of standard algorithm were found the highest(4.55±0.46 and 4.72±0.43), and images scores of these two image sets had no statistical difference(P=0.100). At 40%, 50%, 60%, 70%,80% and 90% levels of ASiR-V groups, the image score of lung algorithm was above 3.5 points. At 40%, 50%, 60%, 70% and 80%, the image score of standard algorithm was above than 3.5 points.*Conclusions ASiR-V algorithm could reduce image noise of low dose chest CT. At 70% and 80% blending levels of ASiR-V, image quality were found best for lung algorithm,and at 60% and 70% blending levels of ASiR-V, image quality were best for standard algorithm. High blending level of ASiR-V may cause "fuzzy" effects in the images.*Clinical Relevance/Application ASiR-V algorithm could reduce image noise of low dose chest CT. At 70% and 80% blending levels of ASiR-V, image quality were found best for lung algorithm,and at 60% and 70% blending levels of ASiR-V, image quality were best for standard algorithm.

RESULTS

With ASiR-V blending level increase, the image noise of aorta, lung tissue and muscle decreased gradually (p<0.05). At 70% and

80% blending levels of ASiR-V, the image scores of lung algorithm were found the highest(4.88±0.31 and 4.72±0.52), and images scores of these two image sets were found no statistical difference(P=0.102). At 60% and 70% blending levels of ASiR-V, the image scores of standard algorithm were found the highest(4.55±0.46 and 4.72±0.43), and images scores of these two image sets had no statistical difference(P=0.100). At 40%, 50%, 60%, 70%,80% and 90% levels of ASiR-V groups, the image score of lung algorithm was above 3.5 points. At 40%, 50%, 60%, 70% and 80%, the image score of standard algorithm was above than 3.5 points.

CLINICAL RELEVANCE/APPLICATION

ASiR-V algorithm could reduce image noise of low dose chest CT. At 70% and 80% blending levels of ASiR-V, image quality were found best for lung algorithm,and at 60% and 70% blending levels of ASiR-V, image quality were best for standard algorithm.

SDP-PH-82 Pneumothorax Detection In CT Localizer Scans Using Faster R-CNN

Participants
Michael Grass, PhD, Hamburg, Germany (*Presenter*) Employee, Koninklijke Philips NV

PURPOSE

The localizer scans acquired as part of computed tomography (CT) exams are essential for planning purposes. In addition, they also offer promising options for the early detection of pathologies, especially for critical findings such as pneumothorax. Even though Deep Learning techniques have been successfully applied for a broad range of medical imaging applications, the analysis of localizer images has received limited attention. Depending on the clinical indication, localizer scan planning exhibits a considerable variability with regard to the z-coverage. Therefore, we investigate the feasibility of a joined anatomy localization, and pathology classification, using a Faster R-CNN architecture.*Methods and Materials For a case study, 576 patients with and 554 without pneumothorax were identified from radiology reports using Natural Language Processing (NLP), covering 1300 anterior-posterior (AP) and 1200 lateral (LAT) scans. Next to the report-based findings, the lung region was annotated in every localizer image. For the localization of the lung and the detection of a potential pneumothorax, a Faster R-CNN architecture was employed. Compared to a conventional CNN, this network architecture comprises multiple sub-networks, including a Region Proposal Network (RPN). The RPN predicts the object regions, which are subject to classification. For this application, the Faster R-CNN was trained to localize four classes (lung region with and without pneumothorax in PA and LAT images). For the evaluation, the Faster-RCNN was fine-tuned in a patient stratified 5-fold cross-validation scheme. The network was trained with Stochastic Gradient Decent, an initial learning rate of 0.0001 and a decay of 5% after each epoch. Furthermore, data augmentation was employed including translations, rotations, and additive noise.*Results For the identification of the lung area, average Dice values of 0.94 (AP) and 0.91 (LAT) were obtained, indicating a precise localization in both image types (see Fig. 1). Since every imaging study was associated with one or more images (including multiple PA and LAT scans), an average prediction score was computed based on all images, resulting in an average AUC of 0.85.*Conclusions In this study, we investigated the feasibility of a joined anatomy localization and pathology classification using a Faster R-CNN architecture. This architecture can handle varying fields of view, which is an important step towards the practical deployment of such technologies.*Clinical Relevance/Application The study shows promising options for the detection of pathologies using CT localizer images. Potential applications include the early diagnosis of critical and incidental findings for worklist prioritization and protocol optimization.

RESULTS

For the identification of the lung area, average Dice values of 0.94 (AP) and 0.91 (LAT) were obtained, indicating a precise localization in both image types (see Fig. 1). Since every imaging study was associated with one or more images (including multiple PA and LAT scans), an average prediction score was computed based on all images, resulting in an average AUC of 0.85.

CLINICAL RELEVANCE/APPLICATION

The study shows promising options for the detection of pathologies using CT localizer images. Potential applications include the early diagnosis of critical and incidental findings for worklist prioritization and protocol optimization.

SDP-PH-83 Accuracy Of Iodine Quantification And Image Quality With Dual-energy CT Using Deep Learning-based Image Reconstruction In Abdomen: Preliminary In Vitro And Vivo Study

Participants
Tomoki Maebayashi, Kobe, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Dual-energy CT (DECT) has potential benefit of quantitative capability of iodinated contrast agent. However, increased image noise potentially affects accurate measurement of the iodine quantification in the tissue on iodine density images. Deep learning-based image reconstruction algorithm has been recently implemented into fast-kilovoltage (kV) switching DECT to improve image quality. The purpose of this study was to determine the accuracy of iodine quantification and image quality with DECT across three different image reconstruction algorithms in a phantom experiment and abdominal clinical study.*Methods and Materials In a phantom experiment, an elliptical torso phantom containing iodine (1, 3, 5, 8, and 12 mgI/mL) was imaged with fast-kV switching DECT (Revolution CT, GE Healthcare) five times for CTDIvol levels of 9, 15, and 24 mGy. All images were reconstructed with 1.25 mm section thickness using conventional (FBP), iterative (ASiR-V 30% and 50%), and deep learning-based (True Fidelity, medium) reconstruction algorithms on iodine density images. The measured and nominal iodine concentrations were compared with the percentage of error and root mean square deviation (RMSD) among the four reconstruction algorithms for each CTDIvol level. In a clinical study, abdominal contrast-enhanced CT was acquired in 30 patients (mean age, 70.3 years; mean body mass index 22.2 kg/m2) in the same CT scanner. All images were reconstructed with 1.25 mm section thickness using ASiR-V 30%, ASiR-V 50% and True Fidelity medium. On arterial and portal venous phase images, iodine density and image noise of the artery, portal vein, liver, and pancreas were measured and compared among the three reconstruction algorithms by using one-way repeated measures ANOVA test.*Results In the phantom experiment, the measured values of the percentages of error ranged from -6.11% to 7.57%, and the RMSDs were equivalent among the four reconstruction algorithms for each level of CTDIvol. The error and RMSDs were relatively larger for CTDIvol of 9 mGy. In the clinical study, no significant differences were observed among the three reconstruction algorithms regarding iodine density in each tissue (P=.999 for all). Image noise with True Fidelity was lower than that with ASiR-V 30% (P<.001) and ASiR-V 50% (P<.1).*Conclusions Accurate iodine quantification can be achieved across different image reconstruction algorithms in fast-kV switching DECT. Deep learning-based reconstruction has potential advantages of quantitative abdominal DECT with high image quality.*Clinical Relevance/Application Fast-kV switching dual-energy CT with deep learning-based image reconstruction algorithm can offer accurate iodine quantification with controlled image noise.

RESULTS

In the phantom experiment, the measured values of the percentages of error ranged from -6.11% to 7.57%, and the RMSDs were equivalent among the four reconstruction algorithms for each level of CTDIvol. The error and RMSDs were relatively larger for CTDIvol of 9 mGy. In the clinical study, no significant differences were observed among the three reconstruction algorithms regarding iodine density in each tissue (P=.999 for all). Image noise with True Fidelity was lower than that with ASiR-V 30% (P<.001) and ASiR-V 50% (P<.1).

CLINICAL RELEVANCE/APPLICATION

Fast-kV switching dual-energy CT with deep learning-based image reconstruction algorithm can offer accurate iodine quantification with controlled image noise.

SDP-PH-84 Practical Tools For An Objective Image Quality Characterisation Of An Angiographic Equipment. Detection Of Moving Details And Contrast Media Perfusion Of Blood Vessels With Generalised Spatio-temporal Model Observers

Participants
Raffaele Villa, Monza, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To propose an objective image quality characterisation of an angiographic equipment, applying generalised spatio-temporal model observer with details in motion and simulated blood vessels perfusion of contrast media.*Methods and Materials Cerebral and cardiac protocols, characterized by different fps, dose levels and filtration, have been investigated. Contrast media flow has been simulated with the moving component of the CIRS Dynamic Thorax Phantom. Image quality of pulsed fluoroscopy has been characterised with circular details of different diameters (from 2 to 6 mm to simulate typical small vessels sizes) and moved, with a speed ranging from 2.5 to 10 mm/s, in order to simulate blood flow. Furthermore, Digital Subtraction Angiography (DSA) image quality has been characterised using cylindrical glue cylinders, with diameters of 3 and 5 mm, moved with speeds ranging from 5 to 10mm/s to simulate contrast media perfusion. Non-Prewhitening Eye filter (NPWE) with eye spatio-temporal contrast sensitivity function and Channelized Hotelling Observer (CHO) with spatio-temporal Gabor filters have been used to evaluate detection performances.*Results Effects of acquisition parameters, dose level and frame rate on pulsed fluoroscopy show consistent results especially with NPWE. CHO show less consistent results, especially comparing images with framerate and temporal resolution, suggesting the need for a deeper investigation. Simulation of Contrast media perfusion with DSA protocols shows analogous results, especially comparing the standard protocol and the low dose one.*Conclusions Results underline the potential of simulating the perceived clinical image quality with mathematical observers.*Clinical Relevance/Application Image Quality characterisation is still an open topic, especially with DSA that lack a consolidated objective approach, able to simulate contrast media perfusion that taken into account temporal resolution properties and lag.

RESULTS

Effects of acquisition parameters, dose level and frame rate on pulsed fluoroscopy show consistent results especially with NPWE. CHO show less consistent results, especially comparing images with framerate and temporal resolution, suggesting the need for a deeper investigation. Simulation of Contrast media perfusion with DSA protocols shows analogous results, especially comparing the standard protocol and the low dose one.

CLINICAL RELEVANCE/APPLICATION

Image Quality characterisation is still an open topic, especially with DSA that lack a consolidated objective approach, able to simulate contrast media perfusion that taken into account temporal resolution properties and lag.

SDP-PH-85 The Accuracy Of Vbmd Using One-stop-shop Low-dose CT Lung Screening Combined With Upper Lumbar Spine Qct Using Deep Learning Iterative Reconstruction Compared With Adaptive Statistical Iterative Reconstruction (asir-v): A European Spine Phantom Study

Participants
Ya Li I, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this phantom study is to assess the accuracy of vBMD using the above scanning protocol using DLIR compared with ASiR-V.*Methods and Materials The image acquisitions were performed on Revolution CT (GE Healthcare, Waukesha, WI) using ESP (No. 145, Germany ORM company) reconstructed with three levels of TrueFidelityTM DLIR (low, medium and high) at 0.25mGy and 0.75mGy. ESP contains three nominal trabecular BMD values of L1(50mg/cm3), L2(100mg/cm3), and L3 (200mg/cm3) of calcium hydroxypatite (HA) concentrations, respectively. The quality assurance (QA) phantom (Mindways software Inc., Austin, TX, USA) was scanned for bone densitometry calibration in this study, and the ESP was placed on top of the QA phantom. The phantoms were scanned ten times successively without repositioning. The images were transferred to the dedicated QCT PRO BMD workstation (Mindways QCT PRO workstation) and analyzed by the Mindways QCT PRO software (Mindways software Inc., Austin, TX, USA) to analyze the lumbar spine vBMD of the cancellous bone in three vertebral inserts. We firstly identified the L1, L2 and L3 vertebral inserts, manually placed three circular ROIs on sagittal images. A difference with P <0.05 was considered to be statistically significant.*Results In total, the average BMD values of L1, L2, L3 were 44.36 ±0.26, 97.48 ±0.13, 195.21± 0.17 mg/cm3, respectively, the average BMD values of three lumbar spine vertebral bodies was 111.67 ±0.15 mg/cm3. At two dose levels of 0.25mGy and 0.75mGy, for ASiR-V50% algorithm, the vBMD values of L1, L2, L3 were 43.72±0.97, 97.09±0.53, 193.80±0.46 mg/cm3, respectively; 44.12±0.83, 98.39±0.51, 195.30±0.40 mg/cm3, respectively. For DLIR-L, the vBMD values of L1, L2, L3 were 43.94±1.04, 97.42±0.44, 194.44±0.71 mg/cm3, respectively; 44.15±0.84, 96.26±0.43, 194.87±0.21 mg/cm3, respectively. For DLIR-M, the vBMD values of L1, L2, L3 were 45.12±0.45, 97.15±0.73, 195.71±0.75mg/cm3, respectively; 45.43±0.42, 96.86±0.71, 194.14±0.36mg/cm3, respectively. For DLIR-H, the vBMD values of L1, L2, L3 were 44.71±0.58, 98.92±0.55, 196.42±0.43mg/cm3, respectively; 44.41±0.45, 97.34±0.73, 197.03±0.43mg/cm3, respectively. There were no significant differences between three levels of DLIR and ASiR-V50% at two radiation dose levels (P>0.05).*Conclusions The vBMD values of L1, L2, and L3 were stable at different iterative reconstruction algorithms and radiation dose levels at 120kV tube voltage, which has high feasibility of assessing the vBMD values.*Clinical Relevance/Application The accurate measurement of osteoporosis for elderly.

RESULTS

In total, the average BMD values of L1, L2, L3 were 44.36 ±0.26, 97.48 ±0.13, 195.21± 0.17 mg/cm3, respectively, the average BMD values of three lumbar spine vertebral bodies was 111.67 ±0.15 mg/cm3. At two dose levels of 0.25mGy and 0.75mGy, for ASiR-V50% algorithm, the vBMD values of L1, L2, L3 were 43.72±0.97, 97.09±0.53, 193.80±0.46 mg/cm3, respectively; 44.12±0.83, 98.39±0.51, 195.30±0.40 mg/cm3, respectively. For DLIR-L, the vBMD values of L1, L2, L3 were 43.94±1.04, 97.42±0.44, 194.44±0.71 mg/cm3, respectively; 44.15±0.84, 96.26±0.43, 194.87±0.21 mg/cm3, respectively. For DLIR-M, the vBMD values of L1, L2, L3 were 45.12±0.45, 97.15±0.73, 195.71±0.75mg/cm3, respectively; 45.43±0.42, 96.86±0.71, 194.14±0.36mg/cm3, respectively. For DLIR-H, the vBMD values of L1, L2, L3 were 44.71±0.58, 98.92±0.55, 196.42±0.43mg/cm3, respectively; 44.41±0.45, 97.34±0.73, 197.03±0.43mg/cm3, respectively. There were no significant differences between three levels of DLIR and ASiR-V50% at two radiation dose levels (P>0.05).

CLINICAL RELEVANCE/APPLICATION

The accurate measurement of osteoporosis for elderly.

SDP-PH-86   Understanding The Role Of Imaging Factors In The Variability Of CT-based Texture Analysis (ctta) Metrics

Participants
Bino A. Varghese, PhD, Los Angeles, California (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the variability in CT-based texture analysis (CTTA) metrics across different 1) dose levels 2) reconstruction algorithms and 3) slice thickness*Methods and Materials A commercial anthropomorphic liver phantom CCT288 comprising of a simplified torso section with 7 cylindrical rods; four of the rods simulating liver tissue CT density within a liver morphology was imaged under a variety of routine clinical imaging protocols on a 16 cm detector GE Revolution CT scanner. We examined 3 sets of variations 1) three different slice-thicknesses: 0.625mm, 1.25mm and 2.5mm; 2) three different dose levels: standard dose of 13, 86 mGy (CTDIvol), 40 % reduction and 60 % reduction; and 3) two different reconstruction algorithms: a deep learning image reconstruction (DLIR-high) algorithm and a hybrid iterative reconstruction (IR) algorithm ASiR-V50% (AV50) were explored, with one scan for each variation. The texture panel comprised of 70 features belonging to 2 subgroups of texture extraction methods, namely histogram and intensity analysis. Generalized linear model was used to assess the linear and nonlinear change in radiomic features by each set of variation. Beta coefficients of each of the radiomic metrics were extracted from the images of all the 7 tissue rods.*Results First-order CTTA metrics including but not limited to coefficient of variation (CV), inter-quartile range (IQR) and standard deviation (SD) were observed to have a high positive beta coefficient indicative of an increase with reduction in dose and slice thickness. This is in line with current literature about CTTA being more reliable with low image noise and softer reconstruction. Lower values of CV, IQR and SD were observed in DLIR-high reconstructions compared to AV50. The lower CV is likely due to the lower image noise associated with DLIR-high compared to AV50. Understanding the association of radiomic metrics with imaging variables may help improve imaging quality by compensating one variable for another e.g., increasing dose for reducing slice thickness etc., with known physics relationships.*Conclusions Radiomics studies isolating the effects of structure vs. imaging vs. image processing are key in understanding CTTA variability.*Clinical Relevance/Application Establishing reliable associations between the CTTA metrics and imaging variables across different acquisition protocols may provide the quality assurance required for clinical radiomics.

RESULTS

First-order CTTA metrics including but not limited to coefficient of variation (CV), inter-quartile range (IQR) and standard deviation (SD) were observed to have a high positive beta coefficient indicative of an increase with reduction in dose and slice thickness. This is in line with current literature about CTTA being more reliable with low image noise and softer reconstruction. Lower values of CV, IQR and SD were observed in DLIR-high reconstructions compared to AV50. The lower CV is likely due to the lower image noise associated with DLIR-high compared to AV50. Understanding the association of radiomic metrics with imaging variables may help improve imaging quality by compensating one variable for another e.g., increasing dose for reducing slice thickness etc., with known physics relationships.

CLINICAL RELEVANCE/APPLICATION

Establishing reliable associations between the CTTA metrics and imaging variables across different acquisition protocols may provide the quality assurance required for clinical radiomics.

SDP-PH-87   Dosimetry Of Vascular And Interventional Radiology Procedures 5 Years Analysis In A Tertiary Care Institution

Participants
Ali Rajeh, MBBS, Riyadh, Saudi Arabia (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the dosimetry of vascular and interventional radiology procedures at a single tertiary care institution and compare it to the previously reported international diagnostic reference levels (DRLs).*Methods and Materials Retrospective review of the radiation doses of the vascular and interventional procedures done between Jan 2015- Dec 2019 at a tertiary care institution. A total of 18068 fluoroscopy guided procedures were screened. Radiation records were retrieved form the dose management software (DoseWatchTM) for all adult patients. Pediatric and neuro interventions procedures were excluded from the current analysis. The collected data included the age (>14 years), sex, height and weight, reference dose (RD) point air kerma (mGy), Dose area product (DAP) (Gy.cm2), and &8;uoroscopy time (sec.) of the following procedures: vascular access, dialysis interventions, axial embolization, interventional oncology, portal hypertension and transplant vascular interventions, peripheral arterial interventions, non-vascular procedures such as gastrostomy, nephrostomy and biliary procedures. Body mass index (BMI) and peak skin dose were calculated. The study cohort included 8942 adult patients (M:F=54.4%:45.6%) with mean age of 56.96 years (SD=20.14) and mean BMI of 26.86 (SD=7.97).Two independent sample t-test was used to compare this study's mean values with the previously reported values in the RAD-IR and CIRD studies.*Results TIPSS creation recorded the highest mean &8;uoroscopy time of 69.41 minutes (SD=37.82 minutes) followed by central venous recanalization with mean of 39.67 minutes (SD=40.83) and uterine fibroid embolization 32.27 minutes (SD=15.06minutes). TIPSS creation had the highest mean DAP 1161.16 Gy.cm2 (SD= 840.93) followed by trans arterial chemo embolization 500.63 Gy.cm2 (SD=346.02) and post liver transplant vascular interventions 479.42 Gy.cm2 (SD=394.10). TIPSS creation was associated with the highest PSD of 2766.81 mGy (SD=2024.54), followed by Trans arterial chemo embolization 1588.29 mGy (SD=928.98) and post liver transplant vascular interventions 1480.66 mGy (SD=1204.36). Compared to

the CIRD and RAD-IR studies, TIPS creation and TACE are associated with significantly higher DAP.*Conclusions This analysis establishes the dosimetry of the most commonly performed vascular and interventional procedures in a tertiary care center. The majority of these procedures demonstrate no significant institutional variation in dosimetry when compared to other studies.*Clinical Relevance/Application Optimization of radiation precautions is paramount to maintain exposure as low as reasonably achievable.

RESULTS

TIPSS creation recorded the highest mean &8;uoroscopy time of 69.41 minutes (SD=37.82 minutes) followed by central venous recanalization with mean of 39.67 minutes (SD=40.83) and uterine fibroid embolization 32.27 minutes (SD=15.06minutes). TIPSS creation had the highest mean DAP 1161.16 Gy.cm2 (SD= 840.93) followed by trans arterial chemo embolization 500.63 Gy.cm2 (SD=346.02) and post liver transplant vascular interventions 479.42 Gy.cm2 (SD=394.10). TIPSS creation was associated with the highest PSD of 2766.81 mGy (SD=2024.54), followed by Trans arterial chemo embolization 1588.29 mGy (SD=928.98) and post liver transplant vascular interventions 1480.66 mGy (SD=1204.36). Compared to the CIRD and RAD-IR studies, TIPS creation and TACE are associated with significantly higher DAP.

CLINICAL RELEVANCE/APPLICATION

Optimization of radiation precautions is paramount to maintain exposure as low as reasonably achievable.

SDP-PH-88 Validation Of A New Monte Carlo Radiation Transport Code Through Utilization Of The AAPM TG195 Report

Participants
Hannah Kitten, San Antonio, Texas (*Presenter*) Nothing to Disclose

PURPOSE

Monte Carlo radiation transport (MCRT) algorithms can be applied to a broad range of applications. A new MCRT simulation code, PHENX, was developed for streamlined research in diagnostic imaging. The purpose of this paper is to present the validation of the physics model and geometry engine implemented in PHENX.*Methods and Materials PHENX was validated by comparing simulation results to those from previously validated and generally accepted MCRT software packages by utilizing the results from AAPM TG195. Cases 1, 2, and 4 allowed validation of PHENX's various capabilities. The use of monoenergetic beams and polyenergetic spectra were tested in both pencil beam and projection field configurations. Both stationary and rotating sources were simulated. Dose was scored explicitly using both a detector plane geometry and within simple phantoms. Scatter and primary components were also scored independently to one another. The scatter component was further broken down into both collective and 1st order incoherent and coherent scatter. PHENX results were compared to individual program results (Geant4, MCNP, EGSnrc, and Penelope), as well as their collective mean.*Results Each test had varying levels of agreement with both the other MCRT code packages and the overall mean. 89% of PHENX data points were within 1% of the mean values from TG195, and all were within 2%. The levels of variation seen by PHENX from the mean were comparable to the variation seen with the individual program results. For each test, PHENX was run with enough particle histories to reach a statistical uncertainty of less than 1%.*Conclusions Results from the 3 comparison cases in TG195 provide validation that the physics model utilized in PHENX is appropriate for clinical and research applications with a high level of confidence. Variation between PHENX and the other MCRT programs is likely due to differences between utilized cross section libraries. The AAPM TG195 report proved to be an excellent investigative tool in testing an entirely new MCRT software package by providing a variety of geometries and results from existing well tested and documented software to serve as benchmarks.*Clinical Relevance/Application Validation of PHENX, a Monte Carlo radiation transport code created for research in diagnostic imaging applications, will allow for its reliable use in clinically relevant research.

RESULTS

Each test had varying levels of agreement with both the other MCRT code packages and the overall mean. 89% of PHENX data points were within 1% of the mean values from TG195, and all were within 2%. The levels of variation seen by PHENX from the mean were comparable to the variation seen with the individual program results. For each test, PHENX was run with enough particle histories to reach a statistical uncertainty of less than 1%.

CLINICAL RELEVANCE/APPLICATION

Validation of PHENX, a Monte Carlo radiation transport code created for research in diagnostic imaging applications, will allow for its reliable use in clinically relevant research.

SDP-PH-89 Performance Evaluation Of Artificial Intelligence-based Technology For Fast And Accurate Bolus-tracking Process In CT Angiography

Participants
Yiran Wang, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Process of bolus-tracking scans before CT angiography usually include monitoring location selection and region-of-interest (ROI) placement to generate time-density curve (TDC) triggering the CTA scan. In this study we aimed to evaluate the performance of an artificial intelligence-based technology (SmartPlan, GE Healthcare) for fast and accurate bolus-tracking process compared with manual operation by technicians.*Methods and Materials 200 CTA scans including the abdominal, pulmonary aorta and coronary CTA performed using the SmartPrep triggering technique were prospectively collected. The monitoring location for placing ROI by CT technicians for dynamic contrast-enhancement monitoring in bolus-tracking scans and TDC generated in the ROI were recorded as the control group; The scout scans and time-resolved images were then imported into the SmartPlan software to automatically determine the monitoring location for placing ROI and to generate TDC, and the results were recorded as the experimental group. The consistency and time consuming of the location selection and the peak value of TDC curve triggering the scan between the experimental and control groups were analyzed using paired sample t-test. P < 0.05 was considered statistically significant. *Results There was significant difference in monitoring position between the experimental group and control group (P<0.05). However, monitoring locations differences were found no real clinical impact due to physicians'personal judgement variation. There was no difference in the peak value of TDC curves between the experimental group (167.99±25.54 e.g. in CCTA) and the control group (169.61±30.98 e.g. in CCTA), (P=0.784).Time consuming were found significant decreased by 19.94 second in the experimental group compared with that in the control group(P<0.05) .*Conclusions The AI-based automatic bolus-tracking technique can simplify CT scan process and physician intervention to provide reliable information for automatically triggering CTA scans.*Clinical Relevance/Application The intelligent automatic bolus-tracking technique based on deep learning neural network may reduce the manual intervention and simplify the process of automatically triggering CTA.

RESULTS

There was significant difference in monitoring position between the experimental group and control group (P<0.05). However, monitoring locations differences were found no real clinical impact due to physicians'personal judgement variation. There was no difference in the peak value of TDC curves between the experimental group (167.99±25.54 e.g. in CCTA) and the control group (169.61±30.98 e.g. in CCTA), (P=0.784).Time consuming were found significant decreased by 19.94 second in the experimental group compared with that in the control group(P<0.05) .

CLINICAL RELEVANCE/APPLICATION

The intelligent automatic bolus-tracking technique based on deep learning neural network may reduce the manual intervention and simplify the process of automatically triggering CTA.

SDP-PH-90   SAME: Fast And Accurate Algorithm For Deformable Image Registration On CT

Participants
Liu Fengze, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Image registration is widely used to relate or fuse information in different images when analyzing the longitudinal studies or comparing across multi-modality images for lesion diagnosis, treatment planning and respond assessment. Many abstracts in RSNA2020 (different categories) used or relied on registration in their studies. We propose and validate a fast and accurate dense deformable registration method on 3D CT scans based on a novel self-supervised anatomical embedding (SAM) algorithm that produces pixel-wise anatomical semantic information.*Methods and Materials We propose SAM-Enhanced registration (SAME) to find dense pixel correspondences between a pair of images. The key innovation of SAME is to use the high-level anatomical SAM features to directly predict point mapping between images, as well as to incorporate them into an unsupervised deep learning registration framework. We collected 2 datasets. 1) A chest CT dataset of 94 subjects, each with a contrast-enhanced (CE) and a non-contrast (NC) scan. For testing, we constructed 90 pairs using 10 patients for inter-subject registration, where 35 organs were manually labeled for each CT scan. We also tested on registering CE scans to NC counterparts. 2) An abdominal CT dataset of 30 patients with 13 labeled organs. For testing, 45 CT scan pairs using 10 patients were constructed for inter-subject registration. For both datasets, the atlas-based segmentation accuracy was calculated as evaluation metric.*Results In the test set of chest CT, SAME obtained 54.42% on the average Dice score (DSC) over all 35 organs when matching between CE and CE scans. Previous widely used state-of-the-art method, DEEDS, achieved 52.72% and took 45.35 seconds to match one pair of 3D scans, while SAME took 1.16 seconds. Another popular deep learning registration method, VoxelMorph, had 42.72% DSC using 4.02 seconds. On CE-to-NC registration, our result (50.96%) is comparable to DEEDS (51.15%). In the abdominal CT dataset, SAME achieved 49.78% DSC averaging over 13 organs, which is at least 3.2% higher than all previous works.*Conclusions We present a novel algorithm for 3D CT image registration with the state-of-the-art accuracy and fast inference speed. It can handle different imaging contrasts and body regions.*Clinical Relevance/Application Our proposed automated registration method is a useful tool for clinicians to align two CT volumes accurately in less than 2 seconds, which could be very helpful in various clinical and research tasks.

RESULTS

In the test set of chest CT, SAME obtained 54.42% on the average Dice score (DSC) over all 35 organs when matching between CE and CE scans. Previous widely used state-of-the-art method, DEEDS, achieved 52.72% and took 45.35 seconds to match one pair of 3D scans, while SAME took 1.16 seconds. Another popular deep learning registration method, VoxelMorph, had 42.72% DSC using 4.02 seconds. On CE-to-NC registration, our result (50.96%) is comparable to DEEDS (51.15%). In the abdominal CT dataset, SAME achieved 49.78% DSC averaging over 13 organs, which is at least 3.2% higher than all previous works.

CLINICAL RELEVANCE/APPLICATION

Our proposed automated registration method is a useful tool for clinicians to align two CT volumes accurately in less than 2 seconds, which could be very helpful in various clinical and research tasks.

SDP-PH-91   Comparison Of Dose Calculation Accuracy For Scattered Components By Heterogeneous External Radiotherapy

Participants
Takahiro Hirai, Kanagawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

The accuracy of the dose calculation algorithm was compared by comparing the calculated results of the radiotherapy planning device (TPS) with the measured values for the scattered components generated from the inhomogeneous substances in the water phantom.*Methods and Materials 1. An ionization chamber dosimeter was installed in the water phantom, and inhomogeneous substances (lung equivalent, bone equivalent, titanium) were arranged concentrically around the dosimeter, and measurements were made by changing the angle and distance. 2. TPS created the same geometry as the actual measurement. The dose calculation algorithm used was the Analytical Anisotropic Algorithm (AAA) and Acuros XB (AXB). 3. The results were calculated by calculating the scattering component as a relative value from the change in dose depending on the presence or absence of the heterogeneous phantom, and comparatively evaluated based on the measured value.*Results All AXB were in agreement with the measured values within ± 2.0%. AAA showed a maximum difference from the measured value as the angle was 45 ° and the distance was closer, and a difference of 6% or more was observed with titanium. Regarding the distance, AAA matched within ± 0.3% when the distance between the ionization chamber and the heterogeneous material was 20 mm or more. In addition, when the distance was within 20 mm, the scattering component tended to be different from the measured value and AXB. This tendency was significantly affected at 6 MV for lung equivalent and 10 MV for bone equivalent and titanium.*Conclusions It was suggested that the calculation accuracy of AXB is higher than that of AAA because the scattering component generated from the inhomogeneous substance in the water phantom has the same tendency as the measured value.*Clinical Relevance/Application By using dose calculation algorithm AXB installed in TPS, it is possible to calculate the scattering component from inhomogeneous substances more accurately than AAA.

RESULTS

All AXB were in agreement with the measured values within ± 2.0%. AAA showed a maximum difference from the measured value as the angle was 45 ° and the distance was closer, and a difference of 6% or more was observed with titanium. Regarding the distance, AAA matched within ± 0.3% when the distance between the ionization chamber and the heterogeneous material was 20

mm or more. In addition, when the distance was within 20 mm, the scattering component tended to be different from the measured value and AXB. This tendency was significantly affected at 6 MV for lung equivalent and 10 MV for bone equivalent and titanium.

CLINICAL RELEVANCE/APPLICATION

By using dose calculation algorithm AXB installed in TPS, it is possible to calculate the scattering component from inhomogeneous substances more accurately than AAA.

IN02-B3   **Image Content Prediction Using Deep Learning For Quality Assurance Of MR Images**

Participants
Keshav Datta, PhD, Los Altos, California (*Presenter*) Employee, Subtle Medical, Inc

PURPOSE

Safely deploying AI-based prediction tools requires the input image content e.g. body part, modality and imaging plane etc. to match the expected input. Also, to ensure reliable performance it is imperative that the test data is not too different from the training data. Here, we present a deep learning based image content prediction system that detects mismatches in the DICOM header and image content.*Methods and Materials A 2D multi-task ResNet34 convolutional neural network, was trained using T1 and T2 weighted brain MRI volumes (n=2345) from multiple institutions and scanners to predict the modality (T1 vs. T2) and imaging plane (axial, sagittal, coronal), using the DICOM header as the ground-truth. To discriminate brain images from non-brain, 4 models trained using different random seeds, were used to detect out-of-distribution (OOD) data using the variance of the predicted probabilities as an uncertainty estimate. Three separate test sets were used. The first contained (n=118) volumes from the same sites as the training data. The open IXI dataset (n=581 T1, n=577 T2) was used to test generalizability to new sites and a third set of n=535 spine images from the L-spine open dataset were used to assess the discrimination of spine from brain data. Performance of the algorithm was assessed using classification accuracy for brain vs spine discrimination, modality and imaging plane prediction.*Results The deep learning model achieved overall accuracies of 100%, 99.9% and 100%, respectively, in predicting the modality, imaging plane and OOD task. On the first test set, there was only a single case of mismatch in imaging plane identification between the DICOM header and the predicted image content, likely due to the poor image quality. There was one misclassification error also on the imaging plane prediction task in the IXI test set, indicating that the model generalized well to new site data. On the OOD task, the uncertainty measurement was able to distinguish between the OOD spine data from the in-distribution brain data with 100% accuracy.*Conclusions Deep learning based image content identification can automatically detect mismatch between the DICOM header and information in the image with a high level of accuracy.*Clinical Relevance/Application Deep learning based image content prediction can potentially identify mismatches between image headers and content, which can significantly improve the reliability of AI based image analysis.

RESULTS

The deep learning model achieved overall accuracies of 100%, 99.9% and 100%, respectively, in predicting the modality, imaging plane and OOD task. On the first test set, there was only a single case of mismatch in imaging plane identification between the DICOM header and the predicted image content, likely due to the poor image quality. There was one misclassification error also on the imaging plane prediction task in the IXI test set, indicating that the model generalized well to new site data. On the OOD task, the uncertainty measurement was able to distinguish between the OOD spine data from the in-distribution brain data with 100% accuracy.

CLINICAL RELEVANCE/APPLICATION

Deep learning based image content prediction can potentially identify mismatches between image headers and content, which can significantly improve the reliability of AI based image analysis.

BR02-A1   MR Screening For Breast Cancer: DWI-based Short Protocols In Comparison To Full Length Clinical Protocols With Contrast Enhancement

Participants
Sabine Ohlmeyer, Erlangen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Purpose of this study was to evaluate the capability to detect and characterize suspicious breast lesions with an abbreviated, non-contrast-enhanced MRI protocol featuring ultra-high b-value diffusion-weighted imaging (DWI) compared to a full clinical protocol with dynamic contrast enhanced (DCE) images.*Methods and Materials The study was approved by the local ethics committee. MRI examinations (advanced DWI with b-values ??1500 s/mm2 and 2500 s/mm2, T1w / T2w native and DCE, 1.5 and 3T.) of 254 breasts were subjected to a four-stage evaluation, each separately for b1500 and b2500: (A) MIP evaluation only, (B) DWI data including ADC, (C) DWI data including ADC with T1w / T2w native and (D) DWI data including ADC with T1w / T2w native and DCE (full-length standard protocol). The evaluation was performed by two blinded independend readers (4 and 16 years of experience in breast MRI). Histological confirmation for conspicuous lesions served as reference standard, DCE-MRI for inconspicuous and clearly benign lesions (e.g. cysts). Statistical analysis was performed for diagnostic accuracy and interrater agreement.*Results The cohort comprised 116 cases with BI-RADS 1 findings and 138 cases with BI-RADS =2 findings, including 38 histologically confirmed malignancies. For (A), breasts without pathological findings could be recognized with high diagnostic accuracy (negative predictive value, =97.0%; sensitivity, =92.1% for both readers), but with a limited specificity (=58.3%; positive predictive value, =28.6%). Within the native readings, approach (C) with b2500 performed best (negative predictive value, 99.5%; sensitivity, 97.4%; specificity, 88.4%). The intraclass correlation coefficient was between 0.683 (MIP b1500) and 0.996 (full protocol).*Conclusions A native short breast MRI with advanced high b-value DWIs ??seems to be nearly equivalent to DCE-breast-MRI in terms of diagnostic accuracy and appears to be suitable as a screening method.*Clinical Relevance/Application A native short breast MRI with advanced high b-value DWIs seems to be suitable as a screening method.

RESULTS

The cohort comprised 116 cases with BI-RADS 1 findings and 138 cases with BI-RADS =2 findings, including 38 histologically confirmed malignancies. For (A), breasts without pathological findings could be recognized with high diagnostic accuracy (negative predictive value, =97.0%; sensitivity, =92.1% for both readers), but with a limited specificity (=58.3%; positive predictive value, =28.6%). Within the native readings, approach (C) with b2500 performed best (negative predictive value, 99.5%; sensitivity, 97.4%; specificity, 88.4%). The intraclass correlation coefficient was between 0.683 (MIP b1500) and 0.996 (full protocol).

CLINICAL RELEVANCE/APPLICATION

A native short breast MRI with advanced high b-value DWIs seems to be suitable as a screening method.

BR02-A10   Axillary Lymph Node Evaluation After COVID-19 Vaccine In Patients With And Without COVID-19 History

Participants
Ignacio Soriano, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the axillary lymph node response to the COVID-19 vaccine (Pfizer-BioNTech) between patients who had previously passed the infection and patients who did not.*Methods and Materials Between February to April 2021, 91 volunteers (workers at our institution who participated in a COVID-19 vaccination program) were recruited to participate in a prospective study with IRB approval. All participants provided written consent to participate. Three axillary ultrasound (US) examinations of the ipsilateral vaccinated arm were performed: the first one, previous to the first dose of vaccine (basal control); the second one, performed the week after the first dose (control 1) and the last one, done the week after the second dose (control 2). Number of lymph nodes, maximum long-axis diameter and cortical thickness (in mm), Bedi's classification (grade 1 to 6) and color Doppler (grade 0 to 3, being 0 no color signal and 3 high intense color signal) were evaluated. Patients were classified according to previous infection with SARS-CoV-2 or not. Differences among groups were evaluated with the Mann-Whitney U test.*Results Out of 91 patients, 26 (28.6%) had previously passed COVID-19. No statistical differences in the basal US examination between groups were found. In control 1, a higher cortical thickness (mean 3.99 mm vs 2.89 mm; p<0.001), a higher grade of Bedi's classification (49.2% of grade 3 vs 57.7% of grade 2; p=0.004) and a greater grade of color Doppler (44.6% of grade 2 vs 42.3% of grade 1; p=0.004) were identified in the non-infected group regarding the previously infected group. Moreover, these statistically significant differences were also found in control 2, with a greater number of lymph nodes (mean 6.6 vs 5.23; p=0.006), higher cortical thickness (mean 4.98 mm vs 3.49 mm; p=0.001), major grade of Bedi's classification (43.1% of grade 3 vs 38.5% of grade 2; p=0.009) and higher grade of color Doppler (53.8% of grade 2 vs 46.2% of grade 1; p<0.001) in the group who had not passed previously the infection.*Conclusions Patients with no previous infection history by SARS-CoV-2 showed a higher axillary lymph node response with COVID-19 vaccine compared to patients who had positive infection history.*Clinical Relevance/Application Enlarged axillary lymph nodes are a common finding after COVID-19 vaccination. According to our data, patients who previously suffered the COVID-

19 infection developed less intense lymph node response after de vaccination.

RESULTS

Out of 91 patients, 26 (28.6%) had previously passed COVID-19. No statistical differences in the basal US examination between groups were found. In control 1, a higher cortical thickness (mean 3.99 mm vs 2.89 mm; p<0.001), a higher grade of Bedi's classification (49.2% of grade 3 vs 57.7% of grade 2; p=0.004) and a greater grade of color Doppler (44.6% of grade 2 vs 42.3% of grade 1; p=0.004) were identified in the non-infected group regarding the previously infected group. Moreover, these statistically significant differences were also found in control 2, with a greater number of lymph nodes (mean 6.6 vs 5.23; p=0.006), higher cortical thickness (mean 4.98 mm vs 3.49 mm; p=0.001), major grade of Bedi's classification (43.1% of grade 3 vs 38.5% of grade 2; p=0.009) and higher grade of color Doppler (53.8% of grade 2 vs 46.2% of grade 1; p<0.001) in the group who had not passed previously the infection.

CLINICAL RELEVANCE/APPLICATION

Enlarged axillary lymph nodes are a common finding after COVID-19 vaccination. According to our data, patients who previously suffered the COVID-19 infection developed less intense lymph node response after de vaccination.

BR02-A11   Challenging Breast Cryoablation Procedures and Imaging Follow-up

Participants
Celina Hsieh, Providence, Rhode Island (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To outline the mechanism and indications of cryoablation for breast cancer.2. To explain procedural steps of ultrasound-guided cryoablation.3. To discuss challenging procedural cases and how to approach them.4. To explore the use of multiple imaging modalities (US, MG, MRI, PET/CT) to evaluate cryoablation candidacy and to assess post-ablative changes.5. To review multimodality imaging findings after cryoablation, including expected evolution of benign post-ablation change, false positive fat necrosis, and true positive recurrent disease.

TABLE OF CONTENTS/OUTLINE

Introduction to Cryoablation- Mechanism- IndicationsCryoablation Procedure- Equipment and Technique- Expected Outcome-Potential ComplicationsChallenging Procedures- Present a series of challenging cryoablation cases, each addressed by a different procedural technique. Examples include asymmetric lesions and lesions too close to the skin/muscle.Challenging Follow-Up Imaging-Present a series of challenging follow-up cases where multiple complementary imaging modalities may be used to assess treatment response and to help differentiate expected benign post-ablation change from suspicious findings.Future of Cryoablation- Discuss cryoablation combined with immunotherapy

BR02-A12   Correlation Analysis Between Hyperplasic Axillary Lymph Node Reaction And Immunogenicity Of The COVID-19 Mrna Vaccine.

Participants
Alba Cristina Igual Rouilleault, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To explore the correlation between axillary lymph node response to the COVID-19 mRNA vaccine and seroprevalence of SARS-CoV-2 antibodies.*Methods and Materials Sixty-five volunteer employees from our center were prospectively ruled-out between February to April 2021. The study was conducted with the approval of our IRB and all participants provided written consent to participate. Patients recruited were Pfizer-BioNTech COVID-19 or Moderna vaccine recipients. Each patient underwent an axillary US evaluation of the ipsilateral vaccinated arm, within the week after the second dose of vaccination, and a SARS-CoV-2 serology test within the month after it. Findings recorded in our study included: the total number of visible nodes, the maximum measurements of the long-axis size and cortical thickness (mm), Bedi's classification (grade 1 to 6) and color Doppler evaluation (grade 0 to 3, being 0 no color signal and 3 high intense color signal). Serologic test was performed to detect SARS-CoV-2 antibodies in bloody components quantifying total IgM and IgG (U/mL). Data collected were analyzed using Pearson correlation coefficient for quantitative continuous variables (number of nodes, long-axis size and cortical thickness) and Spearman's rank-order correlation coefficient for ordinal variables (Bedi's classification and Doppler scale). Variables with a p value < 0.05 were considered statistically significant.*Results Pfizer-BioNTech was administered in 64.6% of the volunteers. Correlation analysis of US findings and antibodies quantification (IgM + IgG U/mL) evidenced weak negative correlation in cortical thickness (-0.305) and Bedi's grade classification (-0,344) with statistically significant differences (p=0.013 and p=0,005, respectively). Not statistically significant differences were found between quantified IgM and IgG antibodies with the total number of visible nodes, long-axis size measurement and Doppler signal scale.*Conclusions Hyperplasic axillary lymphadenopathy induced by recent vaccination didn't associate a higher seroprevalence of SARS-CoV-2 IgG antibodies response.*Clinical Relevance/Application In patients with axillary lymphadenopathy, recent vaccination should be ruled out. However, not enlarged axillary lymph nodes could be a normal response to COVID-19 vaccine.

RESULTS

Pfizer-BioNTech was administered in 64.6% of the volunteers. Correlation analysis of US findings and antibodies quantification (IgM + IgG U/mL) evidenced weak negative correlation in cortical thickness (-0.305) and Bedi's grade classification (-0,344) with statistically significant differences (p=0.013 and p=0,005, respectively). Not statistically significant differences were found between quantified IgM and IgG antibodies with the total number of visible nodes, long-axis size measurement and Doppler signal scale.

CLINICAL RELEVANCE/APPLICATION

In patients with axillary lymphadenopathy, recent vaccination should be ruled out. However, not enlarged axillary lymph nodes could be a normal response to COVID-19 vaccine.

BR02-A4   Systematic Surveillance Of Women After Breast Conserving Treatment Using Breast MRI Alone

Participants
Vanessa Raaff, PhD, Aachen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Current recommendations for follow up after breast conserving treatment (BCT) recommend serial two-view mammography, possibly accompanied by targeted ultrasound. Breast MRI has been shown to be useful to improve detection of recurrence in this situation. Our aim was to investigate the utility of MRI as a standalone imaging method for this purpose.*Methods and Materials Between 01/2011 and 03/2021, a total 426 women who, after breast conserving surgery plus RT, underwent MRI alone (without mammogram) for routine follow-up. Contrast enhanced MRI was performed at 1.5T using a dedicated multichannel breast coil according to a standardized protocol that took 11 minutes to complete. Women started MRI screening at variable intervals (median: 2 years; range: 1-28 years) after treatment and underwent MRI screening annually. Validation of the respective last negative MRI study was achieved by tomosynthesis plus clinical examination (137/426) and/or by clinical follow-up for at least 2 years (289/426).*Results Women were followed by 1,553 MRI studies (on average 3.6 MRI studies per patient), covering a total 1,727 women years (on average 4.06 years per patient). Follow-up MRI was positive in 108/1,553 examinations (6.9%) and in 85/426 women (19.9%) across the entire follow-up period. Recurrent breast cancer was confirmed in 64/108 MRI studies and in 55/85 women (8 women had more than one recurrence), for a PPV of 59.3% per positive MRI study and 64.7% per patient. Cancer-detection-rate was 37.0 per 1000 women years. Recurrent cancers were detected on average 8.9 (1-28) years after BCT. Recurrent cancers were DCIS in 11/64 (17.2%), invasive in 53/64 (82.8%). Mean size of invasive recurrent cancer was 11.4 mm, range 4-50 mm, staged as T1a in 5/53; T1b in 24/53; T1c in 16/53; T2 in 5/53; T3 or T4 in 0/53; stage was unknown in 3/53. None of the women received a diagnosis of breast cancer in between MRI screening rounds, or within the 2-year follow up after the respective last negative MRI, or upon DBT after the last study MRI.*Conclusions MRI alone is a powerful method for the follow-up of women after breast conserving treatment and ensures early detection of recurrent cancer.*Clinical Relevance/Application Women in the follow up after breast cancer who have access to breast MRI may safely forgo additional mammographic or DBT follow up.

RESULTS

Women were followed by 1,553 MRI studies (on average 3.6 MRI studies per patient), covering a total 1,727 women years (on average 4.06 years per patient). Follow-up MRI was positive in 108/1,553 examinations (6.9%) and in 85/426 women (19.9%) across the entire follow-up period. Recurrent breast cancer was confirmed in 64/108 MRI studies and in 55/85 women (8 women had more than one recurrence), for a PPV of 59.3% per positive MRI study and 64.7% per patient. Cancer-detection-rate was 37.0 per 1000 women years. Recurrent cancers were detected on average 8.9 (1-28) years after BCT. Recurrent cancers were DCIS in 11/64 (17.2%), invasive in 53/64 (82.8%). Mean size of invasive recurrent cancer was 11.4 mm, range 4-50 mm, staged as T1a in 5/53; T1b in 24/53; T1c in 16/53; T2 in 5/53; T3 or T4 in 0/53; stage was unknown in 3/53. None of the women received a diagnosis of breast cancer in between MRI screening rounds, or within the 2-year follow up after the respective last negative MRI, or upon DBT after the last study MRI.

CLINICAL RELEVANCE/APPLICATION

Women in the follow up after breast cancer who have access to breast MRI may safely forgo additional mammographic or DBT follow up.

BR02-A6   Power Spectrum Analysis Of Breast Parenchyma With Digital Breast Tomosynthesis Images In A Longitudinal Screening Cohort From Different Vendors

Participants
Kai Yang, PhD, Boston, Massachusetts (*Presenter*) Research Consultant, Malcova, LLC.

PURPOSE

To quantitatively compare breast parenchymal texture between two Digital Breast Tomosynthesis (DBT) vendors using images from the same patients.*Methods and Materials This retrospective study included consecutive patients who had normal screening DBT exams performed on a GE unit in January 2018 and normal screening DBT exams in adjacent years from a Hologic unit. Power spectrum analysis was performed within the breast tissue region, followed by a linear fit of log-frequency to log-power in the anatomical spatial frequency range 0.15 mm-1 to 0.8 mm-1. The slope of that linear function, ß, was used as a quantitative measure of breast texture and compared within and across vendors along with secondary parameters (laterality, view, year, image format, and breast density) with correlation tests and t-tests.*Results A total of 24,339 DBT slices or 2D synthetic images from 85 exams in 25 women (mean age, 58 years ± 10 [standard deviation]) were included. Strong power-law behavior was verified (R2>0.99) from all images. Values of ß do not differ significantly for laterality, view, or year. Significant (P<0.01) differences of ß were observed across vendors for DBT images (Hologic: 3.4±0.2 vs. GE: 3.1±0.2, 95% CI on difference: 0.27 to 0.30) and synthetic 2D images (Hologic: 2.7±0.3 vs. GE: 3.0±0.2, 95% CI on difference: -0.36 to -0.27), and density groups with each vendor: scattered (GE 3.0±0.3, Hologic 3.3±0.3) vs. heterogeneous (GE 3.2±0.2, Hologic 3.4±0.1), 95% CI (-0.27, -0.08) and (-0.21, -0.05), respectively.*Conclusions There are quantitative differences in the presentation of breast imaging texture between DBT vendors and across breast density categories observed in this cohort. Our findings have relevance and importance for external validation across vendors in AI and other automated density assessment programs.*Clinical Relevance/Application 1. Significant differences in anatomical noise power coefficient, ß, were observed between two digital breast tomosynthesis (DBT) vendors (Hologic vs. GE, P<0.001), using images from the same 25 patients in consecutive years, quantifying different DBT imaging presentation of breast parenchymal structures between vendors. 2. Observed values of ß were significantly different between scattered and heterogeneous mammographic breast densities (P<0.01). This directly associates ß with identified risk groups that bound the criterion for mammographically dense breasts.

RESULTS

A total of 24,339 DBT slices or 2D synthetic images from 85 exams in 25 women (mean age, 58 years ± 10 [standard deviation]) were included. Strong power-law behavior was verified (R2>0.99) from all images. Values of ß do not differ significantly for laterality, view, or year. Significant (P<0.01) differences of ß were observed across vendors for DBT images (Hologic: 3.4±0.2 vs. GE: 3.1±0.2, 95% CI on difference: 0.27 to 0.30) and synthetic 2D images (Hologic: 2.7±0.3 vs. GE: 3.0±0.2, 95% CI on difference: -0.36 to -0.27), and density groups with each vendor: scattered (GE 3.0±0.3, Hologic 3.3±0.3) vs. heterogeneous (GE 3.2±0.2, Hologic 3.4±0.1), 95% CI (-0.27, -0.08) and (-0.21, -0.05), respectively.

CLINICAL RELEVANCE/APPLICATION

1. Significant differences in anatomical noise power coefficient, ß, were observed between two digital breast tomosynthesis (DBT) vendors (Hologic vs. GE, P<0.001), using images from the same 25 patients in consecutive years, quantifying different DBT imaging presentation of breast parenchymal structures between vendors. 2. Observed values of ß were significantly different between scattered and heterogeneous mammographic breast densities (P<0.01). This directly associates ß with identified risk groups that bound the criterion for mammographically dense breasts.

Analysis Of The Added Value Of An Artificial Intelligence System In Assisting Radiologists On Indeterminate BI-RADS 0 Mammograms

Participants
Jie Ma, Shenzhen, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the value of an artificial intelligence (AI) system in assisting entry- and mid-level radiologists to improve the assessment accuracy of initial BI-RADS (Breast imaging reporting and data system) 0 cases in mammograms.*Methods and Materials We included 34,654 consecutive digital mammography studies, collected between 2011 and 2019, among which, 1,088 cases from 1,010 patients with initial BI-RADS 0 assessment who were recalled during 2 years of follow-up were used in this study. In the first reader study, two mid-level radiologists retrospectively re-assessed these BI-RADS 0 cases with the assistance of an AI system developed by us previously. In the second reader study, four entry-level radiologists were split into two groups to cross-read 80 cases with and without the AI. Diagnostic performance was evaluated using the follow-up diagnosis or biopsy results as the reference standard.*Results In the first reader study, of the 1,088 cases, 626 were BI-RADS 1 and 462 were BI-RADS 2 and above according to the reference standard. Assisted by the AI, the two mid-level radiologists would have correctly identified 351 and 362 BI-RADS 1 cases respectively, and significantly reduced the false recall cases by 56% and 58% (P<0.005), respectively. However, 12 and 6 out of 70 malignant cases would have been missed for the recall, respectively. In other words, the cancer detection rate of the radiologist plus AI stands at 5.33% and 5.88%, respectively, compared to that of 6.43% based on the mammography plus other imaging and biopsy tests. In the second reader study, the inter-rater reliability of the entry-level radiologists was increased from 0.20 to 0.30 (P<0.005) by introducing the AI, and the average reading time was reduced to 85 seconds per case from 113 seconds per case (P<0.005). In terms of the F1 score, the AI system (0.53) surpassed the entry-level radiologists (0.34) (P<0.005).*Conclusions The AI system can effectively assist mid-level radiologists in substantially reducing the false recalls of BI-RADS 0 cases. The AI system can also improve the inter-rater reliability and reduce the reading time of entry-level radiologists in assessing potential lesions in BI-RADS 0 mammograms.*Clinical Relevance/Application The assessment of BI-RADS 0 is affected by the experience of the radiologists. The abuse of BI-RADS 0 (especially by entry- and mid-level radiologists) will increase the psychological and economic burden on patients. The introduction of an AI system could significantly reduce unnecessary follow-ups and improve the overall performance of entry- and mid-level radiologists. This research can lead to further development and understanding of an AI system in enhancing the clinical decision-making of indeterminate BI-RADS 0 mammograms.

RESULTS

In the first reader study, of the 1,088 cases, 626 were BI-RADS 1 and 462 were BI-RADS 2 and above according to the reference standard. Assisted by the AI, the two mid-level radiologists would have correctly identified 351 and 362 BI-RADS 1 cases respectively, and significantly reduced the false recall cases by 56% and 58% (P<0.005), respectively. However, 12 and 6 out of 70 malignant cases would have been missed for the recall, respectively. In other words, the cancer detection rate of the radiologist plus AI stands at 5.33% and 5.88%, respectively, compared to that of 6.43% based on the mammography plus other imaging and biopsy tests. In the second reader study, the inter-rater reliability of the entry-level radiologists was increased from 0.20 to 0.30 (P<0.005) by introducing the AI, and the average reading time was reduced to 85 seconds per case from 113 seconds per case (P<0.005). In terms of the F1 score, the AI system (0.53) surpassed the entry-level radiologists (0.34) (P<0.005).

CLINICAL RELEVANCE/APPLICATION

The assessment of BI-RADS 0 is affected by the experience of the radiologists. The abuse of BI-RADS 0 (especially by entry- and mid-level radiologists) will increase the psychological and economic burden on patients. The introduction of an AI system could significantly reduce unnecessary follow-ups and improve the overall performance of entry- and mid-level radiologists. This research can lead to further development and understanding of an AI system in enhancing the clinical decision-making of indeterminate BI-RADS 0 mammograms.

GU04-C2   **Muscle-invasive Bladder Cancer: Pretreatment Prediction Of Response To Neoadjuvant Chemotherapy With Diffusion-weighted MR Imaging**

Participants
Xinxin Zhang, MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the performance of diffusion-weighted (DW) MR imaging for predicting the neoadjuvant chemotherapy (NAC) response in patients with muscle-invasive bladder cancer (MIBC).*Methods and Materials Fifty-eight patients with clinical T2-4a MIBC underwent DW-MR imaging before and after NAC followed by surgery. The evaluation of response to NAC was based on the change in tumor maximum diameter between pre- and posttreatment. The apparent diffusion coefficient value (2D-ADC value) measured from a single section region of interest and ADC histogram parameters derived from whole-tumor volume were compared between responders and non-responders. The Mann-Whitney-U test, the independent-samples t test, receiver operating characteristic curve with area under the curve (AUC) analysis were performed.*Results After NAC, 33 (57%) patients were classified as responders, and 25 (43%) were classified as non-responders. 2D-ADC values were significantly different between responders ([1.30(±0.17)] ×10-3mm2/s) and non-responders ([1.09(±0.14)] ×10-3mm2/s) (p < .001). The mean percentage increase in ADC of responders was higher than that of non-responders (29.3%±27.0 vs 16.2%±30.5, p=.051). Some ADC histogram parameters (ADCmean, ADCmax ADC50th ADC75th, ADC90th, Entropy, Kurtosis, Uniformity, Skewness)were significantly different between responders and non-responders (P = .042). The AUC was highest for the 2D-ADC value (0.842).*Conclusions The 2D-ADC value and ADC histogram parameters were useful for predicting tumor response to NAC in patients with MIBC. And the 2D-ADC value was superior to ADC histogram parameters in predicting the therapeutic response.*Clinical Relevance/Application In patients with MIBC, baseline 2D-ADC value and ADC histogram parameters before NAC have potential for predicting the treatment response to NAC, and it is helpful for providing appropriate treatment for individuals.

RESULTS

After NAC, 33 (57%) patients were classified as responders, and 25 (43%) were classified as non-responders. 2D-ADC values were significantly different between responders ([1.30(±0.17)] ×10-3mm2/s) and non-responders ([1.09(±0.14)] ×10-3mm2/s) (p < .001). The mean percentage increase in ADC of responders was higher than that of non-responders (29.3%±27.0 vs 16.2%±30.5, p=.051). Some ADC histogram parameters (ADCmean, ADCmax ADC50th ADC75th, ADC90th, Entropy, Kurtosis, Uniformity, Skewness)were significantly different between responders and non-responders (P = .042). The AUC was highest for the 2D-ADC value (0.842).

CLINICAL RELEVANCE/APPLICATION

In patients with MIBC, baseline 2D-ADC value and ADC histogram parameters before NAC have potential for predicting the treatment response to NAC, and it is helpful for providing appropriate treatment for individuals.

PH05-B2   **Application Of Low-dose And Low-flow Contrast Agent Injection Program With Dual-energy CT In Head And Neck CTA**

Participants
Yu Ziting, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the feasibility of using dual-energy CT to head and neck angiography, optimize the contrast injection protocol, and reduce the dosage and flow rate of contrast agent.*Methods and Materials Sixty patients underwent head and neck CT angiography scans were prospectively enrolled in 2019 with the approval of the Ethics Committee. All patients signed informed consent before their examinations, and randomly divided into two groups (A&B, A is normal scan and B is dual-energy scan). 370mgI/mL was used as the contrast agent in both two groups. The two groups used different injection protocol, group A with the flow rate of 5mL/s and 0.8 mL/kg of contrast medium(CM),automatic tube voltage, automatic tube current; group B with 2.5mL/s flow rate and 0.4 mL/kg of contrast medium, dual energy data acquisition mode (fast kV switching of 100/sn140kVp) was used and monochromatic images reconstructed at 50 keV. The left common carotid artery bifurcates (below 1cm) as the region of interest, and the sternocleidomastoid muscles in the same layer are selected as the background tissue. The CT value, noise value (SD) of the ROI and the background tissue are measured and recorded respectively. The SNR and CNR are calculated according to the formula, and the differences between the two groups of data are compared.*Results The CT value of the ROI in the group A and B can both reach more than 350 Hu, meeting the diagnostic requirements; and there was no significant difference in the two groups' imaging quality (P > 0.05).*Conclusions The image quality in the group A and B both can meeting the diagnostic requirements, but the group B with dual energy scan can significantly reduce the 50% CM and 50% flow rate of contrast agent, more safety.*Clinical Relevance/Application It is clinical possible to apply very low flow rate such as 2.5mL/s and low dosage contrast medium in dual-energy CT for some patients so that obtained safety of diagnosis and treatment.

RESULTS

The CT value of the ROI in the group A and B can both reach more than 350 Hu, meeting the diagnostic requirements; and there was no significant difference in the two groups' imaging quality (P > 0.05).

CLINICAL RELEVANCE/APPLICATION

It is clinical possible to apply very low flow rate such as 2.5mL/s and low dosage contrast medium in dual-energy CT for some patients so that obtained safety of diagnosis and treatment.

PH05-B3   **Study On the Effect Ofadaptivestatistical Iterative Reconstruction-veo Algorithmon Image Quality in Thyroid CT Scans**

Participants
Jie Sun, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the effect of different adaptive statistical iterative reconstruction-Veo (ASiR-V) algorithm level on the image quality of thyroid non-spectrum CT scanning.*Methods and Materials Twenty-five patients prepared for enhanced CT scan of the neck examination in our hospital were collected prospectively. Enhanced scanning used 120 kV tube voltage and automatic tube current (440 mA), noise index(NI) 11, thickness 1.25 mm. Six groups of ASiR-V images with different levels (1:0%,2:20%,3:40%,4:60%,5:80% and 6:100%) were reconstructed for comparative analysis. Region of interest (ROI) were placed at the maximum level of thyroid parenchyma, the same level of trapezius muscle and the subcutaneous fat of anterior. CT values, background noise (SD) of ROI in monochromatic images of 74keV in six groups were measured and compared respectively. The subjective image scores were assessed blindly by two experienced physicians using a 5-point system. The dose length product (DLP) of each scan was recorded after scanning, and the value of effective dose (ED) was calculated according to the formula: ED(mSv)=k(mSv*mGy-1*cm-1)*DLP(mGy*cm). The differences of SD among different ASiR-V groups were compared by one-way analysis of variance, and the differences of subjective scoring between two observers were compared by Kappa test.*Results SD values of different ASiR-V level were (29.94±5.62)HU,(26.13±5.24)HU,(22.70±5.07)HU,(19.27±4.78)HU,(15.56±4.69)HU, (11.83±4.07)HU respectively .With the level of ASiR-V increase, image noise (SD) decreased gradually. The average DLP of thyroid scan of 25 patients was (279.58±39.89)mGy*cm, ED was (1.65±0.23)mSv. The result of subjective score between observer A and observer B showed that both too high and too low ASiR-V would reduce the diagnostic confidence. Observer A and B believed that 80% ASiR-V can obtain the best image quality , and the Kappa value of consistency between the two observers was 0.78 respectively, indicating good consistency.*Conclusions Iterative reconstruction can effectively affect the image quality of non-spectral scan, and both too high and too low ASiR-V will affects the diagnostic confidence of images. Based on the results of subjective scores and objective indicators, this study confirmed that 80% ASiR-V can obtain the best image quality of thyroid scan.*Clinical Relevance/Application By exploring the application value of the ASiR-V with different levels in the optimization of image quality of thyroid non-spectral scan, it provides more choices for the clinical application of the ASiR-V to optimize the image quality of other examination sites, and has guiding significance for the selection of different levels of ASiR-V algorithm.

RESULTS

SD values of different ASiR-V level were (29.94±5.62)HU,(26.13±5.24)HU,(22.70±5.07)HU,(19.27±4.78)HU,(15.56±4.69)HU, (11.83±4.07)HU respectively .With the level of ASiR-V increase, image noise (SD) decreased gradually. The average DLP of thyroid scan of 25 patients was (279.58±39.89)mGy*cm, ED was (1.65±0.23)mSv. The result of subjective score between observer A and observer B showed that both too high and too low ASiR-V would reduce the diagnostic confidence. Observer A and B believed that 80% ASiR-V can obtain the best image quality , and the Kappa value of consistency between the two observers was 0.78 respectively, indicating good consistency.

CLINICAL RELEVANCE/APPLICATION

By exploring the application value of the ASiR-V with different levels in the optimization of image quality of thyroid non-spectral scan, it provides more choices for the clinical application of the ASiR-V to optimize the image quality of other examination sites, and has guiding significance for the selection of different levels of ASiR-V algorithm.

PH05-B4   Radiation Dose Reduction For CT Assessment Of Urolithiasis Using Deep Learning Reconstruction Algorithm -a Prospective Intra-individual Study

Participants
Xiaohu Li, MD, Hefei, China (*Presenter*) Nothing to Disclose

PURPOSE

To assess the performance of ASIR-V and Deep learning reconstruction algorithm(DL) in patients with urolithiasis at ultralow-dose CT*Methods and Materials 36 patients scheduled for unenhanced abdominal CT for follow-up of urolithiasis were prospectively included. Routine dose acquisition was followed by two low-dose acquisitions at 60% and 90% reduced doses. All images were reconstructed with FBP, ASIR-V and DL. Urolithiasis detection rates, gall bladder, appendix and rectosigmoid evaluation and overall subjective image quality were evaluated by two observers.*Results 114stones were present in 36 patients. 70% stones were not detected on FBP at the lowest dose level, but this improved with DL to a sensitivity of 100%. ASIR-V resulted in a slight decrease in sensitivity at the lowest dose to 85 %, but out performed FBP. Evaluation of other structures with ASIR-V at 60% and with DL at 90% dose reductions was comparable to FBP at routine dose, but 80% and 90% dose reduction resulted in non-evaluable images.*Conclusions CT radiation dose for urolithiasis detection can be safely reduced by 60(ASIR-V)-90(DL)% without affecting assessment of urolithiasis, possible extra-urinary tract pathology or overall image quality.*Clinical Relevance/Application The most frequent cause of acute flank pain is urolithiasis, which affects 3-5% of the population.Technical advancements like iterative reconstruction (IR) algorithms have resulted in substantial radiation dose reduc- tions. IR results in reduced noise, allowing acquisition ofim- ages at reduced radiation dose levels without intrinsically hampering image quality.

RESULTS

114stones were present in 36 patients. 70% stones were not detected on FBP at the lowest dose level, but this improved with DL to a sensitivity of 100%. ASIR-V resulted in a slight decrease in sensitivity at the lowest dose to 85 %, but out performed FBP. Evaluation of other structures with ASIR-V at 60% and with DL at 90% dose reductions was comparable to FBP at routine dose, but 80% and 90% dose reduction resulted in non-evaluable images.

CLINICAL RELEVANCE/APPLICATION

The most frequent cause of acute flank pain is urolithiasis, which affects 3-5% of the population.Technical advancements like iterative reconstruction (IR) algorithms have resulted in substantial radiation dose reduc- tions. IR results in reduced noise, allowing acquisition ofim- ages at reduced radiation dose levels without intrinsically hampering image quality.

PH05-B5   Clinical Application Of Coronary CT Angiography Fractional Flow Reserve Based On Different Reconstruction Algorithms In Normal Coronary Arteries

Participants
Hongjing Zhang, Shizuishan, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the clinical application of coronary CT angiography flow reserve fraction (FFRCT) software independently developed by Xingmai Technology in China to normal coronary arteries in different reconstruction algorithms.*Methods and Materials 10 patients with suspected myocardial ischemia underwent coronary CT angiography with the GE Revolution wide-body detector,No positive lesions were found.The images are divided into three groups based on different reconstruction algorithms:Group A: Soft algorithm, Group B: Stnd algorithm, Group C:Detail algorithm. 90 blood vessels (240 images) were reconstructed, and the images of each group were sent to the GE AW 4.7 workstation to analyze and compare the differences in the coronary artery SD values between the groups. The Region of Interest(ROI) was placed on the anterior chest wall muscle and the root of the right coronary artery. Region of interest was placed to avoid blood vessels and lesions,CT value, SD, signal-to-noise ratio (SNR=CTvessel/SD vessel) and contrast-to-noise ratio [CNR=(CTvessel-CT muscle)/SDmuscle] was measured and calculated. FFR value of each group was calculated using Xingmai software, and the FFRCT value=0.8 was taken as the positive result. The positive rate of the two groups of FFRCT was counted at the segment level, patient level and blood vessel level.SPSS 23.0 software was used, and one-way ANOVA analysis was used for comparison among multiple groups.Pearson chi-squarewas used for comparison between the two groups, and p<0.05 was statistically different.*Results The SD values of the three different reconstruction algorithms are 25.77±2.87, 31.40±3.12 and 41.07±4.27HU, the difference was statistically significant (P<0.05). The difference between SNR and CNR is statistically significant (p<0.05). The positive rates of FFR at the image segment level of the three groups were3.75%, 6.25% and 7.5%,the difference was not statistically significant (P>0.05). The positive rates of FFRCT in patients were 20%, 40% and 40%,the difference was not statistically significant(P>0.05). There was no statistically significant difference in the positive rate of FFRCT at the vascular level(P>0.05).*Conclusions Flow reserve fraction (FFRCT) software was used to analyze the coronary arteries of different reconstruction algorithms without affecting the FFRCT value of patients, showing good robustness.*Clinical Relevance/Application Use Fractional Flow Reserve (FFR) software to analyze coronary artery FFRCT value will not change with the change of reconstruction algorithm during scanning,Shows good robustness.In order to clinically judge whether there is ischemia in normal coronary arteries, it is of guiding significance.

RESULTS

The SD values of the three different reconstruction algorithms are 25.77±2.87, 31.40±3.12 and 41.07±4.27HU, the difference was statistically significant (P<0.05). The difference between SNR and CNR is statistically significant (p<0.05). The positive rates of FFR

at the image segment level of the three groups were3.75%, 6.25% and 7.5%,the difference was not statistically significant (P>0.05). The positive rates of FFRCT in patients were 20%, 40% and 40%,the difference was not statistically significant(P>0.05). There was no statistically significant difference in the positive rate of FFRCT at the vascular level(P>0.05).

CLINICAL RELEVANCE/APPLICATION

Use Fractional Flow Reserve (FFR) software to analyze coronary artery FFRCT value will not change with the change of reconstruction algorithm during scanning,Shows good robustness.In order to clinically judge whether there is ischemia in normal coronary arteries, it is of guiding significance.

PH05-B9   Deep Silicon-based Photon Counting CT: Improved Estimation Accuracy Of Radiomics Features For Lung Lesions

Participants
Shobhit Sharma, MSc, BEng, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To quantify the impact of improved spatial resolution performance of a prospective deep silicon-based photon-counting CT (Si-PCCT) on the estimation accuracy of morphological radiomics features of lung lesions.*Methods and Materials Computational models for lung lesions ("ground truth") across three spiculation categories - low, medium, and high - were generated using a dynamic nutrient-access-based stochastic growth model. The lesion models were inserted into high resolution computational human models (0.1 mm voxel size) that incorporate detailed lung architecture including airways, vasculature, and parenchymal structures. A CT simulation platform (DukeSim) was extended to model the scanner-specific geometry and components for a prospective Si-PCCT system. The simulation process involved incorporating response and crosstalk characteristics of the Si detector (pixel size: 0.2-0.4 mm in x, 0.5-0.7 mm in z), energy-binning of photon counts, addition of Poisson noise, generation of energy-summed grayscale images, and correcting for effects of beam hardening. The human models with lesions were "imaged" using helical scans (120 kV, pitch 1) with the largest pixel size (0.4 mm in x, 0.7 mm in z) at clinically representative dose levels and the resulting sinograms were reconstructed using typical specifications (FOV: 150 mm, size: 512x512, slice thickness: 0.4 mm). The lesions were segmented from the simulated images using Advantage Workstation (GE Healthcare). A series of 21 morphological radiomics features were estimated for both "ground truth" and imaged lesions using repeated simulated acquisitions, and the resulting bias from truth was quantified as relative differences. To compare performance to conventional CT, corresponding features from images simulated for an energy-integrating (ECT) system (Revolution CT, GE Healthcare) (slice thickness: 0.6 mm) were also estimated and the improvement in estimation accuracy from Si-PCCT was quantified as differences of biases from "ground truth".*Results The simulations revealed noted improvements in estimation accuracy for Si-PCCT over ECT, with mean differences (averaged over all radiomics features) at 43.47%, 30.71%, and 41.53% for low, medium, and high spiculation categories, respectively.*Conclusions The quantitative imaging performance of Si-PCCT for estimation of morphological radiomics features was superior to ECT with noted improvements in estimation accuracy for most features across all lesion categories.*Clinical Relevance/Application Shape-based morphological radiomics features serve as imaging biomarkers for a variety of malignancies. The improved spatial resolution performance of Si-PCCT has the potential to enhance the measurement accuracy of such features.

RESULTS

The simulations revealed noted improvements in estimation accuracy for Si-PCCT over ECT, with mean differences (averaged over all radiomics features) at 43.47%, 30.71%, and 41.53% for low, medium, and high spiculation categories, respectively.

CLINICAL RELEVANCE/APPLICATION

Shape-based morphological radiomics features serve as imaging biomarkers for a variety of malignancies. The improved spatial resolution performance of Si-PCCT has the potential to enhance the measurement accuracy of such features.

NR03-D1   Brain Tumor Connectomics: Mapping The Intra-tumoral Complex Interaction Network Using Graph Theoretic Machine Learning

Participants

Michael A. Jacobs, PhD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Brain tumors are heterogeneous with intratumoral microenvironments. Functional brain networks have been studied using both task- and resting state-based fMRI with applications in brain cancer for presurgical brain mapping and therapeutic planning. To better understand brain tumor microenvironments, we developed a tumor connectomics framework (TCF) based on advanced graph theory with unsupervised machine learning to model the interactions within the brain tumor microenvironment.*Methods and Materials The brain tumor TCF was modeled using a nonlinear machine learning with advanced graph theoretic metrics to map complex intratumoral networks. This allows for unbiased evaluation of the tumor microenvironment without assumption of a fixed classes or segmentation boundaries. The graph metrics were centrality measures, average path length, and clustering from a multiparametric MRI (T1, T2, FLAIR, DWI, and post contrast images from brain subjects (n=24) in a retrospective study. Quantitative mpMRI and graph metrics were calculated. A two-sided t-test was performed to compare the tumor grades. We computed the area under the receiver operating characteristic curve (AUC) for each of the graph metrics for tumor grade separation. Statistical significance was set at p<0.05.*Results The mean age of the patients was 51±15 years (13 male,11 female). Nine patients with WHO grade II (37.5%) and fifteen patients (62.5%) with WHO grade IV tumor. The Grade IV tumors demonstrated lower clustering coefficient (0.84±0.06) and degree centrality (0.56±0.17) compared to Grade II (0.90±0.04,0.74±0.15). Grade IV demonstrated greater betweenness centrality and average path length than Grade II tumors. The most predictive metric for classifying Grade II from Grade IV tumors was the average path length (AUC=0.85 (95% CI=0.69-1.00)) with sensitivity and specificity values of 60% and 100%. For tumor segmentation with peri-tumoral edema, there were no significant differences between the ADC values for Grade IV (1.38±0.34x10-3mm2/s) and Grade II tumors(1.54±0.29x10-3mm2/s). However, the ADC values for brain tumor segmentations without peritumoral edema were significantly different (p=0.002) between Grade II (1.58±0.29x10-3mm2/s) and Grade IV tumors (1.13±0.25x10-3mm2/s).*Conclusions We have developed a brain TCF for classification, visualization, and analysis of the tumor environments by using complex graph network theory based on mpMRI permitting regional analysis of the lesions.*Clinical Relevance/Application The TCF features derived from mpMRI of brain tumors reveal the complex interactions of brain tumor core and peritumoral environments. These features will help in improving diagnostics and treatment planning in clinical decision-making.

RESULTS

The mean age of the patients was 51±15 years (13 male,11 female). Nine patients with WHO grade II (37.5%) and fifteen patients (62.5%) with WHO grade IV tumor. The Grade IV tumors demonstrated lower clustering coefficient (0.84±0.06) and degree centrality (0.56±0.17) compared to Grade II (0.90±0.04,0.74±0.15). Grade IV demonstrated greater betweenness centrality and average path length than Grade II tumors. The most predictive metric for classifying Grade II from Grade IV tumors was the average path length (AUC=0.85 (95% CI=0.69-1.00)) with sensitivity and specificity values of 60% and 100%. For tumor segmentation with peri-tumoral edema, there were no significant differences between the ADC values for Grade IV (1.38±0.34x10-3mm2/s) and Grade II tumors(1.54±0.29x10-3mm2/s). However, the ADC values for brain tumor segmentations without peritumoral edema were significantly different (p=0.002) between Grade II (1.58±0.29x10-3mm2/s) and Grade IV tumors (1.13±0.25x10-3mm2/s).

CLINICAL RELEVANCE/APPLICATION

The TCF features derived from mpMRI of brain tumors reveal the complex interactions of brain tumor core and peritumoral environments. These features will help in improving diagnostics and treatment planning in clinical decision-making.

NR03-D2   Multiphase Computed Tomography Angiography In Acute Ischemic Stroke, Beyond Collaterals: Can It Obviate The Need For Computed Tomography Perfusion?

Participants

Aanchal Gupta, MD, Jodhpur, India (*Presenter*) Nothing to Disclose

PURPOSE

Multimodal imaging has been in use in patients presenting with an acute ischemic stroke which comprises of Non-contrast Computed Tomography (NCCT), Computed Tomography Angiography (CTA), and Computed Tomography Perfusion (CTP). Our study aims to evaluate the correlation between source images derived from multiphase CTA with CTP parameters.*Methods and Materials After the approval of the institutional ethics committee, a prospective study included all patients presenting with acute ischemic stroke within 24 hours of onset who had anterior circulation major vessel occlusion. All images were acquired on Siemens, Somatom Definition Flash Dual Energy 128x2 Slice Multidetector CT. ASPECTS (Alberta Stroke program early CT score) was calculated for each: NCCT, 3 phases of CTA, Cerebral blood flow (CBF), and cerebral blood volume (CBV) color maps of CTP. Data analysis was done by using IBM, SSPS statistical software version 23. Pearson's correlation coefficient (r) was derived and p-value <0.01 was considered statistically significant.*Results The study included 55 patients with 40 males and 15 females. The mean duration of

presentation from the onset of ictus was 4.7 + 4.98 hours, mean NIHSS score was 12.4 + 5.09. The mean ASPECTS on NCCT was 8.16 + 1.77. Significant positive correlation was found between CBF with 1st and 2nd phase of CTA (r=0.845, p=<0.01 and r=0.842, p=<0.01 respectively). CBV correlated significantly with 3rd phase of CTA (r=0.904, p=<0.01). The 3rd phase of CTA correlated significantly with NCCT (r=0.737, p=<0.01).*Conclusions Multiphase CTA, apart from depicting collateral status and true clot length, can be used similar to CBV and CBF in determining the penumbra and infarcted core and can obviate the need for obtaining CTP.*Clinical Relevance/Application Multiphase CTA requires no additional contrast bolus and provides valuable information regarding major vessel occlusion, true clot length, and collateral status in the ischemic zone. Our study casts light on how the source images derived from multiphase CTA correlate with CTP parameters and can be valuable in determining the penumbra and infarcted core and guide the decision for mechanical thrombectomy.

RESULTS

The study included 55 patients with 40 males and 15 females. The mean duration of presentation from the onset of ictus was 4.7 + 4.98 hours, mean NIHSS score was 12.4 + 5.09. The mean ASPECTS on NCCT was 8.16 + 1.77. Significant positive correlation was found between CBF with 1st and 2nd phase of CTA (r=0.845, p=<0.01 and r=0.842, p=<0.01 respectively). CBV correlated significantly with 3rd phase of CTA (r=0.904, p=<0.01). The 3rd phase of CTA correlated significantly with NCCT (r=0.737, p=<0.01).

CLINICAL RELEVANCE/APPLICATION

Multiphase CTA requires no additional contrast bolus and provides valuable information regarding major vessel occlusion, true clot length, and collateral status in the ischemic zone. Our study casts light on how the source images derived from multiphase CTA correlate with CTP parameters and can be valuable in determining the penumbra and infarcted core and guide the decision for mechanical thrombectomy.

NR03-D3 Is The RSNA Challenge-winner's Deep Learning Model Generalizable?: Intracranial Hemorrhage Detection For Independent Population Datasets

Participants
Changwon Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To verify if the RSNA-challenge-winner deep learning model could work equally well for independent patient populations despite the potential differences in CT scan protocols and disease patterns in cerebral hemorrhage detection.*Methods and Materials We used the deep learning model (DLM) publicly released from the 1st place winner in the machine learning challenge for RSNA 2019 intracranial hemorrhage detection (ICH) challenge. The DLM is a unique composite of 2D CNN, LSTM, and 1D CNN integrating information on CT image sequences and meta data. We repeated the training and testing of the DLM with the challenge dataset. We tested the trained DLM with two independent population datasets: CQ500 dataset from Indian population with scan protocols of standard and high dose (120 ~ 140 kV, 178 ~ 610 mAs); Korea University Medical Center (KUMC) dataset from Korean population with low dose scan protocol (100 ~ 120 kV, 59 ~ 100 mAs). Both datasets contained ICH subtypes similar to those of RSNA challenge dataset. Gold stands for both datasets were established by experienced neuroradiologists. Sensitivity and specificity were obtained for two datasets and compared with that of RSNA dataset.*Results While the RSNA DLM produced an overall good performance for CQ500 dataset with 84.9% sensitivity and 95.4% specificity which were comparable to the RSNA test dataset (93.2% sensitivity, 98.8% specificity), the performance was much lower for the KUMC dataset with 43.3% sensitivity and 81.3% specificity.*Conclusions The RSNA challenge winner DLM showed different performances for independent population datasets. Even though a DLM was proven in a challenge contest, care should be taken when applying the model to a different clinical environment especially with lower dose scan settings.*Clinical Relevance/Application This study is to be a basis for pre-processing studies of intracranial hemorrhage detection using artificial intelligence in non-contrast enhanced head CT images.

RESULTS

While the RSNA DLM produced an overall good performance for CQ500 dataset with 84.9% sensitivity and 95.4% specificity which were comparable to the RSNA test dataset (93.2% sensitivity, 98.8% specificity), the performance was much lower for the KUMC dataset with 43.3% sensitivity and 81.3% specificity.

CLINICAL RELEVANCE/APPLICATION

This study is to be a basis for pre-processing studies of intracranial hemorrhage detection using artificial intelligence in non-contrast enhanced head CT images.

NR03-D5 Post-mortem Correlates Of Virchow-robin Spaces Detected On In-vivo MRI

Participants
Lukas Haider, MD,PhD, Vienna, Austria (*Presenter*) Nothing to Disclose

PURPOSE

To quantify the extent, to which Virchow-Robin spaces (VRS) detected on in-vivo MRI can be found post-mortem.*Methods and Materials Double Echo Steady State MRIs were acquired post-mortem in 49 double- and 32 single-hemispheric formalin-fixed brain sections from 12 control subjects at 3T, who underwent conventional diagnostic 1.5 or 3T MRI within 5 months before death.VRS were manually segmented in in-vivo and post-mortem. The post-mortem MRIs were manually co-registered with the corresponding in-vivo MRIs based on anatomical landmarks with Freesurfer. The overlap of in-vivo- and post-mortem VRS segmentations was manually determined for each tissue-block. Histological validation of post-mortem VRS was obtained in on a double hemispheric section.*Results The median age at death was 62 years (25% to 75%: 50 to 77). The time from MRI to death was in median 22 days (25% to 75%: 12 to 134). The formalin fixation-time at post-mortem MRI acquisition was in median 236 days (25% to 75%: 136 to 407). Subjects died in the course of various conditions including malignant/metastatic disease (n=7), interventional complications (n=2), cardio-pulmonary resuscitation (n=1), tuberculosis (n=1) and amyloid angiopathy (n=1).In the supratentorial white matter, in median 80% (25% to 75%: 60 to 100) of VRS found on in-vivo MRI were reproduced by post-mortem imaging, in total numbers in median 15 VRS/ patient (25% to 75%: 9 - 36). A lower percentage was reproduced in the basal ganglia, in median 47% (25% to 75%: 30 to 50).In the supratentorial white matter, in median 44 VRS/patient (25% to 75%: 17 - 87) were detected on post-mortem MRI without in-vivo correlate and in the basal ganglia in median 1.5 VRS/patient (25% to 75%: 0 - 5.8).Post-mortem VRS segmentations were histologically confirmed in one double hemispheric section.*Conclusions The majority of VRS found on in-vivo MRI was stable throughout death and formalin fixation.*Clinical Relevance/Application Post-mortem MRI can guide tissue dissection to further investigate the histological and biological correlates of VRS.

RESULTS

The median age at death was 62 years (25% to 75%: 50 to 77). The time from MRI to death was in median 22 days (25% to 75%: 12 to 134). The formalin fixation-time at post-mortem MRI acquisition was in median 236 days (25% to 75%: 136 to 407). Subjects died in the course of various conditions including malignant/metastatic disease (n=7), interventional complications (n=2), cardio-pulmonary resuscitation (n=1), tuberculosis (n=1) and amyloid angiopathy (n=1).In the supratentorial white matter, in median 80% (25% to 75%: 60 to 100) of VRS found on in-vivo MRI were reproduced by post-mortem imaging, in total numbers in median 15 VRS/ patient (25% to 75%: 9 - 36). A lower percentage was reproduced in the basal ganglia, in median 47% (25% to 75%: 30 to 50).In the supratentorial white matter, in median 44 VRS/patient (25% to 75%: 17 - 87) were detected on post-mortem MRI without in-vivo correlate and in the basal ganglia in median 1.5 VRS/patient (25% to 75%: 0 - 5.8).Post-mortem VRS segmentations were histologically confirmed in one double hemispheric section.

CLINICAL RELEVANCE/APPLICATION

Post-mortem MRI can guide tissue dissection to further investigate the histological and biological correlates of VRS.

IN03-A1   Local And Contextual Information Used By A Deep Learning Model For Carina Detection

Participants
Alec Baenen, Waukesha, Wisconsin (*Presenter*) Employee, General Electric Company

PURPOSE

The carina serves as a key anatomical reference point in chest x-rays. In some images, the carina is clearly visible where the trachea bifurcates into the left and right main bronchi. In other cases, the local features of the carina may be obscured by foreign objects or pathology. In such cases, carina location can be estimated based on contextual information (e.g., location of vertebrae or aortic arch). This study investigates how a deep learning model trained for carina detection can use local and contextual information to detect the location of the carina in chest X-rays.*Methods and Materials A carina detection model within a commercially available AI algorithm was evaluated on a test set of 400 frontal chest X-ray images. Within this test set, a synthetic, circular patch of constant intensity and varying widths was included to cover the carina and assess the impact of the patch on localization accuracy. Note that during model development the synthetic patch was not applied in any form.*Results Results showed that the model detected the carina with consistent robustness in the presence of the patch. When increasing the patch radius from 0cm to 2cm, the detection success rate dropped slightly from 100% to 98.8%, and the average detection error increased from 0.44 cm to 0.96 cm, indicating that in most cases the detected carina was inside the patch. Additionally, the histogram of detection errors showed carina detection was pushed to the edge for small patches. For larger patches, a second histogram peak became dominant which corresponded to a detection inside the patch. Our initial interpretation suggests that for small patches the area around the patch still offers reasonable carina locations, consistent with both local and contextual information. If the patch is too large and points outside the patch become inconsistent with the contextual information, then the model ignores the local information and picks a point inside the patch. The saliency maps highlighting the areas contributing to the selected carina location are consistent with the initial interpretation.*Conclusions This study supports the conclusion that a deep learning AI model can accurately determine carina location based on contextual information even when all local information is erased, mirroring the estimation practices currently in place with radiologists interpreting chest X-rays.*Clinical Relevance/Application Given the variability in X-ray imaging (i.e., presence of foreign objects, pathology, and image quality), deep learning models must maintain robust performance in the presence of local disturbing factors. This study offers one method of evaluating this robustness, however additional methodologies for assessing deep learning models in real-world clinical context are needed.

RESULTS

Results showed that the model detected the carina with consistent robustness in the presence of the patch. When increasing the patch radius from 0cm to 2cm, the detection success rate dropped slightly from 100% to 98.8%, and the average detection error increased from 0.44 cm to 0.96 cm, indicating that in most cases the detected carina was inside the patch. Additionally, the histogram of detection errors showed carina detection was pushed to the edge for small patches. For larger patches, a second histogram peak became dominant which corresponded to a detection inside the patch. Our initial interpretation suggests that for small patches the area around the patch still offers reasonable carina locations, consistent with both local and contextual information. If the patch is too large and points outside the patch become inconsistent with the contextual information, then the model ignores the local information and picks a point inside the patch. The saliency maps highlighting the areas contributing to the selected carina location are consistent with the initial interpretation.

CLINICAL RELEVANCE/APPLICATION

Given the variability in X-ray imaging (i.e., presence of foreign objects, pathology, and image quality), deep learning models must maintain robust performance in the presence of local disturbing factors. This study offers one method of evaluating this robustness, however additional methodologies for assessing deep learning models in real-world clinical context are needed.

IN03-A2   Machine Learning Based CT Texture Analysis For Assessing Acute Pulmonary Radiation Injury

Participants
Shayan Shafiee, MSc,MSc, Wauwatosa, Wisconsin (*Presenter*) Nothing to Disclose

PURPOSE

While CT density of lungs is projected to be a marker of radiation pneumonitis, robust quantitative metrics that are not sensitive to image acquisition or scanner variability do not exist. We propose the use of machine learning enhanced noninvasive methods to track the lung morphology changes caused by acute radiation injury, only using the non-contrast-enhanced X-ray CT imaging data. We implemented and quantitatively assessed state-of-the-art CT image texture-based radiomic measures with Machine Learning (ML) algorithms to determine their efficacy in classifying a subject's radiation injury status.*Methods and Materials A validated rat model of radiation injury was employed with rats treated with partial body 13Gy radiation and lungs assessed with periodic micro-CT measurements. Rats were randomized into blinded control and injury groups. Auto-segmented lung images were analyzed to extract five texture-type groups, including First-order histogram (or global), Gray-level co-occurrence matrix, Gray-level run-length matrix, Gray-level size zone matrix, and Neighborhood gray-tone difference matrix resulting in 334 different radiomics features. To develop

an accurate yet optimal prognosis model, we used supervised ML algorithms to refine and extract features with significant correlation with progressive pulmonary radiation injury. We used this algorithm to classify endpoint events to determine if the case was radiated or not.*Results The accuracy of the classification of a subject into control or radiated was up to 98% in a separate validation cohort of animals. The algorithm computed p-values for Pearson's correlation by transforming the correlation to create a t-statistic with 14 degrees of freedom and p-values for the Kendall rank correlation using the exact permutation distributions for small sample size approximations. In both cases, the feature selection and classification were performed based on p-values<0.001.*Conclusions The high accuracy of this method, validated on an unobserved group study, indicates the potential of machine learning approaches in assessing pulmonary radiation injury and other diagnostic assessments.*Clinical Relevance/Application Quantitative assessment of radiation toxicity is critical for indicating treatment strategies for accidental radiation and cancer patients. Such an assessment can help with the prognosis of the clinical outcomes and likelihood of developing adverse cardiovascular conditions due to radiotherapy. Our proposed method uses machine learning-enhanced noninvasive methods to track the pulmonary system changes caused by radiation, only using the non-contrast-enhanced X-ray CT imaging data.

RESULTS

The accuracy of the classification of a subject into control or radiated was up to 98% in a separate validation cohort of animals. The algorithm computed p-values for Pearson's correlation by transforming the correlation to create a t-statistic with 14 degrees of freedom and p-values for the Kendall rank correlation using the exact permutation distributions for small sample size approximations. In both cases, the feature selection and classification were performed based on p-values<0.001.

CLINICAL RELEVANCE/APPLICATION

Quantitative assessment of radiation toxicity is critical for indicating treatment strategies for accidental radiation and cancer patients. Such an assessment can help with the prognosis of the clinical outcomes and likelihood of developing adverse cardiovascular conditions due to radiotherapy. Our proposed method uses machine learning-enhanced noninvasive methods to track the pulmonary system changes caused by radiation, only using the non-contrast-enhanced X-ray CT imaging data.

IN03-A3   Not So Smart - What To Consider If You Think The AI Has Made The Wrong Call

Participants
Kobi Fogel, MD, Bronx, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

• AI algorithms in Radiology make mistakes, both misses (false negatives) and incorrect calls (false positives). Radiologists need to develop the skills to recognize AI mistakes so that they do not reach patients, and do not influence the read.• The smart assistant is like having a resident to read out with. While it is nice to have an extra set of eyes and an opinion on the findings, the radiologist is ultimately responsible for the final interpretation of the case.• Radiologists should always read the study 1st without looking at the AI results, to avoid bias.• If there is significant artifact in a study, and the call is likely based on that artifact, disregard the call. • If the call AI call is discrepant from your initial read but the result is not clear to the reader: o Consider the test characteristics of the algorithm (on local cases if available). Should we expect false positives or false negatives by design? o Consider other factors about the study that may be influencing the algorithm. Would this case have been in the test set? o Take clinical context and prior images into account. The algorithm usually does not use this information. o When in doubt, ask another human.• Keep an open mind. Did your biases cause you to miss a call? Always learn from your mistakes. AI can also teach us.

TABLE OF CONTENTS/OUTLINE

• Discrepant AI output - a new type of interpretative error• Situations where you should dismiss an AI call• Framework to handle a discrepancy.

NR04-A1   Reconstruction Of Resting State Fmri On Subcortical Morphology Using Sequential Graph Variational Autoencoder.

Participants
Yunan Wu, Evanston, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

To develop a graph-based variational autoencoder (gVAE) with a sequential Long Short Term Memory (LSTM) to learn the patterns of resting state functional MRI (rsfMRI) subcortical activity in healthy subjects from the mesh representations of subcortical structures.*Methods and Materials Fully preprocessed rsfMRI from 195 healthy subjects from the UK Biobank were included. Each rsfMRI session included 480 time points with a repetition time of 0.735s. Seven subcortical structures per hemisphere were modeled as surface meshes and converted to graphs where nodes (N =14848) of the graphs were surface vertices and edges were links across vertices. rsfMRI intensities sampled at each vertex and each time point were used as input features. The gVAE model consisted of an encoder and a decoder, where the encoder represented low-dimensional rsfMRI activities (N = 256) using latent vectors, and the decoder reconstructed those vectors back to the original signals. The LSTM was used within the gVAE to extract the temporal representations of rsfMRI signals by training six time points at a time. Mean Square Error (MSE) and Pearson's coefficient of correlation (R) measured the spatial and temporal reconstruction performances. Our gVAE was trained on 80 healthy subjects and validated on 20 subjects to learn the representations of rsfMRI activities. The 95 remaining subjects composed the testing set and were used to map the average reconstruction error at each vertex and each time point to quantify the reconstruction performance across the subcortical structures.*Results The reconstruction performance of rsfMRI on the 95 healthy subjects of the testing set yielded an average spatial MSE = 0.399 ± 0.115 and R = 0.756 ± 0.102, and an average temporal MSE = 0.405 ± 0.129 and R = 0.752 ± 0.040. Excellent reconstruction maps were obtained for seven subcortical structures with the exception of moderate performance in the pallidum and nucleus accumbens.*Conclusions Our novel gVAE method is capable of successfully reconstructing patterns of normal subcortical activity with good reconstruction performance. This paves the way to develop this as a tool for investigating subcortical rsfMRI activity in the context of neurologic disorders. Additional development can also lead to application for gVAE rsfMRI analysis of the cortical surface.*Clinical Relevance/Application Our novel gVAE approach can predict subcortical rsfMRI signal in healthy subjects. Further development can impact the clinical investigation of a variety of neurologic conditions. Of particular interest is epilepsy whereby reconstruction "errors" may potentially reflect underlying perturbations within the epilepsy network, yielding a novel tool for use in the presurgical evaluation of patients with refractory seizures.

RESULTS

The reconstruction performance of rsfMRI on the 95 healthy subjects of the testing set yielded an average spatial MSE = 0.399 ± 0.115 and R = 0.756 ± 0.102, and an average temporal MSE = 0.405 ± 0.129 and R = 0.752 ± 0.040. Excellent reconstruction maps were obtained for seven subcortical structures with the exception of moderate performance in the pallidum and nucleus accumbens.

CLINICAL RELEVANCE/APPLICATION

Our novel gVAE approach can predict subcortical rsfMRI signal in healthy subjects. Further development can impact the clinical investigation of a variety of neurologic conditions. Of particular interest is epilepsy whereby reconstruction "errors" may potentially reflect underlying perturbations within the epilepsy network, yielding a novel tool for use in the presurgical evaluation of patients with refractory seizures.

NR04-A4   Altered Brain Network Centrality In Patients With Non-npsle: A Resting-state Functional Magnetic Resonance Imaging Study

Participants
XiaoLou Li, DaLian, China (*Presenter*) Nothing to Disclose

PURPOSE

Neuropsychiatric manifestations are highly prevalent in systemic lupus erythematosus (SLE) patients. However, it is hard to diagnose&the potential pathogenic mechanisms are still unclear. The aim of this study was to explore potential changes in brain function network activity in SLE patients without major neuropsychiatric manifestations (non-NPSLE) using the voxel-wise degree centrality (DC) method.*Methods and Materials A total of 32 non-NPSLE patients&28 healthy controls (HCs) were recruited in this study. Degree centrality (DC)—a graph theory-based measurement of global connectivity at the voxel level by measuring the number of instantaneous functional connections between one region and the rest of the brain—can map brain hubs with high sensitivity, specificity, reproducibility. Independent twos ample t-test&receiver operating characteristic (ROC) curve analysis were performed to compare the difference of DC values between the two groups, so as to distinguish the accuracy of non-NPSLE diagnosis. Spearman's linear regression correlation analysis was used to examine the relationships between mean DC values in various brain regions&clinical features in non-NPSLE patients.*Results Compared to the HCs group, the non-NPSLE patients showed remarkably increased DC values in the bilateral postcentral gyrus,decreased in the left frontal mid orb (p<0.05, AlphaSim corrected). There were no significant differences in other gray matter regions. ROC curve analysis indicated that the area under the curve

(AUC) of some cerebral region studied had a perfect diagnostic value (AUC=0.812 and 0.865, respectively). The sensitivity of the DC of the bilateral postcentral gyrus was 0.714 ,0.786 respectively, while the specificity of those parameters was 0.926,0.815 respectively. In addition, linear analysis indicated that the DC values of the left frontal mid orb were positively correlated with SLE disease activity index (SLEDAI) (r = 0.503, p<0.05) ,the IgA of non-NPSLE patients were positively correlated with the DC values of the right postcentral gyrus&left frontal mid orb (r =0.513, p<0.05; r=0.469, p<0.05, respectively).*Conclusions Non-NPSLE patients exhibit abnormal brain network activity in various brain regions, indicating that rs-fMRI is a promising tool for detecting the brain function disorders in non-NPSLE patients.*Clinical Relevance/Application These changes of DC may be useful to underlie the pathological mechanism of non-NPSLE&provide new ideas for monitoring&treating non-NPSLE patients.

RESULTS

Compared to the HCs group, the non-NPSLE patients showed remarkably increased DC values in the bilateral postcentral gyrus,decreased in the left frontal mid orb (p<0.05, AlphaSim corrected). There were no significant differences in other gray matter regions. ROC curve analysis indicated that the area under the curve (AUC) of some cerebral region studied had a perfect diagnostic value (AUC=0.812 and 0.865, respectively). The sensitivity of the DC of the bilateral postcentral gyrus was 0.714 ,0.786 respectively, while the specificity of those parameters was 0.926,0.815 respectively. In addition, linear analysis indicated that the DC values of the left frontal mid orb were positively correlated with SLE disease activity index (SLEDAI) (r = 0.503, p<0.05) ,the IgA of non-NPSLE patients were positively correlated with the DC values of the right postcentral gyrus&left frontal mid orb (r =0.513, p<0.05; r=0.469, p<0.05, respectively).

CLINICAL RELEVANCE/APPLICATION

These changes of DC may be useful to underlie the pathological mechanism of non-NPSLE&provide new ideas for monitoring&treating non-NPSLE patients.

NR04-A7 Deep Learning-aided Prediction Of Stereotactic Neurosurgical Resection Status: Analysis Of Preoperative Magnetic Resonance Imaging Data Of Intracranial Meningiomas

Participants
Manoj Mannil, Muenster, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Meningiomas are the most frequently encountered extra-axial tumors of the central nervous system and are usually treated by surgical resection. Incomplete surgical removement is a risk factor for tumor progression and recurrence. In this retrospective analysis we investigated the predictive ability of transfer deep learning regarding incomplete Meningioma resection status in a multicenter cohort trial.*Methods and Materials In this study we analyzed 287 of 413 patients with intracranial meningiomas. Included patients had pre- and post-treatment diagnostic magnetic resonance T1 post-contrast sequence images. Tumor resection status was evaluated based on surgical assessment according to the Simpson classification and postoperative imaging. As a deep learning framework we used PyTorch in its fast.ai implementation and for transfer learning 'VGG19 bn' was utilized. The images were split into training, testing and validation data sets.*Results Based on the unseen validation data set out deep learning model was able to correctly predict meningioma resection status with a sensitivity of 81%, a specificity of 80%, a precision of 0.91 and an accuracy of 0.8.*Conclusions A deep learning analysis of preoperative MR imaging of Meningiomas may add value by identifying patients in risk of incomplete resection.*Clinical Relevance/Application Possible identification of patients with high risk of incomplete Meningioma resection and support in further therapy planning.

RESULTS

Based on the unseen validation data set out deep learning model was able to correctly predict meningioma resection status with a sensitivity of 81%, a specificity of 80%, a precision of 0.91 and an accuracy of 0.8.

CLINICAL RELEVANCE/APPLICATION

Possible identification of patients with high risk of incomplete Meningioma resection and support in further therapy planning.

NR04-A9 Comprehensive Fully Automated Intracranial Occlusion Detection On Multiphase CT Angiography

Participants
Luis Souto Maior Neto, MSc, Calgary, Alberta (*Presenter*) Developer, Circle Cardiovascular Imaging Inc

PURPOSE

This study aims to develop and validate a data driven fully automated approach that differentiates large vessel occlusions (LVO), medium vessel occlusions (MeVO), and distal occlusions from each other on multiphase CT Angiography (mCTA) and CT Perfusion (CTP).*Methods and Materials A total of 346 cases (173 LVO, 91 MeVO, 82 distal occlusions) with mCTA and CTP were used as the reference database. The data was uniformly split 80%/20% for training/validation purpose. Tmax maps were extracted by the StrokeSENS mCTA Perfusion software, which estimates CT Perfusion (CTP) parameters from mCTA using convolutional neural networks. Hand engineered features were derived from these Tmax maps for each of 20 ASPECTS brain regions and used to train a logistic regression model for detecting occlusion type. To evaluate performance, validation metrics were reported in comparison to ground-truth CTP Tmax maps.*Results The validation scores for the three differentiations, namely, "LVO vs. not", "MeVO vs. not", "Distal occlusion vs. not" respectively for the mCTA perfusion model were the following i.e. AUC: 0.901, 0.857, 0.971; Sensitivity [95% CI]: 0.71 [0.55, 0.869], 0.6 [0.387, 0.781], 1 [0.806, 1.0]; Specificity [95% CI]: 0.917 [0.782, 0.971], 0.872 [0.777, 0.968], 0.843 [0.743, 0.943]. Comparative results for the ground truth CTP models were the following i.e. AUC: 0.873, 0.838, 0.997; Sensitivity [95% CI]: 0.645 [0.477, 0.814], 0.7 [0.481, 0.855], 0.938 [0.717, 0.989]; Specificity [95% CI]: 0.861 [0.713, 0.939], 0.787 [0.67, 0.904], 0.941 [0.841, 0.98].*Conclusions An automated mCTA perfusion-based method was able to achieve excellent performance in differentiation of LVO, MeVO and distal occlusions when compared to assessment of ischemia extent on CTP.*Clinical Relevance/Application Timely, efficient and reliable detection of different types of intracranial vessel occlusions are critical in helping physicians determine what therapy (if required) can be effective in patients with acute ischemic stroke.

RESULTS

The validation scores for the three differentiations, namely, "LVO vs. not", "MeVO vs. not", "Distal occlusion vs. not" respectively for the mCTA perfusion model were the following i.e. AUC: 0.901, 0.857, 0.971; Sensitivity [95% CI]: 0.71 [0.55, 0.869], 0.6 [0.387, 0.781], 1 [0.806, 1.0]; Specificity [95% CI]: 0.917 [0.782, 0.971], 0.872 [0.777, 0.968], 0.843 [0.743, 0.943]. Comparative results for the ground truth CTP models were the following i.e. AUC: 0.873, 0.838, 0.997; Sensitivity [95% CI]: 0.645

[0.477, 0.814], 0.7 [0.481, 0.855], 0.938 [0.717, 0.989]; Specificity [95% CI]: 0.861 [0.713, 0.939], 0.787 [0.67, 0.904], 0.941 [0.841, 0.98].

CLINICAL RELEVANCE/APPLICATION

Timely, efficient and reliable detection of different types of intracranial vessel occlusions are critical in helping physicians determine what therapy (if required) can be effective in patients with acute ischemic stroke.

SDP-NMMI-1 Outcome Prediction In Hodgkin Lymphoma - Utility Of Pre-treatment FDG PET/CT Derived Machine Learning Models

Participants
Russell Frood, MBBCh, Leeds, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

2-[18F]fluoro-D-glucose (FDG) positron emission tomography/computed tomography (PET/CT) plays an integral role in staging, response assessment and treatment stratification of classical Hodgkin lymphoma (cHL), with therapy adaptation based on imaging after 2 cycles of chemotherapy. However, even with this strategy, approximately 20% will recur or relapse. The aim of the study was to explore the utility of machine learning (ML) models using features derived from pre-treatment PET/CT for prediction of 2-year event free survival (2-EFS) in cHL patients.*Methods and Materials All patients who underwent baseline PET/CT for staging of cHL at our institution between January 2008 and January 2018 were retrospectively identified. Patients were excluded if they received treatment prior to imaging, had primary cutaneous or central nervous system involvement, were aged < 16 years or had stage 1 disease. A semi-automated contour with a threshold of 1.5 times mean liver standardised uptake value was applied to the PET and the contour translated to and adjusted to the soft tissue on the CT. Feature extraction was performed using PyRadiomics with neuroCombat subsequently applied. Cases were split into training (80%) and testing (20%) cohorts, stratified around 2-EFS, age, gender and disease stage. Four ML models (logistic regression, random forest, k-nearest neighbour, support vector machine (SVM)) were trained and hyperparameters tuned on the training cohort using stratified 4-fold cross validation. The optimum number of features were selected using a forward wrapper method. The model with the highest mean area under the curve (AUC) derived from the receiver operator characteristic (ROC) curve from the training cohort cross validation with the smallest difference between the mean training and validation AUCs was tested once on the unseen test cohort.*Results 261 patients (126 female, 135 male, median age 36 years (range 16-88 years)) were included in the study. There was no significant difference in patient characteristics between the training cohort (n= 208) and test cohorts (n=53) (p-value > 0.05). The SVM model provided the best results within the cross validated training set with a mean training AUC of 0.78 (std 0.02), mean validation AUC of 0.75 (std 0.06) and test AUC of 0.72 with age, least length in axis on PET and PET grey level dependence matrix - low grey level emphasis selected as features.*Conclusions Outcome prediction using features derived from pre-treatment FDG PET/CT in cHL patients is feasible, although further external validation is required.*Clinical Relevance/Application The ability to predict patient outcome pre-treatment aids clinical prognostication and in the future may help guide personalised therapy and improve survival.

RESULTS

261 patients (126 female, 135 male, median age 36 years (range 16-88 years)) were included in the study. There was no significant difference in patient characteristics between the training cohort (n= 208) and test cohorts (n=53) (p-value > 0.05). The SVM model provided the best results within the cross validated training set with a mean training AUC of 0.78 (std 0.02), mean validation AUC of 0.75 (std 0.06) and test AUC of 0.72 with age, least length in axis on PET and PET grey level dependence matrix - low grey level emphasis selected as features.

CLINICAL RELEVANCE/APPLICATION

The ability to predict patient outcome pre-treatment aids clinical prognostication and in the future may help guide personalised therapy and improve survival.

SDP-NMMI-10 Optimal Cut-off On Standardized Static 18F-FET PET CT Imaging For Differentiating Recurrence From Post Treatment Changes In Who High Grade Glioma.

Participants
Indraja Dev, MBBS, Mumbai, India (*Presenter*) Nothing to Disclose

PURPOSE

To assess the utility of 18F FET PET/CT and derive an optimal cut-off of T-Wm ratio in differentiating recurrence from post treatment changes in WHO grade III and IV glioma.*Methods and Materials We retrospectively analyzed 72 patients of post treatment high grade glioma (WHO grade III, IV) with equivocal features on follow up MRI. Patients were injected with 5-6 mCi (185-222MBq) of 18F O-(2-[18F]fluoroethyl)-l-tyrosine (FET). Dedicated static imaging of the brain was performed at 20 minutes post injection. T-Wm ratio was used as semi quantitative parameter. It is ratio of SUVmax at the tumor divided by SUVmean of contralateral white matter. Cutoff of 2.5 was used for image interpretation. Imaging findings were confirmed with either histopathological diagnosis in a multidisciplinary joint clinic or based on clinicoradiological follow up of patients.*Results Out of 72 patients, 41 were reported as recurrent disease, on follow up, 35 of them were confirmed as having recurrent disease and remaining 6 patients were interpreted as false positive. 31 patients were reported to have post treatment change, on follow up, 27 were confirmed as post treatment changes and 4 patients had confirmed recurrence on subsequent MR imaging. A cut-off of 2.65 with Youden's index of 0.7 was derived based on Receiver operating characteristic curve (ROC) analysis with sensitivity of 80% & specificity of 87.5%.*Conclusions Single point static 18F FET PET/CT can be used as specific imaging modality with optimal cut-off of 2.65 for T-Wm ratio to differentiate recurrence from post treatment changes in WHO grade III, IV Glioma with equivocal MRI

features.*Clinical Relevance/Application 18F FET PET/CT Imaging can help in early detection of recurrence & guide further treatment management and prognostication.

RESULTS

Out of 72 patients, 41 were reported as recurrent disease, on follow up, 35 of them were confirmed as having recurrent disease and remaining 6 patients were interpreted as false positive. 31 patients were reported to have post treatment change, on follow up, 27 were confirmed as post treatment changes and 4 patients had confirmed recurrence on subsequent MR imaging. A cut-off of 2.65 with Youden's index of 0.7 was derived based on Receiver operating characteristic curve (ROC) analysis with sensitivity of 80% & specificity of 87.5%.

CLINICAL RELEVANCE/APPLICATION

18F FET PET/CT Imaging can help in early detection of recurrence & guide further treatment management and prognostication.

SDP-NMMI-11   Impact Of Regularized Ordered Subsets Expectation-maximization Reconstruction Algorithm On Total-body 68Ga-FAPI-04 PET/CT

Participants
Yanchao Huang, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the impact of the regularized ordered subsets expectation-maximization (R-OSEM) reconstruction algorithm in total-body 68Ga-FAPI-04 PET/CT imaging and compare to OSEM reconstruction algorithm.*Methods and Materials Eleven patients (age 58.6± years, BMI 28.2±17.8 kg) with lung cancer have been enrolled in this study. They underwent a single-bed total-body 68Ga-FAPI PET examination (10 min) with standard administered dose (0.05±0.01 mCi/kg) using a 194-cm long axial field-of-view digital PET/CT scanner (uEXPLORER, United Imaging Healthcare). A series of PET images with various durations (e.g., 40 s, 60 s, 180 s, 300 s) were reconstructed using R-OSEM (Hyper Iterative, United Imaging Healthcare) and OSEM. To evaluate image quality, the overall image quality, lesion conspicuity, and image noise were scored using 5-point Likert scale. For quantitative assessment, we tracked the evolution of the time and regularization strength (ß) dependent PET-images (ß = 0.1, 0.25, 0.5, 0.75, and 1) where the objective metrics, for instance, the SUVmax at lesions, the SUVmean and SD at muscle and lesion-to-background ratio (LBR) were systematically analyzed and compared with OSEM.*Results Based on the reconstructed images of 68Ga-FAPI PET/CT, we revealed that the use of the R-OSEM reconstruction algorithm suppressed image noise and increased SUVmax at lesions. Although in 40-s PET images, the SUVmax at lesions and LBR did not show a significant difference than OSEM (T-test with/without Bonferroni correction, p > 0.2), SD at muscle illustrated an obvious difference (p < 0.05). Such improvement increased the image quality, consistent with the subjective evaluations. Specifically, R-OSEM-TOF with ß = 0.25 enables 60-s 68Ga-FAPI PET imaging to achieve a better anatomic profile and lesion conspicuity than that of OSEM.*Conclusions Combining both the R-OSEM and state-of-the-art PET/CT scanner, one can yield a PET with better image quality even at a short acquisition time.*Clinical Relevance/Application The regularized OSEM reconstruction algorithm has the potential to shorten the PET acquisition time while retaining the image quality.

RESULTS

Based on the reconstructed images of 68Ga-FAPI PET/CT, we revealed that the use of the R-OSEM reconstruction algorithm suppressed image noise and increased SUVmax at lesions. Although in 40-s PET images, the SUVmax at lesions and LBR did not show a significant difference than OSEM (T-test with/without Bonferroni correction, p > 0.2), SD at muscle illustrated an obvious difference (p < 0.05). Such improvement increased the image quality, consistent with the subjective evaluations. Specifically, R-OSEM-TOF with ß = 0.25 enables 60-s 68Ga-FAPI PET imaging to achieve a better anatomic profile and lesion conspicuity than that of OSEM.

CLINICAL RELEVANCE/APPLICATION

The regularized OSEM reconstruction algorithm has the potential to shorten the PET acquisition time while retaining the image quality.

SDP-NMMI-12   F-18 Amyvid PET CT In Asymptomatic Patients: Manual Versus Automated Analysis And Association With Patients' Global Cognitive Function

Participants
Riham El Khouli, MD,PhD, Nicholasville, Kentucky (*Presenter*) Nothing to Disclose

PURPOSE

Amyloid (Aß) deposition occurs years or even decades before the start of cognitive decline (preclinical Alzheimer's disease [pAD]). Amyloid (Aß)-PET imaging has been reliably used to detect pAD across numerous studies. Although visual assessment of Aß-PET imaging is considered gold standard, it is subject to inter-reader variability. Various software packages have been created to provide quantitative analysis to support clinical interpretation. The present study sought to (1) explore the correlation between the fully automated analysis using the commercial image analysis tool available at University of Kentucky- Siemens Syngo.via® Neurology software package with manual analysis using Mirada (version XD3, Mirada Medical Ltd, New Road, Oxford, UK) and (2) evaluate the performance of each method in reference to the Montréal Cognitive Assessment (MoCA) test performance as global cognitive function*Methods and Materials 90 participants with normal cognition or mild cognitive impairment underwent Aß-PET imaging and cognitive testing using MOCA. Regional and global standardized uptake value ratio (SUVr) were determined using the Siemens Syngo.via® and manually using Mirada. Pearson correlation was used to assess agreement between the two software readings . Relationships between global SUVr and MoCA test performance were analyzed using adjusted linear regression models.*Results Participants included 58 women and 32 men with a mean age of 73.9±6.1 years, education 16.4±2.7 years, MoCA 25.7± 2.9, Global Aß-PET SUVr using Mirada 1.27± .27 and Global Aß-PET SUVr using Syngo.via 1.31± .24. There was significant correlation between the two methods (Pearson correlation coefficient 0.7 p value <.001). Age, gender and education adjusted linear regression analysis demonstrated that both manual and automated segmentation were significantly associated with the MoCA score (P-value 0.025 & 0.034, respectively).*Conclusions Very good agreement between the manual and fully automated analysis of F-18 Amyvid PET images. In normal and mild cognitive impairment patients, there was significant association between global amyloid SUVr and global cognitive function.*Clinical Relevance/Application In preclinical Alzheimer's disease patients, global SUVr was significantly associated with global cognitive function assessed with MoCA test.

RESULTS

Participants included 58 women and 32 men with a mean age of 73.9±6.1 years, education 16.4±2.7 years, MoCA 25.7± 2.9, Global Aß-PET SUVr using Mirada 1.27± .27 and Global Aß-PET SUVr using Syngo.via 1.31± .24. There was significant correlation between the two methods (Pearson correlation coefficient 0.7 p value <.001). Age, gender and education adjusted linear regression analysis demonstrated that both manual and automated segmentation were significantly associated with the MoCA score (P-value 0.025 & 0.034, respectively).

CLINICAL RELEVANCE/APPLICATION

In preclinical Alzheimer's disease patients, global SUVr was significantly associated with global cognitive function assessed with MoCA test.

SDP-NMMI-13   IVIM-DWI And DTI In Pancreatic Cancer: Comparison With Normal Pancreas And Multiparametric PET/MR Imaging Biomarkers

Participants
Bang Bin Chen, MD, Taipei, Taiwan (*Presenter*) Nothing to Disclose

PURPOSE

To compare intravoxel incoherent motion (IVIM) diffusion-weighted imaging (DWI) and diffusion tensor imaging (DTI) biomarkers between pancreatic cancer and normal pancreas, and correlate with clinical stages and other PET/MR imaging biomarkers*Methods and Materials Twenty-four patients (mean age 62.30 ± 12.3 years, 11 men, 13 women) with pancreatic ductal adenocarcinoma were prospectively enrolled in this study. All of them received PET/MR before treatment. The imaging biomarkers from IVIM (D*, D, f) and DTI [axial, radial, mean diffusivity, fractional anisotropy (FA) from DTI] were obtained from pancreatic cancer and normal pancreas respectively. Besides, these biomarkers were correlated with clinical TNM stages and other PET/MR imaging biomarkers of pancreatic cancer, including dynamic contrast-enhanced MRI (Peak, AUC, Ktrans, Kep, Ve), DWI (ADCmin), MR spectroscopy (Creatine, NAA, Choline, Glutamine and Glutamate(Glx), and Lipid) and PET parameters [SUVmax, SUVmean, MTV (metabolic tumor volume), TLG (total lesion glycolysis]. The paired t-test, Pearson correlation test and t-test were used for statistical analysis.*Results When compared with normal pancreatic parenchyma, pancreatic cancer had significantly decreased f (P < .001). DCE-MRI parameters, Ktrans and Ve, were significantly correlated with f, mean diffusivity, axial diffusivity, and radial diffusivity. ADCmin was correlated with D*, D, and axial diffusivity. MRS metabolites, creatine and lipid, were negatively correlated with f and D, respectively. PET parameters, SUVmean and SUVmax, were correlated with FA, mean diffusivity and axial diffusivity (all P < 0.05). No differences were found in the IVIM and DTI parameters with clinical TNM stages.*Conclusions IVIM and DTI parameters may reflect tumor vascular permeability, interstitial space, cellularity, metabolites and metabolic activity in pancreatic cancer.*Clinical Relevance/Application IVIM and DTI biomarkers may be used to detect and evaluate pancreatic cancer aggressiveness noninvasively.

RESULTS

When compared with normal pancreatic parenchyma, pancreatic cancer had significantly decreased f (P < .001). DCE-MRI parameters, Ktrans and Ve, were significantly correlated with f, mean diffusivity, axial diffusivity, and radial diffusivity. ADCmin was correlated with D*, D, and axial diffusivity. MRS metabolites, creatine and lipid, were negatively correlated with f and D, respectively. PET parameters, SUVmean and SUVmax, were correlated with FA, mean diffusivity and axial diffusivity (all P < 0.05). No differences were found in the IVIM and DTI parameters with clinical TNM stages.

CLINICAL RELEVANCE/APPLICATION

IVIM and DTI biomarkers may be used to detect and evaluate pancreatic cancer aggressiveness noninvasively.

SDP-NMMI-14   PSMA PET/CT To Decrease Futile Interventions In High-risk And Biochemically Recurrent Prostate Cancer

Participants
Guillaume Chausse, MD, Montreal, Quebec (*Presenter*) Nothing to Disclose

PURPOSE

High-risk and biochemically recurrent prostate cancers are challenging to diagnose and therefore to treat optimally, in part due to the lack of sensitivity of conventional imaging (CT abdomen and pelvis and bone scintigraphy) for metastases. Prostate-specific membrane antigen (PSMA) PET/CT is the most accurate available imaging tool to image prostate cancer metastases. We aimed to determine the impact on patient management of 18F-DCFPyL (PSMA) PET/CT and thereby quantify the number of futile therapies avoided and what replaced them.*Methods and Materials Patients referred for high-risk staging (HRS) and biochemical recurrence (BCR) of prostate cancer underwent PSMA PET/CT as part of a prospective clinical trial (NCT03459820). Treating physicians completed a standardized questionnaire of planned treatment prior to PET/CT referral and a second questionnaire of final treatment after PETCT results. All planned treatments before PSMA PET/CT that were cancelled after PSMA PET/CT results were considered "futile". Final treatments that were not initially planned were considered "added".*Results One hundred forty-two (142) patients (91 biochemical recurrences; 51 high-risk staging) underwent 18F-DCFPyL PET/CT. Change of management by PSMA PET/CT was 44% for BCR and 45% for HRS. In total for HRS and BCR, 7 surgeries (radical prostatectomy/pelvic lymph node dissection), 14 radiation therapies (salvage prostate or pelvic radiation) were spared; 23 planned systemic therapies (ADT, NAAD, chemotherapy) and two targeted radiation treatments to metastases were cancelled. Added treatments were 5 surgeries, 22 radiation therapies, 13 systemic therapies, 14 metastases-targeted radiation treatments. Four patients opted for follow-up only. Surgeries were cancelled when unresectable lesions were found, and added when false-positive metastases outside the pelvis on conventional imaging were considered true-negative on PSMA PET/CT. Deferral of androgen deprivation therapy was a common management change after PSMA PET for BCR patients (n=16, 18%) while addition of pelvic radiation was a common treatment plan change in the HRS group (added n=9, 18%; futile n = 5, 10%).*Conclusions Many futile therapies can be avoided with more accurate staging and restaging through PSMA PET/CT. Its use, as suggested by high change of management, may eventually lead to improved quality of care. Further analysis will reveal the cost related PSMA PET and treatment changes.*Clinical Relevance/Application Clinical use of PSMA PET/CT is rapidly increasing and quantification of its pertinence is paramount in improving cost-efficiency of medical procedures.

RESULTS

One hundred forty-two (142) patients (91 biochemical recurrences; 51 high-risk staging) underwent 18F-DCFPyL PET/CT. Change of management by PSMA PET/CT was 44% for BCR and 45% for HRS. In total for HRS and BCR, 7 surgeries (radical

prostatectomy/pelvic lymph node dissection), 14 radiation therapies (salvage prostate or pelvic radiation) were spared; 23 planned systemic therapies (ADT, NAAD, chemotherapy) and two targeted radiation treatments to metastases were cancelled. Added treatments were 5 surgeries, 22 radiation therapies, 13 systemic therapies, 14 metastases-targeted radiation treatments. Four patients opted for follow-up only. Surgeries were cancelled when unresectable lesions were found, and added when false-positive metastases outside the pelvis on conventional imaging were considered true-negative on PSMA PET/CT. Deferral of androgen deprivation therapy was a common management change after PSMA PET for BCR patients (n=16, 18%) while addition of pelvic radiation was a common treatment plan change in the HRS group (added n=9, 18%; futile n = 5, 10%).

CLINICAL RELEVANCE/APPLICATION

Clinical use of PSMA PET/CT is rapidly increasing and quantification of its pertinence is paramount in improving cost-efficiency of medical procedures.

SDP-NMMI-15 Diagnostic Performance Of CT, MRI, And FDG PET For Detection Of Liver Metastases In Rectal Cancer Patients Under Primary Staging: A PET/MRI Comparative Study

Participants
Poliana Zampieri, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

To compare the diagnostic performance of fluorine 18 fluorodeoxyglucose (FDG) positron emission tomography (PET), abbreviated (T2w and DWI) liver magnetic resonance imaging (MRI), and abdominopelvic contrast-enhanced computed tomography (ceCT) for detection of liver metastasis in patients with rectal cancer under primary staging.*Methods and Materials Retrospective analysis of ninety patients that underwent PET/MRI and abdominopelvic CT within 2 weeks between October/2016 and December/2018 for primary rectal cancer staging. Six readers (two in consensus for each method) analyzed FDG-PET, MRI, and ceCT images for detection of liver metastases. For ceCT, three categories were defined (positive, negative, or indeterminate). Indeterminate lesions on ceCT were independently reclassified on MRI and PET. Number of lesions (at a maximum of five) was recorded for ceCT and MRI. Standard of reference was biopsy and/or clinical follow-up. McNemar test and ROC curves were used to calculate diagnostic accuracy.*Results A total of 97 liver metastases were confirmed in 24 (27%) of the 90 patients. The detection rate of liver lesions was 77/97 (79.4%), 93/97 (95.9%), and 90/97 (92.8%) on ceCT, MRI, and FDG-PET. On a patient-based analysis, the sensitivity/specificity of CT, MR and FDG PET for detection of liver metastasis were 66.7%/98.5%, 91.7%/97.0%, and 87.5%/98.5%, respectively. AUC was 82.6% for ceCT, 93.0% for PET, and 94.3% for MRI. Twelve patients presented indeterminate lesions on CT, which 5 were true positive on FDG-PET and MRI, 1 was true positive of MRI (and false positive on FDG-PET), and 6 were true negative on FDG-PET and MRI.*Conclusions MRI presented the highest detection rate, sensitivity and specificity to detect liver metastases of rectal cancer under primary staging in comparison to ceCT and FDG-PET. MRI more accurately reclassified indeterminate lesions on ceCT.*Clinical Relevance/Application MRI is the preferred imaging modality to evaluate liver metastases of rectal cancer in patients under primary staging.

RESULTS

A total of 97 liver metastases were confirmed in 24 (27%) of the 90 patients. The detection rate of liver lesions was 77/97 (79.4%), 93/97 (95.9%), and 90/97 (92.8%) on ceCT, MRI, and FDG-PET. On a patient-based analysis, the sensitivity/specificity of CT, MR and FDG PET for detection of liver metastasis were 66.7%/98.5%, 91.7%/97.0%, and 87.5%/98.5%, respectively. AUC was 82.6% for ceCT, 93.0% for PET, and 94.3% for MRI. Twelve patients presented indeterminate lesions on CT, which 5 were true positive on FDG-PET and MRI, 1 was true positive of MRI (and false positive on FDG-PET), and 6 were true negative on FDG-PET and MRI.

CLINICAL RELEVANCE/APPLICATION

MRI is the preferred imaging modality to evaluate liver metastases of rectal cancer in patients under primary staging.

SDP-NMMI-16 Effects Of Liver Diseases On Liver And Blood Pool As Metabolic References In FDG PET/CT

Participants
Kwok Sing Ng, PhD,MBBS, Hong Kong, Hong Kong (*Presenter*) Nothing to Disclose

PURPOSE

The liver and the bloodpool activity are commonly referred as metabolic standards in FDG PET/CT for lesion characterization, including lymphoma, solid tumors and vasculitis. This study aims to evaluate the effects of different liver diseases on the liver and bloodpool activity.*Methods and Materials A total of 168 patients who underwent FDG PET/CT for tumor staging were included, all without evidence of liver tumor. Their clinical background, blood results, radiological images and endoscopic findings were reviewed. Each subject was categorized into one of the five groups accordingly: the control (N = 50), hyperbilirubinemia (N = 29), cirrhosis (N = 27), fatty liver (N = 52) and polycystic liver disease (N = 10). The mean Standardized Uptake Values (SUV) of liver and blood pool of each subject were measured. The SUVliver/SUVbloodpool ratio, an analogue of visual interpretation, of each subject was evaluated. Statistical analyses were performed, including two-sample t tests and linear regressions.*Results The control had a mean SUVliver/SUVbloodpool ratio of 1.39, with all of the subjects having liver activity greater than bloodpool activity (i.e. SUV ratio > 1). For hyperbilirubinemia group, the serum bilirubin levels of the 29 subjects ranged from 23 to 667μmol/L, and 89.7% of the subjects had elevated bilirubin as well as other liver enzyme(s). Hyperbilirubinemia group had mean SUV ratio of 1.49, which was greater than that in the control with statistical significance (p=0.0053). Subsequent linear regression analysis showed that the SUV ratio increased for increasing serum bilirubin level. For cirrhosis group, 59.3% of the subjects had cirrhotic features documented in at least two modalities (e.g. USG, CT and OGD). Its mean SUV ratio of 1.29 was less than that of the control and the difference was statistically significant (p=0.0003). For fatty liver group, the mean SUV ratio of 1.28 is less than that of the control and this difference was statistically significant (p=0.0002). Linear regression analysis showed that the more fatty became the liver, the less the SUV ratio was. For polycystic liver disease group, the mean SUV ratio was 0.75. This striking finding was in opposite to the control and other groups which all had ratios =1.*Conclusions This study showed that different liver diseases could alter liver and bloodpool activity in FDG PET/CT. As the liver diseases were more severe, their effects on the metabolic reference became more prominent.*Clinical Relevance/Application Many FDG PET/CT guidelines recommend to characterize a lesion using visual interpretation, based on liver and bloodpool activity as metabolic reference. This study demonstrates the importance of reviewing hepatic condition before referring liver and blood pool in visual interpretation.

RESULTS

The control had a mean SUVliver/SUVbloodpool ratio of 1.39, with all of the subjects having liver activity greater than bloodpool

activity (i.e. SUV ratio > 1). For hyperbilirubinemia group, the serum bilirubin levels of the 29 subjects ranged from 23 to 667μmol/L, and 89.7% of the subjects had elevated bilirubin as well as other liver enzyme(s). Hyperbilirubinemia group had mean SUV ratio of 1.49, which was greater than that in the control with statistical significance (p=0.0053). Subsequent linear regression analysis showed that the SUV ratio increased for increasing serum bilirubin level. For cirrhosis group, 59.3% of the subjects had cirrhotic features documented in at least two modalities (e.g. USG, CT and OGD). Its mean SUV ratio of 1.29 was less than that of the control and the difference was statistically significant (p=0.0003). For fatty liver group, the mean SUV ratio of 1.28 is less than that of the control and this difference was statistically significant (p=0.0002). Linear regression analysis showed that the more fatty became the liver, the less the SUV ratio was. For polycystic liver disease group, the mean SUV ratio was 0.75. This striking finding was in opposite to the control and other groups which all had ratios =1.

CLINICAL RELEVANCE/APPLICATION

Many FDG PET/CT guidelines recommend to characterize a lesion using visual interpretation, based on liver and bloodpool activity as metabolic reference. This study demonstrates the importance of reviewing hepatic condition before referring liver and blood pool in visual interpretation.

SDP-NMMI-17 Appropriate B Value For Computed DWI Results In Superior Capability For N-stage Assessment Of Non-small Cell Lung Cancer Patients Than That Of Actual DWI, STIR Imaging Or FDG-PET/CT

Participants
Yoshiharu Ohno, MD,PhD, Toyoake, Japan (Presenter) Research Grant, Canon Medical Systems Corporation;Research Grant, DAIICHI SANKYO Group

PURPOSE

Computed DWI (cDWI) using an appropriate b value may result in better malignant lesion detection capability than actual DWI (aDWI) in oncologic patients. The purpose of this study was to prospectively determine the appropriate b value for cDWI to attain a better diagnostic capability for N-staging of non-small cell lung cancer (NSCLC) patients than can be attained with aDWI, short inversion time inversion recovery (STIR) imaging or FDG-PET/CT.*Methods and Materials aDWI with b values of 0 and 1000 (aDWI1000) s/mm2, STIR imaging and FDG-PET/CT were administered to 245 NSCLC patients (127 men, 118 women; mean age 75 years). Each subject generated cDWIs using 400 (cDWI400), 600 (cDWI600), 800 (cDWI800) and 2000 (cDWI2000) s/mm2. Based on pathological examination results, 114 metastatic nodes and 114 non-metastatic nodes were selected for evaluation of contrast ratio (CR) for each cDWI and aDWI, ADC, lymph node to muscle ratio (LMR) on STIR imaging and SUVmax, as well as probability of lymph node metastasis score of each method. ROC analysis was performed to determine threshold value on a per node basis. Accuracy (AC) of each method for N-stage classification on a per patient basis was also compared by using McNemar's test.*Results Area under the curve (AUC) of CR600 (AUC=0.86) was significantly higher than that of other quantitative indexes (0.69=AUC=0.81, p<0.0001). Moreover, AUCs (0.80=AUC=0.82) of qualitatively assessed cDWI600, cDWI800, ADC map, aDWI1000 and STIR imaging were significantly higher than those of cDWI400 (AUC=0.76: p<0.05), cDWI2000 (AUC=0.76: p<0.05) and PET/CT (AUC=0.75: p<0.05). ACs for N-stage classification of CR600 (AC=90.2%) and CR800 (AC=89.4%) were significantly higher than those of others (p<0.05). In addition, ACs of qualitatively assessed cDWI600 (AC=86.5%) and cDWI800 (AC=86.1%) were significantly higher than those of cDWI400, cDWI2000 and PET/CT (p<0.05).*Conclusions Computed DWI using an appropriate b value can result in significantly superior N-staging accuracy compared to that of actual DWI and PET/CT and can be considered at least as effective as STIR imaging for NSCLC patients.*Clinical Relevance/Application cDWI using an appropriate b value can result in significantly superior N-staging accuracy compared to that of aDWI and PET/CT and can be considered at least as effective as STIR imaging for NSCLC.

RESULTS

Area under the curve (AUC) of CR600 (AUC=0.86) was significantly higher than that of other quantitative indexes (0.69=AUC=0.81, p<0.0001). Moreover, AUCs (0.80=AUC=0.82) of qualitatively assessed cDWI600, cDWI800, ADC map, aDWI1000 and STIR imaging were significantly higher than those of cDWI400 (AUC=0.76: p<0.05), cDWI2000 (AUC=0.76: p<0.05) and PET/CT (AUC=0.75: p<0.05). ACs for N-stage classification of CR600 (AC=90.2%) and CR800 (AC=89.4%) were significantly higher than those of others (p<0.05). In addition, ACs of qualitatively assessed cDWI600 (AC=86.5%) and cDWI800 (AC=86.1%) were significantly higher than those of cDWI400, cDWI2000 and PET/CT (p<0.05).

CLINICAL RELEVANCE/APPLICATION

cDWI using an appropriate b value can result in significantly superior N-staging accuracy compared to that of aDWI and PET/CT and can be considered at least as effective as STIR imaging for NSCLC.

SDP-NMMI-18 The Usefulness Of Machine Learning Approach Using 18F-FDG-PET-based Radiomic And Deep Learning Features For Differentiating Between Thymic Cancer And Thymoma

Participants
Masatoyo Nakajo, MD, PhD, Kagoshima, Japan (Presenter) Nothing to Disclose

PURPOSE

Pretreatment differentiation between thymic cancer and thymoma is important, as their treatment strategies and prognoses are markedly different. The purpose of this study was to determine whether the machine learning (ML) approach using 18F-FDG-PET-based radiomic and deep learning features is useful for differentiating thymic cancer from thymoma.*Methods and Materials Included in this retrospective study were 79 patients with pathologically diagnosed thymic epithelial tumors (TETs) who underwent 18F-FDG-PET/CT before treatment. The patients were classified into thymic cancer (n=21) and thymoma (n=58) groups. The PET-based 107 radiomic features including 3 conventional SUV-related parameters (SUVmax, MTV, TLG) were extracted from the pyradiomics package, and 1024 deep learning features were extracted from the convolutional neural network. These radiomics and deep learning features were used to predict thymic cancer using six different ML algorithms (random forest, k-nearest neighbors, logistic regression, decision tree, gradient boost and support vector machine) with a five-fold cross-validation and bagging method. Each ML algorithm calculated the probability for thymic cancer based on which tumor was classified as either thymic cancer (probability =0.50) or thymoma (probability <0.50). The AUCs were calculated to compare the predictive performances between the conventional parameters and the ML algorithms.*Results On the ROC analysis for conventional SUV-related parameters, the AUC for predicting thymic cancer was 0.71 for SUVmax (sensitivity 0.71, specificity 0.67, accuracy 0.68), 0.44 for MTV (sensitivity 0.52, specificity 0.31, accuracy 0.37) and 0.48 for TLG (sensitivity 0.48, specificity 0.43, accuracy 0.44), respectively. Among 6 ML algorithms, the logistic regression showed the highest AUC with 0.90 (sensitivity 0.77, specificity 0.82, accuracy 0.79). The AUC of this logistic regression model was significantly higher than that of each conventional SUV-related parameter (p<0.05,

each).*Conclusions The ML approach using 18F-FDG-PET-based radiomic and deep learning features may be useful for differentiating between thymic cancer and thymoma.*Clinical Relevance/Application The ML approach using 18F-FDG-PET-based radiomic and deep learning features may be more useful than SUV-related parameters for differentiating between thymic cancer and thymoma in patients with TET.

RESULTS

On the ROC analysis for conventional SUV-related parameters, the AUC for predicting thymic cancer was 0.71 for SUVmax (sensitivity 0.71, specificity 0.67, accuracy 0.68), 0.44 for MTV (sensitivity 0.52, specificity 0.31, accuracy 0.37) and 0.48 for TLG (sensitivity 0.48, specificity 0.43, accuracy 0.44), respectively. Among 6 ML algorithms, the logistic regression showed the highest AUC with 0.90 (sensitivity 0.77, specificity 0.82, accuracy 0.79). The AUC of this logistic regression model was significantly higher than that of each conventional SUV-related parameter (p<0.05, each).

CLINICAL RELEVANCE/APPLICATION

The ML approach using 18F-FDG-PET-based radiomic and deep learning features may be more useful than SUV-related parameters for differentiating between thymic cancer and thymoma in patients with TET.

SDP-NMMI-19 Estimation Of 123I-IMP Arterial Blood Activity Concentration By Using Neural Network; Possibility Of Omitting Arterial Blood Sampling

Participants
Tetsuro Kaga, MD, Gifu, Japan (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to estimate 123I-IMP arterial blood radioactivity concentration in dual table autoradiography (DTARG) method by using artificial neural network.*Methods and Materials This Retrospective study included 164 patients who underwent measurement of regional cerebral blood flow using DTARG method with 123I-IMP. Neural network was applied to regression problems. Objective variable was 123I-IMP arterial blood radioactivity concentration, while explanatory variable was defined as 28 numeric parameters in the first scan, including patient characteristic value, total injection 123I-IMP radiation dose, and distribution of 123I-IMP in brain. We divided the dataset into training (n = 125), validation (n = 22), and testing sets (n = 17), machine learning with neural networks was performed. Levenberg-Marquardt algorithm was used as loss function. We obtained two estimated values which were determined by our algorithm and conventional method developed by iida et al. The correlation coefficient and the root mean squared error were calculated to evaluate the goodness of fit between the estimated values and the actual measured values by arterial blood sampling.*Results The coefficient of determination of our algorithm was higher than that of conventional method (0.865 and 0.322, respectively). The root mean squared error of our algorithm was smaller than that of conventional method (8.677 and 19.788, respectively).*Conclusions Our proposed neural network-based algorithm could more accurately estimate 123I-IMP arterial blood radioactivity concentration in DTARG than conventional method.*Clinical Relevance/Application It is expected to reduce burden of patient and doctor associated with arterial blood sampling in DTARG. Not only in DTARG, our proposed method could be applied to all regional cerebral blood flow test using 123I-IMP.

RESULTS

The coefficient of determination of our algorithm was higher than that of conventional method (0.865 and 0.322, respectively). The root mean squared error of our algorithm was smaller than that of conventional method (8.677 and 19.788, respectively).

CLINICAL RELEVANCE/APPLICATION

It is expected to reduce burden of patient and doctor associated with arterial blood sampling in DTARG. Not only in DTARG, our proposed method could be applied to all regional cerebral blood flow test using 123I-IMP.

SDP-NMMI-2 Glucose Metabolic Rate By Dynamic18F-fdg Pet/ct Scan With A Silicon Photomultiplier: Detection Of Active Inflammation In Cardiac Sarcoidosis

Participants
Michinobu Nagao, MD, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Sarcoidosis is a systemic chronic inflammatory disease characterized by the presence of noncaseating granulomas. Cardiac involvement is one of the major causes of disease-related death.Long-term fasting 18F-Fludeoxyglucose positron emission tomography (FDG-PET)has contributed to the diagnosis of active inflammation in CS. Monitoring of the standard uptake value (SUV) alone is limited in differentiating it from physiological accumulation and in diagnosing relapse during steroid therapy. Pharmacokinetic analysis of dynamic 18F-FDG PET/CT allows quantitative assessment of in vivo glucose metabolic rate (MRglc). Here, we examine the potential of MRglcestimated from dynamic18F-FDG PET/CT to detect active inflammation in CS.*Methods and Materials 32 CS patients who underwent dynamic18F-FDG PET/CT scan with a silicon photomultiplierwere enrolled in this study. After fasting for at least 18 hours, FDG (150-220 MBq) was administered. Parametric images of MRglcwere derived from tissue and plasma blood time-activity concentration curves using the Patlak linearization approach, with data acquired between 25 and 55 min after injection. Then, 60 min later, a standard scan performed to calculate SUV. The correlation between MRglc and SUV for each myocardial segment was analyzed. The area above MRglccorresponding to SUV 3 was defined as active inflammation. The contrast ratio between active inflammation and normal myocardium (CR) was compared in MRglc and SUV images.*Results MRglcin myocardial segment showed a significant positive correlation with SUV (Pearson r, 0.79; p<0.0001). The area with SUV 3 corresponded to that with MRglc12.6 nmol/mL/min. Active inflammation was observed in 12 patients in MRglc images (MRglcrange, 12.7 to 46.5 nmol/mL/min) and 13 patients in SUV images (SUV range, 3.02 to 10.9). CR of MRglcimages was significantly higher than that of SUV images (mean CR, 11.8 versus 2.9; p<0.0001).*Conclusions The MRglcrange of active inflammation is wider than in SUV range. The contrast of the active inflammation to normal myocardium is approximately four times greater in MRglc images than in SUV images.*Clinical Relevance/Application MRglcimages has a shorter scan time than standard SUV images and can detect accurately detect the location and severity of localized inflammation.

RESULTS

MRglcin myocardial segment showed a significant positive correlation with SUV (Pearson r, 0.79; p<0.0001). The area with SUV 3 corresponded to that with MRglc12.6 nmol/mL/min. Active inflammation was observed in 12 patients in MRglc images (MRglcrange, 12.7 to 46.5 nmol/mL/min) and 13 patients in SUV images (SUV range, 3.02 to 10.9). CR of MRglcimages was significantly higher

than that of SUV images (mean CR, 11.8 versus 2.9; p<0.0001).

CLINICAL RELEVANCE/APPLICATION

MRglcimages has a shorter scan time than standard SUV images and can detect accurately detect the location and severity of localized inflammation.

SDP-NMMI-20 Effects Of A New Reconstruction Method On Noise Reduction And Contrast Improvement In Digital PET/CT

Participants
YUYA SHIRAKAWA, Tokyo, Japan (*Presenter*) Research funded, Nihon Medi-Physics Co, Ltd

PURPOSE

The digital Cartesion Prime PET/CT scanner (Canon Medical Systems, Otawara, Japan) has been in clinical operation in Japan since 2020. The scanner has SiPM technology with complete coverage, 1:1 coupling to the scintillator crystals and TOF time resolution of < 280 psec. In addition to a conventional Gaussian filter, statistical noise is reduced while maintaining contrast by a new technique called, "Clear adaptive Low-noise Method" (CaLM), based on the non-local-means principle. This technology was designed to improve image quality. Therefore, this study aimed to determine whether noise is reduced and contrast is improved more effectively by CaLM than by conventional methods.*Methods and Materials The background activity of a NEMA body phantom with hot spheres (inner diameters: 10, 13, 17, 22, 28, and 37 mm) containing 18F-FDG was set at 2.53 kBq/mL(Hot/BG = 4) according to the standard Japanese imaging protocol in which images are acquired from 60 minutes after 18F-FDG (3.7 MBq/kg) is administered. Images were acquired for 30 min/bed and reconstructed between 30-300 sec/bed at intervals of 30 sec/bed under the following clinical conditions: TOF-3D-OSEM: 3 iterations, 12 subsets, PSF(-)) with filters off, Gaussian filter 4 mm, CaLM mild. Image quality was physically evaluated as QH 10 mm, N 10 mm, and QH 10 mm/N 10mm and quantified as the SUVmax of the hot spheres with data collection for 30 minutes.*Results The noise was reduced to the same degree in PET images (N10 mm) between the Gaussian filter and CaLM; the difference of < 1% between 30 and 300 seconds. The contrast (QH 10 mm) and contrast noise ratio (QH 10 mm/N 10 mm) of PET images were up to 11% at = 90 seconds, which is the clinically applied acquisition duration, and 40% in CaLM than in Gaussian at 90-300 seconds, respectively . The SUVmax was 46% and 16% higher in CaLM than in the Gaussian filter in 10- and 13-mm spheres, respectively.*Conclusions Contrast can be further enhanced and image quality can be improved more effectively using digital PET/CT with CaLM than by the conventional method.*Clinical Relevance/Application State-of-the-art digital PET/CT with novel CaLM reconstruction can further improve noise reduction and lesion contrast, thus improving the quality of PET/CT diagnosis.

RESULTS

The noise was reduced to the same degree in PET images (N10 mm) between the Gaussian filter and CaLM; the difference of < 1% between 30 and 300 seconds. The contrast (QH 10 mm) and contrast noise ratio (QH 10 mm/N 10 mm) of PET images were up to 11% at = 90 seconds, which is the clinically applied acquisition duration, and 40% in CaLM than in Gaussian at 90-300 seconds, respectively . The SUVmax was 46% and 16% higher in CaLM than in the Gaussian filter in 10- and 13-mm spheres, respectively.

CLINICAL RELEVANCE/APPLICATION

State-of-the-art digital PET/CT with novel CaLM reconstruction can further improve noise reduction and lesion contrast, thus improving the quality of PET/CT diagnosis.

SDP-NMMI-21 Prognostic Value Of Bmipp Spect And Late Gadolinium Enhancement MRI In Cardiac Sarcoidosis

Participants
Atsushi Yamamoto, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Sarcoidosis is a systemic chronic inflammatory disease characterized by the presence of noncaseating granulomas. Cardiac involvement is one of the major causes of disease-related death. Steroid therapy is the mainstay of treating cardiac sarcoidosis (CS). Previous studies reported that late gadolinium enhancement cardiac magnetic resonance (LGE-CMR) could predict prognosis in patients with CS. However, the evaluation of LGE was limited due to implant of cardiac device or renal dysfunction. 123I-betamethyl-p-iodophenyl-pentadecanoic acid single-photon emission computed tomography (BMIPP) was developed to evaluate fatty acid metabolism and effective in detecting myocardial damage in CS. Present study aimed to investigate the relationship between LGE and myocardial damage obtained from BMIPP SPECT, and to explore the potential of BMIPP SPECT as prognostic factors in CS patients undergoing steroid therapy.*Methods and Materials Forty-one CS patients who underwent BMIPP SPECT and LGE-CMR within 2 months were enrolled. The left ventricle was divided into 17 myocardial segments on BMIPP and LGE-CMR. BMIPP defects were assessed in each segment using a scoring system from 0 to 4 (0 normal; 1 mild; 2 moderate; 3 severe; 4 absent), and total BMIPP defect score (BDS) in the entire left ventricle were calculated. LGE in each segment was assessed using a scoring system from 0 to 2 (0 none; 1 partially positive; 2 homogeneously positive), and total LGE extent score (LES) in the entire left ventricle was also calculated. The predictability of the initial BDS and LES for major adverse cardiac events (MACE), consisting of all-cause death, hospitalization due to heart failure, and recurrence or onset of sustained ventricular tachycardia and ventricular fibrillation, was analyzed using Kaplan-Meier analysis.*Results BDS showed a significant correlation with LES (r = 0.82, p < 0.0001). Patients with LES =9 had a significantly higher MACE rate than patients with BDS <9 (log-rank test, p=0.030). Patients with BDS =16 also had a significantly higher MACE rate than patients with BDS <16 (log-rank test, p=0.016).*Conclusions Myocardial damage assessed by BMIPP SPECT correlated with LGE extent. Both BDS and LES have the predictive values of MACE in CS.*Clinical Relevance/Application In CS, many patients have cardiac devices implanted, including defibrillation, which limits the evaluation of CMR. In comparison, BMIIPP has the advantage of being performed without the influence of cardiac devices.

RESULTS

BDS showed a significant correlation with LES (r = 0.82, p < 0.0001). Patients with LES =9 had a significantly higher MACE rate than patients with BDS <9 (log-rank test, p=0.030). Patients with BDS =16 also had a significantly higher MACE rate than patients with BDS <16 (log-rank test, p=0.016).

CLINICAL RELEVANCE/APPLICATION

In CS, many patients have cardiac devices implanted, including defibrillation, which limits the evaluation of CMR. In comparison, BMIIPP has the advantage of being performed without the influence of cardiac devices.

SDP-NMMI-22 **Differentiation Of Trauma And Bone Metastasis Of RI Accumulation In The Ribs Of Bone Scintigraphy Using AI, And Visualization Of The Site Of Interest Of AI By Grad-CAM**

Participants
Shigeaki Higashiyama, MD,PhD, Osaka, Japan (*Presenter*) Nothing to Disclose

PURPOSE

There are many studies by applying deep learning technology all over the world. In recent years, in the field of diagnostic images using Deep Convolutional Neural Network (DCNN), a method for visualizing the diagnostic basis called Grad-CAM has been proposed, but there is no report of visualizing the diagnostic basis in bone scintigraphy. Our aim is to develop an algorithm that uses DCNN to classify and diagnose whether RI accumulation on the ribs is bone metastasis or trauma using only anterior chest SPOT images in bone scintigraphy. Furthermore, it is also intended to visualize the area of ??interest of DCNN for abnormal accumulation of bone scintigraphy.*Methods and Materials The subjects were 100 cases in which abnormal RI accumulation in the ribs was diagnosed as bone metastasis by bone scintigraphy performed at our hospital, and 100 cases in which it was accumulated in trauma. We equally divided all 200 cases into ten groups. Nine groups for the training dataset, one group for the testing dataset. To prevent the overfitting, 10-fold cross-validation were applied. Using the Transfer Learning method, we classified RI abnormal accumulation on the ribs, and by using Grad-CAM, we visualized the area of ??interest of DCNN.*Results Bone metastasis lesions could be detected with an accuracy of 88.2%. In addition, it was possible for DCNN to visualize bone metastases and areas of interest.*Conclusions It is possible to diagnose bone metastasis with high diagnostic accuracy using the algorithm we have developed this time.In addition, clarifying the diagnostic criteria that DCNN judged to be bone metastasis will contribute to the development of deep learning in the nuclear medicine department.*Clinical Relevance/Application Diagnosing abnormal RI accumulation on the ribs without adding oblique imaging is useful in reducing imaging time rand educing burden on patients.

RESULTS

Bone metastasis lesions could be detected with an accuracy of 88.2%. In addition, it was possible for DCNN to visualize bone metastases and areas of interest.

CLINICAL RELEVANCE/APPLICATION

Diagnosing abnormal RI accumulation on the ribs without adding oblique imaging is useful in reducing imaging time rand educing burden on patients.

SDP-NMMI-23 **Differentiation Between Sarcopenia And Nonsarcopenia In Non-small Cell Lung Cancer Patients Using Skeletal Muscle PET Radiomics**

Participants
Dong Xing, MD, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

Sarcopenia has been recognized as an independent risk factor for patients with non-small cell lung cancer (NSCLC), reducing patients' life quality and shortening overall survival. However, there are some shortages in the existing imaging diagnostic methods for sarcopenia. This article aimed to study the ability of skeletal muscle PET radiomics features combined with machine learning classifiers to identify sarcopenia in advanced NSCLC patients.*Methods and Materials This study retrospectively analyzed the clinical and imaging data of 99 patients with NSCLC who underwent 18F-FDG-PET/CT examination before treatment. The patients were randomly divided into the training set (n = 69) and the test set (n = 30). Sarcopenia was diagnosed by skeletal muscle index at the third lumbar vertebrae level (L3-SMI). Then, 474 skeletal muscle PET imaging radiomics were extracted from a single slice of PET images at the first lumbar (L1) vertebrae level. This study used 42 machine learning classification combinations (including six feature selection methods and seven machine learning classifiers) to assess the ability of skeletal muscle PET radiomics features on the differentiation of sarcopenia and non-sarcopenia in NSCLC patients. The receiver operating characteristic (ROC) area under the curve (AUC) was used as the leading indicator to evaluate the performance of different classification schemes.*Results A total of 40 sarcopenias were found in 99 patients with advanced NSCLC. Among 42 machine learning classification schemes, the LightGBM machine learning algorithm combined with the Boruta feature selection method (LGB_Bo) had optimal performance in identifying sarcopenia in NSCLC patients, with accuracy and AUC on the test set were 0.867 and 0.977, respectively. The Logistic Regression classifier (AUC, 0.956; accuracy, 0.828) and Boruta feature selection method (AUC, 0.952; accuracy, 0.829) showed excellent average performance among the classifiers and feature selection methods employed in our study, respectively.*Conclusions Based on skeletal muscle PET radiomics combined with machine learning classifiers could provide a new method for diagnosing sarcopenia in NSCLC patients.*Clinical Relevance/Application This study proves that skeletal muscle PET imaging features combined with an appropriate machine learning classification can effectively distinguish sarcopenia and non-sarcopenia patients with non-small cell lung cancer, providing a new and potential tool for the early and non-invasive diagnosis of tumor sarcopenia.

RESULTS

A total of 40 sarcopenias were found in 99 patients with advanced NSCLC. Among 42 machine learning classification schemes, the LightGBM machine learning algorithm combined with the Boruta feature selection method (LGB_Bo) had optimal performance in identifying sarcopenia in NSCLC patients, with accuracy and AUC on the test set were 0.867 and 0.977, respectively. The Logistic Regression classifier (AUC, 0.956; accuracy, 0.828) and Boruta feature selection method (AUC, 0.952; accuracy, 0.829) showed excellent average performance among the classifiers and feature selection methods employed in our study, respectively.

CLINICAL RELEVANCE/APPLICATION

This study proves that skeletal muscle PET imaging features combined with an appropriate machine learning classification can effectively distinguish sarcopenia and non-sarcopenia patients with non-small cell lung cancer, providing a new and potential tool for the early and non-invasive diagnosis of tumor sarcopenia.

SDP-NMMI-24 **Relationship Between Metabolic Status On 18F-FDG PET/CT With Expression Of Programmed Death Ligand 1 (PD-L1) And Mutation Of EGFR And KRAS In Pulmonary Invasive Mucinous Adenocarcinomas**

Participants
Zhao Long, MD, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

Pulmonary invasive adenocarcinoma (ADA) is a series of heterogeneous tumours with different genetic characteristics. Previous studies have shown that clinical stage, tumour size and histologic subtype influence 18F-fluorodoxyglucose (18F-FDG) uptake in ADA. The purpose of this study is to investigate the predictive value of 18F-FDG positron emission tomography/computed tomography (PET/CT) in evaluating PD-L1 expression and Mutation of EGFR and KRAS in invasive mucinous adenocarcinomas (IMA).*Methods and Materials From April 2016 to December 2020, IMA were retrospectively identified in 209 consecutive patients who underwent 18F-FDG PET/CT scan. All patients underwent surgical resection and the diagnosis were confirmed. The maximum standardized uptake value (SUVmax) of 18F-FDG uptake were calculated for the primary lesion. PD-L1 expression test and mutation status of EGFR and KRAS were underwent.*Results PD-L1 expression were identified in 4/64 patients (6.3%). EGFR and KRAS mutations were identified in 6/130 patients (4.6%) and 32/68 patients (47.1%), respectively. The study shown that only SUVmax was significantly associated with PD-L1 expression (P = 0.023). Using a SUVmax cut-off value of 5.5 in predicting PD-L1-positivity, the receiver operating characteristic curve analysis showed that the AUC was 0.833(95%CI, 0.728-0.938; P = 0.027). The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy in predicting PD-L1-positivity were 100.0%, 75.0%, 21.1%, 100.0%, and 76.6%, respectively.*Conclusions With a high sensitivity and negative predictive value, the SUVmax should be used for predicting PD-L1 expression in IMA. However, the SUVmax was not significant differences between the mutation status of EGFR and KRAS.*Clinical Relevance/Application For the first time, we demonstrated that the SUVmax could predict PD-L1 expression in patients with IMA, and could not predict mutation status of EGFR and KRAS.

RESULTS

PD-L1 expression were identified in 4/64 patients (6.3%). EGFR and KRAS mutations were identified in 6/130 patients (4.6%) and 32/68 patients (47.1%), respectively. The study shown that only SUVmax was significantly associated with PD-L1 expression (P = 0.023). Using a SUVmax cut-off value of 5.5 in predicting PD-L1-positivity, the receiver operating characteristic curve analysis showed that the AUC was 0.833(95%CI, 0.728-0.938; P = 0.027). The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy in predicting PD-L1-positivity were 100.0%, 75.0%, 21.1%, 100.0%, and 76.6%, respectively.

CLINICAL RELEVANCE/APPLICATION

For the first time, we demonstrated that the SUVmax could predict PD-L1 expression in patients with IMA, and could not predict mutation status of EGFR and KRAS.

SDP-NMMI-25   Imaging-visible Bioprinted Microcapsules For Beta Cell Encapsulation Treating Type I Diabetes

Participants
Yingli Fu, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

To investigate whether bioprinted, perfluorinated, fibrin-alginate composite microcapsules can be generated to improve cell survival and function and enable image-guided, targeted delivery via small-bore catheters or needles.*Methods and Materials Mouse insulinoma cells were used to develop the prototype fibrin-alginate microcapsules. Cell printing was performed using a custom-made, fully automated, 3D bioprinting system equipped with a single-jet stationary piezoelectric printhead of 80 or 100 μm. The formulations of bioink consisting of fibrin, alginate, and a contrast agent, perfluorooctyl bromide (PFOB), were optimized to ensure the continuous generation of cell-encapsulated, monodisperse, imaging-visible microcapsules. The viability of bioprinted cells was assessed using a live/dead staining and cell function was analyzed by immunocytochemistry and glucose-stimulated insulin production assays. The bioprinted microcapsules were fully characterized in terms of size, permeability, X-ray visibility, and small-bore catheter/needle compatibility.*Results Using an 80 μm-sized printhead, the bioprinted microcapsules with perfluorinated fibrin-alginate hydrogel can be generated with an average size of 55.8 ± 4.1 μm. There was no significant cell viability loss after printing and the viability in both bioprinted small-sized microcapsules and conventional larger (~ 300 μm) microcapsules was maintained for up to 2 weeks (>90%). Bioprinted microcapsules were visible on X-ray and could pass 2.4 Fr catheters or 22 G needles without significant deformation or breakage. Cell function as measured by insulin secretion was preserved. The bioprinted cells had a slightly higher glucose responsiveness stimulation index (4.8 ± 0.4) than conventionally encapsulated cells (4.3 ± 0.5).*Conclusions Beta cell printing using perfluorinated fibrin-alginate hydrogel shows promise for minimally invasive, targeted treatment of diabetes.*Clinical Relevance/Application Bioprinted, X-ray-visible, small size microcapsules could facilitate targeted delivery of beta cell therapeutic via minimally invasive injections for Type I diabetes treatment.

RESULTS

Using an 80 μm-sized printhead, the bioprinted microcapsules with perfluorinated fibrin-alginate hydrogel can be generated with an average size of 55.8 ± 4.1 μm. There was no significant cell viability loss after printing and the viability in both bioprinted small-sized microcapsules and conventional larger (~ 300 μm) microcapsules was maintained for up to 2 weeks (>90%). Bioprinted microcapsules were visible on X-ray and could pass 2.4 Fr catheters or 22 G needles without significant deformation or breakage. Cell function as measured by insulin secretion was preserved. The bioprinted cells had a slightly higher glucose responsiveness stimulation index (4.8 ± 0.4) than conventionally encapsulated cells (4.3 ± 0.5).

CLINICAL RELEVANCE/APPLICATION

Bioprinted, X-ray-visible, small size microcapsules could facilitate targeted delivery of beta cell therapeutic via minimally invasive injections for Type I diabetes treatment.

SDP-NMMI-26   Brazilian Multicentric Experience Of Peptide Receptor Radionuclide Therapy In Neuroendocrine Tumors

Participants
Claudio Mesquita, MD,PhD, Niteroi, Brazil (*Presenter*) Speakers Bureau, SERVIER;Speakers Bureau, Pfizer Inc

PURPOSE

Peptide receptor radionuclide therapy (PRRT) is a well-established treatment modality for gastroenteropancreatic neuroendocrine tumors (GEPNETs). PRRT received FDA approval in 2018 for treatment of somatostatin receptor-positive GEPNETs based on NETTER-1 trial data that included grade 1 and 2 midgut neuroendocrine tumors but in the clinical practice, PRRT is used other types of NETs. We present real-world data of PRRT outcomes and implementation from four tertiary treatment centers in Brazil with PRRT. This multicenter study adds to the evidence regarding the utility of PRRT for NETs of different sites besides GEPNETs.*Methods and Materials A retrospective review of patients with NETs who received 177Lu-dotatate PRRT between January 2007 and January 2021 in 4 hospitals across Brazil was undertaken. Data from 160 histologically proven NET were evaluated. Data regarding demographics, efficacy, and toxicity was evaluated at each site by the treating clinician.*Results Hundred and sixty patients (83 female) received

a median of four 177Lu-dotatate treatments (range from 1-8). Primary tumor localizations were midgut (28%), pancreas (27.5%), foregut (17.5%), neuroendocrine CUP (11%), hindgut (7%), lung (3%), and other sites (6%). Complete follow-up was obtained in 96 patients. Median progression-free survival (PFS) was 11.9 months and 30 patients died (31%). Complete response was found in 4 patients (4%) and 18 patients had disease progression during PRRT (18%). Only four patients had significant renal toxicity. PRRT was associated with hematological toxicity in 12 patients.*Conclusions We noted a higher rate of PRRT use in non-midgut sites like the pancreas and the foregut. Median PFS was considerably lower than observed in Netter-1 trial, reflecting the higher risk tumors included. Despite this, treatment-related toxicity in our cohort was considerably low. PRRT was considered safe with minimal hematological and renal toxicity.*Clinical Relevance/Application These results demonstrate the potential benefit of PRRT in a range of NETs. PRRT was safe with very few adverse effects. Randomized clinical trials are needed to consolidate the potential impact of PRRT in other NET localizations than GEPNETS allowing the inclusion of this therapy in oncological guidelines.

RESULTS

Hundred and sixty patients (83 female) received a median of four 177Lu-dotatate treatments (range from 1-8). Primary tumor localizations were midgut (28%), pancreas (27.5%), foregut (17.5%), neuroendocrine CUP (11%), hindgut (7%), lung (3%), and other sites (6%). Complete follow-up was obtained in 96 patients. Median progression-free survival (PFS) was 11.9 months and 30 patients died (31%). Complete response was found in 4 patients (4%) and 18 patients had disease progression during PRRT (18%). Only four patients had significant renal toxicity. PRRT was associated with hematological toxicity in 12 patients.

CLINICAL RELEVANCE/APPLICATION

These results demonstrate the potential benefit of PRRT in a range of NETs. PRRT was safe with very few adverse effects. Randomized clinical trials are needed to consolidate the potential impact of PRRT in other NET localizations than GEPNETS allowing the inclusion of this therapy in oncological guidelines.

SDP-NMMI-3 18F-thk5351 Pet/ct In Patients With Newly Diagnosed High Grade Glioma

Participants
Katsuya Mitamura, Kagawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

18F-THK5351 (THK5351) has a high binding affinity and selectivity for tau. However, the potential for off-target binding with monoamine oxidase-B (MAO-B), which is a highly expressed enzyme in astrocytes, has been shown recently. The purpose of this study was to evaluate the accumulation of THK5351 PET in patients with newly diagnosed high grade glioma.*Methods and Materials Thirteen patients with newly diagnosed high grade glioma (3 WHO grade III and 10 WHO grade IV) were investigated with THK5351 PET/CT before therapy. PET emission data were acquired for 50-70 min after an intravenous injection of THK5351. The maximum standardized uptake value (SUVmax) and tumor-to-ipsilateral normal cerebellum (T/N) ratio were calculated.*Results All tumors had increased THK5351 uptake. The mean (±SD) SUVmax of the tumor in grade IV (2.34 ± 1.16) was significantly higher than that in grade III (0.54 ± 0.11) (p = 0.01). The mean (±SD) T/N ratio in grade IV (7.96 ± 3.72) was significantly higher than that in grade III (1.84 ± 0.19) (p = 0.01).*Conclusions These preliminary results suggest that THK5351 PET may be useful for the detection and differentiating WHO grade, in patients with newly diagnosed high grade glioma.*Clinical Relevance/Application THK5351 PET may be useful for the detection and differentiating WHO grade, in patients with newly diagnosed high grade glioma.

RESULTS

All tumors had increased THK5351 uptake. The mean (±SD) SUVmax of the tumor in grade IV (2.34 ± 1.16) was significantly higher than that in grade III (0.54 ± 0.11) (p = 0.01). The mean (±SD) T/N ratio in grade IV (7.96 ± 3.72) was significantly higher than that in grade III (1.84 ± 0.19) (p = 0.01).

CLINICAL RELEVANCE/APPLICATION

THK5351 PET may be useful for the detection and differentiating WHO grade, in patients with newly diagnosed high grade glioma.

SDP-NMMI-4 FDG PET-CT In Atherosclerosis: Role In Assessing Disease Activity.

Participants
Sikandar Shaikh, DMRD, Hyderabad, India (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the role of FDG PET-CT in the assessment of disease activity in large vessel atherosclerosis with associated vasculitis.*Methods and Materials 55 Whole body PET/CT scans were performed in 18 pts with known atherosclerosis and associated Large Vessel Vasculitis (giant cell arteritis, Takayasu arteritis or idiopatic aortitis). Vascular uptake evaluated and quantified by using the graded 4-point scale of evaluation (0=no uptake, 1=less than liver, 2=similar to liver, 3=higher than liver). Grade 0-1 uptake was negative, Grade 2 uptake was moderately positive and Grade 3 uptake was markedly positive. These PET/CT findings were correlated with clinical indices including ITAS (Indian Takayasu Activity Score) and Kerr/National Institute of Health (Kerr/NIH), serum acute-phase reactants (ESR, C-reactive protein [CRP]) levels as well as interleukin-6 (IL-6) and the soluble IL-6 receptor (sIL-6R). Based on these findings the assessment was quantified.*Results 43% of 55 PET-CT cases were negative, 31% were moderately positive, and 26% were markedly positive. The significant correlation between the FDG uptake and ESR and CRP levels was also found. Significantly higher ESR values were observed in pts with markedly positive PET/CT (48.4 + 35.5 mm/1st h) compared with moderately positive (26 + 20 mm/1st h, p = 0.0001) and inactive scans (21.7 + 15.9 mm/1st h, p=0.0001). The range of the CRP levels were 0.8+1.0 mg/dL in pts with inactive scans, 1.3+ 2.2 mg/dL in pts with moderately positive (p=0.001) and 3.0 + 3.6 in patients with markedly positive scans (p = 0.0001). Higher levels of IL-6 had aresulted in patients with markedly positive scans (10.0 + 8.9 pg/ml) compared to those with inactive scans (8.1+18.5 pg/ml, p=0.013). We found no association and correlation between sIL-6R levels and vascular FDG uptake. There was a significant association between vascular FDG uptake and both ITAS and Kerr/NIH scores.*Conclusions Thus Whole Body FDG PET/CT is a useful tool for evaluating disease activity in patients with atherosclerosis and associated Large Vessel Vasculitis.*Clinical Relevance/Application Thus FDG has very important role in the evaluation of the Atherosclerosis and Large Vessel vasculitis

RESULTS

43% of 55 PET-CT cases were negative, 31% were moderately positive, and 26% were markedly positive. The significant correlation between the FDG uptake and ESR and CRP levels was also found. Significantly higher ESR values were observed in pts with markedly positive PET/CT (48.4 + 35.5 mm/1st h) compared with moderately positive (26 + 20 mm/1st h, p = 0.0001) and

inactive scans (21.7 + 15.9 mm/1st h, p=0.0001). The range of the CRP levels were 0.8+1.0 mg/dL in pts with inactive scans, 1.3+ 2.2 mg/dL in pts with moderately positive (p=0.001) and 3.0 + 3.6 in patients with markedly positive scans (p = 0.0001). Higher levels of IL-6 had aresulted in patients with markedly positive scans (10.0 + 8.9 pg/ml) compared to those with inactive scans (8.1+18.5 pg/ml, p=0.013). We found no association and correlation between sIL-6R levels and vascular FDG uptake. There was a significant association between vascular FDG uptake and both ITAS and Kerr/NIH scores.

CLINICAL RELEVANCE/APPLICATION

Thus FDG has very important role in the evaluation of the Atherosclerosis and Large Vessel vasculitis

SDP-NMMI-5 Poly(n-vinyl Caprolactam) Nanogels Conjugated With Mno2And Cytosine-phosphorothioate-guanine Oligodeoxynucleotides For Radiotherapy Of Orthotopic Glioblastoma

Participants
Meijuan He, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

Multiforme glioblastoma (GBM) is among the most aggressive and fatal primary brain tumours, and many modern treatments are ineffective against GBM. We designed an immune-activated nanoplatform of poly(N-vinyl caprolactam) nanogels (PVCL NGs) loaded with MnO2 and cytosine-phosphorothioate-guanine oligodeoxynucleotides (CpG ODNs) as a theranostic platform for magnetic resonance imaging (MRI)-guided immune-activated radiotherapy for GBM.*Methods and Materials We synthesized CpG NGs (PVCL-MnO2-CpG) by combining MnO2 with CpG ODNs within PVCL NGs. The anti-tumor efficiency of CpG NGs combined with RT was determined in vitro. C6 cells were treated with irradiation combined with PBS, PVCL-CpG, PVCL-MnO2, or PVCL-MnO2-CpG. Then, the cell viability, survival fraction and generation of histone ?-H2AX (?-H2AX) were detected. Besides, the expression of stimulator of interferon genes (STING) and interferon-ß (IFN-ß) in C6 cells were detected by western blotting. To evaluate the maturation of dendritic cells (DCs), bone- marrow-derived DCs were cocultured with C6 cells. In vivo, T1-weighted magnetic resonance images were taken before and at 1h, 2h, 4h, 10h, 24h post-injection of PVCL-MnO2 on glioblastoma-bearing mice. Afterwards, we evaluated the synergistic effect of RT and PVCL-MnO2-CpG. The tumour volume was recorded every 3 days. Finally, tumors were dissected for TUNEL staining and detection of protein levels. Moreover, single-cell suspensions of lymph nodes, spleens and tumor tissues were prepared and analysed by flow cytometry.*Results According to the study in vitro, PVCL-MnO2-CpG not only activated cyclic GMP-AMP synthase (cGAS)/stimulator of interferon genes (STING) pathway based on DNA damage, but also promoted the maturation of DCs. Compared with the group of RT, PVCL-MnO2-CpG + RT reduced the tumour growth rate in mice by 3.4 times (P<0.05) in vivo. Moreover, the number of CD3+CD8+ T cells in tumour sites of RT+PVCL-MnO2-CpG was nearly 20 folds higher than that RT alone (P<0.01). Besides, RT+PVCL-MnO2-CpG-treated mice displayed stronger immune activation in lymph nodes and spleen.*Conclusions The results indicated that Mn2+ could successfully traverse the blood-brain barrier and realised T1-weighted imaging. DNA damage caused by RT strengthened the cGAS/STIN kG pathway synergistic with Mn2+, and the resulting secretion of cytokines enhanced anti-tumour immunity. Upon treatment with CpG ODNs, DCs are activated and exhibited excellent therapeutic efficacy in inhibiting glioblastoma growth.*Clinical Relevance/Application Magnetic resonance imaging (MRI)-guided immune-activated radiotherapy may serve as an effective method for improving the therapeutic efficacy of the of GBM.

RESULTS

According to the study in vitro, PVCL-MnO2-CpG not only activated cyclic GMP-AMP synthase (cGAS)/stimulator of interferon genes (STING) pathway based on DNA damage, but also promoted the maturation of DCs. Compared with the group of RT, PVCL-MnO2-CpG + RT reduced the tumour growth rate in mice by 3.4 times (P<0.05) in vivo. Moreover, the number of CD3+CD8+ T cells in tumour sites of RT+PVCL-MnO2-CpG was nearly 20 folds higher than that RT alone (P<0.01). Besides, RT+PVCL-MnO2-CpG-treated mice displayed stronger immune activation in lymph nodes and spleen.

CLINICAL RELEVANCE/APPLICATION

Magnetic resonance imaging (MRI)-guided immune-activated radiotherapy may serve as an effective method for improving the therapeutic efficacy of the of GBM.

SDP-NMMI-6 Diagnostic Algorithm To Predict Malignancy In New Nodules Detected On 18 FDG PET-CT During Follow Up Of Lung Cancer Patients

Participants
Ankush Jajodia, DMRD,MBBS, New Delhi, India (*Presenter*) Nothing to Disclose

PURPOSE

To classify new nodules detected during follow-up imaging with 18 FDG PET-CT in treated lung cancer patients.*Methods and Materials Two radiologists with different levels of clinical experience interpreted attenuation corrected CT images, without the use of iodinated contrast and PET fused images in a cohort of 101 patients diagnosed and treated with lung cancer from Jan 2013- Jan 2019. Doubts were resolved in consensus by senior thoracic radiologists with more than 25 years of experience. Nodule diameter,morphology (round, lobulated, spiculated), attenuation, and SUV max were recorded on an excel sheet. Readers were blinded to each other's interpretation and final clinical outcome (Gold standard was tissue sampling in the majority and follow up of 1 year). Interobserver agreement was assessedwith kappa statistic. AUC was calculated for individual parameters to assess diagnostic performance. Ten-fold cross-validated, multivariate classification analysis, using the classification and regression trees (CRT) algorithm was used to develop a stratification algorithm to classify nodules.*Results Sixty-five patients had malignant nodules proven on histopathology and 36 were benign. The range of diameter of the nodule was 3-26 mm, HU was 2-59 HU and SUV max was 1.1- 38.4. The best diagnostic performance was given by SUV max (AUC = 0.87), followed by nodule diameter (AUC =0.659) and nodule attenuation (AUC = 0.507), with statistical significance between attenuation andSUV max. The interobserver agreement between readers was substantial (k?=?0.796; 95% CI, 0.67-0.91). Multivariate classification analysis using the CRT algorithm retained two variables: SUV max and morphology of nodule. Diagnostic accuracy was 84.8 % in the testing set with 100% correctidentification of all benign nodules and false downgrade to benign in 20% of malignant cases.*Conclusions Our study showed that incorporating nodule morphology with SUV max metrics could help avoid re-biopsy in lung cancer patients with new nodules.*Clinical Relevance/Application New nodules during treatment and follow-up in lung cancer patients have an impact on management. Re-biopsy can be avoided by appropriate combined interpretation of nodule morphology and SUV.

RESULTS

Sixty-five patients had malignant nodules proven on histopathology and 36 were benign. The range of diameter of the nodule was 3-26 mm, HU was 2-59 HU and SUV max was 1.1- 38.4. The best diagnostic performance was given by SUV max (AUC = 0.87),

followed by nodule diameter (AUC =0.659) and nodule attenuation (AUC = 0.507), with statistical significance between attenuation andSUV max. The interobserver agreement between readers was substantial (k?=?0.796; 95% CI, 0.67-0.91). Multivariate classification analysis using the CRT algorithm retained two variables: SUV max and morphology of nodule. Diagnostic accuracy was 84.8 % in the testing set with 100% correctidentification of all benign nodules and false downgrade to benign in 20% of malignant cases.

CLINICAL RELEVANCE/APPLICATION

New nodules during treatment and follow-up in lung cancer patients have an impact on management. Re-biopsy can be avoided by appropriate combined interpretation of nodule morphology and SUV.

SDP-NMMI-7 Dosimetry Of Absorbed Dose Using Single-Photon Emission Computed Tomography Images In I-131 Therapy For Hyperthyroidism

Participants
Haruna Ikeda, Nagoya, Japan (*Presenter*) Nothing to Disclose

PURPOSE

This study calculated the thyroid uptake rate (RIU), effective half-life (EHL), and absorbed dose after I-131 therapy using single-photon emission computed tomography (SPECT) images and compared them with the pretreatment data.*Methods and Materials Forty-five patients with Graves' disease were recruited and retrospectively evaluated. Before dosimetry, we used a phantom filled with uniform iodine-131 (78 MBq) to obtain the conversion factor for calculating radioactivity based on SPECT counts. Four uptake assessments performed at 3, 24, 96, and 168 h after oral administration of I-131 (3.7 MBq) were used to deduce the RIU and EHL before I-131 therapy. The I-131 uptake rate after therapy was calculated by setting a volume of interest on the thyroid gland on SPECT images 24 and 168 h after I-131 administration, converting the counts obtained into radioactivity and dividing the administered radioactivity. The EHL was calculated by approximating RIUs after 24 and 168 h as a mono-exponential function. The absorbed dose before and after therapy were calculated using the Marinelli-Quimby equation. We used the Bonferroni-corrected Wilcoxon-Mann-Whitney test to assess the relationship between the therapeutic outcomes (hypothyroidism, euthyroidism, and hyperthyroidism) and the thyroid-absorbed dose before and after therapy. We used Peaprerson's correlation coefficient to assess the association among EHL, 24-h RIU, and absorbed dose before and after therapy.*Results We found a positive correlation among the 24-h RIU (r=0.58), EHL (r=0.60), and absorbed dose (r=0.68) before and after therapy, but the value decreased after therapy in many cases. The absorbed doses before and after treatment were significantly higher in patients with hypothyroidism (n=28) than in those with hyperthyroidism (n=11). In those with euthyroidism (n=6), there were many cases have lower absorbed dose after therapy.*Conclusions The EHL, RIU, and absorbed dose after treatment well correlated with the pretreatment values but decreased after treatment. The absorbed dose tends to reflect the therapeutic outcome; thus, it is necessary to determine the absorbed dose after therapy.*Clinical Relevance/Application Dosimetry of absorbed dose using SPECT imaging can visualize the distribution of iodine in the thyroid gland in therapy and may be useful in I-131 therapy planning.

RESULTS

We found a positive correlation among the 24-h RIU (r=0.58), EHL (r=0.60), and absorbed dose (r=0.68) before and after therapy, but the value decreased after therapy in many cases. The absorbed doses before and after treatment were significantly higher in patients with hypothyroidism (n=28) than in those with hyperthyroidism (n=11). In those with euthyroidism (n=6), there were many cases have lower absorbed dose after therapy.

CLINICAL RELEVANCE/APPLICATION

Dosimetry of absorbed dose using SPECT imaging can visualize the distribution of iodine in the thyroid gland in therapy and may be useful in I-131 therapy planning.

SDP-NMMI-8 Simple And Cost-free Strategies For Occupational Radiation Dose Reduction In 13N-ammonia Myocardial Perfusion PET

Participants
Takahiro Yano, RT, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

13N-ammonia myocardial perfusion positron emission tomography (Ammonia PET) is an established modality to assess myocardial ischemia and quantitate myocardial blood flow. However, Ammonia PET procedures include complicated tasks contributing to occupational radiation exposure (ORE). The purpose of this study was to evaluate the radiation dose of medical staff and establish the feasible strategies for ORE reduction in Ammonia PET.*Methods and Materials Forty-five Ammonia PET were performed by 2 workflows. In workflow A (n=28), a rest scan was first performed, and a nuclear medicine technologist (NMT) placed electrodes for the electrocardiogram (ECG) on the patient before stress scan (n=28). In workflow B (n=17), NMT first placed ECG electrodes on the patient and rest and stress images were scanned. The total radiation dose of NMT in one examination was compared between workflow A and B. For each scan, 370-450 MBq of 13N-ammonia was filled in the infusion system by a physician (Phys) and injected into a right antecubital vein using PET shielding. During pharmacological stress, Phys monitored ECG either on the patient's cranial side (n=17) or the left side of PET gantry (n=28). The radiation dose of Phys for 13N-ammonia injection and ECG monitoring were measured separately. To find out the appropriate point of monitoring ECG, we compared the radiation dose of Phys at these 2 points. All radiation doses were measured with electric dosemeters over their chests.*Results The average total radiation dose of NMT by workflow B was significantly lower than that by workflow A (4.91 ± 2.24 µSv vs 6.58 ± 2.20 µSv, p<0.05). The radiation dose of Phys for 13N-ammonia injection was 3.50 ± 1.17 µSv per examination. Interestingly, Phys received lower ORE on the left side of PET gantry than on the patient's cranial side (0.11 ± 0.02 µSv vs 1.53 ± 0.25 µSv, p<0.05) during pharmacological stress.*Conclusions The radiation dose of NMT in Ammonia PET can be easily reduced by adjusting the workflow. ORE in Ammonia PET can be minimized by standing on the left side of PET gantry instead of the patient's cranial side. These are simple strategies for ORE reduction without additional cost.*Clinical Relevance/Application Reordering the workflow and standing on the left side of PET gantry during pharmacological stress were simple strategies to reduce ORE in Ammonia PET without additional cost.

RESULTS

The average total radiation dose of NMT by workflow B was significantly lower than that by workflow A (4.91 ± 2.24 µSv vs 6.58 ± 2.20 µSv, p<0.05). The radiation dose of Phys for 13N-ammonia injection was 3.50 ± 1.17 µSv per examination. Interestingly, Phys received lower ORE on the left side of PET gantry than on the patient's cranial side (0.11 ± 0.02 µSv vs 1.53 ± 0.25 µSv, p<0.05) during pharmacological stress.

SDP-NMMI-9 A Pilot Study Of 68Ga-PSMA11 And 68Ga-RM2 PET/MRI For Biopsy Guidance In Patients With Suspected Prostate Cancer

Participants
Heying Duan, MD, Stanford, California (*Presenter*) Nothing to Disclose

PURPOSE

Targeting of lesions seen on prostate multiparametric MRI (mpMRI) improves prostate cancer (PC) detection at biopsy. However, 20-65% of highly suspicious lesions on MRI (PIRADS 4 or 5) prove to be false positives (FP) at biopsy. Here, we evaluated the potential utility of 68Ga-PSMA11 and 68Ga-RM2 PET/MRI for biopsy guidance in patients with suspected PC and prior negative biopsy or equivocal MRI.*Methods and Materials Nine men, aged 59.8±4.6 years, with suspected PC were prospectively enrolled to undergo 68Ga-PSMA11 and 68Ga-RM2 PET/MRI, including mpMRI. The prostate was divided into 12 segments (apex lateral, apex medial, base lateral, base medial, mid lateral, mid medial, left and right, respectively) using PET/MRI data and MIM software. Maximum standardized uptake values (SUVmax) of suspected PC lesions and background for each segment was collected. Biopsies after PET/MRI included 1 core through each of the 12 segments and targeted sampling of any lesions seen on PET. PET/MRI results were then compared to the gold standard biopsy.*Results PSA and PSA density were 11.07±6.57 ng/mL and 0.20±0.12 ng/mL2, respectively. Prostate biopsy prior to imaging was available in 7/9 patients of which 4 were negative and 3 showed Gleason score (GS) 7. mpMRI was negative in 4 patients, 4 showed PIRADS 4 and 1 patient PIRADS 5. 68Ga-PSMA11 and 68Ga-RM2 PET/MRI each identified 18 lesions, however 6 lesions in 3 patients were incongruent. PET/MRI guided biopsy led to the additional finding of 3 clinically significant tumors with GS 7 in 3 patients as well as 2 with GS 6 in 2 patients. Suspected lesions concordant between mpMRI and both radiotracers were seen in 2 patients: PET/MRI guided biopsy confirmed GS 7 in one patient and GS 6 for the other patient, whereas 1 GS 7 lesion was missed by all modalities. All other biopsy verified GS 7 and GS 6 lesions were identified by both radiotracers. Mean SUVmax for true positives (TP) was slightly higher than FP, however not statistically significant (Mean SUVmax for TP (GS 7) vs. FP lesions: 10.64±8.07 vs. 6.44±4.64 [P=0.38] for 68Ga-PSMA11, and 19.24±17.8 vs. 12.5±13 [P=0.47] for 68Ga-RM2).*Conclusions Our preliminary results show that both 68Ga-PSMA11 and 68Ga-RM2 PET/MRI are not only feasible for biopsy guidance in suspected PC, but also identified additional cancers not seen on mpMRI. However, larger studies are needed to shed light on the different expression patterns of PSMA and gastrin releasing peptide receptor in PC.*Clinical Relevance/Application Molecular imaging with 68Ga-PSMA11 and 68Ga-RM2 PET/MRI are feasible for biopsy guidance in suspected PC and may identify additional cancers not seen on mpMRI.

RESULTS

PSA and PSA density were 11.07±6.57 ng/mL and 0.20±0.12 ng/mL2, respectively. Prostate biopsy prior to imaging was available in 7/9 patients of which 4 were negative and 3 showed Gleason score (GS) 7. mpMRI was negative in 4 patients, 4 showed PIRADS 4 and 1 patient PIRADS 5. 68Ga-PSMA11 and 68Ga-RM2 PET/MRI each identified 18 lesions, however 6 lesions in 3 patients were incongruent. PET/MRI guided biopsy led to the additional finding of 3 clinically significant tumors with GS 7 in 3 patients as well as 2 with GS 6 in 2 patients. Suspected lesions concordant between mpMRI and both radiotracers were seen in 2 patients: PET/MRI guided biopsy confirmed GS 7 in one patient and GS 6 for the other patient, whereas 1 GS 7 lesion was missed by all modalities. All other biopsy verified GS 7 and GS 6 lesions were identified by both radiotracers. Mean SUVmax for true positives (TP) was slightly higher than FP, however not statistically significant (Mean SUVmax for TP (GS 7) vs. FP lesions: 10.64±8.07 vs. 6.44±4.64 [P=0.38] for 68Ga-PSMA11, and 19.24±17.8 vs. 12.5±13 [P=0.47] for 68Ga-RM2).

CLINICAL RELEVANCE/APPLICATION

Molecular imaging with 68Ga-PSMA11 and 68Ga-RM2 PET/MRI are feasible for biopsy guidance in suspected PC and may identify additional cancers not seen on mpMRI.

Reproductive Imaging Wednesday Poster Discussions

Sub-Events

RI04-A1   **Role Of Biplanar Evaluation Of The Fetal Palate In The 11-14 Weeks' Sonogram**

Participants
Divya Singh, MBBS, MD, Chandigarh, India (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the role of analysing the fetal palate in the coronal and sagittal planes in the 11-14 weeks' sonogram*Methods and Materials 15 cases of fetal facial clefts diagnosed between 11-14 weeks were included in the study. 200 normal fetuses were included. Coronal and sagittal scanning of the face in B mode was used in screening for palatine clefts. The sagittal plane was the same as that used for assessing the nuchal translucency. Besides the traditional anterior coronal plane of retronasal triangle used for assessing the primary hard palate, a posterior coronal plane was sought for to assess the secondary hard palate. Diagnosis of cleft palate was confirmed on postnatal evaluation in all cases.*Results Cleft palate was seen in the anterior coronal plane in more than 90 per cent cases. In one case of isolated cleft of secondary hard palate, posterior coronal plane was useful. Mid-sagittal plane revealed clefts in more than 60 per cent cases. Parasagittal plane showed cleft in 30 percent cases. There were two false positive calls of cleft palate in the sagittal plane which were clarified in the coronal plane.*Conclusions Antenatal screening for clefts of the hard palate at 11-14 weeks is accurate using a biplanar approach. Mid-sagittal plane that has been used traditionally for nuchal translucency needs to be supplemented with coronal plane for comprehensive evaluation of fetal palate. Posterior coronal plane has an additional advantage of assessing for isolated cleft in secondary hard palate.*Clinical Relevance/Application A biplanar approach using coronal and sagittal scanning of the palate in the 11-14 weeks' scan improves the detection rate for facial clefts. First trimester is an optimal time for screening as the shadowing from facial bones is negligible. Also, early detection helps the couple to make a timely informed decision regarding further management.

RESULTS

Cleft palate was seen in the anterior coronal plane in more than 90 per cent cases. In one case of isolated cleft of secondary hard palate, posterior coronal plane was useful. Mid-sagittal plane revealed clefts in more than 60 per cent cases. Parasagittal plane showed cleft in 30 percent cases. There were two false positive calls of cleft palate in the sagittal plane which were clarified in the coronal plane.

CLINICAL RELEVANCE/APPLICATION

A biplanar approach using coronal and sagittal scanning of the palate in the 11-14 weeks' scan improves the detection rate for facial clefts. First trimester is an optimal time for screening as the shadowing from facial bones is negligible. Also, early detection helps the couple to make a timely informed decision regarding further management.

NMMI04-C1 Evaluation Of Catabolism In Patients With Cancer-associated Cachexia By PET/CT

Participants
Yang Jiang, Nanjing, China (*Presenter*) Nothing to Disclose

PURPOSE

We investigated the differences in clinical characteristics and fluorine-18-labelled fluoro-2-deoxy-d-glucose (18F-FDG) uptakes in different metabolism organs of cancer patients who developed cachexia versus those who did not. *Methods and Materials Two thousand two hundred thirty-one positron emission tomography/computed tomography (PET/CT) scans of two thousand one hundred forty-four patients with known or suspected malignancy as training set were retrospectively analyzed. When we measured fluoro-2-deoxy-d-glucose (FDG) uptakes in metabolism organs, different slices were selected and delineated with the volume of interest (VOI) of the corresponding size. Baseline characteristics, laboratory examination results, and FDG uptakes of the various organs among cachexia group (n = 200, e = 204) and non-cachexia group (n = 96, e = 106) were compared in the training set. In the validation set, we include one hundred and eleven examinations of one hundred and ten patients to confirm the reliability and feasibility of risk factors derived from the training set.*Results In the training set, the FDG uptakes of the visceral fat and subcutaneous fat in the cachexia group were all higher than those in the non-cachexia group. We finally included white blood cell count and minimum standardized uptake value of lean body mass of subcutaneous fat into the multivariate logistic regression analysis.*Conclusions A multiple logistic regression model incorporating clinical variables and positron emission tomography (PET) metabolic features was better able to predict the risk of cachexia in cancer patients.*Clinical Relevance/Application When reviewing PET/CT images of cancer patients, a nuclear medicine physician may focus on changes in FDG uptake values in subcutaneous fat, which will be beneficial in the clinical assessment of the risk of cachexia in cancer patients.

RESULTS

In the training set, the FDG uptakes of the visceral fat and subcutaneous fat in the cachexia group were all higher than those in the non-cachexia group. We finally included white blood cell count and minimum standardized uptake value of lean body mass of subcutaneous fat into the multivariate logistic regression analysis.

CLINICAL RELEVANCE/APPLICATION

When reviewing PET/CT images of cancer patients, a nuclear medicine physician may focus on changes in FDG uptake values in subcutaneous fat, which will be beneficial in the clinical assessment of the risk of cachexia in cancer patients.

NMMI04-C3 FDG-PET/MRI In Graft-versus-host-disease (gvhd)

Participants
Wolfgang Roll, Muenster, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Graft versus host disease (GvHD) is a frequent complication of allogeneic stem cell transplantation (alloSCT), significantly increasing mortality. Previous imaging studies focused on the assessment of intestinal GvHD with contrast-enhanced MRI/CT or 18F-FDG-PET imaging alone. This pilot study aimed to elucidate the diagnostic value of a combined 18F-FDG-PET-MRI protocol in patients with acute intestinal GvHD.*Methods and Materials Between 2/2015 and 8/2019, 21 patients with acute intestinal GvHD underwent 18F-FDG-PET-MRI. PET, MRI and PET-MRI datasets were independently reviewed. Readers assessed the reliability of the diagnosis on a 5-point Likert scale (1="no GvHD", to 5="definitely GvHD"). Quantitative PET (SUVmax, SUVpeak, metabolic volume (MV)) and MRI parameter (wall thickness), were correlated to clinical staging of acute intestinal GvHD.*Results The detection rate for acute intestinal GvHD was 56.8 % for PET, 61.4 % for MRI and 100% for PET-MRI. PET-MRI (median Likert-scale value: 5; range: 4-5) offers a significantly higher reliability of the diagnosis compared to PET (median: 4; range: 2-5; p=0.01) and MRI alone (median: 4; range: 3-5; p=0.03). The number of affected segments in PET-MRI (rs=0.677; p<0.001) and the MV (rs=0.703; p<0.001) correlated significantly with clinical stage. SUVmax (rs=0.345; p=0.14), SUVpeak (rs=0.276; p=0.24) and wall thickness (rs=0.174; p=0.17) did not correlate with clinical stage.*Conclusions In this pilot study combined 18F-FDG-PET-MRI allows for a highly reliable assessment of acute intestinal GvHD. 18F-FDG-PET-MRI parameters add information indicating clinical severity.*Clinical Relevance/Application 18F-FDG-PET-MRI allows for advanced assessment of acute intestinal GvHD combining advantages of molecular and morphological imaging. Quantitative 18F-FDG-PET-MRI parameter correlate with clinical stage and thus add information indicating clinical severity.

RESULTS

The detection rate for acute intestinal GvHD was 56.8 % for PET, 61.4 % for MRI and 100% for PET-MRI. PET-MRI (median Likert-scale value: 5; range: 4-5) offers a significantly higher reliability of the diagnosis compared to PET (median: 4; range: 2-5; p=0.01) and MRI alone (median: 4; range: 3-5; p=0.03). The number of affected segments in PET-MRI (rs=0.677; p<0.001) and the MV (rs=0.703; p<0.001) correlated significantly with clinical stage. SUVmax (rs=0.345; p=0.14), SUVpeak (rs=0.276; p=0.24) and wall thickness (rs=0.174; p=0.17) did not correlate with clinical stage.

CLINICAL RELEVANCE/APPLICATION

18F-FDG-PET-MRI allows for advanced assessment of acute intestinal GvHD combining advantages of molecular and morphological imaging. Quantitative 18F-FDG-PET-MRI parameter correlate with clinical stage and thus add information indicating clinical severity.

PH03-A2   Influence Of Administered Contrast Agents On The Water Equivalent Diameter For CT Abdomen

Participants

An Dedulle, MSc, Leuven, Belgium (*Presenter*) Researcher, Qaelum NV;Research Grant, VLAIO

PURPOSE

A commonly used metric for patient size in personalized dosimetry is the water equivalent diameter (WED). Considering that this metric is attenuation-based and its calculation comes from the Hounsfield units in the CT image, the WED might be affected by injected contrast. The purpose of this study was to investigate the impact of administered contrast on the WED for three abdominal CT protocols.*Methods and Materials Data from three abdominal CT protocols, namely aorta (446 exams), kidney (498 exams) and upper abdomen (498 exams) protocols, were acquired with a dose management software. All exams had a non-contrast series and an arterial phase. The WED of the two series was compared with a paired t-test (significance level 0.05) for each protocol. The scan length and the tube voltage were also considered in the analysis, as they could influence the region used for the WED calculation, and the Hounsfield units, respectively.*Results For the exams under study, the mean injected volume of contrast in our hospital is 86±18ml. With the scan length being only marginally different between the non-contrast and arterial phase (mean of respectively 57cm and 57cm for the aorta, 28cm and 27cm for the kidney and 37cm and 37cm for the abdomen exams), comparison of the WED in terms of impact of administered contrast is possible without any adaptation of the WED algorithms. The mean WED for all the exams of the non-contrast series was 30±4cm. For all protocols, the WED from the two series (non-contrast and arterial phase) was found significantly different (p<0.01 for all three). The difference in WED was however less than 1cm for 85%, 91% and 95% of the aorta, kidney and upper abdomen exams respectively. From the overall dataset, only <1% of aorta, 40% of kidney and 40% of upper abdominal exams had the same tube potential and scan length between the two phases. From this smaller subset, it was found that the WED between the two phases (non-contrast and arterial phase) was again significantly different for the kidney and upper abdominal protocol (p<0.01 for both). The mean differences were respectively 0.3±0.3cm and 0.3±0.8cm. The aorta subset was excluded from this second analysis, due to the limited number of exams with constant tube voltage.*Conclusions In scans with similar scan length, the differences in WED due to contrast enhancement were small and will not be clinically relevant in most applications.*Clinical Relevance/Application When using WED as a patient size metric (e.g. for size-specific dosimetry), the impact of any non-size parameter has to be ruled out. Administered contrast does not have to be taken into account.

RESULTS

For the exams under study, the mean injected volume of contrast in our hospital is 86±18ml. With the scan length being only marginally different between the non-contrast and arterial phase (mean of respectively 57cm and 57cm for the aorta, 28cm and 27cm for the kidney and 37cm and 37cm for the abdomen exams), comparison of the WED in terms of impact of administered contrast is possible without any adaptation of the WED algorithms. The mean WED for all the exams of the non-contrast series was 30±4cm. For all protocols, the WED from the two series (non-contrast and arterial phase) was found significantly different (p<0.01 for all three). The difference in WED was however less than 1cm for 85%, 91% and 95% of the aorta, kidney and upper abdomen exams respectively. From the overall dataset, only <1% of aorta, 40% of kidney and 40% of upper abdominal exams had the same tube potential and scan length between the two phases. From this smaller subset, it was found that the WED between the two phases (non-contrast and arterial phase) was again significantly different for the kidney and upper abdominal protocol (p<0.01 for both). The mean differences were respectively 0.3±0.3cm and 0.3±0.8cm. The aorta subset was excluded from this second analysis, due to the limited number of exams with constant tube voltage.

CLINICAL RELEVANCE/APPLICATION

When using WED as a patient size metric (e.g. for size-specific dosimetry), the impact of any non-size parameter has to be ruled out. Administered contrast does not have to be taken into account.

PH03-A4   Does Energy Spectral CT Scanning Require More Radiation Dose Than Non-spectral CT Scanning?

Participants

Zhenhua Wang, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the effects of energy spectral CT scanning and non-spectral CT scanning on the image quality and radiation dose of head and neck CT examination.*Methods and Materials 30 patients with clinical multi-stage CT angiography imaging of head and neck in our hospital using spectral CT (Revolution CT, GE Healthcare) were collected. Non-spectral scanning was used for non-contrast scanning, and energy spectral imaging (GSI) was used for multi-stage CT angiography (arterial phase, venous phase and late venous phase) enhanced scan.The weight of pre-ASIR-V of both non-spectral scan and energy spectral scan (venous phase) were 40%, the non-spectral scanning protocol were as follows: tube voltage 120kV, automatic modulation tube voltage (Smart mA, range 140-740mA,the energy spectral scanning protocol were as follows: tube voltage fast kV switch (80/140 kV), tube current 200mA, noise index (NI) of both non-spectral scan and energy spectrum scan (venous phase) was 9. The CT values and SD values of the bifurcation of common carotid artery, frontal parenchyma and sternocleidomastoid muscle in non-spectral CT images and

120kVp-like energy spectral scanning (venous phase) images were measured and compared. The Dose Length Product (DLP) of non-spectral scan and spectral scan (venous phase) was recorded, and the effective dose (ED) was calculated. One-way ANOVA was used to compare the difference of SD and radiation dose between non-spectral scan and energy spectral scan (venous phase) with p<0.05 being statistically significant difference.*Results The SD of common carotid artery bifurcation, frontal lobe and sternocleidomastoid muscle in non-spectral and spectral images were 13.86±3.40, 17.19±3.01, 11.91±2.50 HU and 14.98±4.38, 18.67±6.24, 14.09±3.87 HU, respectively, with no significant difference(P>0.05).The DLP and ED of non-spectral and spectral scan were(304.94±44.96)mGy*cm,(0.94±0.13)mSv and(284.77±45.38)mGy*cm,(0.88±0.14) mSv, respectively with significant difference(P<0.05). The DLP and ED of energy spectral scan were reduced by 6.6% and 6.4%, respectively, compared with non-spectral scan.*Conclusions The image quality of head and neck were not affected by energy spectral scan and non-spectral scan, but the radiation dose of energy spectral scan was lower than that of non-spectral scan.*Clinical Relevance/Application Some scholars often believe that energy spectral scan will produce a lot of radiation dose, but this study found that energy spectral scan, on the premise of maintaining the same image quality, the radiation dose is lower than non-spectral scan, and can provide more information than non-spectral scan, so as to improve the efficiency of disease diagnosis.

RESULTS

The SD of common carotid artery bifurcation, frontal lobe and sternocleidomastoid muscle in non-spectral and spectral images were 13.86±3.40, 17.19±3.01, 11.91±2.50 HU and 14.98±4.38, 18.67±6.24, 14.09±3.87 HU, respectively, with no significant difference(P>0.05).The DLP and ED of non-spectral and spectral scan were(304.94±44.96)mGy*cm,(0.94±0.13)mSv and(284.77±45.38)mGy*cm,(0.88±0.14) mSv, respectively with significant difference(P<0.05). The DLP and ED of energy spectral scan were reduced by 6.6% and 6.4%, respectively, compared with non-spectral scan.

CLINICAL RELEVANCE/APPLICATION

Some scholars often believe that energy spectral scan will produce a lot of radiation dose, but this study found that energy spectral scan, on the premise of maintaining the same image quality, the radiation dose is lower than non-spectral scan, and can provide more information than non-spectral scan, so as to improve the efficiency of disease diagnosis.

PH03-A5   A Novel CT Tube Current Modulation Technique That Minimizes Patient Risk

Participants
Laura Klein, Heidelberg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To propose a novel tube current modulation (TCM) technique optimized for modern reconstruction methods that minimizes the effective dose as measure for patient risk in comparison to classical TCM algorithms that minimize the mAs-product.*Methods and Materials The exposure to ionizing radiation in computed tomography (CT) examinations is a concern to public health and should be kept at a minimum. Several methods for dose reduction have been proposed in scope of automatic exposure control (AEC) methods. A popular example are TCM algorithms that minimize the mAs-product (mAsTCM) but not the actual patient risk. We herein propose riskTCM, a novel TCM that minimizes effective dose as measure of risk. Based on a coarse, initial reconstruction of the patient, e.g. obtained from the topogram(s), dose can be estimated in real-time on a per-view basis using the deep dose estimation (DDE) algorithm. Combined with a segmentation, organ doses can be estimated and the effective dose per view can be computed. The optimization of a novel cost function allows for the estimation of a TCM curve that minimizes the effective dose of the CT examination. We retrospectively applied riskTCM to 20 patients covering all relevant anatomical regions and tube voltages from 70 kV to 150 kV. The resulting effective dose is compared to the dose administered without TCM (noTCM) and using mAsTCM.*Results All evaluated anatomical regions, e.g. neck, thorax, abdomen and the pelvis, benefit from riskTCM. On average, a reduction of effective dose of about 19% for the thorax, 45% for the abdomen, 26% for the pelvis, and 23% for the neck have been observed compared to today's state-of-the-art mAsTCM. Compared to noTCM, riskTCM achieves a dose reduction of about 48% on average over all considered anatomical regions.*Conclusions Risk-specific TCM allows for a reduction of effective dose and hence of patient risk in modern CT scanners. Since it modulates tube current similar to mAsTCM, an implementation of this technique on actual scanners would be straight forward and requires changes in software only. Furthermore, the cost function could be adapted to account for other risk measures besides effective dose.*Clinical Relevance/Application riskTCM can reduce the exposure to x-rays in CT examinations, particularly for organs sensitive to ionizing radiation.

RESULTS

All evaluated anatomical regions, e.g. neck, thorax, abdomen and the pelvis, benefit from riskTCM. On average, a reduction of effective dose of about 19% for the thorax, 45% for the abdomen, 26% for the pelvis, and 23% for the neck have been observed compared to today's state-of-the-art mAsTCM. Compared to noTCM, riskTCM achieves a dose reduction of about 48% on average over all considered anatomical regions.

CLINICAL RELEVANCE/APPLICATION

riskTCM can reduce the exposure to x-rays in CT examinations, particularly for organs sensitive to ionizing radiation.

PH03-A7   Single-Volume Quantitative CT Myocardial Perfusion Measurement

Participants
Logan Hubbard, BS, Irvine, California (*Presenter*) Nothing to Disclose

PURPOSE

Dynamic CT myocardial perfusion imaging enables accurate physiological assessment of coronary artery disease (CAD). However, its routine clinical use remains limited by the high radiation dose attributed to serial acquisition of 10 or more volume scans per exam. Hence, the purpose of this study was to validate a novel, low-dose, single-volume quantitative CT myocardial perfusion technique in a cardiovascular perfusion phantom, using ultrasound flow probe measurement as the reference standard.*Methods and Materials The single-volume quantitative CT perfusion technique was retrospectively validated over a range of perfusion rates (0.97 to 2.45 mL/min/g). For each perfusion rate, 15 mL of contrast material was injected (5 mL/s) with a saline chaser, followed by dynamic imaging at 100 kVp and 200 mA with a 320-slice CT scanner to capture the entire aortic enhancement curve. The image data were then used retrospectively to simulate prospective 2-mm-slice dynamic bolus tracking with aortic triggering at 150 HU followed by "acquisition" of a single whole-heart volume scan six cardiac cycles later. Importantly, the dynamic bolus tracking, trigger, and single volume scan data were then used as analytical inputs in a novel first-pass analysis compartment model to derive quantitative perfusion in mL/min/g. The error of single-volume quantitative CT perfusion measurement versus reference standard ultrasound perfusion measurement was then determined after which regression was performed.*Results The average error of single-volume

quantitative CT perfusion measurement was -0.02 ± 0.09 mL/min/g (-1.2 ± 6.3%), with a corresponding root-mean-square-error of 0.09 mL/min/g (0.11%). The CT measurements (PCT) were also related to reference standard ultrasound flow probe measurements (PUS) by PCT = 1.04 PUS - 0.1 (Pearson's r = 0.98). The average CT dose index of the technique was only 5.4 mGy.*Conclusions Using bolus tracking data and only one whole-heart volume scan, the single-volume quantitative CT perfusion technique provides accurate, low-dose, myocardial perfusion measurement in mL/min/g.*Clinical Relevance/Application The technique incorporates bolus tracking data to dramatically reduce the dose of dynamic CT perfusion. It may also be used simultaneously as a CT angiogram if acquired at a diagnostic tube current.

RESULTS

The average error of single-volume quantitative CT perfusion measurement was -0.02 ± 0.09 mL/min/g (-1.2 ± 6.3%), with a corresponding root-mean-square-error of 0.09 mL/min/g (0.11%). The CT measurements (PCT) were also related to reference standard ultrasound flow probe measurements (PUS) by PCT = 1.04 PUS - 0.1 (Pearson's r = 0.98). The average CT dose index of the technique was only 5.4 mGy.

CLINICAL RELEVANCE/APPLICATION

The technique incorporates bolus tracking data to dramatically reduce the dose of dynamic CT perfusion. It may also be used simultaneously as a CT angiogram if acquired at a diagnostic tube current.

PH03-A9   Preliminary Study Of DECT Imaging With Limited-angular-range Data

Participants
Buxin Chen, PHD, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

Dual-energy computed tomography (DECT) usually collects low- and high-kVp data with two full rotations. DECT with limited-angular-range (LAR) data can potentially reduce radiation dose and scan time, and avoid collision with patient. In this work, we investigate image reconstruction for DECT imaging with data of LAR that is smaller than 180o.*Methods and Materials We design scan configurations with overlapping scanning arcs of LAR for low- and high-kVp data. An array of LARs, spanning from 14o to 180o, is investigated. We then formulate the Image reconstruction problem from LAR data as a convex optimization problem with constraints on image's directional-total-variations (DTVs) along orthogonal axes, together with a data-l2 objective function. A first-order primal-dual algorithm is tailored, referred to as the DTV algorithm, and used to solve the optimization problem and reconstruct images. Numerical studies are carried out using a digital breast phantom with iodine contrast agent enhancement, where reconstructed images are visually assessed for artifact reduction and quantitatively analyzed for iodine concentration estimation.*Results Monochromatic images at 34 keV, as well as low- and high-kVp images, obtained with the DTV algorithm from LAR data show substantially reduced artifacts, which are observed often in images reconstructed with existing algorithms, such as FBP, in DECT. In addition, iodine-contrast concentrations can be estimated from LAR data as accurately as those from the full-scan data with 360o.*Conclusions The preliminary study reveals that it may be possible to obtain, from low- and high-kVp data of LAR, monochromatic images visually, and to estimate iodine-contrast concentration quantitatively, comparable to their counterparts obtained from full-angular-range data in DECT.*Clinical Relevance/Application The results acquired in the study may engender insights into the design of DECT with LAR scan configurations of practical application significance, for reducing radiation dose and scan time, and/or avoiding patient collision, e.g., in a C-arm CBCT.

RESULTS

Monochromatic images at 34 keV, as well as low- and high-kVp images, obtained with the DTV algorithm from LAR data show substantially reduced artifacts, which are observed often in images reconstructed with existing algorithms, such as FBP, in DECT. In addition, iodine-contrast concentrations can be estimated from LAR data as accurately as those from the full-scan data with 360o.

CLINICAL RELEVANCE/APPLICATION

The results acquired in the study may engender insights into the design of DECT with LAR scan configurations of practical application significance, for reducing radiation dose and scan time, and/or avoiding patient collision, e.g., in a C-arm CBCT.

PH01-A1   Clinical Cadmium-Telluride-Based Photon-Counting Detector In Cadaveric Wrist Imaging

Participants
Jan Grunz, MD, Wuerzburg, Germany (*Presenter*) Research Consultant, Siemens AG

PURPOSE

Detailed display of bone microarchitecture is essential for evaluating subtle wrist fractures in computed tomography. The goal of this study was to assess the performance of a novel CT with clinical cadmium-telluride-based photon-counting detector (PCD-CT) compared to a third-generation dual-source CT scanner with energy-integrating detector build (EID-CT).*Methods and Materials Eight cadaveric wrists were examined with both systems using radiation dose equivalent acquisition protocols (low-/standard-/full-dose: CTDIvol=1.5/5.8/8.7 mGy). All wrists were scanned with the two operating modes of the photon-counting CT (standard-resolution mode, ultra-high-resolution mode). After reformation with comparable convolution kernels, three radiologists performed subjective evaluation of image quality for each dataset. In order to estimate the interrater agreement, the intraclass correlation coefficient was calculated (based on absolute agreement in a two-way random-effects model). Signal-to-noise and contrast-to-noise ratios were computed based on CT number measurements in predefined regions of interest to provide an additional semiquantitative measure of image quality.*Results Subjective image quality of standard-dose PCD-CT scans in ultra-high-resolution mode was superior compared to full-dose EID-CT (p=.040) and full-dose PCD-CT in standard-resolution mode (p=.016). No difference was ascertained between low-dose PCD-CT in ultra-high-resolution mode and standard-dose scans with either EID-CT (p=.470) or PCD-CT in standard-resolution mode (p=.108). Observer evaluation of EID-CT and standard-resolution PCD-CT delivered similar results in full-dose and standard-dose examinations (p=.248/.509). Intraclass correlation coefficient was 0.876 (95% confidence interval: 0.744-0.925; p<.001), indicating good reliability. Between dose equivalent studies, signal-to-noise and contrast-to-noise ratios were substantially higher in photon-counting CT examinations (all p<.001).*Conclusions Superior visualization of fine anatomy can be achieved with a clinical PCD-CT system in cadaveric wrist scans. The ultra-high-resolution scan mode suggests potential for considerable dose reduction over conventional EID-CT.*Clinical Relevance/Application High-resolution imaging of the appendicular skeleton is feasible with a cadmium-telluride-based photon-counting detector. Compared to energy-integrating detector builds, the novel technique enables superior image quality, hence allowing for dose reduction.

RESULTS

Subjective image quality of standard-dose PCD-CT scans in ultra-high-resolution mode was superior compared to full-dose EID-CT (p=.040) and full-dose PCD-CT in standard-resolution mode (p=.016). No difference was ascertained between low-dose PCD-CT in ultra-high-resolution mode and standard-dose scans with either EID-CT (p=.470) or PCD-CT in standard-resolution mode (p=.108). Observer evaluation of EID-CT and standard-resolution PCD-CT delivered similar results in full-dose and standard-dose examinations (p=.248/.509). Intraclass correlation coefficient was 0.876 (95% confidence interval: 0.744-0.925; p<.001), indicating good reliability. Between dose equivalent studies, signal-to-noise and contrast-to-noise ratios were substantially higher in photon-counting CT examinations (all p<.001).

CLINICAL RELEVANCE/APPLICATION

High-resolution imaging of the appendicular skeleton is feasible with a cadmium-telluride-based photon-counting detector. Compared to energy-integrating detector builds, the novel technique enables superior image quality, hence allowing for dose reduction.

PH01-A10   Feasibility Of A New 3D Resolution Phantom As An Investigative Tool For Protocol Selection On CT

Participants
Joshua Levy, Salem, New York (*Presenter*) Stockholder, The Phantom Laboratory;President, The Phantom Laboratory ;Stockholder, Image Owl, Inc;CEO, Image Owl, Inc;

PURPOSE

As CT has moved into even more 3D approaches, awareness of volumetric resolution has become more critical. We investigate a novel phantom for measurement of 3D spatial resolution in CT as a tool for protocol selection in an optimization setting.*Methods and Materials A Catphan 700 (The Phantom Laboratory, Salem NY) phantom, equipped with a 3D resolution module (CTP721) was scanned on two CT scanners; GE Revolution CT and Siemens Somatom Force. The module, CTP721, contains two oppositely angled wave ramps that create waveform profiles in the CT image. These waveform profiles will vary depending on scanning parameters, reflecting the spatial resolution in three dimensions. Initial testing performed on the GE Revolution scanner focused on confirmation and reproducibility of the results. A set of standard parameters were chosen, and for subsequent scans one and one parameter was changed in order to compare the change in effect on spatial resolution when changing slice thickness, pitch, ASiR-V, kernels and scan modes. To assess the phantom as a tool for protocol selection, it was scanned with ultra-fast scan (HyperDrive (GE) and Turbo Flash (Siemens)) in addition to standard scans. Images were analyzed using the SMARI® software (The Phantom Laboratory), where in-plane modulation transfer function (MTFxy) and the harmonics of the wave pattern was obtained. From this we derived combined MTF (MTFxyz) and z-axis MTF (MTFz).*Results Changes in resolution from the initial testing were as expected, and the results reproducible. 0.6mm slice thickness had superior resolution compared to 1.2mm slice thickness in z-

direction. Varying pitch had only minor impact on the resolution, and varying ASiR-V level did not impact the resolution. Axial scan showed superior resolution compared to helical scan in z-direction, and of the chosen kernels, detail kernel gave the best resolution, and soft kernel had the lowest resolution in z-direction. The analyses of the HyperDrive and Turbo Flash scans are WIP.*Conclusions The results show that the phantom can be useful for assessment of 3D resolution and changes in z-axis resolution when optimizing protocols.*Clinical Relevance/Application A reliable phantom that can evaluate resolution in all dimensions, both mathematically and visually, is an important tool in protocol optimization with the increasing number of 3D approaches in CT.

RESULTS

Changes in resolution from the initial testing were as expected, and the results were reproducible. 0.6mm slice thickness had superior resolution compared to 1.2mm slice thickness in z-direction. Varying pitch had only minor impact on the resolution, and varying ASiR-V level did not impact the resolution. Axial scan showed superior resolution compared to helical scan in z-direction, and of the chosen kernels, detail kernel gave the best resolution, and soft kernel had the lowest resolution in z-direction. The analyses of the HyperDrive and Turbo Flash scans are WIP.

CLINICAL RELEVANCE/APPLICATION

A reliable phantom that can evaluate resolution in all dimensions, both mathematically and visually, is an important tool in protocol optimization with the increasing number of 3D approaches in CT.

PH01-A12 Dependency Of TrueFidelity On Acquisition And Reconstruction Parameters Using NMR-CFR

Participants
Akira Hasegawa, PhD, Chapel Hill, North Carolina (*Presenter*) Employee, AlgoMedica, Inc

PURPOSE

In recent years, several deep learning CT image noise reduction techniques have been commercialized. These techniques, designed from learning of their own training data, are black boxes to the users. We had proposed the metrics of noise magnitude ratio and central frequency ratio (NMR-CFR) from noise power spectrum (NPS) as a tool for evaluation and comparison of noise reduction techniques. The purpose of this study was to investigate the dependence of GE's TrueFidelity (TF) on acquisition and reconstruction parameters using NMR-CFR, and to find the acquisition and reconstruction parameters optimal for the TF.*Methods and Materials An ACR phantom was scanned at 120 kVp, 10, 20, 40, 80, 120 and 160 mA, and each was reconstructed using FBP and all strengths of TF with the slice thicknesses of 1.25, 2.5 and 3.75 mm and FOVs of 250 and 350 mm. From each acquisition and reconstruction, NMR-CFR was calculated and compared. CFR is defined as the NPS center frequency ratio between noise reduction and FBP, and NMR is defined as the area under NPS between noise reduction and FBP. In an ideal noise reduction, both the xy- and z- CFRs should be close to 1 (less blur or texture change in the xy and z directions) and the NMR close to 0 (more noise reduction).*Results In the xy-plane, we found- the 1.25mm not only has less dependence on radiation dose but also has less blur and higher noise reduction than the 2.5mm or 3.75mm,- the noise reduction is higher for = 40mA than < 40mA, and- the change on noise texture was almost the same for the FOV 200mm and 350mm, but the noise reduction was more for the FOV 350mm than FOV 200mm.On the other hand, in the z-axis direction,- the change on noise texture was almost the same for 120mA and 160mA,- the thicker the slice, the less change on noise texture in the z-axis direction, and- the change on noise texture was less on FOV 350mm than 200mm.The data suggested that higher noise reduction and less change on noise texture in the xy and z directions can be achieved at tube current > 120 mA and reconstructed with a slice thickness of 1.25 mm with FOV 350 mm.*Conclusions In TF, a larger FOV and a thinner slice thickness, at tube current > 120 mA, would result in less blur or change of noise texture, and more noise reduction for imaging the ACR phantom.*Clinical Relevance/Application The results are useful for optimizing protocols using TrueFidelity. This method can also be applied to other denoising techniques.

RESULTS

In the xy-plane, we found- the 1.25mm not only has less dependence on radiation dose but also has less blur and higher noise reduction than the 2.5mm or 3.75mm,- the noise reduction is higher for = 40mA than < 40mA, and- the change on noise texture was almost the same for the FOV 200mm and 350mm, but the noise reduction was more for the FOV 350mm than FOV 200mm.On the other hand, in the z-axis direction,- the change on noise texture was almost the same for 120mA and 160mA,- the thicker the slice, the less change on noise texture in the z-axis direction, and- the change on noise texture was less on FOV 350mm than 200mm.The data suggested that higher noise reduction and less change on noise texture in the xy and z directions can be achieved at tube current > 120 mA and reconstructed with a slice thickness of 1.25 mm with FOV 350 mm.

CLINICAL RELEVANCE/APPLICATION

The results are useful for optimizing protocols using TrueFidelity. This method can also be applied to other denoising techniques.

PH01-A2 CT/CT-Fluoroscopy And FDG-PET Contributions To Patient And Staff Radiation Dose In FDG-PET/CT-Guided Interventions

Participants
Liwei Jiang, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

PET/CT scanners with an installed CT-fluoroscopy option can be used to guide biopsies and tumor ablations. Adding FDG-PET guidance to CT guidance alone could increase radiation dose to patients and staff. Of potential concern for operators, 0.5mm lead-equivalent aprons do not attenuate 511 keV photons from FDG. This study assesses radiation dose to patients, operators, and room personnel during procedures performed using a PET/CT scanner equipped with CT-fluoroscopy.*Methods and Materials An IRB-approved, prospective, single-institution study enrolled 10 consecutive patients referred for 10 PET/CT-guided tumor ablations from January to March of 2021. An attending radiologist and trainee performed the procedures using PET/CT, CT and intermittent CT-fluoroscopy acquisitions. Mean injected FDG activity was 192 MBq. Patient radiation dose was estimated using published conversion factors for injected FDG activity and CT dose-length-product. Personnel radiation dose was estimated using 11 direct-ion storage dosimeters at fixed and wearable locations (Figure). Operators worked behind a custom 1-inch-thick lead rolling floor shield raised to mid-chest level (positioned 2 feet from patient). To differentiate FDG-related dose from CT/CT-fluoroscopy scatter dose, two dosimeters were placed in front of the 1" lead shield near the operator, with one behind a 0.5mm lead equivalent thyroid shield.*Results The mean procedural doses to patients from FDG and CT were 3.7 (SD ±0.2) and 29.5 (±19.3) mSv, respectively. Dose (FDG+CT) behind the 1" lead shield was unmeasurable (less than 0.03 mSv) cumulatively and for every procedure. Continuous, unshielded mean total (FDG+CT) dose at 2 feet from the patient was 0.18 (±0.10) mSv with FDG contributing 0.03 mSv (15%) and

CT contributing 0.15 mSv (85%). The primary operator's mean collar dose (FDG+CT) was 0.02 (±0.04) mSv and mid chest dose 0.01 (±0.03) mSv. The secondary operator's doses were comparable to the primary. Operator doses were higher at the collar than at the chest, primarily due to positioning of the rolling 1" lead shield. Collar doses for the circulating nurses and anesthesiologist were unmeasurable for every procedure.*Conclusions CT contributed much more to patient radiation dose (87.5%) than FDG. No radiation dose to operators was measurable behind the 1" lead shield. Operator dose (FDG+CT) at the neck collar level (above the 1" lead shield) was very small.*Clinical Relevance/Application During PET/CT-guided interventions, FDG dose to patients and operators is minimal, compared to CT dose, and should not be a barrier to using PET/CT guidance.

RESULTS

The mean procedural doses to patients from FDG and CT were 3.7 (SD ±0.2) and 29.5 (±19.3) mSv, respectively. Dose (FDG+CT) behind the 1" lead shield was unmeasurable (less than 0.03 mSv) cumulatively and for every procedure. Continuous, unshielded mean total (FDG+CT) dose at 2 feet from the patient was 0.18 (±0.10) mSv with FDG contributing 0.03 mSv (15%) and CT contributing 0.15 mSv (85%). The primary operator's mean collar dose (FDG+CT) was 0.02 (±0.04) mSv and mid chest dose 0.01 (±0.03) mSv. The secondary operator's doses were comparable to the primary. Operator doses were higher at the collar than at the chest, primarily due to positioning of the rolling 1" lead shield. Collar doses for the circulating nurses and anesthesiologist were unmeasurable for every procedure.

CLINICAL RELEVANCE/APPLICATION

During PET/CT-guided interventions, FDG dose to patients and operators is minimal, compared to CT dose, and should not be a barrier to using PET/CT guidance.

PH01-A4   Virtual Unenhanced Images Obtained From Spectral Dual Energy Ct: Which Phase Is More Suitable For The Detection And Measurement Of Urinary Stones?

Participants
Yannan Cheng, BS,BS, Xi'an, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the detection and quantification of urinary stones using virtual unenhanced (VUE) images at nephrographic phase (VUE(NP)) and excretory phase (VUE(EP) in dual-energy CT Urography (DECTU) with different image slice thicknesses in comparison with true unenhanced (TUE) images.*Methods and Materials 112 patients with urinary stones who required unenhanced and contrast-enhanced DECTU were prospectively included. TUE, VUE(NP) and VUE(EP) images were generated with 1.25 and 5mm slice thicknesses. Stone location, diameter and CT number on different image types were recorded by two radiologists. Stones were divided into =5mm and <5mm groups. Stone detection rates were evaluated using Chi-square test. Wilcoxon signed rank and repeated measures analysis of variance (ANOVA) with Bonferroni correction was performed to compare stone quantitative measurements. P <0.05 was considered statistically significant.*Results 163 and 67 urinary stones with size =5mm and <5mm were detected on the 1.25mm TUE images, respectively. Correspondingly, 163(52), 158(25), 140(31) and 131(16) stones were detected on the VUE(NP)_1.25mm, VUE(NP)_5mm; VUE(EP)_1.25mm and VUE(EP)_5mm images, resulting in detection rates of 100%(77.6%), 96.9(37.3%), 85.9(46.3%) and 80.4(23.9%), respectively (Figure 1). VUE(NP) images significantly improved the stone detection rate and CT number measurement accuracy compared with the VUE(EP) images (Table 1 and 2, Figure 2-4). In general, VUE images presented stones with smaller sizes, but thinner slice thickness images reduced the inaccuracy to about 10%.*Conclusions VUE(NP) images in DECTU with 1.25mm thickness detects 100% and 77.6% of urinary stones with size =5mm and <5mm, respectively with accurate CT number. Stone size measurement in VUE images needs 10% systematic correction.*Clinical Relevance/Application Virtual unenhanced images of 1.25mm obtained at the nephrographic phase in dual-energy CT urography provides a high detection rate and accurate measurement for urinary stones.

RESULTS

163 and 67 urinary stones with size =5mm and <5mm were detected on the 1.25mm TUE images, respectively. Correspondingly, 163(52), 158(25), 140(31) and 131(16) stones were detected on the VUE(NP)_1.25mm, VUE(NP)_5mm; VUE(EP)_1.25mm and VUE(EP)_5mm images, resulting in detection rates of 100%(77.6%), 96.9(37.3%), 85.9(46.3%) and 80.4(23.9%), respectively (Figure 1). VUE(NP) images significantly improved the stone detection rate and CT number measurement accuracy compared with the VUE(EP) images (Table 1 and 2, Figure 2-4). In general, VUE images presented stones with smaller sizes, but thinner slice thickness images reduced the inaccuracy to about 10%.

CLINICAL RELEVANCE/APPLICATION

Virtual unenhanced images of 1.25mm obtained at the nephrographic phase in dual-energy CT urography provides a high detection rate and accurate measurement for urinary stones.

PH01-A5   Machine Learning Decision Support For Predicting Metabolic Syndrome In Japanese Adults Associate With Chest Radiographs Obtained In Annual Health Examinations

Participants
Tadahiro Sakamoto, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

In annual health examinations for Japanese adults, metabolic syndrome is usually determined by measuring visceral fat area using CT or abdominal circumference. The former is more accurate than the latter, but involves radiation exposure. On the other hand, in health examinations, a chest radiograph is taken for the purpose of preventing tuberculosis and lung cancer, irrespective of the prediction of metabolic syndrome. Therefore, focusing on the fact that fat at the cardiac apex is related to visceral fat, we assumed that metabolic syndrome would be predicted by using the image information of the cardiac apex in chest radiograph and patient information.*Methods and Materials In this study, 1216 patients who underwent chest radiography, CT visceral fat area measurement, and blood test were included. For each chest radiograph, a sample image of ROI size 192×192 was cropped to include the region of cardiac apex from a heart area which was automatically extracted by machine learning (U-Net). We used patient information (age, gender, height, weight, and blood pressure), the area ratio of the heart and lung fields obtained by automatic extraction using U-Net, and the sample images as input data to predict metabolic syndrome using another machine learning (DCNN). The gold standard for training the DCNN was determined from blood pressure, blood test results, and the visceral fat area obtained from CT scans according to the diagnostic criteria for metabolic syndrome (the Japanese committee of the criteria for metabolic syndrome in 2005). For the evaluation of metabolic syndrome judgment by DCNN, we used a 10-fold cross-validation method and a binormal ROC analysis.*Results The prediction accuracy for the metabolic syndrome performed by the DCNN

showed an AUC of 0.865, which was higher than CT only (0.854) and abdominal circumference (0.749).*Conclusions By using chest radiograph and patient information as the input of the DCNN, the metabolic syndrome could be predicted without unnecessary patient radiation due to CT visceral fat area measurement and invasive blood test.*Clinical Relevance/Application This proposed method required no additional equipment and examination time, but would yield precise decision without unnecessary radiation exposure and the cost of CT examination.

RESULTS

The prediction accuracy for the metabolic syndrome performed by the DCNN showed an AUC of 0.865, which was higher than CT only (0.854) and abdominal circumference (0.749).

CLINICAL RELEVANCE/APPLICATION

This proposed method required no additional equipment and examination time, but would yield precise decision without unnecessary radiation exposure and the cost of CT examination.

PH01-A6   Diagnostic Value Of A Deep Learning-based Ai Detection System In Chest Ldct Imaging For The Detection Of Pleural Nodules (PN)

Participants
Fang Wang, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

The missed diagnosis rate of Pleural Nodules (PN)is high. The purpose of this study was to assess the diagnostic performance of deep learning based artificial intelligence (AI) diagnostic system for the detection of PN on chest LDCT images.*Methods and Materials 104 healthy patients underwent low-dose chest CT screening using a 256 slice wide-detector CT(Revolution,GE Healthcare)were enrolled. Protocols were adjusted so that effective dose was set to approximately 1.5 mSv. Readings by two residents were conducted to detect PNs: use Deep Learning-Based AI detection System (InferRead CT Lung Research) and without using AI. The total number and location of nodules in each patient detected were recorded. Two senior chief radiologists' consensus readings were used as the gold standard. The detection rate and false positive rate in each reading were calculated accordingly.*Results 176 PNs were confirmed as gold standard. The pooled diagnostic sensitivity of PNs for two residents (96.59%, 170/176) with AI was significantly higher than without using AI (82.95%, 146/176). Without using AI, the detection sensitivity of PNs near the mediastinum pleura for residents was 37.5% (6/16) and the false positive rate was 2.9% (3/104). When AI was used, the sensitivity was increased to 87.5% (14/16) and the false positive rate was 1.0% (1/104).*Conclusions Deep learning-based AI detection system significantly improves detection performance of Pleural Nodules in LDCT scans for residents.*Clinical Relevance/Application It is recommended to use deep learning assisted lung nodule detection system to improve the detection efficiency of pleural nodules which are easily missed due to its proximity to pleural.

RESULTS

176 PNs were confirmed as gold standard. The pooled diagnostic sensitivity of PNs for two residents (96.59%, 170/176) with AI was significantly higher than without using AI (82.95%, 146/176). Without using AI, the detection sensitivity of PNs near the mediastinum pleura for residents was 37.5% (6/16) and the false positive rate was 2.9% (3/104). When AI was used, the sensitivity was increased to 87.5% (14/16) and the false positive rate was 1.0% (1/104).

CLINICAL RELEVANCE/APPLICATION

It is recommended to use deep learning assisted lung nodule detection system to improve the detection efficiency of pleural nodules which are easily missed due to its proximity to pleural.

PH01-A8   A Fast Geometric Approximation Of Water Equivalent Diameter For Calculating Size-specific Dose Estimate In Computed Tomography

Participants
Jan Pachon, chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study is to provide an accurate and automated calculation of water-equivalent diameter (DW) from axial CT images using a novel geometric approximation. AAPM Report 204 shows that the SSDE is the product of CTDIvol and a conversion factor based on either effective diameter (Deff) or water equivalent diameter (Dw). Dw has long been adopted as a more accurate patient size surrogate because it accounts for patient attenuation; however, calculating Dw is computationally expensive, requiring long runtimes and memory. We demonstrate a fast and novel geometric approximation of Dw using axial CT images.*Methods and Materials Axial Images were obtained from a clinical CT scanner including 22 adult abdomen, 34 pediatric abdomen, and 23 adult head exams. Each axial image was contoured automatically using thresholding to remove the patient table. The second step was to determine the AP and lateral dimensions by bounding the anatomy. These dimensions were used as the major and minor axes of the elliptical approximation of the contour. The third step was to determine the largest rectangle that could be inscribed in the ellipse from step 2. The mean HU and area were then determined within the pixel array defined by the coordinates of the rectangle. A Riemann sum approximation was used to estimate the mean and area outside the rectangle and within the ellipse by partitioning this region into rectangles of one pixel in width. The geometric mean (μ) and area (A) approximation were calculated using the following equations: μgeo approx.= μlarge rect. in ellipse + S(mean(f(xi) + ?Xi)Ageo approx.= Alarge rect. in ellipse + S(f(xi) + ?XiWhere the summation in each equation represents the Riemann sum of the rectangles (one pixel in width) outside of the large rectangle and within the ellipse. Dw can then be calculated as: Dw = 2* (1/1000 * (μgeo approx +1) * (Ageo approx./p))0.5 (AAPM 204)p*Results The results of the geometric DW approximation were compared to those calculated manually where the contouring was done by freehand. These two measurements are in good agreement with differences of 2.96% ±1.44% for abdomen images and 5.26±2.52% for head images. Furthermore, the runtime of the DW geometric approximation is less than 0.1 msecs per axial slice on a Win10 16GB CPU with an intel i5 processor.*Conclusions The geometric approximation of Dw gives an accurate estimate of patient size and can be used for accurate SSDE calculations. The advantage of this approximation is that it provides real-time SSDE measurements and is not computationally expensive.*Clinical Relevance/Application The geometric approximation of Dw is particularly useful in the case of modern CT scanners that produce more than 500 images (slices) for every exam.

RESULTS

The results of the geometric DW approximation were compared to those calculated manually where the contouring was done by

freehand. These two measurements are in good agreement with differences of 2.96% ±1.44% for abdomen images and 5.26±2.52% for head images. Furthermore, the runtime of the DW geometric approximation is less than 0.1 msecs per axial slice on a Win10 16GB CPU with an intel i5 processor.

CLINICAL RELEVANCE/APPLICATION

The geometric approximation of Dw is particularly useful in the case of modern CT scanners that produce more than 500 images (slices) for every exam.

PH01-A9   Physics Image Quality Evaluation Of A High Resolution Computed Tomography (CT) Scanner With Denoising Deep Learning Reconstruction Vs Normal Resolution CT With Hybrid Iterative Reconstruction For Lung

Participants
Kirsten Lee Boedeker, PHD, Los Angeles, California (*Presenter*) Employee, Canon Medical Systems Corporation

PURPOSE

To evaluate a Denoising Deep Learning Reconstruction algorithm (AiCE DLR) applied to a commercial High Resolution Computed Tomography (HR-CT) scanner for a Lung protocol using physics-based image quality performance metrics, with a focus on the potential for quantitative precision. Results are compared to Normal Resolution CT (NR-CT) with hybrid iterative reconstruction (AIDR). A variety of dose levels are examined.*Methods and Materials A 20cm Catphan was scanned on a High Resolution CT scanner (Canon Aquilion Precision) with a Lung protocol and tube current range 10-500mA. The data was reconstructed with AiCE DLR and AIDR. The raw data was then downsampled to generate simulated NR-CT data and reconstructed with AIDR. The AiCE DLR was trained using high-dose HR-CT images as the training target and simulated low dose images as the training input. The contrast-dependent modulation transfer function (MTF), Noise Power Spectra (NPS), and Noise Equivalent Quanta (NEQ) were determined via Fourier analysis. The Standard Deviation of Noise (SD) was measured for all conditions. The NEQ was applied to estimate Low Contrast (LCD) detectability index and Size Change detectability index, i.e. the ability for an observer to distinguish a 1mm change in diameter; a Non-Prewhitening Model Observer was used for both tasks.*Results HR-CT with AiCE DLR has the same or improved standard deviation of noise and LCD compared to NR-CT with AIDR for the Lung protocol examined for all dose levels. NEQ was increased across all frequencies, with new NEQ generated in the high frequencies for HR-CT with AiCE vs NR-CT with AIDR. The ability to distinguish a 1mm change in diameter increased by 107% (range 54-152%) across mA values for HR-CT with AiCE vs NR-CT with AIDR. When AIDR is used for both HR-CT and NR-CT reconstruction the ability to distinguish a 1mm change in diameter increased by 34% (range 14-51%) across mA values.*Conclusions For the protocols examined, High resolution CT with Denoising DLR improves image quality across dose levels and the potential for quantitative lung applications relative to normal resolution CT with hybrid iterative reconstruction.*Clinical Relevance/Application High resolution CT combined with Denoising Deep Learning reconstruction increases the potential of diagnostic and quantitative Lung applications.

RESULTS

HR-CT with AiCE DLR has the same or improved standard deviation of noise and LCD compared to NR-CT with AIDR for the Lung protocol examined for all dose levels. NEQ was increased across all frequencies, with new NEQ generated in the high frequencies for HR-CT with AiCE vs NR-CT with AIDR. The ability to distinguish a 1mm change in diameter increased by 107% (range 54-152%) across mA values for HR-CT with AiCE vs NR-CT with AIDR. When AIDR is used for both HR-CT and NR-CT reconstruction the ability to distinguish a 1mm change in diameter increased by 34% (range 14-51%) across mA values.

CLINICAL RELEVANCE/APPLICATION

High resolution CT combined with Denoising Deep Learning reconstruction increases the potential of diagnostic and quantitative Lung applications.

BR04-D4   Volumetric Breast Density Is A Strong Predictor Of Breast Tumour Size In A US Screening Population

Participants
Stamatia Destounis, MD, Rochester, New York (*Presenter*) Medical Advisory Committee, Hologic, Inc;Medical Advisory Board, iCAD, Inc

PURPOSE

To investigate the associations of mammographic density (MD) and breast tumour characteristics (TC) with tumour size in a US screening setting.*Methods and Materials All screen-detected (SD) and interval (IC) breast cancers (BC; n=2,312) diagnosed at our breast imaging clinic from 2009-2012 were identified. After exclusions (outside screening interval, missing size, prior biopsy/surgery/BC, implants, bilateral BC, women <40 y), the final dataset comprised of 406 BC. TC and risk factors were extracted from clinical records. MD metrics included quartiles (Q1-4) of volumetric breast density (VBD)/dense volume (DV)/breast volume (BV)/fat volume (FV), and Volpara Density Grades (VDG). BI-RADS&VDG categories were dichotomized to non-dense vs dense (VDG&BI-RADS 1+2 vs 3+4). Size associations with MD, risk factors and TC were tested using linear regression and non-parametric tests. Multivariate logistic regression modelled the association between the binary outcome size>2cm and MD, adjusting for age, menopausal status, mode of detection (SD/IC), and FV as a surrogate for BMI.*Results Size ranged from 1-130mm (median=15mm) and differed for SD vs IC (median=14/18 mm, p<0.001). Size was associated with age (r=-.17,p<0.001), VBD (r=0.51,p<0.001) and DV (r=0.08,p<0.001). Medians differed for menopausal status (p<0.001), estrogen/HER2 receptor status (p<0.02), molecular subtype (p<0.02), and grade (p<0.001). In logistic regression models, age and menopausal status were no longer associated with size>2cm. VBD measures had the strongest associations, with odds ratios (OR) of 3.1-fold comparing Q4:Q1 for both VBD and dense volume (p<0.02). Comparing VDG 4 vs combined VDG 1/2, OR were 3.8-fold (p<0.01). Compared to non-dense women, BI-RADS 4 was not significant and OR=1.9 (p<0.03) for BI-RADS 3. Stratified by SD or IC, ORs tended to increase for all MD measures but lost significance for IC. Comparing VBD or FGV Q4 vs Q1, women with SD were 5-fold more likely to be diagnosed with size>2cm (p<0.02).*Conclusions For SD, but not IC, MD is a strong predictor of breast tumour size>2cm. Strategies to improve earlier detection in women with denser breasts could improve prognostic factors at diagnosis.*Clinical Relevance/Application Larger tumour size is an important factor in the evaluation of patient outcomes after BC diagnosis. Understanding associations with mammographic density can be beneficial to inform better strategies for screening women with dense breasts.

RESULTS

Size ranged from 1-130mm (median=15mm) and differed for SD vs IC (median=14/18 mm, p<0.001). Size was associated with age (r=-.17,p<0.001), VBD (r=0.51,p<0.001) and DV (r=0.08,p<0.001). Medians differed for menopausal status (p<0.001), estrogen/HER2 receptor status (p<0.02), molecular subtype (p<0.02), and grade (p<0.001). In logistic regression models, age and menopausal status were no longer associated with size>2cm. VBD measures had the strongest associations, with odds ratios (OR) of 3.1-fold comparing Q4:Q1 for both VBD and dense volume (p<0.02). Comparing VDG 4 vs combined VDG 1/2, OR were 3.8-fold (p<0.01). Compared to non-dense women, BI-RADS 4 was not significant and OR=1.9 (p<0.03) for BI-RADS 3. Stratified by SD or IC, ORs tended to increase for all MD measures but lost significance for IC. Comparing VBD or FGV Q4 vs Q1, women with SD were 5-fold more likely to be diagnosed with size>2cm (p<0.02).

CLINICAL RELEVANCE/APPLICATION

Larger tumour size is an important factor in the evaluation of patient outcomes after BC diagnosis. Understanding associations with mammographic density can be beneficial to inform better strategies for screening women with dense breasts.

BR04-D6   Repeat Breast Ultrasound Demonstrates Utility For Added Cancer Detection In Patients Following Breast Imaging Second Opinion Recommendations

Participants
Robert J. Weinfurtner, MD, Tampa, Florida (*Presenter*) Nothing to Disclose

PURPOSE

For patients pursuing breast imaging second opinions, the aim of our study was to determine ultrasound review discrepancy frequency and the subsequent utility and impact on patient management.*Methods and Materials An IRB-approved retrospective chart review was conducted on 400 consecutive patients with second opinion radiology interpretations which included mammograms and sonograms. These second opinion interpretations were performed by subspecialized breast radiologists at a designated cancer center. The outside institution imaging reports were compared with second opinion reports to categorize ultrasound review discrepancies which were defined as any BI-RADS category change. The discrepancy frequency, relevant alterations in patient management, and incremental cancer detection were measured.*Results Discrepant second opinion breast and axillary ultrasound review was seen in 108/400 patients (27%). Discrepancies included 70 repeat ultrasounds for better characterization of a breast lesion, 11 repeat ultrasounds of a negative region, 20 repeat ultrasounds for benign axillary lymph nodes, 5 downgrades from BI-RADS 3 to BI-RADS 2, and 2 upgrades from BI-RADS 2 to BI-RADS 4. Repeat ultrasounds of the axilla in 19 patients resulted in 13 biopsy recommendations, and 4 were metastatic (PPV3 31%). In the breast, repeat ultrasounds in 81 patients resulted in 14 upgrades to BI-RADS 4 or BI-RADS 5. Of these, 5 yielded malignancy (PPV3 36%). In addition, one patient was upgraded from a BI-

RADS 2 to a BI-RADS 4 category based on the outside image, with pathology revealing malignancy. Breast lesion BI-RADS category downgrades in 27 patients resulted in 10 avoided biopsies. Ultimately, second opinion ultrasound review resulted in altered management in 12 % of patients (47/400). This included discovery of additional breast malignancies in 6 patients, metastatic lymph nodes in 4 patients, excisional biopsy for atypia in 1 patient, 4 patients proceeding to mastectomy, 10 patients who avoided biopsies, and 22 patients who avoided follow-up of benign findings.*Conclusions Subspecialized second opinion ultrasound review discrepancies resulted in detection of additional breast malignancy in 7% (6/82). Similarly, recommendations for repeat axillary ultrasound yielded additional metastatic cancer detection in 21% (4/19). Finally, the discrepancy downgrade frequency was 30% (32/108) eliminating additional follow-up or unnecessary percutaneous biopsies.*Clinical Relevance/Application The overall incremental cancer detection rate in both the breast and axilla as well as downgrade frequency show that second opinion review of outside ultrasound examinations are of value when performed by subspecialized breast imagers at a dedicated cancer center.

RESULTS

Discrepant second opinion breast and axillary ultrasound review was seen in 108/400 patients (27%). Discrepancies included 70 repeat ultrasounds for better characterization of a breast lesion, 11 repeat ultrasounds of a negative region, 20 repeat ultrasounds for benign axillary lymph nodes, 5 downgrades from BI-RADS 3 to BI-RADS 2, and 2 upgrades from BI-RADS 2 to BI-RADS 4. Repeat ultrasounds of the axilla in 19 patients resulted in 13 biopsy recommendations, and 4 were metastatic (PPV3 31%). In the breast, repeat ultrasounds in 81 patients resulted in 14 upgrades to BI-RADS 4 or BI-RADS 5. Of these, 5 yielded malignancy (PPV3 36%). In addition, one patient was upgraded from a BI-RADS 2 to a BI-RADS 4 category based on the outside image, with pathology revealing malignancy. Breast lesion BI-RADS category downgrades in 27 patients resulted in 10 avoided biopsies. Ultimately, second opinion ultrasound review resulted in altered management in 12 % of patients (47/400). This included discovery of additional breast malignancies in 6 patients, metastatic lymph nodes in 4 patients, excisional biopsy for atypia in 1 patient, 4 patients proceeding to mastectomy, 10 patients who avoided biopsies, and 22 patients who avoided follow-up of benign findings.

CLINICAL RELEVANCE/APPLICATION

The overall incremental cancer detection rate in both the breast and axilla as well as downgrade frequency show that second opinion review of outside ultrasound examinations are of value when performed by subspecialized breast imagers at a dedicated cancer center.

BR04-D8   Covid Vaccine-Related Lymphadenopathy - What We Know

Participants
Vidhi Kacharia, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Breast radiologists are faced with diagnostic dilemmas every day regarding axillary lymphadenopathy with the new Covid vaccines. The Centers for Disease Control and Prevention report lymphadenopathy as an unsolicited adverse event in the arm and neck region in 1.1% of subjects who received the Moderna vaccine and 58 more cases in the vaccine group than the placebo group for the Pfizer vaccine. The median duration of lymphadenopathy was 1 to 2 days for the Moderna vaccine and 10 days for the Pfizer vaccine. Adding data to the literature after the first few months of vaccine administration will help clinicians provide data-driven reassurance and avoid unnecessary imaging with confidence. The primary purpose of this study is to assess the duration of Covid-vaccine related lymphadenopathy at our institution. Secondary endpoints include prevalence and presenting symptoms.*Methods and Materials This retrospective HIPAA-compliant study was approved by the Institutional Review Board. Electronic medical record review was performed to identify patients with ipsilateral axillary lymphadenopathy detected during screening or diagnostic breast imaging from December 1, 2020 to March 31, 2021 after recent Covid vaccination (within 4 weeks of initial imaging.) We examined the charts of all patients > 18 years old diagnosed with axillary lymphadenopathy at our institution's breast radiology department. We collected data from any follow-up imaging or biopsy performed for the purpose of evaluating axillary lymphadenopathy.*Results A total of 73 female patients were evaluated for axillary lymphadenopathy ipsilateral to the vaccinated arm on screening or diagnostic imaging. Of the 18 patients assigned BIRADS 0 and the 14 patients assigned BIRADS 3, a total of 23 patients had follow-up imaging. Of these 23 patients, 7 patients had resolved axillary lymphadenopathy in less than 3 weeks and 6 patients had resolved axillary lymphadenopathy in less than 6 weeks. These patients were assigned BIRADS 1 or 2 and no longer followed. A total of 9 patients had unchanged axillary lymphadenopathy at first follow-up < 6 weeks since the initial study. 1 patient had worsened axillary lymphadenopathy at first follow-up for which biopsy was recommended and showed benign tissue.*Conclusions The length of Covid-vaccine related lymphadenopathy is variable, with the majority of cases resolving within 6 weeks. Most patients were asymptomatic and diagnosed on screening mammograms.*Clinical Relevance/Application Lymphadenopathy from the Covid vaccine may last longer than expected. While appropriate work-up such as ultrasound and biopsy should be performed when needed, it is important to keep benign causes such as vaccine-related lymphadenopathy in our differential to reduce patient anxiety.

RESULTS

A total of 73 female patients were evaluated for axillary lymphadenopathy ipsilateral to the vaccinated arm on screening or diagnostic imaging. Of the 18 patients assigned BIRADS 0 and the 14 patients assigned BIRADS 3, a total of 23 patients had follow-up imaging. Of these 23 patients, 7 patients had resolved axillary lymphadenopathy in less than 3 weeks and 6 patients had resolved axillary lymphadenopathy in less than 6 weeks. These patients were assigned BIRADS 1 or 2 and no longer followed. A total of 9 patients had unchanged axillary lymphadenopathy at first follow-up < 6 weeks since the initial study. 1 patient had worsened axillary lymphadenopathy at first follow-up for which biopsy was recommended and showed benign tissue.

CLINICAL RELEVANCE/APPLICATION

Lymphadenopathy from the Covid vaccine may last longer than expected. While appropriate work-up such as ultrasound and biopsy should be performed when needed, it is important to keep benign causes such as vaccine-related lymphadenopathy in our differential to reduce patient anxiety.

SDP-VA-1   Acute Left Iliofemoral Vein Thrombosis: Revisiting With Bony May-thurner Syndrome Variant

Participants
Eu Hyun Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the underlying causes of acute left iliofemoral deep vein thrombosis (DVT) using computed tomography (CT) and discuss their clinical significance for diagnosis and prognosis.*Methods and Materials We retrospectively analyzed 57 patients with acute left iliofemoral DVT from 2015 to 2020. By CT evaluation, patients were divided into absence or presence of left common iliac vein (LCIV) stenosis. The number and site of stenosis were recorded as proximal and distal portion of LCIV. The causes of LCIV stenosis were categorized to simple May-Thurner syndrome (sMTS) and bony MTS related to lumbar degeneration (bMTS). We excluded other causes of LCIV stenosis. Initial CT scans regarding location and extent of thrombus, and fibrotic change of LCIV were evaluated. Medical chart was reviewed for onset age, symptom duration, and treatment. Follow-up CT scans were assessed for therapeutic effect.*Results Among the 54 patients, LCIV stenosis was present in 53 patients (92.9%), and the cause of stenosis were sMTS in 27 patients (50.9%) and bMTS in 26 patients (49.1%). There was no significant difference in gender distribution between the sMTS and bMTS groups (p=0.925). The mean onset age of was significantly younger in sMTS than bMTS (52.8 ± 20.1 vs. 72.5 ± 10.4, p< 0.001). There was no significant difference in symptom duration (3.9 ± 3.8 vs. 6.4 ± 5.3, p=0.050). Based on the results of image analysis, most of sMTS showed stenosis occurred only in the proximal segment of LCIV (24/27, 88.9%) and most of bMTS showed stenosis in both proximal and distal segments of LCIV (17/26, 65.4%) (p<0.001), while the diameter of stenotic segment showed no significant difference in both groups at proximal (4.5 ±1.4 vs. 4.7 ±2.3, p=0.774) and distal segments (6.2±3.6 vs. 4.9±1.5, p=0.484). The chronic fibrotic change of LCIV was observed 6 out of 27 patients (22.2%) in sMTS group and 14 out of 26 patients (53.8%) in bMTS, showing statistical significance (p=0.037). However, there was no significant difference in the extent of DVT centered on popliteal vein level (p=1.000) and treatment response (p=0.950) between the two groups.*Conclusions LCIV stenosis is an important predisposing factor of iliofemoral DVT and it can be caused by both sMTS and bMTS. Compared to sMTS, bMTS occurs in older patients, presenting more than one stenosis at LCIV, and inducing more chronic fibrotic change of LCIV.*Clinical Relevance/Application Clinical attention is needed to bMTS, which is often overlooked. DVT CT might be recommended for the elderly patients with severe lumbar spine degeneration among the patients who are expected to have immobilized condition such as surgery.

RESULTS

Among the 54 patients, LCIV stenosis was present in 53 patients (92.9%), and the cause of stenosis were sMTS in 27 patients (50.9%) and bMTS in 26 patients (49.1%). There was no significant difference in gender distribution between the sMTS and bMTS groups (p=0.925). The mean onset age of was significantly younger in sMTS than bMTS (52.8 ± 20.1 vs. 72.5 ± 10.4, p< 0.001). There was no significant difference in symptom duration (3.9 ± 3.8 vs. 6.4 ± 5.3, p=0.050). Based on the results of image analysis, most of sMTS showed stenosis occurred only in the proximal segment of LCIV (24/27, 88.9%) and most of bMTS showed stenosis in both proximal and distal segments of LCIV (17/26, 65.4%) (p<0.001), while the diameter of stenotic segment showed no significant difference in both groups at proximal (4.5 ±1.4 vs. 4.7 ±2.3, p=0.774) and distal segments (6.2±3.6 vs. 4.9±1.5, p=0.484). The chronic fibrotic change of LCIV was observed 6 out of 27 patients (22.2%) in sMTS group and 14 out of 26 patients (53.8%) in bMTS, showing statistical significance (p=0.037). However, there was no significant difference in the extent of DVT centered on popliteal vein level (p=1.000) and treatment response (p=0.950) between the two groups.

CLINICAL RELEVANCE/APPLICATION

Clinical attention is needed to bMTS, which is often overlooked. DVT CT might be recommended for the elderly patients with severe lumbar spine degeneration among the patients who are expected to have immobilized condition such as surgery.

SDP-VA-3   Possibilities Of Computed Tomographic Angiography In Management Of Patients With Aortic Dissection After Surgery

Participants
Eugenii Kobelev, MD, Novosibirsk, Russian Federation (*Presenter*) Nothing to Disclose

PURPOSE

To assess the thoracoabdominal aorta's remodeling by the method of volumetric aortic calculation after hybrid and endovascular prosthetics for aortic dissections.*Methods and Materials ?re-, postoperative, and at least one 1-year follow-up computed tomography data sets were available for 12 patients. The median follow-up was 18 months. CTA of the thoracic and abdominal aorta was performed from the lungs' apex to the femoral heads' middle. In the aorta, three segments were identified: "A" - the level of the stent-graft, "B" - from the distal end of the stent-graft to the celiac trunk, segment "C" from the celiac trunk to the aortic bifurcation. In each segment, the total aortic volumes, the volume of the true lumen (TL), and the false lumen (FL) volume were calculated.*Results The average ages of the patients treated were 50.5±7. Positive or stable remodeling was found in segments A (50% - after surgery, 83% - one year after surgery), B (83% - after surgery, 66.7% - one year after surgery), and C (83% - after surgery, 58.3% - one year after surgery), and the FL thrombosis rate was 100% in A, 73.5% in B and 38% in C during the first

year. Statistically significant increase in the volume of TL in "A" segment (p = 0.002), decrease in perfused false lumen (PFL) (p = 0.001). Statistically significant increase in the volume of TL in "B" segment (p = 0.015), decrease in PFL (p = 0.041) and an increase in thrombosed false lumen (TFL) (p = 0.041). Statistically significant increase in the volume of TFL in the "C" segment (p = 0.004). The median area of residual fenestrations in B and C was 2.25 cm2 [1.54-4.53].*Conclusions In segment A in all patients after surgical intervention, positive aortic remodeling in the form of FL thrombosis is determined. Residual FL perfusion results from entries in the thoracoabdominal segment, which is frequently essential for the visceral, renal, spinal, or peripheral perfusion. This study demonstrated the possibility of using a volume-measuring method of the true and false lumen aortic lumen.*Clinical Relevance/Application We believe that the measurement of the volume has the advantage before measuring the maximum diameter of the aorta to clarify the dynamics of the postoperative period.

RESULTS

The average ages of the patients treated were 50.5±7. Positive or stable remodeling was found in segments A (50% - after surgery, 83% - one year after surgery), B (83% - after surgery, 66.7% - one year after surgery), and C (83% - after surgery, 58.3% - one year after surgery), and the FL thrombosis rate was 100% in A, 73.5% in B and 38% in C during the first year. Statistically significant increase in the volume of TL in "A" segment (p = 0.002), decrease in perfused false lumen (PFL) (p = 0.001). Statistically significant increase in the volume of TL in "B" segment (p = 0.015), decrease in PFL (p = 0.041) and an increase in thrombosed false lumen (TFL) (p = 0.041). Statistically significant increase in the volume of TFL in the "C" segment (p = 0.004). The median area of residual fenestrations in B and C was 2.25 cm2 [1.54-4.53].

CLINICAL RELEVANCE/APPLICATION

We believe that the measurement of the volume has the advantage before measuring the maximum diameter of the aorta to clarify the dynamics of the postoperative period.

SDP-VA-4   Machine Learning Of The Patient Characteristics And Of Vascular Features Observed On Pre-procedural Computed Tomography Angiographs Helps To Predict Endovascular Leaks After Thoracic Endovascular Aneurysm Repair

Participants
Takanori Masuda, Okayama, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To predict endoleaks after thoracic endovascular aneurysm repair (TEVAR) we submitted patient characteristics and vessel features observed on pre-procedural computed tomography angiography (CTA) to machine-learning.*Methods and Materials We evaluated the effect of machine learning of the patient age, sex, weight, and height, plus 22 vascular features on the ability to predict post-TEVAR endoleaks. We calculated their importance by applying XGBoost to machine learning and calculated the area under the curve (AUC) of our receiver operating characteristic analysis of machine learning and compared our findings with those of conventional vessel measurement-based methods.*Results There was a significant difference between the two methods with respect to the vessel angle (p < 0.05). With machine learning, the AUC was 0.97, accuracy was 97.5%, the 95% confidence interval (CI) was 97.5%, sensitivity was 0.941 - 1.0, and specificity was 0.95. With the conventional method these values were 0.88, 84.0%, 0.81 - 0.96, 0.82, and 0.84. for the vessel angle and 0.74, 87.5%, 0.61-0.88, 0.45, and 0.95 for the diameter between the subclavian artery and the aneurysm. Machine-learning yielded a significantly higher AUC than the conventional vessel measurement-based method (p = 0.01).*Conclusions To predict the risk for post-TEVAR endoleaks, machine learning was superior to the conventional vessel measurement cut-off method when factors such as patient characteristics, and vascular features (vessel length, diameter, and angle) were evaluated on pre-TEVAR thoracic CTA images.*Clinical Relevance/Application Machine learning using the patient age, sex, and body habitus and specific vascular features observed on pre-TEVAR thoracic CT angiographs helps to predict post-procedural endoleaks.

RESULTS

There was a significant difference between the two methods with respect to the vessel angle (p < 0.05). With machine learning, the AUC was 0.97, accuracy was 97.5%, the 95% confidence interval (CI) was 97.5%, sensitivity was 0.941 - 1.0, and specificity was 0.95. With the conventional method these values were 0.88, 84.0%, 0.81 - 0.96, 0.82, and 0.84. for the vessel angle and 0.74, 87.5%, 0.61-0.88, 0.45, and 0.95 for the diameter between the subclavian artery and the aneurysm. Machine-learning yielded a significantly higher AUC than the conventional vessel measurement-based method (p = 0.01).

CLINICAL RELEVANCE/APPLICATION

Machine learning using the patient age, sex, and body habitus and specific vascular features observed on pre-TEVAR thoracic CT angiographs helps to predict post-procedural endoleaks.

SDP-VA-5   Diagnostic Ability Of Fresh Blood Imaging At 3T In Peripheral Artery Disease In Comparison With Angiography

Participants
Katsumi Nakamura, MD, Kitakyushu, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic ability of Fresh Blood Imaging at 3T (3T-FBI) in peripheral artery disease (PAD) using angiography (AG) as the gold standard. In cases where CT angiography (CTA) was performed, the diagnostic ability of FBI and CTA is compared according to the TASC II criteria.*Methods and Materials Twenty-nine patients (17 males and 12 females, mean age 75.9 years) who had enrolled in both 3T-FBI and AG examinations from November 2017 to March 2021 were included. All AG examination was performed at the time of endovascular treatment, and thus not including the bilateral entire lower limbs arteries in most cases. Nine cases also underwent CTA. The pelvis-lower extremity arteries were divided into 17 arteries, and the diagnostic ability of FBI to diagnose the hemodynamically significant stenosis (more than 50%) was evaluated against AG as a gold standard. In the cases of CTA, the classifications using FBI and CTA were compared according to the TASC II criteria in aorto-iliac (AI) and femoral-popliteal region (FP). The diagnostic ability of the below-the-knee (BK) region was also compared.*Results The 344 arteries were evaluated where AG was performed. Of these, 97 arteries (10 in AI, 37 is FP, and 50 in BK) showed significant stenosis. The overall diagnostic ability of 3T-FBI showed sensitivity 98.9%, specificity 94.6%, positive predictive value (PPV) 88.1%, negative predictive value (NPV) 99.6%, and accuracy 95.6%. In AI, there were some false positives due to signal reduction at sharp bending portions. In TASC II classification, the correlation between 3T-FBI and CTA was good. However, it was difficult to determine by 3T-FBI in a

case of type C in AI because that requires to evaluate the presence of heavily calcification. Some CTA showed to be difficult to accurately evaluate the lumen even with the original images and curved multi-planar reconstruction images when the arterial wall was heavily calcified. In the BK region, arterial visualization was excellent due to the high signal intensity at 3T-FBI, and the diagnostic ability was relatively good.*Conclusions 3T-FBI shows excellent diagnostic ability in evaluation of PAD. Having the high specificity and NPV is suitable as a screening examination. 3T-FBI improves the diagnostic ability in the BK region because of its high signal intensity, as compared to our previous experience at 1.5T.*Clinical Relevance/Application 3T-FBI shows excellent diagnostic ability in evaluation of patients with PAD in comparison with conventional angiography. Considering its high specificity and NPV, FBI is suitable for the screening examination.

RESULTS

The 344 arteries were evaluated where AG was performed. Of these, 97 arteries (10 in AI, 37 is FP, and 50 in BK) showed significant stenosis. The overall diagnostic ability of 3T-FBI showed sensitivity 98.9%, specificity 94.6%, positive predictive value (PPV) 88.1%, negative predictive value (NPV) 99.6%, and accuracy 95.6%. In AI, there were some false positives due to signal reduction at sharp bending portions. In TASC II classification, the correlation between 3T-FBI and CTA was good. However, it was difficult to determine by 3T-FBI in a case of type C in AI because that requires to evaluate the presence of heavily calcification. Some CTA showed to be difficult to accurately evaluate the lumen even with the original images and curved multi-planar reconstruction images when the arterial wall was heavily calcified. In the BK region, arterial visualization was excellent due to the high signal intensity at 3T-FBI, and the diagnostic ability was relatively good.

CLINICAL RELEVANCE/APPLICATION

3T-FBI shows excellent diagnostic ability in evaluation of patients with PAD in comparison with conventional angiography. Considering its high specificity and NPV, FBI is suitable for the screening examination.

PD03-B1   **Clinical And MR Imaging Findings In Children With Myelin Oligodendrocyte Glycoprotein (MOG) Antibody-associated Disease**

Participants
Elizabeth George, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To describe the clinical and MRI findings in children with MOG-antibody associated disease.*Methods and Materials From our institutional pediatric demyelinating disease cohort (1998-2019), 32 patients with positive MOG titers and MRI at presentation were identified. Demographics, clinical symptoms, and MRI at presentation and first imaging follow-up were reviewed.*Results The median age at presentation was 6 years (IQR: 4-10). 50% (16/32) of patients presented with visual symptoms and 25% (8/32) presented with myelopathy. Other presenting symptoms were fever (22%), headache (38%), and seizure (9%).The median time from presentation to initial MRI was 14 days (IQR: 1-31). Brain involvement was seen in 78% (25/32, Table), most commonly affecting frontal lobes (84%, 21/25) and subcortical white matter (88%, 22/25). Deep gray nuclei were involved in 64% (16/25). 96% (24/25) had supratentorial and 76% (19/25) had infratentorial involvement. Pons was the most common infratentorial location (48%, 12/25). Reduced diffusion was rare (1/25, 4%) and none had susceptibility artifact. 52% (13/25) demonstrated enhancement, most frequently solid or ill-defined (both 28%, 7/25), followed by linear (24%, 6/25). Orbital involvement was seen in 50% (16/32). Involvement was bilateral in 75% (12/16) and most commonly of the anterior segments in 81% (13/16). Spine involvement was seen in 22% (7/32) and was multifocal in 57% (4/7). The most common imaging pattern was an ADEM-like brain pattern with optic neuritis (ON) (9/32, 28%) (Figure), followed by isolated ADEM-like brain pattern (8/32, 25%) and isolated ON (5/32, 16%). The median time to first follow-up MRI was 75.5 days (IQR: 27.5-241.5). At the time of follow-up, brain lesions demonstrated mixed response in 35% (10/29) and improvement in 24% (7/29). The overall imaging pattern was same (or resolved) at the time of follow-up in 78% (25/32), while 22% (7/32) demonstrated a new pattern of involvement.*Conclusions The most common imaging pattern of MOG antibody-associated disease at presentation was ADEM-like brain involvement with optic neuritis. At follow-up, 22% demonstrated a new pattern of involvement.*Clinical Relevance/Application Recognizing the MRI patterns of disease involvement in children with MOG antibody-associated disease at initial presentation and follow-up will assist with diagnosis and treatment.

RESULTS

The median age at presentation was 6 years (IQR: 4-10). 50% (16/32) of patients presented with visual symptoms and 25% (8/32) presented with myelopathy. Other presenting symptoms were fever (22%), headache (38%), and seizure (9%).The median time from presentation to initial MRI was 14 days (IQR: 1-31). Brain involvement was seen in 78% (25/32, Table), most commonly affecting frontal lobes (84%, 21/25) and subcortical white matter (88%, 22/25). Deep gray nuclei were involved in 64% (16/25). 96% (24/25) had supratentorial and 76% (19/25) had infratentorial involvement. Pons was the most common infratentorial location (48%, 12/25). Reduced diffusion was rare (1/25, 4%) and none had susceptibility artifact. 52% (13/25) demonstrated enhancement, most frequently solid or ill-defined (both 28%, 7/25), followed by linear (24%, 6/25). Orbital involvement was seen in 50% (16/32). Involvement was bilateral in 75% (12/16) and most commonly of the anterior segments in 81% (13/16). Spine involvement was seen in 22% (7/32) and was multifocal in 57% (4/7). The most common imaging pattern was an ADEM-like brain pattern with optic neuritis (ON) (9/32, 28%) (Figure), followed by isolated ADEM-like brain pattern (8/32, 25%) and isolated ON (5/32, 16%). The median time to first follow-up MRI was 75.5 days (IQR: 27.5-241.5). At the time of follow-up, brain lesions demonstrated mixed response in 35% (10/29) and improvement in 24% (7/29). The overall imaging pattern was same (or resolved) at the time of follow-up in 78% (25/32), while 22% (7/32) demonstrated a new pattern of involvement.

CLINICAL RELEVANCE/APPLICATION

HN04-C1   **Quantitative Analysis Of Dual-energy Computed Tomography For Detection Of Cartilage Invasion By Laryngeal Squamous Cell Carcinoma**

Participants
Hillary R. Kelly, MD, Boston, Massachusetts (*Presenter*) Investigator, Bayer AG;Institutional research agreement, Bayer AG

PURPOSE

The purpose of this study is to identify quantitative metrics on dual energy computed tomography (DECT) to differentiate laryngeal cancer, cancer in thyroid cartilage (CIC), non-ossified cartilage (NOC) and ossified thyroid cartilage.*Methods and Materials DECT data acquired on a single source rapid-switching platform on 30 patients (26 men, 4 women, mean age 64± 10.2 years) with histopathology-confirmed squamous cell carcinoma involving the larynx were retrospectively evaluated. 540 regions of interests were drawn within tumor and cartilage to determine the calculated HU of these structures at virtual monoenergetic images (VMIs) of 40keV and140keV, differences between HU measured on 40keV and 140keV VMIs, iodine density, and water density. Normalization of HU (on 40keV and 140keV VMIs) and iodine density was also performed using the internal jugular vein as the reference standard.*Results Water density, absolute and normalized iodine densities, absolute and normalized HU (on 40keV and 140keV VMIs), were significantly different between all the structures (p= 0.0012), except for cancer versus CIC. In comparing CIC to NOC, all characteristics were statistically significant (p=0.0002). ROC curve analysis showed that both absolute water density and normalized HU (on 40keV and 140keV VMIs) can differentiate CIC from NOC with AUC of 1. Absolute iodine density, normalized iodine density and HU (on 40keV and 140keV VMIs) were also excellent differentiators (AUC =0.918).*Conclusions Thyroid cartilage invaded by cancer has distinctly different iodine density, water density, and HU ranges on 40keV and 140keV VMIs compared to normal cartilage. The addition of water density derived images ("water maps") to iodine density ("iodine maps") and VMIs may increase the accuracy of DECT for differentiating cartilage invaded by laryngeal cancer from normal non-ossified cartilage.*Clinical Relevance/Application Accurate assessment of laryngeal cancer for cartilage invasion is important for staging and management, as it is a major factor in stratifying patients to surgery (total laryngectomy) or nonoperative management (radiation +/- chemotherapy). However, it can be difficult to differentiate normal non-ossified cartilage from cancer invading cartilage on conventional single energy CT. Quantitative information derived from DECT as demonstrated in this study shows that laryngeal squamous cell carcinoma, its invasion into thyroid cartilage, normal non-ossified cartilage and ossified thyroid cartilage have distinctly different characteristics, which can be objectively measured.

RESULTS

Water density, absolute and normalized iodine densities, absolute and normalized HU (on 40keV and 140keV VMIs), were significantly different between all the structures (p= 0.0012), except for cancer versus CIC. In comparing CIC to NOC, all characteristics were statistically significant (p=0.0002). ROC curve analysis showed that both absolute water density and normalized HU (on 40keV and 140keV VMIs) can differentiate CIC from NOC with AUC of 1. Absolute iodine density, normalized iodine density and HU (on 40keV and 140keV VMIs) were also excellent differentiators (AUC =0.918).

CLINICAL RELEVANCE/APPLICATION

Accurate assessment of laryngeal cancer for cartilage invasion is important for staging and management, as it is a major factor in stratifying patients to surgery (total laryngectomy) or nonoperative management (radiation +/- chemotherapy). However, it can be difficult to differentiate normal non-ossified cartilage from cancer invading cartilage on conventional single energy CT. Quantitative information derived from DECT as demonstrated in this study shows that laryngeal squamous cell carcinoma, its invasion into thyroid cartilage, normal non-ossified cartilage and ossified thyroid cartilage have distinctly different characteristics, which can be objectively measured.

GI03-D10 CT-body Composition Of Sarcopenia And Sarcopenic Obesity: Predictors Of Postoperative Complications And Survival In Patients With Locally Advanced Esophageal Adenocarcinoma

Participants
Timo Auer, MD, Berlin, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To assess the impact of body composition markers in computed tomography (CT) on perioperative morbidity and survival after surgery for patients with esophageal cancer (EC).*Methods and Materials Eighty-five patients who underwent esophagectomy for locally advanced EC between 2014 and 2019 were retrospectively enrolled. Pre- and postoperative CT scans were used to assess body composition markers (visceral [VAT] and subcutaneous adipose tissue [SAT] areas, psoas muscle area [PMA] and volume [PMV], total abdominal muscle area [TAMA]). Sarcopenia was defined as lumbar skeletal muscle index (LSMI) =38.5 cm2/m2 for women and =52.4 cm2/m2 for men. Patients with a body mass index (BMI) of =30 were considered obese. These imaging markers were correlated to major complications, anastomotic leakage, postoperative pneumonia, length of hospitalization, disease-free survival (DFS), and overall survival (OS).*Results Preoperatively, sarcopenia was identified in 58 patients (68.2%) and sarcopenic obesity was present in 7 patients (8.2%). Sarcopenic patients showed an elevated risk for the occurrence of major complications (OR: 2.587, p=0.048). Neither sarcopenia nor sarcopenic obesity was an independent risk factor for the occurrence of anastomotic leakage (p>0.05). Patients with sarcopenic obesity had a significantly higher risk for postoperative occurrence of pneumonia (OR: 6.364 p=0.018) and a longer hospital stay after surgery (71d vs. 24d, p=0.003). A decrease in PMV and TAMA in the follow-up period showed a significant correlation to shorter DFS and OS (beta coefficient: -0.291 to -0.356; p=0.018 to 0.044).*Conclusions Sarcopenic patients with locally advanced esophageal cancer undergoing surgery are at increased risk for major complications and patients with sarcopenic obesity are more prone to postoperative pneumonia and prolonged hospitalization. Decreasing muscle mass during postoperative follow-up is associated with lower DFS and OS.*Clinical Relevance/Application Preoperative staging examinations are carried out on every patient and the image data contain valuable information about the patient's physical condition in addition to the routinely assessed tumor extension. Our analysis showed that sarcopenic patients with low muscle mass were more likely to have major complications and that hospitalization was prolonged, especially in patients with sarcopenic obesity. A decrease in muscle mass during the follow-up also indicated poorer overall survival. CT-body composition parameters should therefore be assessed routinely in the imaging work-up.

RESULTS

Preoperatively, sarcopenia was identified in 58 patients (68.2%) and sarcopenic obesity was present in 7 patients (8.2%). Sarcopenic patients showed an elevated risk for the occurrence of major complications (OR: 2.587, p=0.048). Neither sarcopenia nor sarcopenic obesity was an independent risk factor for the occurrence of anastomotic leakage (p>0.05). Patients with sarcopenic obesity had a significantly higher risk for postoperative occurrence of pneumonia (OR: 6.364 p=0.018) and a longer hospital stay after surgery (71d vs. 24d, p=0.003). A decrease in PMV and TAMA in the follow-up period showed a significant correlation to shorter DFS and OS (beta coefficient: -0.291 to -0.356; p=0.018 to 0.044).

CLINICAL RELEVANCE/APPLICATION

Preoperative staging examinations are carried out on every patient and the image data contain valuable information about the patient's physical condition in addition to the routinely assessed tumor extension. Our analysis showed that sarcopenic patients with low muscle mass were more likely to have major complications and that hospitalization was prolonged, especially in patients with sarcopenic obesity. A decrease in muscle mass during the follow-up also indicated poorer overall survival. CT-body composition parameters should therefore be assessed routinely in the imaging work-up.

GI03-D2 Overlooked Area Of Abdomen CT: Utilization Of AI Lung Nodule Detection And Characterization System For Basal Lung Metastasis In Colon Cancer Patients

Participants
Eun Kyoung Hong, MD, Gwangmyeong-Si, Korea, Republic Of (*Presenter*) Research Consultant, VUNO Inc

PURPOSE

Even though the basal lung area covered in the abdomen CT can be easily overlooked by abdominal radiologists, nodules in this area can have important clinical significance, especially if they are malignant. In this study, we aim to assess the performance of an AI system for the detection of lung metastasis on abdomen CTs in colon cancer patients.*Methods and Materials This retrospective study consecutively included 261 colon cancer patients who received primary surgical resection of colon tumors with no definite evidence of lung metastasis on pre-surgical CT evaluation. Portal-venous phase images of preoperative abdomen CTs reconstructed at 2.5-3 mm slice thickness were used for analysis. A fully automated AI lung nodule detection system was utilized for the detection and characterization of lung nodules in the basal lung area that is covered on abdomen CT. Lung nodules detected with the AI system were re-evaluated by one radiologist to confirm the location and characteristics of the nodules. Thereafter, follow-up chest, abdomen or both CTs and the reports from the follow-up scans were reviewed. Nodules in the initial abdomen CT that 1) showed an increment in size and number and 2) reported as metastasis in the follow-up imaging were considered as metastasis.

LungRADS scores were automatically calculated with the AI system and compared between patients with metastatic and benign nodules using a Chi-squared test.*Results Of 216 scans of patients with no previously diagnosed lung metastasis, a total of 294 lung nodules were detected in 71 patients (metastasis = 12, benign = 55, unconfirmed = 4 patients) using the AI system; automatically calculated LungRADS score of 2 (n = 41), 3 (n = 7), 4a (n = 16), 4b (n = 3), 4x (n = 4). For the patients with lung metastasis detected by the AI system (n = 12), LungRADS scores were 2 (n = 2), 4a (n = 6), 4b (n = 3), 4x (n = 1). On the other hand, patients with benign nodules detected by the AI system (n = 55) presented with LungRADS scores of 2 (n = 37), 3 (n = 6), 4a (n = 9), 4x (n = 3). There was a significant difference in LungRADS scores of patients with AI-detected metastatic and benign nodules (p < 0.001).*Conclusions The AI lung nodule detection system was able to automatically identify and characterize basal lung metastasis on abdomen CT.*Clinical Relevance/Application Detection and characterization of lung metastasis in the basal lung covered on abdomen CT with the use of AI system can aid in treatment decision making and prognosis prediction of colon cancer patients. We carefully propose the utilization of an AI system for the detection of lung nodules in abdomen CT for better personalized medicine of colon cancer patients.

RESULTS

Of 216 scans of patients with no previously diagnosed lung metastasis, a total of 294 lung nodules were detected in 71 patients (metastasis = 12, benign = 55, unconfirmed = 4 patients) using the AI system; automatically calculated LungRADS score of 2 (n = 41), 3 (n = 7), 4a (n = 16), 4b (n = 3), 4x (n = 4). For the patients with lung metastasis detected by the AI system (n = 12), LungRADS scores were 2 (n = 2), 4a (n = 6), 4b (n = 3), 4x (n = 1). On the other hand, patients with benign nodules detected by the AI system (n = 55) presented with LungRADS scores of 2 (n = 37), 3 (n = 6), 4a (n = 9), 4x (n = 3). There was a significant difference in LungRADS scores of patients with AI-detected metastatic and benign nodules (p < 0.001).

CLINICAL RELEVANCE/APPLICATION

Detection and characterization of lung metastasis in the basal lung covered on abdomen CT with the use of AI system can aid in treatment decision making and prognosis prediction of colon cancer patients. We carefully propose the utilization of an AI system for the detection of lung nodules in abdomen CT for better personalized medicine of colon cancer patients.

GI03-D4   Feasibility Of Compressed Sensing-sensitivity Encoding In Magnetic Resonance Imaging Of The Rectum

Participants
Serin Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the feasibility of compressed sensing-sensitivity encoding (CS-SENSE) in patients with anorectal cancer, focused on the image quality and acquisition time.*Methods and Materials Sixty-one anorectal cancer patients (56.7 years ± 8.9 [standard deviation]) who underwent anorectal MR were included in this retrospective study. T2 weighted axial rectal MRI with SENSE (acceleration factor, 2) and CS-SENSE (acceleration factor, 3) were compared in each patient by two experienced radiologists. Margin sharpness, image noise, artifacts, synthetic appearance, lesion conspicuity, and overall image quality were assessed using 5-point Likert scale (1, inferior; 3, similar; 5, superior) and compared using Wilcoxon signed-rank test between two image sets. Interobserver agreement was measured using PABAK-OS. In addition, acquisition time were compared using paired t test between two groups.*Results Acquisition time of CS-SENSE (mean ± SD, 119.6 ± 21.4 s) was 25.1% shorter than that of SENSE (mean ± SD, 159.6 ± 19.9 s; P < 0.001). Artifact was less observed on CS-SENSE than SENSE significantly in both upper (Reader 1; 3.34 ± 0.48, P < 0.001, Reader 2; 3.38 ± 0.66, P < 0.001, Average; 3.36 ± 0.57, P < 0.001) and lower levels (Reader 1; 3.11 ± 0.36, P =0.011, Reader 2; 3.18 ± 0.51, P =0.008, Average; 3.14 ± 0.44, P < 0.001). For image noise, reader 2 evaluated CS-SENSE more valuable than SENSE (3.05 ± 0.28, P =0.025). No significant differences were found in margin sharpness, synthetic appearance, lesion conspicuity, and overall image quality. Interobserver agreement was mostly moderate to almost perfect for each image quality assessment.*Conclusions Compressed sensing with SENSE is clinically feasible in patients with anorectal patients, resulting in significant reduction in acquisition time without deteriorating image quality.*Clinical Relevance/Application Abbreviations CS = compressed sensing, SENSE = sensitivity encoding, PI = parallel imaging, SNR = signal-to-noise ratio Summary Rectal MR with CS-SENSE can reduce acquisition time without deteriorating image quality.Implications for Patient Care l In T2-weighted axial image, CS-SENSE reduces acquisition time by 25.1%, compared with SENSE. l CS-SENSE could reduce artifact without significant decreasing lesion conspicuity in T2-wgithed image anorectal MR images.

RESULTS

Acquisition time of CS-SENSE (mean ± SD, 119.6 ± 21.4 s) was 25.1% shorter than that of SENSE (mean ± SD, 159.6 ± 19.9 s; P < 0.001). Artifact was less observed on CS-SENSE than SENSE significantly in both upper (Reader 1; 3.34 ± 0.48, P < 0.001, Reader 2; 3.38 ± 0.66, P < 0.001, Average; 3.36 ± 0.57, P < 0.001) and lower levels (Reader 1; 3.11 ± 0.36, P =0.011, Reader 2; 3.18 ± 0.51, P =0.008, Average; 3.14 ± 0.44, P < 0.001). For image noise, reader 2 evaluated CS-SENSE more valuable than SENSE (3.05 ± 0.28, P =0.025). No significant differences were found in margin sharpness, synthetic appearance, lesion conspicuity, and overall image quality. Interobserver agreement was mostly moderate to almost perfect for each image quality assessment.

CLINICAL RELEVANCE/APPLICATION

Abbreviations CS = compressed sensing, SENSE = sensitivity encoding, PI = parallel imaging, SNR = signal-to-noise ratio Summary Rectal MR with CS-SENSE can reduce acquisition time without deteriorating image quality.Implications for Patient Care l In T2-weighted axial image, CS-SENSE reduces acquisition time by 25.1%, compared with SENSE. l CS-SENSE could reduce artifact without significant decreasing lesion conspicuity in T2-wgithed image anorectal MR images.

GI03-D6   Quantitative Evaluation Of Gastric Cancer Lauren Classification Using CT Perfusion Imaging

Participants
Zhang Min, Jinan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the value of quantitative parameters of CT Perfusion imaging in Lauren classification of gastric cancer.*Methods and Materials From July 2018 to November 2019,fifty-twopatients(44 men, 8 women; mean age 58±4.8, range 44-85) with gastric cancer confirmed by gastroscopy were enrolled in our study. All patients underwent preoperative CT perfusion (CTP) and curative gastrectomy. The enrolled cases were divided into intestinal type group, diffuse type group and mixed type group according to Lauren classification. Perfusion parameters including blood-flow (BF), blood volume (BV), mean transmit time (MTT), time to peak (TTP) and permeability surface (PS) were calculated. One-way analysis of variance (ANOVA) were performed between Lauren

groups for each perfusion parameter. A receiver operating characteristic (ROC) analysis was applied to evaluate the diagnostic performance of perfusion parameters.*Results The patient number in intestinal type, diffuse type and mixed type were 19, 13 and 20, respectively. PS and BV of mixed type group were significantly higher than intestinal and diffuse type groups(all p<0.05).To distinguish mixed type group with the other Lauren groups, PS showed the largest area under ROC curve (AUC) of 0.962 (sensitivity, 94.7%; specificity, 93.9%)with a cut-off value of 45.23ml/100g/min. BV had AUC of 0.735, sensitivity of 94.7% and specificity of 84.8% with the cut-off value of 5.04 ml/100g. PS and BV of intestinal group were significantly lower than other Lauren types and PS showed the largest area under ROC curve (AUC) of 0.922 (sensitivity, 80.0%; specificity, 93.7%).*Conclusions PCT can accurately evaluate the Lauren types of gastric cancer with certain perfusion parameters.*Clinical Relevance/Application The PCT can serve as alternative diagnosis method to distinguish different Lauren types.

RESULTS

The patient number in intestinal type, diffuse type and mixed type were 19, 13 and 20, respectively. PS and BV of mixed type group were significantly higher than intestinal and diffuse type groups(all p<0.05).To distinguish mixed type group with the other Lauren groups, PS showed the largest area under ROC curve (AUC) of 0.962 (sensitivity, 94.7%; specificity, 93.9%)with a cut-off value of 45.23ml/100g/min. BV had AUC of 0.735, sensitivity of 94.7% and specificity of 84.8% with the cut-off value of 5.04 ml/100g. PS and BV of intestinal group were significantly lower than other Lauren types and PS showed the largest area under ROC curve (AUC) of 0.922 (sensitivity, 80.0%; specificity, 93.7%).

CLINICAL RELEVANCE/APPLICATION

The PCT can serve as alternative diagnosis method to distinguish different Lauren types.

GI03-D9   Reduction Of Peristalsis-related Streak Artifacts In The Liver With Dual-Layer Spectral CT

Participants
Sergio Grosu, MD, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To assess the performance of dual-layer spectral detector CT image reconstructions for the reduction of intestinal peristalsis-related streak artifacts in the liver.*Methods and Materials We retrospectively evaluated 220 contrast-enhanced abdominal CT scans in 131 consecutive patients (mean age: 68±10 years, 120 men) who underwent routine clinical dual-layer spectral CT imaging. Conventional 120 kVp images, 40 keV and 200 keV monoenergetic image reconstructions, water and iodine material decomposition image reconstructions were analyzed. Two independent readers recorded the presence and severity of peristalsis-related streak artifacts in the right and left liver lobes qualitatively on a five-point Likert scale (1=none to 5=severe) and quantitatively by the depth of streak artifact extension into the liver in mm and ROI measurements of Hounsfield Unit and iodine concentration differences from normal liver. Artifact severity between image reconstructions were compared by Wilcoxon signed-rank and paired t-tests.*Results Intestinal peristalsis-related streak artifacts in the liver were seen in 51/208 (25%) CT scans and involved the left lobe only in 49/51 (96%), the right lobe only in 0/51 (0%), and both lobes in 2/51 (4%) CT scans. The frequency of artifacts was significantly lower in iodine than in 120 kVp image reconstructions (scans 18/208 vs. 51/208, p<0.001). Artifact severity was significantly less in iodine than in 120 kVp image reconstructions (median score 1 vs. 3, p<0.001). The depth of streak artifact extension into the liver was shorter in iodine than 120 kVp image reconstructions (mean length 2±4 vs. 12±5 mm, p<0.001). ROI measurements were significantly different between bright streak artifacts and the neighboring unaffected liver parenchyma in 120 kVp, 40 keV, 200 keV and water image reconstructions (p<0.001, each), but not in iodine image reconstructions (p=0.23).*Conclusions Intestinal peristalsis-related streak artifacts commonly affect the left liver lobe at 120 kVp and can be substantially reduced by viewing iodine DECT image reconstructions.*Clinical Relevance/Application Iodine DECT image reconstructions substantially reduce common peristalsis-related streak artifacts in the liver, particularly for the left lobe by the stomach, at dual layer spectral CT.

RESULTS

Intestinal peristalsis-related streak artifacts in the liver were seen in 51/208 (25%) CT scans and involved the left lobe only in 49/51 (96%), the right lobe only in 0/51 (0%), and both lobes in 2/51 (4%) CT scans. The frequency of artifacts was significantly lower in iodine than in 120 kVp image reconstructions (scans 18/208 vs. 51/208, p<0.001). Artifact severity was significantly less in iodine than in 120 kVp image reconstructions (median score 1 vs. 3, p<0.001). The depth of streak artifact extension into the liver was shorter in iodine than 120 kVp image reconstructions (mean length 2±4 vs. 12±5 mm, p<0.001). ROI measurements were significantly different between bright streak artifacts and the neighboring unaffected liver parenchyma in 120 kVp, 40 keV, 200 keV and water image reconstructions (p<0.001, each), but not in iodine image reconstructions (p=0.23).

CLINICAL RELEVANCE/APPLICATION

Iodine DECT image reconstructions substantially reduce common peristalsis-related streak artifacts in the liver, particularly for the left lobe by the stomach, at dual layer spectral CT.

PH04-C1   Organ-based And Dlp-based Effective Dose As Representations Of Radiation Risk In A Population Of 8946 Patients With Cumulative Effective Dose Greater Than 100 Milli Sievert

Participants
Francesco Ria, DMP, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

Recent studies have shown that it is not uncommon for a patient to undergo multiple CT exams resulting in high cumulative dose above 100 mSv, the radiation risk associated with which is not negligible. The purpose of this study was to compare the estimated radiation risk in a large population of such cases based on effective dose to estimates of risk index including patient age.*Methods and Materials This IRB-approved study included 8946 patients who underwent multiple CT exams over 5 years resulting in a cumulative effective dose over 100 mSv. Organ doses were estimated using Monte Carlo methods. DLP-based effective dose (Ek) and organ dose-based effective dose (EOD) were calculated following ICRP 102 and ICRP 103 publications. The organ dose-based risk index (RI) was calculated according to BEIR VII risk coefficients. A linear regression was applied to assess each metric's dependency to RI, assumed to be the closest patient risk surrogate. The relative sensitivity of EOD and Ek to the estimated risk was calculated in six age groups (30 to 80 years old) in terms of a Risk Sensitivity Index (RSI) computed as a normalized fit slope by the ratio of the mean value of RI for each metric.*Results Across all patients, EOD for the 100 mSv+ cohort ranged between 100.2 and 1184.7 mSv, Ek between 54.1 and 1031.9 mSv, and RI between 152.9 and 7785.1 cancers per 105 patients. Per each age group, the fit R2 was <0.004 for the linear regression of Ek vs. RI and between 0.72 and 0.97 for EOD vs. RI implying that RI and EOD are linearly related. As anticipated, the fit slope increased with patient age. The RSI was <3.15×10-4 for Ek and ranged between 0.01 and 0.26 for EOD.*Conclusions For patient exposed to high cumulative dose (>100 mSv), care should be exercised to properly assess the risk figures and to draw risk predictions from metrics unrepresentative of population risk. Compared to effective dose drawn from DLP, effective dose based on organ doses provides a closer representation of patient and population risk, provided stratification by specific age groups.*Clinical Relevance/Application When patients undergo recurring CT exams, the radiation induced risks should be carefully estimated using metrics that incorporate organ dose and patient age.

RESULTS

Across all patients, EOD for the 100 mSv+ cohort ranged between 100.2 and 1184.7 mSv, Ek between 54.1 and 1031.9 mSv, and RI between 152.9 and 7785.1 cancers per 105 patients. Per each age group, the fit R2 was <0.004 for the linear regression of Ek vs. RI and between 0.72 and 0.97 for EOD vs. RI implying that RI and EOD are linearly related. As anticipated, the fit slope increased with patient age. The RSI was <3.15×10-4 for Ek and ranged between 0.01 and 0.26 for EOD.

CLINICAL RELEVANCE/APPLICATION

When patients undergo recurring CT exams, the radiation induced risks should be carefully estimated using metrics that incorporate organ dose and patient age.

PH04-C10   Feasibility Study Of Spectral CT Virtual Unenhanced Technique In Chest Enhanced CT Imaging

Participants
Dandan Niu, Jinan, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the feasibility of Revolution CT virtual unenhanced CT(VUE) images replacing conventional unenhanced CT(TUE) images.*Methods and Materials Thirty patients underwent conventional un-enhanced CT scan with 120kVp tube voltage,automatic current(200-500mA) and contrast enhanced spectral CT scan with GSI-Assist mode during the arterial phase(AP) and venous phase(VP) were prospectively collected. All the patients were scanned on a 256-row CT scanner (Revolution,healthcare) with the following parameters: 0.092 pitch, noise index(NI)12,detector width 80mm,rotate speed 0.5s,pre-ASiR-V 40%.The images (AP-VUE,VP-VUE)were reconstructed after scan..CT value of lesions in various sites(including thoracic aorta,pulmonar artery,subcutaneous fat and erector spinae),image noise of chest subcutaneous fat(SD) ,effective dose (ED) in all the patients were recorded. CT value of the arterial phase(AP) and venous phase(VP) relative to TUE and AP-VUE,VP-VUE were calculated, respectively. Contrast-to-noise ratio(CNR) of pulmonar artery and thoracic aorta and the lesion net added Subjective image quality were assessed by two radiologists using a 5-point scale (from 1=unaccepted to 5=excellent) in a double -blinded and randomized manner. A score of 3 was required to fulfil minimal clinical diagnose. ANOVA and Kruskal-Wallis H were used to determine the difference of image quality and radiation dose between groups.*Results There was no significant differences in CT value(thoracic aorta(42.22±3.78,41.05±5.38,43.28±5.27,F=1.582,p=0.212),pulmonar artery(48.46±5.00,46.22±4.55,47.92±4.71,F=1.818,p=0.169)) and SD(7.56±1.76,8.30±1.60,8.08±2.10,F=1.313,p=0.274)between AP-VUE,VP-VUE and TUE images.There was no difference in subjective score of three groups.The total radiation dose(DLP) before and after TUE were 525.79±156.97 mGy.cm,725.28±215.43 mGy.cm,The effective dose (ED) before and after TUE were 7.36±2.20mSv,10.15±3.02mSv,respectively.The ED could reduced by 27.58% by using VUE images .*Conclusions The VUE technique can provide the accurate CT value of the lesion in various sites while reducing radiation dose,obtain better image quality,and meet clinical diagnostic requirements.*Clinical Relevance/Application Better image quality can be obtained while reducing radiation dose by using VUE images.

RESULTS

There was no significant differences in CT value(thoracic aorta(42.22±3.78,41.05±5.38,43.28±5.27,F=1.582,p=0.212),pulmonar artery(48.46±5.00,46.22±4.55,47.92±4.71,F=1.818,p=0.169)) and SD(7.56±1.76,8.30±1.60,8.08±2.10,F=1.313,p=0.274)between AP-VUE,VP-VUE and TUE images.There was no difference in subjective score of three groups.The total radiation dose(DLP) before and after TUE were 525.79±156.97 mGy.cm,725.28±215.43 mGy.cm,The effective dose (ED) before and after TUE were 7.36±2.20mSv,10.15±3.02mSv,respectively.The ED could reduced by 27.58% by using VUE images .

CLINICAL RELEVANCE/APPLICATION

Better image quality can be obtained while reducing radiation dose by using VUE images.

PH04-C12   Feasibility Study Of Energy Spectralct Virtual Non-contrast Scansto Replace True Non-contrast Scansin Ctu

Participants
Jie Sun, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the feasibility of energy spectral CT virtual non-contrast scans (VNC) to replace true non-contrast (TNC) scans in computed tomography urography(CTU) examination.*Methods and Materials Twenty-eight patients prepared for CTU examination were collected prospectively. All patients received conventional TNC scanning and spectrum enhanced scan. The protocol of conventional TNC scan: tube voltage 120 kVp, automatic tube current (100-740mA). The energy spectrum enhanced scanning adopts tube voltage fast kV switch (80/140 kV) the tube current 440mA. The energy spectrum images in venous phase were reconstructed by post-processing workstation ADW4.7 to generate virtual non-contrast scanning (VNC) images. CT values, background noise (SD), signal noise ratio (SNR=HUtissue/SDtissue), contrast signal noise ratio (CNR=HUtissue-HUmuscule)/SDfat) of liver, spleen, pancreas, right renal cortex, renal medulla, abdominal aorta , erector spinae and abdominal fat in VNC and TNC image were measured and compared respectively. The subjective image scores were assessed blindly by two experienced physicians using a 5-point system. The dose length product (DLP) of each scan was recorded after scanning, and the value of effective dose (ED) was calculated according to the formula: ED(mSv)=k(mSv*mGy-1*cm-1)*DLP(mGy*cm). The differences of CNR,SNR and SD among VNC and TNC were compared by one-way analysis of variance, and the differences of subjective scoring between two observers were compared by Kappa test.*Results The SD values of liver, spleen, pancreas, abdominal aorta, renal cortex, medulla and abdominal fat were(18.24±2.24)HU,(19.27±2.61)HU,(21.01±2.38)HU,(22.00±2.51)HU,(19.43±2.61)HU,(19.63±2.77)HU,(17.40±1.46)HU respectively in the VNC image , and there were significantly different from the corresponding SD values in TNC image(P <0.05). Similarly, the CNR and SNR of tissue in VNC image were significantly different from the corresponding TNC image(P<0.05). Compared with the DLP of TNC scanning, the DLP decreased by 48% after the application of energy spectrum CT VNC technology. The subjective scores of TNC and VNC imaging was no statistical significance between the two groups (P>0.05).*Conclusions Both VNC images and TNC images can meet the requirements of diagnosis. The VNC scans can replacing TNC in CTU examination, which can significantly reduce the radiation dose while ensuring the requirements of image diagnosis.*Clinical Relevance/Application The material suppressed iodine (MSI) technology provides new ideas and guidance for clinical examination, which can be applied to the examination of all clinical sites and the examination of radiation-sensitive people (children, patients with hyperthyroidism, etc).

RESULTS

The SD values of liver, spleen, pancreas, abdominal aorta, renal cortex, medulla and abdominal fat were(18.24±2.24)HU,(19.27±2.61)HU,(21.01±2.38)HU,(22.00±2.51)HU,(19.43±2.61)HU,(19.63±2.77)HU,(17.40±1.46)HU respectively in the VNC image , and there were significantly different from the corresponding SD values in TNC image(P <0.05). Similarly, the CNR and SNR of tissue in VNC image were significantly different from the corresponding TNC image(P<0.05). Compared with the DLP of TNC scanning, the DLP decreased by 48% after the application of energy spectrum CT VNC technology. The subjective scores of TNC and VNC imaging was no statistical significance between the two groups (P>0.05).

CLINICAL RELEVANCE/APPLICATION

The material suppressed iodine (MSI) technology provides new ideas and guidance for clinical examination, which can be applied to the examination of all clinical sites and the examination of radiation-sensitive people (children, patients with hyperthyroidism, etc).

PH04-C3   Characterization of a New Investigational Dual-source Photon-counting CT System Based on AAPM Task Group 233 Metrology

Participants
Ehsan Samei, PhD, Durham, North Carolina (*Presenter*) Researcher, General Electric Company;Royalties, General Electric Company;Consultant, General Electric Company;Advisory Board, General Electric Company;Researcher, Siemens AG;Researcher, Bracco Grouip;Royalties, medInt Holdings, LLC;Consultant, medInt Holdings, LLC;Advisory Board, medInt Holdings, LLC;Royalties, 12 Sigma Technologies;Royalties, Sun Nuclear Corporation;Royalties, IBM Corporation;Royalties, Metis Health;Consultant, Nano-X Imaging Ltd;Advisory Board, Nano-X Imaging Ltd;;;

PURPOSE

To assess the foundational image quality characteristics of a new investigational dual-source photon-counting CT (PCCT) system according to the standardized metrology of AAPM Task Group 233.*Methods and Materials The ACR phantom was scanned on an investigational full-field of view PCCT system (NAEOTOM Alpha, Siemens Healthineers) using the standard protocols of TG233-F1-6 (120 kV, CTDIvol of 24, 12, 6, 3, 1.5 and 0.79 mGy), in quantum plus mode (M4, 2 energy thresholds of 20 and 65 keV, 352 μm pixel size), and reconstructed as 70 keV mono-energetic image set with 1.5 and 5.0 mm slice thickness and standard body kernel (Br40). An additional data set was acquired at TG233-F6 in quantum high resolution mode (S1, 2 energy thresholds of 20 and 65 keV, 176 μm pixel size), reconstructed with 0.2 and 5.0 mm slice thicknesses with kernels Br78, Br89, and Br98. The images were processed using the TG233 metrology in terms of spatial resolution (TTFn,C, f50 and f10), noise (n, NPSn, and fA), and detectability index (d' for 5mm lesion at 15 HU). The results were compared across acquisitions.*Results The metrics offered superior performance compared to competing CT technologies. Noise magnitudes (n) ranged from 2.0-24.6 HU for 0.79-24 CTDIvol in M4 mode with average noise texture (fA) largely intact. Resolution was also stable across dose levels at 0.33 0.37 mm-1 for f50. This value was markedly increased in the S1 mode to 0.36-1.39 mm-1 with noise correspondingly increasing to 1.8 to 15.6 HU across the three applied recon kernels.*Conclusions PCCT technology offers superior noise and resolution performance compared to other CT systems in either energy integrating or dual energy modes. The technology offers notable potential for improved

diagnostic performance and d' across clinical tasks.*Clinical Relevance/Application Photon-counting CT is rapidly emerging as a viable clinical imaging modality with potential to offer improved resolution, noise, and task performance across diverse clinical applications.

RESULTS

The metrics offered superior performance compared to competing CT technologies. Noise magnitudes (n) ranged from 2.0-24.6 HU for 0.79-24 CTDIvol in M4 mode with average noise texture (fA) largely intact. Resolution was also stable across dose levels at 0.33 0.37 mm-1 for f50. This value was markedly increased in the S1 mode to 0.36-1.39 mm-1 with noise correspondingly increasing to 1.8 to 15.6 HU across the three applied recon kernels.

CLINICAL RELEVANCE/APPLICATION

Photon-counting CT is rapidly emerging as a viable clinical imaging modality with potential to offer improved resolution, noise, and task performance across diverse clinical applications.

PH04-C4   Study On The Difference Of CT Value Between Virtual Plain Scan And True Non-contrast(TNC) In Neck CT Examination

Participants
Wang Xinhui, Shizuishan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the difference in CT values between virtual plain scan (VUE) and conventional plain scan in Revolution energy spectrum CT neck imaging, and to explore the feasibility of virtual plain scan (VUE) instead of conventional plain scan.*Methods and Materials Collected 30 newly diagnosed patients who needed neck plain scan and enhancement, and GE Revolution CT was used to perform true non-contrast neck scan and energy spectrum enhanced scan (arterial phase, venous phase).All patients signed an informed consent form before the examination.True non-contrast scan tube voltage is 120kV, tube current is auto mA, pitch 0.984:1, NI index 9, tube speed 0.5 s/rot, detector width 80mm, layer thickness and layer spacing 5mm, reconstruction layer thickness and layer the spacing is 0.625 mm, the reconstruction matrix is 512×512, and the iterative reconstruction level ASIR-V weight is 30%.The energy spectrum enhancement scan mode (GSI) tube voltage is 80kV-140kV instantaneous switching, the tube current is the energy spectrum automatic milliampere (GSI Assist), the NI index is 9, and the other scan parameters are consistent with the true non-contrast scan. Post-processing to obtain VUE images in arterial phase and venous phase. The AW4.7 workstation was used to measure the CT value of the common carotid artery and the CT value of the sternocleidomastoid muscle.Using SPSS 20.0 software, the CT values of the 3 groups of images were compared by one-way ANOVA analysis.*Results The CT values of common carotid artery in true non-contrast, arterial and venous phases of VUE were 48.10±5.67, 67.35±12.36, 56.12±11.69, respectively, with little change but statistical difference (p<0.05).The CT values of sternocleidomastoid muscle were 57.52±12.65, 54.37±9.38, 58.52±10.1, no statistical difference (p>0.05); Conventional plain scan CTDIvol (10.86±1.44) mSv, energy spectrum arterial and venous enhancement CTDIvol are each (9.99±1.30) mSv, virtual plain scan and energy spectrum enhancement are 35.21% lower than conventional plain scan and energy spectrum enhancement CTDIvol.*Conclusions Although there is a difference between the VUE and the true non-contrast scan blood vessel CT value in the arterial and venous phase, there is little change,there is no significant difference in the CT value of soft tissue, and it has the potential to replace true non-contrast scan images. The effect of VUE in the venous phase is better, so as to effectively reduce the patient's radiation dose.*Clinical Relevance/Application VUE image quality has the potential to replace true non-contrast scan images. The effect of intravenous VUE is better, which can effectively reduce the patient's radiation dose. It can be popularized in patients with neck tumors that require multiple reexaminations.

RESULTS

The CT values of common carotid artery in true non-contrast, arterial and venous phases of VUE were 48.10±5.67, 67.35±12.36, 56.12±11.69, respectively, with little change but statistical difference (p<0.05).The CT values of sternocleidomastoid muscle were 57.52±12.65, 54.37±9.38, 58.52±10.1, no statistical difference (p>0.05); Conventional plain scan CTDIvol (10.86±1.44) mSv, energy spectrum arterial and venous enhancement CTDIvol are each (9.99±1.30) mSv, virtual plain scan and energy spectrum enhancement are 35.21% lower than conventional plain scan and energy spectrum enhancement CTDIvol.

CLINICAL RELEVANCE/APPLICATION

VUE image quality has the potential to replace true non-contrast scan images. The effect of intravenous VUE is better, which can effectively reduce the patient's radiation dose. It can be popularized in patients with neck tumors that require multiple reexaminations.

PH04-C6   Dose Reduction Potential In Cone-beam CT Imaging Of Upper Extremity Joints With A Twin Robotic X-ray System

Participants
Karsten Luetkens, MD, Wuerzburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Cone-beam computed tomography is a powerful tool for 3D imaging of the appendicular skeleton, facilitating detailed visualization of bone microarchitecture. This study evaluated various combinations of acquisition and reconstruction parameters for the cone-beam CT mode of a twin robotic x-ray system in cadaveric wrist and elbow scans, aiming to define the best possible trade-off between image quality and radiation dose.*Methods and Materials Images were acquired with different combinations of tube voltage and tube current-time product, resulting in five scan protocols with varying volume CT dose indices: full-dose (17.4 mGy), low-dose (4.5 mGy), ultra-low-dose (1.15 mGy), modulated low-dose (0.6 mGy) and modulated ultra-low-dose (0.29 mGy). Each set of projection data was reconstructed with three convolution kernels (very sharp, sharp, intermediate). Five radiologists subjectively assessed the image quality of cortical bone, cancellous bone and soft tissue using seven-point scales.*Results Irrespective of the reconstruction kernel, overall image quality of every full-dose, low-dose and ultra-low-dose scan was deemed suitable for diagnostic use in contrast to modulated low-dose (very sharp/sharp/intermediate: 60/55/70%) and modulated ultra-low-dose studies (0/3/5%). Superior depiction of cortical and cancellous bone was achieved in very sharp full-dose and low-dose examinations (p<0.001) with low-dose scans also providing favorable bone visualization compared to sharp and intermediate full-dose studies (p<0.001). Fleiss' kappa was 0.618 (0.594 - 0.641; p<0.001), indicating substantial interrater reliability.*Conclusions In this study, we demonstrate that the radiation exposure in upper extremity joint scans can be substantially reduced while maintaining diagnostic image quality with the cone-beam CT mode of a twin robotic x-ray system. Application of very sharp

convolution kernels for image reconstruction facilitates superior display of bone microarchitecture, hence maximizing the dose reduction potential.*Clinical Relevance/Application Dose reduction of more than 90% compared standard clinical protocols is feasible for certain imaging tasks, while maintaining diagnostic image quality with a dedicated ultra-low-dose scan protocol.

RESULTS

Irrespective of the reconstruction kernel, overall image quality of every full-dose, low-dose and ultra-low-dose scan was deemed suitable for diagnostic use in contrast to modulated low-dose (very sharp/sharp/intermediate: 60/55/70%) and modulated ultra-low-dose studies (0/3/5%). Superior depiction of cortical and cancellous bone was achieved in very sharp full-dose and low-dose examinations (p<0.001) with low-dose scans also providing favorable bone visualization compared to sharp and intermediate full-dose studies (p<0.001). Fleiss' kappa was 0.618 (0.594 - 0.641; p<0.001), indicating substantial interrater reliability.

CLINICAL RELEVANCE/APPLICATION

Dose reduction of more than 90% compared standard clinical protocols is feasible for certain imaging tasks, while maintaining diagnostic image quality with a dedicated ultra-low-dose scan protocol.

PH04-C9   Influence Of Different Reconstruction Methods Of 256-row Detector CT On Image Quality Of Coronary Stent

Participants
Yongpei Cao, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the image quality of 256-row detector CT in different reconstruction kernel of coronary stent.*Methods and Materials CT images of 24 patients (28 stents) were collected from April 2020 to October 2020. All patients were divided into group A and group B. group A: coronary artery images were reconstructed with standard. Group B: coronary artery images were reconstructed with detail. Tube voltage: 120kv, tube current: 250-475mA, noise index: 24.0, rotational speed: 0.28s, ASiR-V: 50%, contrast agent: 370mg/ml, dosage: 0.8 * kg body weight. According to the fixed protocol, the CT value of the stent vessel, the inner diameter of the proximal, middle and distal segments of the stent and the inner diameter of the proximal, middle and distal segments of the stent were measured, The average CT value, SD value and the display rate of the stent inner diameter were calculated. Paired T-test was used to compare the average CT value, subjective image quality and display rate of stent inner diameter in two different reconstruction modes. Two radiologists with more than five years of experience in imaging diagnosis of cardiovascular and thoracic vascular groups scored the reconstructed images of group A and group B subjectively.*Results The average CT value in stent lumen of standard and detail reconstruction mode was (381 ± 71.53) and (380.75 ± 80), the difference was not statistically significant (P = 0. 443). The display rate of stent diameter in the two reconstruction modes was (33.00%± 9.56%) and (45.00% ± 10.23%), the display rate of stent diameter in detail reconstruction mode was higher than that in standard (P = 0. 000). The subjective scores of detail and standard reconstruction models were (2. 83 ± 0.43) and (3.37 ± 0.28), the subjective scores in detail reconstruction mode were significantly higher than those in standard (P = 0. 011).*Conclusions 256-row detector ultra high end CT in detail reconstruction mode can improve the image quality of coronary stent.*Clinical Relevance/Application 256-row detector CT in detail reconstruction mode can improve the image quality of coronary stent, and has important clinical application value in the evaluation of coronary stent image.

RESULTS

The average CT value in stent lumen of standard and detail reconstruction mode was (381 ± 71.53) and (380.75 ± 80), the difference was not statistically significant (P = 0. 443). The display rate of stent diameter in the two reconstruction modes was (33.00%± 9.56%) and (45.00% ± 10.23%), the display rate of stent diameter in detail reconstruction mode was higher than that in standard (P = 0. 000). The subjective scores of detail and standard reconstruction models were (2. 83 ± 0.43) and (3.37 ± 0.28), the subjective scores in detail reconstruction mode were significantly higher than those in standard (P = 0. 011).

CLINICAL RELEVANCE/APPLICATION

256-row detector CT in detail reconstruction mode can improve the image quality of coronary stent, and has important clinical application value in the evaluation of coronary stent image.

IN02-A1   Radiomic P-hacking: Corrupting The Training/validation/test Split

Participants
Mishka Gidwani, BS, Cleveland, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

Radiomic imaging literature frequently contains methodological flaws and inconsistencies that can inflate statistical significance. Specifically, the inadvertent leakage of information between training, validation and test splits can occur in many commonly used workflows. This study attempts to highlight these commonly observed methodological issues by assessing their prevalence and demonstrating their effect through spurious associations in randomly generated data.*Methods and Materials Random facsimile radiomic features are generated by synthetic minority over-sampling (SMOTE) two existing radiomic datasets, extracted from publicly available images: The Cancer Genome Atlas Low-Grade Glioma (TCGA-LGG) and MD Anderson Head and Neck Squamous Cell Carcinoma (HNSCC). In order to examine the effects of inconsistent Training/Validation/Test split, experiments on the Random Data are conducted using conventional machine learning (ML) models fit to data with and without a held-out test set. The effect of three kinds of data leakage were studied: harmonizing features and performing feature selection prior to splitting data, optimizing model hyperparameters using cross-validation of the full dataset, and selecting a final model using the "test" set. Additionally, a random sample of 25 radiomic publications published from 2017-2021 were reviewed for variations of this mistake.*Results We observe performance enhancement resulting from the three areas studied: p = 0.030, p = 0.120, and p = 0.002, respectively. In the subset of studies reviewed, we found these mistakes occurring in 60%, 24%, and 44% papers respectively. When compounded experimentally, these errors result in a 1.49x final performance enhancement.*Conclusions This study reports on the prevalence of common methodological errors in radiomics research and provides a checklist for a more rigorous evaluation for proposed radiomic studies, one that critically evaluates the statistical methodology for accidental leakage of information between training and test data sets.*Clinical Relevance/Application Radiomic studies that rely on flawed statistical methods overpromise the medical relevance of image-derived features. This poses a risk to the affected patient populations and hinders the progress of more discerning methods.

RESULTS

We observe performance enhancement resulting from the three areas studied: p = 0.030, p = 0.120, and p = 0.002, respectively. In the subset of studies reviewed, we found these mistakes occurring in 60%, 24%, and 44% papers respectively. When compounded experimentally, these errors result in a 1.49x final performance enhancement.

CLINICAL RELEVANCE/APPLICATION

Radiomic studies that rely on flawed statistical methods overpromise the medical relevance of image-derived features. This poses a risk to the affected patient populations and hinders the progress of more discerning methods.

IN02-A2   Deep Learning Detection Of Large Vessel Occlusion On CTA Head Using Small Datasets: Comparison Of 2D And 3D Neural Network Approaches

Participants
Paul Yi, MD, Baltimore, Maryland (*Presenter*) Consultant, FH Orthopedics SAS;Consultant, BunkerHill Health

PURPOSE

Deep learning methods to identify large vessel occlusion (LVO) on CTA of the head have been described using 2D and 3D convolutional neural networks (CNN). However, the relative advantages of one approach over the other has not been well established, particularly when using small datasets <1000 images described in prior work. Although 2D CNN transfer learning approaches have been well described in radiology, the use of 3D CNNs is less well established.The purpose of this study was to compare the performance of CNNs for detection of LVO on CTA of the head using 2D and 3D CNN transfer learning approaches on a relatively small dataset.*Methods and Materials Our dataset consisted of 876 single-phase CTAs of the head, of which 438 (50%) had a LVO (66.5% anterior circulation & 33.5% posterior circulation). Standard neuroimaging preprocessing was performed, including registration to template normal CT head and skull stripping.The images were divided at the patient level into 70/10/20% train/validation/test splits and used to train both 2D and 3D CNNs. For 2D CNNs, we created a single 2D RGB image for each CTA consisting of 3 non-overlapping maximum intensity projection (MIP) axial images spanning the brain. These 2D MIP 'slab' images were used to train a variety of 2D CNN classifiers pretrained on ImageNet for identification of LVO.For the 3D CNNs, we used the entire CTA volumes to train three different models: 1) ResNeXt-101 CNN pretrained on Jester video data (human hand gestures), 2) TenCent's MedicalNet CNN pretrained on body CT and MR images for segmentation, and 3) Stanford's PENet CNN pretrained for identification of pulmonary embolism on CTA of the chest.We evaluated CNN performance using AUC and statistically compared them using DeLong's parametric method. Grad-CAM heatmaps were generated to evaluate LVO localization ability of the CNNs.*Results The best performing 2D CNN was a ResNeXt-50 CNN, which achieved an AUC of 0.99. The 3D CNN approaches all achieved AUCs of 0.75 to 0.76 (p<0.001 for all compared to 2D CNN).Grad-CAM heatmaps showed that both 2D CNNs and 3D CNNs could appropriately localize LVOs (Figure 1), although less consistently for the 3D CNNs.*Conclusions Using a relatively small dataset of 876 CTA heads, a 2D CNN trained on 2D MIP images outperformed 3D CNNs trained on 3D CTA head volumes for the

detection of LVO. Although 3D CNNs more closely mimic a radiologist's visual search pattern for volumetric CTA data, in the setting of small amounts of data, 2D CNNs appear to have an advantage in performance at the expense of heavy image preprocessing to 'convert' 3D images into 2D MIP images.*Clinical Relevance/Application With relatively small imaging datasets of CTA head, 2D CNN approaches outperform 3D CNN approaches at the expense of heavy image preprocessing.

RESULTS

The best performing 2D CNN was a ResNeXt-50 CNN, which achieved an AUC of 0.99. The 3D CNN approaches all achieved AUCs of 0.75 to 0.76 ($p<0.001$ for all compared to 2D CNN).Grad-CAM heatmaps showed that both 2D CNNs and 3D CNNs could appropriately localize LVOs (Figure 1), although less consistently for the 3D CNNs.

CLINICAL RELEVANCE/APPLICATION

With relatively small imaging datasets of CTA head, 2D CNN approaches outperform 3D CNN approaches at the expense of heavy image preprocessing.

IN02-A3   Radibot, Instant Messaging Based Radiologist Decision Support

Participants
John Burns, BS, Indianapolis, Indiana (*Presenter*) Nothing to Disclose

PURPOSE

There is a clear need for human-machine interfaces supporting clinical decision support systems (CDSS) and radiologists. With respect to the variety of systems radiologists interact with, there is not a best fit for any solution presented in the literature. No currently implemented system can interact with a radiologist real-time in a desirable format. We propose a novel solution, developing a conversational agent (CA) capable of engaging clinicians with CDSS as an assistant using existing instant messaging (IM) systems supporting hospital communications.We develop a sample intervention using IM for CDSS. The User Acceptance of Information Technology: Toward a Unified View (UTAUT) framework was utilized to test radiologist acceptance of this intervention.H1: Radiologists business intent to use (BI) an IM based conversational agent, and is moderated by expected performance (PE), expected effort (EOU), anxiety (ANX), age, experience with general consumer/domain specific tools, attitude towards the system.H2: Radiologists attitude toward (AF) the IM based conversational agent is positive, and is moderated by factors in H1.*Methods and Materials Electronic survey of 98 radiologists at large academic health center. Partial Least Squares Structured Equation Modeling was utilized to investigate the relationship between constructs.*Results Within our sample group, we found that radiologists' have a BI and a positive AF towards this intervention. We found deviations from the standard UTAUT model, suggesting that clinical professional's acceptance of software tools differs from the standard user.*Conclusions The largest moderating factor for BI is PE. Development efforts for this intervention should focus on speed, reducing clinical stopping, and providing simple interventions. The second largest moderator is AF, which is strongly influenced by PE. EE is a weak moderating factor.*Clinical Relevance/Application Prior efforts argue that radiologist CDSS must be embedded in dictation software. We present an alternative to embedded CDSS in dictation. We have measured a high intent to use an IM based CDSS while still meeting expected capability requirements. The findings surrounding expected EOU and AF are novel. PE significantly outweighs other factors, and we anticipate that this is due to the clinical nature of radiologist's work. This suggests that burdens surrounding EOU and AF are less important to radiologists than clinical outcomes.

RESULTS

Within our sample group, we found that radiologists' have a BI and a positive AF towards this intervention. We found deviations from the standard UTAUT model, suggesting that clinical professional's acceptance of software tools differs from the standard user.

CLINICAL RELEVANCE/APPLICATION

Prior efforts argue that radiologist CDSS must be embedded in dictation software. We present an alternative to embedded CDSS in dictation. We have measured a high intent to use an IM based CDSS while still meeting expected capability requirements. The findings surrounding expected EOU and AF are novel. PE significantly outweighs other factors, and we anticipate that this is due to the clinical nature of radiologist's work. This suggests that burdens surrounding EOU and AF are less important to radiologists than clinical outcomes.

MK04-C1   **Magnetic Resonance Imaging Evaluation Of Osteochondral Allografts In The Knee Using The OCAMRISS Score**

Participants
Benjamin Tintaya, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To correlate Osteochondral Allograft MRI Scoring System (OCAMRISS) in patients undergoing Osteochondral Allograft (OCA) transplantation in the knee with clinical outcomes.*Methods and Materials A retrospective observational study was performed in our center of a cohort of 37 patients that underwent OCA transplantation in the knee from August 2017 to November 2019 and received a postoperative MRI nine months after. Clinical outcomes were evaluated. Correlation between the OCAMRISS and clinical outcomes was calculated using Spearman's correlation coefficients.*Results International Knee Documentation Committee (IKDC) total score was correlated with OCAMRISS cartilage score (? = 0.396, P = 0,015) and total score (? = 0.476, P = 0,003).Kujala score was correlated with OCAMRISS cartilage score (? = 0.339, P = 0,04) and total score (? = 0.467, P = 0,004).Western Ontario Meniscal Evaluation (WOMET) score was correlated with OCAMRISS ancillary score (? = 0.403, P = 0,013).No correlation was observed with Western Ontario Meniscal Evaluation (WOMET) score and OCAMRISS total score.No correlation was observed with Tegner activity score and OCAMRISS total score.*Conclusions The MRI scoring system (OCAMRISS) is a useful, objective, reproducible, and non-invasive monitoring tool for postoperative assessment after osteochondral allograft transplantation surgery.*Clinical Relevance/Application Osteochondral allograft transplantation is indicated for selected cases of cartilage injuries, especially in young patients with lesions that involve subchondral bone, resulting from a variety of pathologies including osteochondritis, traumatic articular fractures with substance loss, avascular necrosis, and focal cystic osteoarthritis. Therefore, is an increasingly available option for treating symptomatic osteochondral lesions.MRI is a non-invasive, objective, and reproducible monitoring tool for postoperative assessment after cartilage repair procedures. It can assess cartilage repair morphology, cartilage volume, peripheral integration, and subchondral bone changes. The present study showed that the OCAMRISS is a reliable scoring system to evaluate patients after osteochondral allograft transplantation.

RESULTS

International Knee Documentation Committee (IKDC) total score was correlated with OCAMRISS cartilage score (? = 0.396, P = 0,015) and total score (? = 0.476, P = 0,003).Kujala score was correlated with OCAMRISS cartilage score (? = 0.339, P = 0,04) and total score (? = 0.467, P = 0,004).Western Ontario Meniscal Evaluation (WOMET) score was correlated with OCAMRISS ancillary score (? = 0.403, P = 0,013).No correlation was observed with Western Ontario Meniscal Evaluation (WOMET) score and OCAMRISS total score.No correlation was observed with Tegner activity score and OCAMRISS total score.

CLINICAL RELEVANCE/APPLICATION

Osteochondral allograft transplantation is indicated for selected cases of cartilage injuries, especially in young patients with lesions that involve subchondral bone, resulting from a variety of pathologies including osteochondritis, traumatic articular fractures with substance loss, avascular necrosis, and focal cystic osteoarthritis. Therefore, is an increasingly available option for treating symptomatic osteochondral lesions.MRI is a non-invasive, objective, and reproducible monitoring tool for postoperative assessment after cartilage repair procedures. It can assess cartilage repair morphology, cartilage volume, peripheral integration, and subchondral bone changes. The present study showed that the OCAMRISS is a reliable scoring system to evaluate patients after osteochondral allograft transplantation.

MK04-C3   **Sonographic Finding Of Medial Ankle Subcutaneous Edema And Its Association With Posterior Tibial Tenosynovitis**

Participants
Kyle Dammeyer, MD, Detroit, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate if the sonographic finding of medial ankle subcutaneous (subQ) edema is associated with posterior tibial tenosynovitis (PTTS).*Methods and Materials Sonographic images of the medial ankle soft tissues from 40 patients with PTTS and 37 patients with a normal posterior tibial tendon (PTT) were randomized and independently evaluated by 2 musculoskeletal radiologists for the presence or absence of subQ edema. Both were blinded to the images and status of the PTT and the patient's history. The association between the presence or absence of medial ankle subQ edema and the presence or absence of PTTS was evaluated. Demographic comparisons of age and gender, in addition to body mass index and body weight were performed between those with PTTS and those with a normal PTT. Comparisons were done using chi-square tests for categorical data and 2-sided sample t-tests for numerical data. The sensitivity and specificity were calculated. Cohen Kappa statistics were used for inter-observer agreement. This sample size resulted in a statistical power of 99%.*Results A statistically significant association was seen for the presence of medial ankle subQ edema and PTTS among both radiologists' findings. Of the 40 patients with PTTS, 33 (82.5%) were found positive by the first radiologist for medial ankle subQ edema, while no subQ edema was found in 28 of the 37 (75.7%) patients with a normal PTT (P < 0.001). Similarly, the second radiologist found that 33 of the 40 (82.5%) with PTTS were positive for subQ edema, while

no subQ edema was found in 24 of the 37 (64.9%) patients with a normal PTT (P < 0.001). There was also substantial inter-observer agreement between the 2 radiologists (?-value = 0.79; 95% CI: 0.65, 0.93).*Conclusions A statistically significant association was present for the association of the sonographic finding of medial ankle subQ edema and the presence of PTTS. Further studies could evaluate if the sonographic finding of medial ankle subQ edema is an early predictor of PTT dysfunction, which if detected early could allow prompt intervention to prevent further complications and healthcare costs related to the progression of PTT dysfunction.*Clinical Relevance/Application The sonographic finding of medial ankle subcutaneous edema is significantly associated with the presence of posterior tibial tenosynovitis, an early indication of posterior tibial tendon dysfunction.

RESULTS

A statistically significant association was seen for the presence of medial ankle subQ edema and PTTS among both radiologists' findings. Of the 40 patients with PTTS, 33 (82.5%) were found positive by the first radiologist for medial ankle subQ edema, while no subQ edema was found in 28 of the 37 (75.7%) patients with a normal PTT (P < 0.001). Similarly, the second radiologist found that 33 of the 40 (82.5%) with PTTS were positive for subQ edema, while no subQ edema was found in 24 of the 37 (64.9%) patients with a normal PTT (P < 0.001). There was also substantial inter-observer agreement between the 2 radiologists (?-value = 0.79; 95% CI: 0.65, 0.93).

CLINICAL RELEVANCE/APPLICATION

The sonographic finding of medial ankle subcutaneous edema is significantly associated with the presence of posterior tibial tenosynovitis, an early indication of posterior tibial tendon dysfunction.

TEACHING POINTS

Many patients with COVID-19 have experienced musculoskeletal symptoms that can linger for months after the initial respiratory syndrome has resolved. We aim to discuss emerging musculoskeletal manifestations of COVID-19 through diagnostic imaging cases and reviewing the proposed pathogenesis of these conditions. After viewing this exhibit, the learner should be able to: • Describe currently known musculoskeletal conditions associated with COVID-19. • Review the possible mechanisms that can lead to these conditions, which may help identify additional disease targets. • Discuss imaging findings that have been seen with these conditions. • Evaluate the future role of imaging in characterizing COVID-19 involvement in the musculoskeletal system.

TABLE OF CONTENTS/OUTLINE

I. Introduction- Impact of COVID-19 on the Musculoskeletal System II. Currently described musculoskeletal conditions associated with COVID-19, with emphasis on reported imaging findings III. Review of the general biochemical pathways present in COVID-19 patients that may result in multisystem involvement IV. Discussion of musculoskeletal conditions associated with COVID-19, including assessment of proposed pathogenesis and imaging examples: A. Peripheral neuropathies B. Myopathies C. Post-COVID reactive synovitis/arthritis D. Hypercoagulability and osteonecrosis E. Heterotopic ossification V. Potential future role of diagnostic imaging in detecting and characterizing sites of disease VI. Summary

RI02-B1   Fetal Weight Percentile Curves Are Significantly Skewed

Participants
Garvit Khatri, MBBS, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

Background: The fetal percentile is based on three parameters: estimated fetal weight, gestational age and ethnic growth charts. All the three parameters are prone to errors, and can overdiagnose growth retardation (IUGR) and macrosomia. However, weight percentiles are generally reported without any error. The calculation of error in fetal weight percentiles has never been assessed. In an attempt to do so, we reviewed the weight percentile distribution of all second and third trimester fetal US exams to determine what the error in weight percentile would be.Aims: Demonstrate that there is significant skew in the assessment of fetal weight percentiles towards the high and low ends of the distribution. This is a cause of false positive diagnoses of IUGR and macrosomia.*Methods and Materials After IRB approval the radiology information system data base was searched for all obstetrical US reports obtained during the late second and third trimesters from 7/1/2014 until 7/1/2020. Demographic information as well as fetal weight and weight percentile information were obtained from these reports and graphed. The resulting data was then integrated by the method of rectangles to determine the number and percent of fetuses 1 and 2 standard deviations from the mean. A graph showing the results if the expected weight percentile distributions were truly Gaussian versus what we actually observed were constructed. This process was repeated by dividing the data by gestational age at the time of the exam, and by ethnicity.*Results Demographic data:- Total:6259, White:3434, Black:403, Asian:91, Native American:499,Hispanics:29, Not available:1803. Mean age : 31.68 years. Distribution of fetal weight were skewed significantly at the tail ends. The graphs of observed to expected weight percentiles for all the data, and by gestational age and ethnicity also add the error.*Conclusions Fetal weight percentiles are significantly skewed at the tails and they should also be reported in a range, and the error should be documented so as to improve screening of such fetus. Mid third trimester ultrasound exams are the best time to evaluated fetal weight and weight percentile and perhaps these should not be reported earlier in gestation.*Clinical Relevance/Application The recognition of the large error associated with the assignment of weight percentile is very important in those clinical situations where the absolute weight and Dopplers suggest a healthy baby but an erroneous weight percentile suggest IUGR or macrosomia.Knowledge of which can potentially save them from overutilization of resources, interventions and reduce maternal stress.

RESULTS

Demographic data:- Total:6259, White:3434, Black:403, Asian:91, Native American:499,Hispanics:29, Not available:1803. Mean age : 31.68 years. Distribution of fetal weight were skewed significantly at the tail ends. The graphs of observed to expected weight percentiles for all the data, and by gestational age and ethnicity also add the error.

CLINICAL RELEVANCE/APPLICATION

The recognition of the large error associated with the assignment of weight percentile is very important in those clinical situations where the absolute weight and Dopplers suggest a healthy baby but an erroneous weight percentile suggest IUGR or macrosomia.Knowledge of which can potentially save them from overutilization of resources, interventions and reduce maternal stress.

RI02-B2   Radiomic Features Of Peritoneal Carcinomatosis On CECT Predict Overall Survival In Recurrent High Grade Serous Ovarian Cancer: Preliminary Findings

Participants
Sepideh Azarianpour Esfahani, Cleveland, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

High-grade serous carcinoma (HGSC) is the most common type of ovarian cancer. It presents in an advanced stage with peritoneal carcinomatosis and portends a poor prognosis despite surgical and medical therapeutic intervention. On CT scans, HGSC has a heterogeneous phenotype with no reliable imaging-based biomarkers to assess tumor aggression, biological behavior, predict disease recurrence, or predict survival following definitive therapy. We investigated texture-based radiomic features of bulky peritoneal lesions on contrast-enhanced CT (CECT) to help stratify patients with low and high-risk of survival.*Methods and Materials This was a single-institution retrospective review of CECT scans, histology data, and overall survival (OS) of HGSC patients from TCIA database, who were treated with cytoreductive surgery and/or platinum-based chemotherapy, but recurred with bulky peritoneal disease. Three separate 1cm regions of interest (ROI) from solid peritoneal deposits on CT scans of 18 patients were obtained and analyzed in consensus with a board-certified abdominal radiologist. Total 181 intratumoral radiomic textural features (raw (1), Gray (20), Haralick (65), Gabor (35), Laws (34), and CoLlAGe (26) features) were extracted from these ROIs. Four statistics (median, variance, kurtosis, and skewness) were applied on 181 pixel-wise radiomic features to construct 724 ROI-based features and the model is trained based on the LASSO Cox regression model.*Results The five most prognostic radiomic features were included in the Cox regression model and resulted in a radiomic risk score (RRS) representing textural heterogeneity inside the ROI, including one Gray feature, two Haralick, and two Gabor features. A threshold was obtained based on the RRS which successfully separated high

and low-risk patients in a cross-validation fashion validation set (p=0.0007, hazard ratio=3.80, 95% confidence interval= [1.76-8.23]).*Conclusions Radiomic features on CT scans of HGSC patients with recurrent peritoneal disease correlated with a low or high risk of survival. Validating these findings on an independent, multi-site test set is warranted. Further, a combination of radiomic features and histology-driven signatures can be a robust surrogate biomarker tool and may predict response to therapy.*Clinical Relevance/Application Radiomic features of peritoneal deposits on CECT scans of recurrent HGSC ovarian cancer patients could predict survival.

RESULTS

The five most prognostic radiomic features were included in the Cox regression model and resulted in a radiomic risk score (RRS) representing textural heterogeneity inside the ROI, including one Gray feature, two Haralick, and two Gabor features. A threshold was obtained based on the RRS which successfully separated high and low-risk patients in a cross-validation fashion validation set (p=0.0007, hazard ratio=3.80, 95% confidence interval= [1.76-8.23]).

CLINICAL RELEVANCE/APPLICATION

Radiomic features of peritoneal deposits on CECT scans of recurrent HGSC ovarian cancer patients could predict survival.

IN03-D1   Hip Knee Ankle Angle Prediction On Postoperative Radiographs By Using A Deep Learning Method

Participants
Shi Yan, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To predict Hip Knee Ankle Angle (HKAA) on post-operative full-limb radiographs of patients who underwent total knee arthroplasty (TKA) by using deep learning techniques.*Methods and Materials We retrieved postoperative full-limb radiographs of 1899 patients who underwent primary TKA at a single academic institution from January 2000 to August 2017. First, we annotated all full-limb radiographs and applied YOLOv3 to detect hip, knee and ankle areas. Second, we annotated the center of hip, knee and ankle and extracted the detected area from step one. Third, we resized the Region of Interest (RoI) with resolution of 512 x 512, and generated heatmaps from annotated coordinates by using Gaussian function. Fourth, we leveraged fine-tuned U-Net model to predict the heatmaps and then transformed the predicted heatmaps back to coordinates. Last, we calculated the HKAA and compared our prediction with annotation.*Results In the stage of U-Net prediction, full-limb radiographs were split into train, validation and test with 562, 187 and 188 images, respectively. We calculated the difference of the predicted HKAA and annotated HKAA and calculated the mean and standard deviation of the differences. Mean (standard deviation) of the difference between human-level and machine-level measurements was 0.645° (0.820). In 95% of the cases, the difference was smaller than 1.5°.*Conclusions We applied YOLOv3 model to detect hip, knee and ankle joints and fine-tuned U-Net model for HKAA prediction on full-limb radiographs. Our model could accurately and precisely predict center of hip, knee, and ankle joints and measure HKAA.*Clinical Relevance/Application This automated tool holds promise as a clinical application if integrated with radiology software.

RESULTS

In the stage of U-Net prediction, full-limb radiographs were split into train, validation and test with 562, 187 and 188 images, respectively. We calculated the difference of the predicted HKAA and annotated HKAA and calculated the mean and standard deviation of the differences. Mean (standard deviation) of the difference between human-level and machine-level measurements was 0.645° (0.820). In 95% of the cases, the difference was smaller than 1.5°.

CLINICAL RELEVANCE/APPLICATION

This automated tool holds promise as a clinical application if integrated with radiology software.

IN03-D2   Impact Of Image Processing On The Efficacy Of Deep Convolutional Neural Networks.

Participants
Paras Lakhani, MD, Media, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Assess the impact of different image processing methods on the accuracy of an artificial intelligence algorithm for pneumothorax assessment.*Methods and Materials A previously validated and published AI algorithm for pneumothorax detection on chest radiographs was used for this study. The algorithm had a specificity of 98.9% and sensitivity of 100.0% on a hold-out test set of 949 consecutive portable chest radiographs at an academic medical center. The algorithm was then assessed on 311 chest radiographs (161 pneumothorax, 150 normal) from another institution in a different country. The DICOM images from the external institution were preprocessed in four different ways, including two different types of contrast limited adaptive histogram equalization (CLAHE1, CLAHE2), and 8-bit PNGs and JPEGs without histogram equalization. The algorithm accuracy was then assessed on all four preprocessing methods.*Results The areas under the curve (AUCs) were 0.90, 0.92, 0.93, and 0.93 for CLAHE1, CLAHE2, PNG and JPEG respectively. The AUCs for the PNG and JPEG images were statistically significantly greater compared to CLAHE1 (P<0.008). No other significant differences were found for all other comparisons. In 38/311 cases (12.2%), there were discordant results among the different preprocessed images. Of the pneumothorax cases, there were 32/161 (19.9%) discordant results.*Conclusions The accuracy of the model was affected by the image processing method in some cases. There were discordant results in up to 20% of pneumothorax cases among the different processing methods.*Clinical Relevance/Application It is important to evaluate performance of a model using many different types of preprocessing techniques prior to clinical deployment.

RESULTS

The areas under the curve (AUCs) were 0.90, 0.92, 0.93, and 0.93 for CLAHE1, CLAHE2, PNG and JPEG respectively. The AUCs for the PNG and JPEG images were statistically significantly greater compared to CLAHE1 (P<0.008). No other significant differences were found for all other comparisons. In 38/311 cases (12.2%), there were discordant results among the different preprocessed images. Of the pneumothorax cases, there were 32/161 (19.9%) discordant results.

BR04-C1   Classification Of Axillary Lymph Nodes For Metastasis On Ultrasound Using Artificial Intelligence

Participants
Aylin Tahmasebi, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate an artificial intelligence (AI) system for the classification of metastatic disease within axillary lymph nodes on ultrasound.*Methods and Materials In this IRB approved study, ultrasound images of 317 axillary lymph nodes from patients referred for ultrasound guided fine needle aspiration or core needle biopsy and corresponding pathology findings were collected. Lymph nodes were classified into benign and malignant groups with histopathological results serving as the reference. Google Cloud AutoML Vision (Mountain View, CA) was used for AI image classification. Three experienced radiologists also classified the images and gave a suspicion score (1-5). To test the accuracy of AI, an external testing dataset of 64 images from 64 independent patients was evaluated by 3 AI models and the three readers. The diagnostic performance of AI and the humans were quantified using receiver operating characteristics curves.*Results In the complete set of 317 images, AutoML achieved a sensitivity of 77.1%, positive predictive value (PPV) of 77.1% and an area under the precision and recall curve of 0.78. Within the same dataset, the three radiologists showed a sensitivity of 87.8%±8.5%, specificity of 50.3%±16.4%, PPV of 61.1%±5.4%, negative predictive value (NPV) of 84.1%±6.6% and accuracy of 67.7%±5.7%. In the three external independent test sets, AI and human readers achieved a sensitivity of 74.0%±0.14 vs. 89.9%±0.06 (p=0.25), a specificity of 64.4%±0.11 vs. 50.1±0.20 (p=0.22), PPV of 68.3%±0.04 vs. 65.4±0.07 (p=0.50), NPV of 72.6%±0.11 vs. 82.1%±0.08 (p=0.33), and accuracy of 69.5%±0.06 vs. 70.1%±0.07 (p=0.90), respectively.*Conclusions These preliminary results indicate AI has comparable performance to trained radiologists and could potentially be used to predict the presence of metastasis in ultrasound images of axillary lymph nodes.*Clinical Relevance/Application A model using AutoML that relies solely on B-mode images appears promising for the prediction of benign vs. malignant axillary lymph nodes in patients with established or suspected breast cancer. Overall, the performance of this model was similar to that of experienced radiologists and encourages future AI model building and prospective validation.

RESULTS

In the complete set of 317 images, AutoML achieved a sensitivity of 77.1%, positive predictive value (PPV) of 77.1% and an area under the precision and recall curve of 0.78. Within the same dataset, the three radiologists showed a sensitivity of 87.8%±8.5%, specificity of 50.3%±16.4%, PPV of 61.1%±5.4%, negative predictive value (NPV) of 84.1%±6.6% and accuracy of 67.7%±5.7%. In the three external independent test sets, AI and human readers achieved a sensitivity of 74.0%±0.14 vs. 89.9%±0.06 (p=0.25), a specificity of 64.4%±0.11 vs. 50.1±0.20 (p=0.22), PPV of 68.3%±0.04 vs. 65.4±0.07 (p=0.50), NPV of 72.6%±0.11 vs. 82.1%±0.08 (p=0.33), and accuracy of 69.5%±0.06 vs. 70.1%±0.07 (p=0.90), respectively.

CLINICAL RELEVANCE/APPLICATION

A model using AutoML that relies solely on B-mode images appears promising for the prediction of benign vs. malignant axillary lymph nodes in patients with established or suspected breast cancer. Overall, the performance of this model was similar to that of experienced radiologists and encourages future AI model building and prospective validation.

BR04-C7   Impact Of Previous Exams Comparison In The Final Bi-rads Assessment In Screening Mammography

Participants
Eduardo F. Fleury, PhD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

To determine the impact of previous exams comparison in the final BI-RADS assessment in screening mammography. We compare the incidence of BI-RADS 0, 1 and 2, 3, 4, and 5 before and after comparison to the previous exam, focused in the category 0. We also compared the final assessment of 2 radiologists, one with 20 years of experience and the second with 5-year experience.*Methods and Materials Prospective observational study, from August-2020 to January-2021. 3.896 consecutive mammography was interpreted independently by 2 radiologists. The final BI-RADS assessment was given for mammography blinded to previous exams and after the previous exam comparison. We also compared the radiologist's final classification according to clinical practice experience.*Results A total of 3.656 patients forward to breast mammography were evaluated. 3.532 screening mammograms were included. The final BI-RADS classification for mammograms blinded to previous exams was as follows: 389 (11.02%), 3,017 (85.44%), 35 (0.99%), 87 (2.46%) and 3 (0.08%) for categories 0, 1 and 2, 3, 4 and 5 respectively. After previous exams comparison the results were as follows: 103 (2.92%), 3.311 (93.77%), 39 (1.10%), 75 (2.12%) and 3 (0.08%) for categories 0, 1 and 2, 3, 4 and 5 respectively.When compared the final assessment category of each reader independently, reader 1 classified the mammograms as: 91 (7,10%), 1.181 (92.19%), 2 (0.16%) and 7 (0.55%) for blinded mammograms and 0, 1.261 (98.44%), 6 (0.47%), 14 (1.09%) for mammograms after previous exams comparison for categories 0, 1 and 2, 3 and 4 respectively.Reader 2 classified the mammograms as: 194 (9.27%), 1.181 (87.52%), 27 (1.29%) and 40 (1.91%) for blinded mammograms and 1 (0.05%), 2.044 (97.71%), 26 (1.24%), 21 (1.00%) for mammograms after previous exams comparison for categories 0, 1 and 2, 3 and 4 respectively.*Conclusions Comparison to previous mammograms in patients' participants for breast cancer screening programs may reduce the number of BI-RADS category 0 final classification by 75%, and may reduce the number

of positive findings final classification, especially for the less experienced reader.*Clinical Relevance/Application The comparison to previous exams directly impacts the screening mammogram final classification, reduces complementary studies and costs, and improves the screening results.

RESULTS

A total of 3.656 patients forward to breast mammography were evaluated. 3.532 screening mammograms were included. The final BI-RADS classification for mammograms blinded to previous exams was as follows: 389 (11.02%), 3,017 (85.44%), 35 (0.99%), 87 (2.46%) and 3 (0.08%) for categories 0, 1 and 2, 3, 4 and 5 respectively. After previous exams comparison the results were as follows: 103 (2.92%), 3.311 (93.77%), 39 (1.10%), 75 (2.12%) and 3 (0.08%) for categories 0, 1 and 2, 3, 4 and 5 respectively.When compared the final assessment category of each reader independently, reader 1 classified the mammograms as: 91 (7,10%), 1.181 (92.19%), 2 (0.16%) and 7 (0.55%) for blinded mammograms and 0, 1.261 (98.44%), 6 (0.47%), 14 (1.09%) for mammograms after previous exams comparison for categories 0, 1 and 2, 3 and 4 respectively.Reader 2 classified the mammograms as: 194 (9.27%), 1.181 (87.52%), 27 (1.29%) and 40 (1.91%) for blinded mammograms and 1 (0.05%), 2.044 (97.71%), 26 (1.24%), 21 (1.00%) for mammograms after previous exams comparison for categories 0, 1 and 2, 3 and 4 respectively.

CLINICAL RELEVANCE/APPLICATION

The comparison to previous exams directly impacts the screening mammogram final classification, reduces complementary studies and costs, and improves the screening results.

BR04-C8 Breast Density Associations With Tumour Characteristics Among Screen-detected And Interval Breast Cancers Diagnosed In A US Screening Setting

Participants
Stamatia Destounis, MD, Rochester, New York (*Presenter*) Medical Advisory Committee, Hologic, Inc;Medical Advisory Board, iCAD, Inc

PURPOSE

Few studies have looked at associations of automated mammographic density (MD) measures and breast tumour characteristics (TCs), in a US screening population. We investigated the associations between several risk factors, including MD and TCs, stratified by mode of detection (screen-detected cancers (SDs) vs interval cancers (ICs)).*Methods and Materials BC cases (n=2,484) that were diagnosed at our breast imaging clinic between 2009-2012, were identified. After exclusions (women missing raw images acquired in the prior screening interval (13 months), prior biopsy/surgery/breast cancer, implants, bilateral cases, women <40 y), the final dataset comprised of 318 SDs and 100 ICs. TCs and risk factor information were extracted from clinical records. Automated MD measures included quartiles (Q1-4) of volumetric breast density (VBD)/dense volume (DV)/breast volume (BV)/fat volumes (FV), and Volpara Density Grades (VDG), as well as visual BI-RADS. Non-parametric statistical analyses were used to compare associations between risk factors, stratified by SD/IC status and MD.*Results Overall VDG was found to have stronger associations with TCs compared with BI-RADS. For all cancers VDG was associated with HER2 status and tumour size >= 2 cm. After splitting the data by mode of detection, BI-RADS showed an association with tumour size for SDs only. DV was associated with T stage, size >=2 cm and grade 3 cancers. Larger breasts and higher FVs were associated with higher grade and ER negative cancers (p<0.5). Comparing BV Q3+4 vs BV Q1+2, there were 60% vs 40% high-grade cancers, respectively, and 53% vs 47% of ER negative cancers, respectively. For ICs, only FV was associated with prognostic features, where the proportion of women in FV Q1 was 12% and 27% for tumour sizes <2 cm and =2 cm, respectively (p<0.05).*Conclusions Compared to density categories (VDG and BI-RADS), volumetric measures of MD showed stronger associations with TCs associated with poor outcomes. When comparing SDs and ICs, this association was seen more so for SDs. Utilizing volumetric MD measures can aid in offering supplemental screening for women with dense breasts which can help reduce the impact of MD on TCs associated with poorer outcomes.*Clinical Relevance/Application Volumetric breast composition metrics are associated with poor prognostic features for both SD and ICs.

RESULTS

Overall VDG was found to have stronger associations with TCs compared with BI-RADS. For all cancers VDG was associated with HER2 status and tumour size >= 2 cm. After splitting the data by mode of detection, BI-RADS showed an association with tumour size for SDs only. DV was associated with T stage, size >=2 cm and grade 3 cancers. Larger breasts and higher FVs were associated with higher grade and ER negative cancers (p<0.5). Comparing BV Q3+4 vs BV Q1+2, there were 60% vs 40% high-grade cancers, respectively, and 53% vs 47% of ER negative cancers, respectively. For ICs, only FV was associated with prognostic features, where the proportion of women in FV Q1 was 12% and 27% for tumour sizes <2 cm and =2 cm, respectively (p<0.05).

CLINICAL RELEVANCE/APPLICATION

Volumetric breast composition metrics are associated with poor prognostic features for both SD and ICs.

BR04-C9 Potential Utility Of SPRMs As A Novel Approach For Contraception And Breast Cancer Risk Reduction; A Randomized Control Trial

Participants
Richard S. Ha, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Ulipristal acetate (UPA), is a selective progesterone receptor modulator (SPRM) currently being evaluated for daily contraception. Changes in MRI background parenchymal enhancement (BPE) with the menstrual cycle correlate with breast cell proliferation based on previous studies with Ki-67 analysis. The purpose of this study is to evaluate the effect of UPA on breast tissue proliferation measured by MRI-BPE to determine potential utility of SPRMs as a novel approach for contraception and breast cancer risk reduction.*Methods and Materials This IRB approved randomized control trial took place from 2016- 2020. We recruited volunteer women aged 18-39 with a BMI <35 kg/m2, and regular menstrual cycles. We defined ovulation as at least one progesterone of >3 ng/mL. Participants, who ovulated during the baseline cycle, underwent a baseline MRI about 8-12 days following the estimated ovulation date. At about day 76 after initiating treatment, participants returned for a second MRI and a progesterone level to evaluate ovulation during the last cycle. Breast MRI scans were performed with gadolinium contrast injection using a dedicated breast coil and 1.5 T magnet. Pre-contrast T1 and three post-contrast dynamic T1 fat-suppressed sagittal images were performed. The order and treatment assignment of the images were masked before analysis. RH analyzed the pairs of anonymized images for the degree of BPE using standard BI-RADS criteria. In addition, quantitative analysis was performed using our previously developed computer generated algorithm. All statistical significance levels quoted are 2-sided.*Results Forty-nine women signed consent and

26 women completed the study undergoing both the initial and post treatment MRI. In the UPA group, the median BPE declined statistically significantly from 2.5 to 1.0 (signed-rank test, p=0.005). In the COC group, the median BPE increased from 2.5 to 3.0, but this was not statistically significant (signed-rank test, p=0.093). The comparison of UPA versus COC results for on-treatment BPE stratified on baseline BPE showed a highly statistically significant greater decline in the UPA group compared to the COC group (ranksum test, p=0.001). Spearman correlation between BPE qualitative values and BPE quantitative values were significantly correlated both at pre-treatment (Rho = 0.66, P<0.001) and at post treatment (Rho = 0.75, P<0.001).*Conclusions The effect of daily 10 mg dose of UPA on breast tissue showed a significant decrease in breast cell proliferation measured by MRI-BPE in comparison to baseline, and to the effect of a commonly prescribed COC.*Clinical Relevance/Application A SPRM agent may lead to a novel approach for contraception and breast cancer risk reduction.

RESULTS

Forty-nine women signed consent and 26 women completed the study undergoing both the initial and post treatment MRI. In the UPA group, the median BPE declined statistically significantly from 2.5 to 1.0 (signed-rank test, p=0.005). In the COC group, the median BPE increased from 2.5 to 3.0, but this was not statistically significant (signed-rank test, p=0.093). The comparison of UPA versus COC results for on-treatment BPE stratified on baseline BPE showed a highly statistically significant greater decline in the UPA group compared to the COC group (ranksum test, p=0.001). Spearman correlation between BPE qualitative values and BPE quantitative values were significantly correlated both at pre-treatment (Rho = 0.66, P<0.001) and at post treatment (Rho = 0.75, P<0.001).

CLINICAL RELEVANCE/APPLICATION

A SPRM agent may lead to a novel approach for contraception and breast cancer risk reduction.

VA03-A1   **4D Flow MR Imaging For Characterization Of Abdominopelvic Venous Flow In Pelvic Venous Disease**

Participants
Christine Boone, MD, PhD, San Diego, California (*Presenter*) Nothing to Disclose

PURPOSE

Pelvic venous disease can arise from multiple etiologies. Diagnosis by conventional CT, MRI, and ultrasound imaging can be challenging. 4D Flow MRI techniques provide flow and velocity data as well as anatomy, which could facilitate differentiation of pelvic venous disease etiologies and detection and localization of venous collaterals or reflux.*Methods and Materials With IRB approval and waiver of informed consent, we retrospectively reviewed clinically indicated abdominopelvic MRI/MRA 3T 750 MRI (GE Healthcare) in 39 patients. Patients were grouped according to clinical indications and/or imaging findings: no vascular abnormalities, left common iliac vein (LCIV) compression, gonadal reflux, left renal vein compression, and venous collaterals/reflux. 4D Flow analysis software (Arterys, San Francisco, CA) was used to measure blood flow and velocity at the right and left central common iliac veins (RCIV, LCIV), LCIV under the common iliac artery crossover (retro CIA LCIV), central inferior vena cava (IVC), and peripheral IVC.*Results Distinct patterns of blood flow were observed among different patient groupings. Notably, patients with LCIV compression had significantly greater mean net flow (mean ± SD, 0.68 ± 0.14) in their RCIV compared to patients lacking venous abnormality (0.44 ± 0.09). Net flow in the upper and lower infrarenal IVC was significantly increased in patients with LCIV compression and gonadal reflux compared to those without venous abnormality. Additionally, among patients with LCIV compression, flow in the retro CIA LCIV was decreased relative to the peripheral LCIV. Further, net flow in the retro CIA L CIV was decreased in patients with LCIV compression with imaging evidence of collaterals/reflux, relative to those with LCIV compression without collaterals/reflux.*Conclusions Abdominopelvic venous 4D Flow revealed hemodynamic significance of venous compression, which can manifest as flow diversion away from the area of stenosis. Increases in net flow along the IVC and decreased blood flow at the site of LCIV compression may be due to diversion by venous collaterals/reflux. Future aims include determination of the severity of flow diversion requiring intervention.*Clinical Relevance/Application Abdominopelvic venous 4D flow may facilitate differentiation of pelvic venous disease etiologies and identification of venous collaterals, which could help guide clinical decisions and interventions.

RESULTS

Distinct patterns of blood flow were observed among different patient groupings. Notably, patients with LCIV compression had significantly greater mean net flow (mean ± SD, 0.68 ± 0.14) in their RCIV compared to patients lacking venous abnormality (0.44 ± 0.09). Net flow in the upper and lower infrarenal IVC was significantly increased in patients with LCIV compression and gonadal reflux compared to those without venous abnormality. Additionally, among patients with LCIV compression, flow in the retro CIA LCIV was decreased relative to the peripheral LCIV. Further, net flow in the retro CIA L CIV was decreased in patients with LCIV compression with imaging evidence of collaterals/reflux, relative to those with LCIV compression without collaterals/reflux.

CLINICAL RELEVANCE/APPLICATION

Abdominopelvic venous 4D flow may facilitate differentiation of pelvic venous disease etiologies and identification of venous collaterals, which could help guide clinical decisions and interventions.

IR03-B1   Comparison Of Intrahepatic Progression Patterns Of Hepatocellular Carcinoma And Colorectal Liver Metastases Following CT-guided High Dose-rate Brachytherapy

Participants
Robin Schmidt, Berlin, Germany (*Presenter*) Travel support, Berliner Krebsgesellschaft e.V.;Traval Grant, German Roentgen Society;Traval Grant, Rolf W. Günter Foundation for Radiological Sciences

PURPOSE

Given the metachronous and multifocal occurrence of hepatocellular carcinoma (HCC) and colorectal cancer metastases in the liver (CRLM), this study aimed to compare intrahepatic progression patterns after CT-guided high dose-rate brachytherapy.*Methods and Materials This retrospective analysis included 164 patients (114 HCC, 50 CRLM) treated with brachytherapy between 01/2016 and 01/2018. Patients received multiparametric MRI before and about 8 weeks after brachytherapy, then every 3 months for the first and every 6 months for the following years until progression or death. MRI scans were assessed for local or distant intrahepatic tumor progression according to RECIST 1.1 and electronic medical records were reviewed prior to therapy. The primary endpoint was progression-free survival (PFS). Specifically, local and distant intra-hepatic PFS were assessed to determine differences between the intrahepatic progression patterns of HCC and CRLM. Secondary endpoints included the identification of predictors of PFS, time to progression (TTP), and overall survival (OS). Statistics included Kaplan-Meier analysis and univariate and multivariate Cox regression modeling.*Results PFS was longer in HCC (11.30 (1.33-35.37) months) than in CRLM patients (8.03 (0.73-19.80) months, p=0.048), respectively. Specifically, local recurrence occurred later in HCC (PFS:36.83 (1.33-40.27) months) than CRLM patients (PFS:12.43 (0.73-21.90) months, p=0.001). On the contrary, distant intrahepatic progression occurred earlier in HCC (PFS:13.50 (1.33-27.80) months) than in CRLM patients (PFS:19.80 (1.43-19.80) months, p=0.456) but without statistical significance. Multivariate Cox regression confirmed tumor type and patient age as independent predictors for PFS.*Conclusions Brachytherapy proved to achieve better local tumor control and overall PFS in patients with unresectable HCC than CRLM. However, distant progression preceded local recurrence in HCC.*Clinical Relevance/Application These findings may help design disease-specific surveillance strategies and personalized treatment planning that highlight the strengths of brachytherapy and elucidate the potential benefits of combinations with other loco-regional or systemic therapies.

RESULTS

PFS was longer in HCC (11.30 (1.33-35.37) months) than in CRLM patients (8.03 (0.73-19.80) months, p=0.048), respectively. Specifically, local recurrence occurred later in HCC (PFS:36.83 (1.33-40.27) months) than CRLM patients (PFS:12.43 (0.73-21.90) months, p=0.001). On the contrary, distant intrahepatic progression occurred earlier in HCC (PFS:13.50 (1.33-27.80) months) than in CRLM patients (PFS:19.80 (1.43-19.80) months, p=0.456) but without statistical significance. Multivariate Cox regression confirmed tumor type and patient age as independent predictors for PFS.

CLINICAL RELEVANCE/APPLICATION

These findings may help design disease-specific surveillance strategies and personalized treatment planning that highlight the strengths of brachytherapy and elucidate the potential benefits of combinations with other loco-regional or systemic therapies.

IR03-B3   The Role Of Blood Pressure In Risk Of Hematoma Following Renal Biopsy: A Retrospective Study

Participants
Jesse Schwalb, Bronx, New York (*Presenter*) Nothing to Disclose

PURPOSE

Post-procedure hematoma is a common complication after percutaneous renal biopsy. Various risk factors exist for this complication. The goal of this paper is to evaluate the role of pre-procedure blood pressure (BP) as it relates to increased risk of bleeding following percutaneous renal biopsy.*Methods and Materials We performed a retrospective review of 473 patients who underwent renal biopsy procedures over a ten-year period between May 2008 and May 2018. The patients were classified based on the presence or absence of a hematoma as noted by post procedure imaging. Patients with hematomas were additionally subdivided into small, medium or large hematomas, per chart review. Student's t-tests were performed to determine if there was a significant difference in pre-procedure mean arterial pressure (MAP), systolic blood pressure (SBP), diastolic blood pressure (DBP), or hematocrit between hematoma and non-hematoma patients. Tests were also performed to determine significant differences between groups of patients with medium/large hematoma from small/no hematoma.*Results 473 patients were included in this study. 136 (28.8%) had a post-procedure hematoma based on physician notes. 51 (10.8%) patients had a medium or large hematoma. The presence of a hematoma was further substantiated by determining the average reduction in hematocrit between the two groups. Hematoma patients had an average post-procedure reduction in hematocrit of -3.02%±3.33 while non-hematoma patients had an average reduction of -1.89%±2.34, with a p-value of 0.03. In the comparison of hematoma versus non-hematoma patients, our analysis found statistically significant differences in pre-procedure MAP [101.2±13.7 mmHg vs 98.2±14.4, p=0.0368] and DBP [81.9±14.0 mmHg vs 78.0±14.4, p = 0.0072]. MAP was also found to be significantly different between small/no hematoma patients and medium/large hematoma patients [103.15±14.6 mmHg vs 98.5±14.1, p = 0.0379].*Conclusions Elevated MAP and DBP is associated with an increased risk of post-procedure hematoma following renal biopsy. Our results suggest that management of

blood pressure pre-procedure and intra-procedure may reduce risk of hematoma post-procedure. Future clinical studies are necessary to evaluate the proper approach for these high-risk patients, including pre-operative artificial lowering of BP when necessary.*Clinical Relevance/Application Post-operative hematoma is a common complication of renal biopsy procedures. However, there exists little data on risk factors for this complication. Our results suggest that management of blood pressure pre-procedure and intra-procedure may reduce risk of hematoma post-procedure.

RESULTS

473 patients were included in this study. 136 (28.8%) had a post-procedure hematoma based on physician notes. 51 (10.8%) patients had a medium or large hematoma. The presence of a hematoma was further substantiated by determining the average reduction in hematocrit between the two groups. Hematoma patients had an average post-procedure reduction in hematocrit of -3.02%±3.33 while non-hematoma patients had an average reduction of -1.89%±2.34, with a p-value of 0.03. In the comparison of hematoma versus non-hematoma patients, our analysis found statistically significant differences in pre-procedure MAP [101.2±13.7 mmHg vs 98.2±14.4, p=0.0368] and DBP [81.9±14.0 mmHg vs 78.0±14.4, p = 0.0072]. MAP was also found to be significantly different between small/no hematoma patients and medium/large hematoma patients [103.15±14.6 mmHg vs 98.5±14.1, p = 0.0379].

CLINICAL RELEVANCE/APPLICATION

Post-operative hematoma is a common complication of renal biopsy procedures. However, there exists little data on risk factors for this complication. Our results suggest that management of blood pressure pre-procedure and intra-procedure may reduce risk of hematoma post-procedure.

IR03-B4   Facet Joint US Guided Radiofrequency Ablation A Feasibility Study

Participants
Stefano Marcia, MD, Cagliari, Italy (*Presenter*) Consultant, Techlamed Srl;Consultant, Spineart;Consultant, Stryker Corporation;

PURPOSE

Imaging guided radiofrequency ablation (RFA) of medial branches is generally followed by a long lasting therapeutic efficacy in patient with lumbar facet joints syndrome (LFJ). CT or fluoroscopic guidance are commonly used for RFA. The aim of the present study was to evaluate the feasibility of RFA under ultrasonography (US) guidance and the clinical outcome.*Methods and Materials 28 patients (7 male, 21 female, age range 32-78) with double positive block test and medical or physical therapy failure were enrolled in the present study; exclusion criteria were in patients responsive to medical and physical therapy over a period <6 months. A written informed consent was obtained from all the patients. The ablation was performed for 3 minutes at 90° Celsius with an average time of 20 minutes in-room time. Visual analog scale (VAS) score and clinical evaluation has been performed before, 1 and 3 months after procedure. Technical success was define as correct placement of RFA needle at the level of the selected zygapophyseal joint joint evaluated with US and optimal response to sensory/motor stimulation.*Results The technical success was reached in all patients. No major or minor complications related to procedure were registered; all patents were discharged after a mean time of 3 hours. In 12 patients the RFA was performed at both sides and in 3 levels in the same session. All patients showed relevant improvement in symptoms with preoperatively mean VAS score of (8) dropped to (5) after 1 month and to (2) within 3 months*Conclusions RFA under US guidance can be effective and safe in patients with LFJ syndrome with positive block test without radiation exposure.*Clinical Relevance/Application The US guided RFA of medial brach has been demonstrated to be feasible Further studies on same topic would be highly desirable to investigate the possible role of US guidance in RFA in comparison with CT or fluoroscopic guidance.A cost analysis could be highly desirable to evaluate the economic impact of this procedure

RESULTS

The technical success was reached in all patients. No major or minor complications related to procedure were registered; all patents were discharged after a mean time of 3 hours. In 12 patients the RFA was performed at both sides and in 3 levels in the same session. All patients showed relevant improvement in symptoms with preoperatively mean VAS score of (8) dropped to (5) after 1 month and to (2) within 3 months

CLINICAL RELEVANCE/APPLICATION

The US guided RFA of medial brach has been demonstrated to be feasible Further studies on same topic would be highly desirable to investigate the possible role of US guidance in RFA in comparison with CT or fluoroscopic guidance.A cost analysis could be highly desirable to evaluate the economic impact of this procedure

IR03-B5   Role Of Embolization In Acquired Uterine Vascular Malformations: A Single Centre Study In India

Participants
Sunanda Nimmalapudi, MBBS, Velangi, India (*Presenter*) Nothing to Disclose

PURPOSE

To determine the efficacy of Uterine Artery Embolization in patients with bleeding acquired uterine arteriovenous malformations (AVMs).*Methods and Materials A prospective review of all patients who underwent Uterine Artery Embolization at our institution between July 2012 and December 2020 was performed. 225 patients were diagnosed with a uterine vascular malformation on doppler and corresponding MRI imaging. Serial ß-human chorionic gonadotropin levels were measured to exclude gestational trophoblastic neoplasia. All patients underwent transcatheter embolization of the uterine arteries. Embolizations were performed with use of standard 5 F Robert's Uterine catheter and 2.7 F Progret microcatheter when necessary. Embolic agents in the 375 procedures included glue only (n = 326), polyvinyl alcohol (PVA) particles and glue (n = 29), PVA particles (n = 5), Gelfoam (n = 5), coils (n = 4), PVA particles and coils (n = 3), glue and Gelfoam (n = 2), and glue and coils (n = 1). Outcomes assessed were cessation of bleeding, persistence or resolution of the AVM, complications and pregnancy after embolization. These were assessed by chart, laboratory and imaging reviews.*Results A total of 375 embolization procedures were performed in 225 patients. 90 patients required repeat embolization (14 patient underwent embolization on six occasions; 76 patients had two embolization procedures each) for recurrence of bleeding. 240 procedures were performed on an elective basis and 35 were performed on an emergent basis. The technical success rate of embolization was 100%. The clinical success rate was 92%: bleeding was controlled in 222 of 225 patients and three patients underwent a hysterectomy. 60 of the 225 patients had uneventful intrauterine pregnancies carried to term. The 210 patients who underwent successful embolization had no recurrence of bleeding at a median follow-up of 53 months (range, 5-122 months) after treatment. 15 patients were eventually lost to follow-up. One minor complication (0.4%) of non-flow-limiting dissection of the internal iliac artery occurred.*Conclusions Uterine Artery Embolization is a

safe and effective treatment for acquired AVMs. This procedure allows for preservation of uterine function with the possibility of future pregnancy and should be considered as a primary treatment option.*Clinical Relevance/Application Uterine Artery Embolization is a safe, effective, and minimally invasive method to treat uterine AVMs with long-term efficacy, which can provide the preservation of fertility.

RESULTS

A total of 375 embolization procedures were performed in 225 patients. 90 patients required repeat embolization (14 patient underwent embolization on six occasions; 76 patients had two embolization procedures each) for recurrence of bleeding. 240 procedures were performed on an elective basis and 35 were performed on an emergent basis. The technical success rate of embolization was 100%. The clinical success rate was 92%: bleeding was controlled in 222 of 225 patients and three patients underwent a hysterectomy. 60 of the 225 patients had uneventful intrauterine pregnancies carried to term. The 210 patients who underwent successful embolization had no recurrence of bleeding at a median follow-up of 53 months (range, 5-122 months) after treatment. 15 patients were eventually lost to follow-up. One minor complication (0.4%) of non-flow-limiting dissection of the internal iliac artery occurred.

CLINICAL RELEVANCE/APPLICATION

Uterine Artery Embolization is a safe, effective, and minimally invasive method to treat uterine AVMs with long-term efficacy, which can provide the preservation of fertility.

IR03-B6 **Intramuscular Imaging-guided Botulinum Toxin Injection Prior To Complex Abdominal Hernia Repair: Technique And Patient Outcomes**

Participants
Albert Jiao, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Large incisional or primary ventral hernias have up to a 24-54% recurrence rate following repair. Recurrences are due to high BMI, tension at first surgery, or mesh complications including surgical site infections. The most common technique to reduce tension of repair involves myofascial release. The injection of botulinum toxin into the musculature of the abdominal wall causes flaccid muscle paralysis and has been shown to reduce muscle tension and intraabdominal pressure facilitating adequate closure of hernia defects. The purpose of this study is to evaluate the safety and efficacy of pre-surgical image-guided botulinum toxin in complex abdominal hernia repair.*Methods and Materials An IRB approved retrospective cohort study was performed on all patients who underwent intramuscular botulinum toxin injection from July 2018-March 2021. Patient demographic data, procedural details, and surgical outcomes were collected and analyzed. For each procedure, diluted Botulinum toxin serotype A was injected under CT-guidance into the abdominal wall musculature. Bilateral injections using a 22G spinal needles were performed at three levels (superior, middle, inferior) along the anterior axillary line between the costal margin and a point anterior to the anterior superior iliac spine. At each site, the external oblique, internal oblique, and transversalis muscles were targeted so each muscular layer received the toxin dose: 8 mL per muscle (2 units/mL 0.9% normal saline), totaling 24mL per site. The full toxin dose is 144 mL (288 units).*Results A total of 32 patients received botulinum toxin injections prior to surgical hernia repair over the study period. The average BMI was 32. Twenty were male and twelve were female. Mean procedure time was 47 minutes, and mean radiation dose was 1019 mGy-cm2. Mean time between toxin administration and surgery was 36 days, and the average abdominal hernia defect size as measured in the long axis was 19 cm. There were no complications during toxin administration, and procedural success for both injections and herniorrhaphy was 100%.*Conclusions Botulinum toxin injection prior to complex abdominal hernia repair facilitates surgical closure. Interventional radiologists can perform this procedure safely and with a high rate of technical success.*Clinical Relevance/Application Imaging-guided botulinum toxin injection by interventional radiologists is a minimally invasive, low risk, and highly successful procedure that facilitates successful surgical repair.

RESULTS

A total of 32 patients received botulinum toxin injections prior to surgical hernia repair over the study period. The average BMI was 32. Twenty were male and twelve were female. Mean procedure time was 47 minutes, and mean radiation dose was 1019 mGy-cm2. Mean time between toxin administration and surgery was 36 days, and the average abdominal hernia defect size as measured in the long axis was 19 cm. There were no complications during toxin administration, and procedural success for both injections and herniorrhaphy was 100%.

CLINICAL RELEVANCE/APPLICATION

Imaging-guided botulinum toxin injection by interventional radiologists is a minimally invasive, low risk, and highly successful procedure that facilitates successful surgical repair.

CH03-A3   Interval Change Detection Of Multiple Abnormalities From Serial Chest Radiographs Using Convolutional Neural Network

Participants
Ju Nam, MD, Seoul, Korea, Republic Of (*Presenter*) Research grant from VUNO.

PURPOSE

To develop and validate a deep learning algorithm detecting interval changes (IC) from serial chest radiographs, focusing on pneumothorax, consolidation, and pleural effusion.*Methods and Materials Deep learning algorithm detecting IC of pneumothorax, consolidation, and pleural effusion (DLAD-IC) was developed using previously reported convolutional neural network developed to detect and localize multiple abnormalities using 224,268 radiographs (DLAD). By combining DLAD and lung segmentation algorithm, DLAD-IC calculates the localized area of each abnormality divided by total lung area. From the values driven from serial radiographs, decision for IC was made. To check feasibility and set thresholds of DLAD-IC, calibration datasets was prepared and labeled (n= 104-177 pairs for three abnormalities). A temporally split validation set was collected separately for pneumothorax (n= 100 pairs), consolidation (n= 114 pairs), and pleural effusion (n= 126 pairs). For clinical validation, two independent datasets were prepared and labeled: paired serial radiographs from 151 consecutive patients showing post-procedural pneumothorax after percutaneous lung biopsy (PCNB dataset; all PA) and those from 73 consecutive patients admitted to manage PCR-confirmed COVID-19 pneumonia (COVID dataset; all AP). The performance in detecting IC for each abnormality of DLAD-IC was evaluated in terms of AUROCs. Sensitivities and specificities of DLAD-IC to detect IC was evaluated for each side (left/right) and compared with those of radiologic formal reports using generalized estimating equations.*Results DLAD-IC showed AUROCs of 0.946 (pneumothorax), 0.898 (consolidation), and 0.804 (pleural effusion) in detecting IC on validation datasets. On PCNB dataset, DLAD-IC showed AUROC of 0.952 in detecting IC of post-procedural pneumothorax, exhibiting significantly higher sensitivity (79.6% [86/108] vs. 59.3% [64/108]; P<.001) and similar specificity (94.3% [183/194] vs. 93.3% [181/194]; P= .82) than radiologic formal reports. On COVID-19 dataset, DLAD-IC showed AUROC of 0.792 in detecting aggravation/improvement of consolidation. It showed substantially higher sensitivity than formal reports (71.4% [35/49] vs. 30.6% [15/49]; P< .001), but demonstrated lower specificity (71.1% [69/97] vs. 92.8% [90/97]; P<.001).*Conclusions DLAD-IC showed high performance in detecting IC of three abnormalities. It showed substantially higher sensitivities than formal radiologic reports in detecting serial change of pneumothorax after PCNB and consolidation of COVID-19 patients.*Clinical Relevance/Application By providing IC information of the abnormalities, DLAD-IC may help provide more accurate and early reporting for clinically urgent radiographs.

RESULTS

DLAD-IC showed AUROCs of 0.946 (pneumothorax), 0.898 (consolidation), and 0.804 (pleural effusion) in detecting IC on validation datasets. On PCNB dataset, DLAD-IC showed AUROC of 0.952 in detecting IC of post-procedural pneumothorax, exhibiting significantly higher sensitivity (79.6% [86/108] vs. 59.3% [64/108]; P<.001) and similar specificity (94.3% [183/194] vs. 93.3% [181/194]; P= .82) than radiologic formal reports. On COVID-19 dataset, DLAD-IC showed AUROC of 0.792 in detecting aggravation/improvement of consolidation. It showed substantially higher sensitivity than formal reports (71.4% [35/49] vs. 30.6% [15/49]; P< .001), but demonstrated lower specificity (71.1% [69/97] vs. 92.8% [90/97]; P<.001).

CLINICAL RELEVANCE/APPLICATION

By providing IC information of the abnormalities, DLAD-IC may help provide more accurate and early reporting for clinically urgent radiographs.

CH03-A4   Developing Robust Chest X-ray Models With Less Data

Participants
Andrew Sellergren, San Francisco, California (*Presenter*) Employee, Alphabet Inc;Stockholder, Alphabet Inc

PURPOSE

Developing deep learning (DL) models for radiology can be limited by the large numbers of images and labels required. Transfer learning is an effective mitigating strategy: a network is pretrained on a large dataset (often non-medical), then finetuned on a smaller, task-specific radiology dataset. In previous work, this finetuning only covered a few conditions while still requiring >100K images and extensive human and compute resources. Here, we investigate reducing these requirements with transfer learning from Supervised Contrastive (SupCon) pretraining, combining contrastive learning with supervised learning using higher-level, easy-to-obtain labels of abnormal vs. normal to improve performance on low-data clinical classification tasks for chest x-rays (CXR).*Methods and Materials We pretrain 2 DL model architectures (EfficientNet-B7 and ResNet-BiT 101x3) on 821,544 CXRs from India and US and abnormal vs. normal labels extracted from radiology reports. We finetune the network on 8 downstream tasks (airspace opacity, pneumothorax, consolidation, pleural effusion, pulmonary edema, fracture, tuberculosis (TB), and COVID-19 outcomes) using 5 datasets comprising 684,955 CXRs from India, US, and Europe, and evaluate using 3 heldout datasets from Zambia and US. As a baseline, we finetune directly from networks pretrained on non-medical datasets (ImageNet and JFT-300M). Finally, we compare retraining the network end-to-end vs. training small linear/nonlinear models (multilayer perceptrons, MLPs) on frozen embeddings. We simulate low-data settings using stratified random samples of labeled datasets.*Results SupCon

consistently improved AUROC (by 0.046—0.090) on downstream tasks across a range of training data amounts (from 64 to 32,768+ images), reducing label requirements by orders of magnitude. At the extreme low-data regime, training small linear models on frozen embeddings using only 64 CXRs yielded an AUROC of 0.82 (non-inferior to radiologist performance) in classifying microbiology-confirmed TB in an external validation set. At a more moderate data regime, SupCon followed by finetuning the network end-to-end using only 490 CXRs at hospital admission yielded an AUROC of 0.80 in predicting ICU admission for COVID-19 inpatients.*Conclusions SupCon enabled performance comparable to state-of-the-art DL models in multiple clinical tasks using as few as 64 images. This is a promising method for predictive modeling using small datasets and for predicting outcomes in shifting patient populations.*Clinical Relevance/Application Training label-efficient models is useful in cases of constrained computational resources, limited data, or distribution shifts, as with COVID-19, where populations and treatments change quickly.

RESULTS

SupCon consistently improved AUROC (by 0.046—0.090) on downstream tasks across a range of training data amounts (from 64 to 32,768+ images), reducing label requirements by orders of magnitude. At the extreme low-data regime, training small linear models on frozen embeddings using only 64 CXRs yielded an AUROC of 0.82 (non-inferior to radiologist performance) in classifying microbiology-confirmed TB in an external validation set. At a more moderate data regime, SupCon followed by finetuning the network end-to-end using only 490 CXRs at hospital admission yielded an AUROC of 0.80 in predicting ICU admission for COVID-19 inpatients.

CLINICAL RELEVANCE/APPLICATION

Training label-efficient models is useful in cases of constrained computational resources, limited data, or distribution shifts, as with COVID-19, where populations and treatments change quickly.

CH03-A5   Artificial Intelligence Enhances Time Efficiency In Reading Chest CT Scans - A Randomized Prospective Study

Participants
Basel Yacoub, MD, Charleston, South Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To determine the impact of incorporating an artificial intelligence (AI) support platform into clinical radiology workflows on chest CT reading times by radiologists at an academic cardiothoracic practice.*Methods and Materials In this prospective study, reading times for chest CT scans by 3 board certified cardiothoracic radiologists were assessed. AI-Rad Companion Chest CT (Siemens Healthineers, Erlangen, Germany), an AI support platform was utilized. It comprising of modules for assessment of pulmonary hypodensity, pulmonary nodules, coronary calcifications, the thoracic aorta and the thoracic spine. The availability of AI results on the institutional picture archiving and communication system, for review by the reading radiologists, was randomized by the CT technologists. Consecutive contrast and non-contrast CT scans were enrolled and each reader was assigned an equal number of cases with and without AI results. Reading times were measured by the radiologists beginning after the cases have been loaded on the reporting workstations and ending prior to dictation. Cases that involved reading interruptions e.g. phone calls were excluded.*Results A total of 390 chest CT scans were included and allocated equally to the AI and non-AI assisted arms. Mean age of patients was 62.8 ± 13.3 years with 52.3 % females. Mean reading time of the radiologists was shorter in the AI arm by 92.9 seconds (s) with 95 % CI: 62.9 - 123.0 s. This accounted for a mean reduction of 22.1 % with 95 % CI: 14.9 - 29.2 % when compared to the mean non-AI reading time (AI: 328.2 ± 122.0 s; non-AI: 421.1 ± 175.0 s; p-value <0.001). This pattern of shorter mean reading times on utilizing results from the AI support platform was observed on non-contrast scans (AI: 325.1 ± 100.7 s; non-AI: 428.7 ± 173.3 s; difference: 24.2 %; p-value <0.001), as well as contrast scans (AI: 331.0 ± 139.2 s; non-AI: 413.6 ± 177.1 s; difference: 20.0 %; p-value <0.001).*Conclusions There was a mean reduction of 22.1 % in reading time of contrast and non-contrast chest CT scans by cardiothoracic radiologists when results from an AI support platform were made available to the readers.*Clinical Relevance/Application The incorporation of AI support platforms into clinical radiology workflows may increase reading efficiency for radiologists and reduce turnaround times for reports.

RESULTS

A total of 390 chest CT scans were included and allocated equally to the AI and non-AI assisted arms. Mean age of patients was 62.8 ± 13.3 years with 52.3 % females. Mean reading time of the radiologists was shorter in the AI arm by 92.9 seconds (s) with 95 % CI: 62.9 - 123.0 s. This accounted for a mean reduction of 22.1 % with 95 % CI: 14.9 - 29.2 % when compared to the mean non-AI reading time (AI: 328.2 ± 122.0 s; non-AI: 421.1 ± 175.0 s; p-value <0.001). This pattern of shorter mean reading times on utilizing results from the AI support platform was observed on non-contrast scans (AI: 325.1 ± 100.7 s; non-AI: 428.7 ± 173.3 s; difference: 24.2 %; p-value <0.001), as well as contrast scans (AI: 331.0 ± 139.2 s; non-AI: 413.6 ± 177.1 s; difference: 20.0 %; p-value <0.001).

CLINICAL RELEVANCE/APPLICATION

The incorporation of AI support platforms into clinical radiology workflows may increase reading efficiency for radiologists and reduce turnaround times for reports.

CH03-A6   Clinical Performance Of A Deep Learning Based Artificial Intelligence Model For Endotracheal Tube (ETT) Detection, Localization And Automated Measurement On Frontal Chest X-rays

Participants
Alec Baenen, Waukesha, Wisconsin (*Presenter*) Employee, General Electric Company

PURPOSE

Up to 45% of ICU patients, including severe COVID-19 cases, receive endotracheal intubation for ventilation. As many as 1 of 4 intubations result in mispositioned ETTs which may lead to severe complications. Technologies which aid in ETT positioning assessment and bring awareness to potentially misplaced ETTs can be clinically valuable and lifesaving. This study investigates the clinical performance of a deep learning model trained for ETT detection, localization, and automated measurement on 30,000 independent chest X-rays.*Methods and Materials A diverse, enriched, and clinically challenging dataset of 635 AP chest X-ray images was reviewed by two expert annotators to determine the presence of an ETT, ETT tip location, and carina location among other image characteristics. Inferencing on this dataset was then performed using a commercially available, deep learning-based AI algorithm.*Results The model achieved an AUC of 0.9999 (0.9998, 1.0000), a sensitivity of 0.9941 (0.9859, 1.0000), and a specificity of 1.0000 (1.0000, 1.0000) for ETT detection. Additionally, the model achieved an ETT tip to Carina distance measurement success rate to within 1cm of 0.9405 (0.9152, 0.9658), a carina localization success rate to within 1cm of 0.9762

(0.9599, 0.9925), an ETT tip localization success rate to within 1cm of 0.9643 (0.9444, 0.9841) and an ETT localization success rate (DICE) of 0.9881 (0.9765, 0.9997). Model ability to accurately distinguish an ETT from a tracheostomy tube (TTT) or nasogastric tube (NGT) and model performance in the presence obscured carinas and technically difficult images was also assessed. Results showed that the model maintained high accuracies for ETT detection (sensitivity and specificity above 99%) and for ETT tip and carina localization (Accuracies above 94.7%) for all local disturbing factors listed above. The model also showed a highly accurate mean distance error of only 0.58mm and absolute distance error of 3.74mm as compared to the ground truth ETT tip to carina distance.*Conclusions This ground truth analysis demonstrates that the ETT model shows very high accuracies in ETT detection, localization of ETT tip and carina, and in calculation of vertical distance between the them. The model also retains consistently high performance across various local disturbing factors within the dataset such as the presence of TTTs or NGTs, images with high technical difficulty or difficult visibility of the carina.*Clinical Relevance/Application A deep learning based algorithm for ETT detection, localization, and automated measurement can provide accurate and clinically relevant information related to potentially misplaced ETTs. Additional studies assessing the prospective clinical impact of this ETT model are warranted.

RESULTS

The model achieved an AUC of 0.9999 (0.9998, 1.0000), a sensitivity of 0.9941 (0.9859, 1.0000), and a specificity of 1.0000 (1.0000, 1.0000) for ETT detection. Additionally, the model achieved an ETT tip to Carina distance measurement success rate to within 1cm of 0.9405 (0.9152, 0.9658), a carina localization success rate to within 1cm of 0.9762 (0.9599, 0.9925), an ETT tip localization success rate to within 1cm of 0.9643 (0.9444, 0.9841) and an ETT localization success rate (DICE) of 0.9881 (0.9765, 0.9997). Model ability to accurately distinguish an ETT from a tracheostomy tube (TTT) or nasogastric tube (NGT) and model performance in the presence obscured carinas and technically difficult images was also assessed. Results showed that the model maintained high accuracies for ETT detection (sensitivity and specificity above 99%) and for ETT tip and carina localization (Accuracies above 94.7%) for all local disturbing factors listed above. The model also showed a highly accurate mean distance error of only 0.58mm and absolute distance error of 3.74mm as compared to the ground truth ETT tip to carina distance.

CLINICAL RELEVANCE/APPLICATION

A deep learning based algorithm for ETT detection, localization, and automated measurement can provide accurate and clinically relevant information related to potentially misplaced ETTs. Additional studies assessing the prospective clinical impact of this ETT model are warranted.

CH03-A7   The Thymus Revisited: Key Multimodality Imaging Features And Pitfalls With Pathological Correlation

Awards
Cum Laude

Participants
Hatice Savas, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Describe the embryologic and anatomic features of the thymus • Describe classification of non-malignant and malignant pathologies of the thymus • Describe imaging features of commonly encountered thymic lesions by CT, MRI, and PET • Correlate key imaging features with pathological features for more accurate staging on imaging

TABLE OF CONTENTS/OUTLINE

• Introduction o Embryology o ITMIG classification of mediastinal compartments o Anatomical and histological description of the normal thymus • Imaging modalities of the thymus • Imaging optimization for high risk group (pregnant women - children) • Age group based normal imaging of the thymusChest Xray - CT - MRI - PET CT • Masaoka-Koga system classification of thymic tumors • Diagnostic approach to commonly encountered thymic pathologies in daily practice • Benign conditions of Thymus o Thymic hyperplasia o True thymic hyperplasia o Thymic lymphoid hyperplasia o Thymic cysts and its mimics o Thymic cyst o Fat containing thymic lesions o Thymolipoma o Lipofibroadenoma • Thymic tumors: o Thymoma o Thymic carcinoma o Thymic lymphoma o Thymic carcinoid o Metastatic disease to the thymus • Common and rare entities for differential diagnosis o Lymphoma o Germ cell tumor o Thyroid origin tumors o Rare entities

BR03-D2   Deep-libra: An Open-Source Artificial-intelligence Method For Robust Quantification Of Breast Density With Independent Validation In Breast Cancer Risk Assessment

Participants
Aimilia Gastounioti, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Breast density is an important risk factor for breast cancer that also affects the specificity and sensitivity of screening mammography. The purpose of our study is to introduce Deep-LIBRA, an open-source artificial intelligence (AI) method for breast density estimation, which combines deep learning with radiomic machine learning techniques to estimate breast density from digital mammograms.*Methods and Materials Our method leverages deep learning using two U-Net convolutional neural networks to remove the image background and the pectoralis muscle, and accurately segment the breast area. An AI algorithm combining superpixel generation and radiomic machine learning is then applied to differentiate dense from non-dense tissue regions within the breast, from which the total dense tissue area (DA) and the relative amount of dense tissue within the breast, also known as breast percent density (PD), are estimated. Our method was trained and validated on a multi-racial, multi-institutional dataset of 15,661 images (4,437 women), and then tested on an independent matched case-control dataset of 6,348 digital mammograms (414 cases; 1,178 controls) for both breast segmentation and breast-density-based case-control discrimination. Breast density measures from state-of-the-art research-based (LIBRA, Cumulus) and commercial software (Volpara) were also analyzed for comparison purposes.*Results On the independent dataset, Deep-LIBRA demonstrated high performance in breast density estimation, reflected in strong correlation (Spearman r = 0.90) and high overlap with expert gold-standard segmentations (Dice score = 92.5%). Moreover, in a conditional logistic regression model adjusted for age and BMI, Deep-LIBRA yielded a higher case-control discrimination performance (area under the ROC curve, AUC for PD = 0.61, 95% CI: [0.58, 0.64] and for DA = 0.64, [0.62, 0.67]) compared to other research and commercial breast density assessment methods (AUCs for PD = 0.53-0.60 and for DA = 0.58-0.63).*Conclusions Our preliminary results suggest a strong agreement of breast density estimates between Deep-LIBRA and gold-standard expert assessment of breast density, as well as similar or improved performance in breast-density-based breast cancer risk assessment to state-of-the-art research and commercial methods.*Clinical Relevance/Application With Deep-LIBRA being an open-source software, we anticipate that this study will provide instrumental evidence for Deep-LIBRA to facilitate larger studies of mammographic breast density and risk.

RESULTS

On the independent dataset, Deep-LIBRA demonstrated high performance in breast density estimation, reflected in strong correlation (Spearman r = 0.90) and high overlap with expert gold-standard segmentations (Dice score = 92.5%). Moreover, in a conditional logistic regression model adjusted for age and BMI, Deep-LIBRA yielded a higher case-control discrimination performance (area under the ROC curve, AUC for PD = 0.61, 95% CI: [0.58, 0.64] and for DA = 0.64, [0.62, 0.67]) compared to other research and commercial breast density assessment methods (AUCs for PD = 0.53-0.60 and for DA = 0.58-0.63).

CLINICAL RELEVANCE/APPLICATION

With Deep-LIBRA being an open-source software, we anticipate that this study will provide instrumental evidence for Deep-LIBRA to facilitate larger studies of mammographic breast density and risk.

BR03-D3   Initial Targeted Ultrasound In Women With Focal Breast Complaints: What About Tomosynthesis?

Participants
Carmen Siebers, Nijmegen, Netherlands (*Presenter*) Research grant, ZonMW

PURPOSE

To assess the potential of initial targeted ultrasound (US) in the diagnostic work-up of women with symptomatic localized breast disease and the supplemental value of digital breast tomosynthesis (DBT) (and synthetic digital mammography) in this setting.*Methods and Materials In this multicenter prospective study the standard breast imaging protocol (first DBT and second US) in women (>30 years), presenting with focal breast complaints in three different hospitals in the Netherlands, was reversed. Initially, US was performed and when required lesions were biopsied. Subsequently the DBT was evaluated. We assessed cancer detection related to the focal complaint based upon initial US alone and in combination with DBT. Furthermore, we evaluated the incidental findings, besides the focal complaint. After follow-up, data was linked to the Nationwide pathology database to evaluate any potential missed breast cancer during the inclusion.*Results Between September 2017 and June 2019 a total of 1961 women were enrolled (mean age 47.1 years). Based upon initial US alone, in 1587 women (80.9%) the complaints were due to normal fibroglandular tissue or benign findings (BI-RADS 1 or 2). However, in three of these women (0.2%) the DBT led to detection of a malignant lesion at the site of the complaint. In 374 women (19.1%) initial US was judged as suspicious and was followed by biopsy, yielding benign results in 182 women (48.7%) and malignant results in 192 women (51.3%) (US sensitivity 98.5%, US specificity 90.7%). In women without cancer at the site of the complaint DBT yielded incidental findings requiring additional investigations in 63 patients (3.2%); eight of these were malignant (0.4%, ductal carcinoma in situ (n=3) and invasive carcinoma (n=5)). After linking the results to PALGA, we found 18 women (age range 31-78 years, M = 55 years) diagnosed with malignancy in

the breast during the follow-up period. Seven of these cancers were in retrospect correlated to the complaint. The final sensitivity of US+DBT for cancer at the site of complaint was 96.5%, compared to 95% for US alone.*Conclusions US is an accurate stand-alone breast imaging modality in the assessment of focal breast complaints when the US shows no or a benign lesion. DBT is a necessary imaging tool only if US shows a suspicious lesion or is inconclusive. In case the DBT is omitted, there is in our opinion an acceptable very small chance that a malignant additional finding will not (yet) be detected.*Clinical Relevance/Application Focal breast complaints are a frequent problem for women, often causing fear for having breast cancer. Roughly 80% of these women would not need to undergo DBT to explain their complaint. Starting with US will reduce discomfort for the patient and save time and money in current daily practice.

RESULTS

Between September 2017 and June 2019 a total of 1961 women were enrolled (mean age 47.1 years). Based upon initial US alone, in 1587 women (80.9%) the complaints were due to normal fibroglandular tissue or benign findings (BI-RADS 1 or 2). However, in three of these women (0.2%) the DBT led to detection of a malignant lesion at the site of the complaint. In 374 women (19.1%) initial US was judged as suspicious and was followed by biopsy, yielding benign results in 182 women (48.7%) and malignant results in 192 women (51.3%) (US sensitivity 98.5%, US specificity 90.7%). In women without cancer at the site of the complaint DBT yielded incidental findings requiring additional investigations in 63 patients (3.2%); eight of these were malignant (0.4%, ductal carcinoma in situ (n=3) and invasive carcinoma (n=5)). After linking the results to PALGA, we found 18 women (age range 31-78 years, M = 55 years) diagnosed with malignancy in the breast during the follow-up period. Seven of these cancers were in retrospect correlated to the complaint. The final sensitivity of US+DBT for cancer at the site of complaint was 96.5%, compared to 95% for US alone.

CLINICAL RELEVANCE/APPLICATION

Focal breast complaints are a frequent problem for women, often causing fear for having breast cancer. Roughly 80% of these women would not need to undergo DBT to explain their complaint. Starting with US will reduce discomfort for the patient and save time and money in current daily practice.

BR03-D7   Performance Of Opto-acoustic Ultrasound With An Artificial Intelligence-based Decision Support Tool Versus Ultrasound Alone To Classify Benign Versus Malignant Breast Masses: A Pivotal Reader Study

Participants
Stephen J. Seiler, MD, Coppell, Texas (*Presenter*) Consultant, Seno Medical Instruments, Inc

PURPOSE

To evaluate the gain in specificity using opto-acoustic and ultrasound fused images (IUS+OA) and an artificial intelligence-based decision support tool (AI-DST) versus ultrasound (IUS) alone, controlling for sensitivity.*Methods and Materials Randomly selected 480 BI-RADS 3-5 masses (0.33-3.89 cm, mean diameter 1.45±0.77 cm) that underwent IUS+OA scanning as part of the multi-site PIONEER-01 trial were evaluated by 15 readers trained in IUS+OA interpretation. Readers first assigned probability of malignancy (POM) and BI-RADS category based on clinical history, mammogram and IUS. Readers then evaluated IUS+OA images, assigning IUS and OA feature scores and viewed a likelihood of malignancy (LOM) prediction score derived from a machine learning AI-DST before issuing a final POM and BI-RADS category. Mean specificity at fixed sensitivity of 98% (fSp), negative likelihood ratio (NLR), positive likelihood ratio (PLR) and partial area under the curve (pAUC) (95-100% sensitivity) of IUS+OA vs. IUS were calculated.*Results The study demonstrated a statistically significant gain in fSp of 9% (averaged over all readers) for IUS+OA compared to IUS (p=0.027, 95% CI: 1.03%, 16.9%). The mean NLR was 0.047 (95% CI: 0.032, 0.062) for IUS+OA and 0.053 (95% CI: 0.037, 0.070) for IUS alone. The mean PLR was 1.959 (95% CI: 1.870, 2.051) for IUS+OA and 1.548 (95% CI: 1.498, 1.597) for IUS alone. The pAUC was 0.0244 (95% CI: 0.0230, 0.0258) for IUS+OA and 0.0205 (95% CI: 0.0191, 0.0219) for IUS alone, a difference of 0.0039.*Conclusions IUS+OA plus an AI-DST has a statistically significantly better fSP than IUS alone. The IUS and OA feature scores can be used as combined qualitative diagnostic and predictive imaging biomarkers.*Clinical Relevance/Application IUS+OA provides useful diagnostic information and, with AI-DST, has the potential to reduce false positives, and thus biopsies of benign masses, versus IUS alone without sacrificing sensitivity.

RESULTS

The study demonstrated a statistically significant gain in fSp of 9% (averaged over all readers) for IUS+OA compared to IUS (p=0.027, 95% CI: 1.03%, 16.9%). The mean NLR was 0.047 (95% CI: 0.032, 0.062) for IUS+OA and 0.053 (95% CI: 0.037, 0.070) for IUS alone. The mean PLR was 1.959 (95% CI: 1.870, 2.051) for IUS+OA and 1.548 (95% CI: 1.498, 1.597) for IUS alone. The pAUC was 0.0244 (95% CI: 0.0230, 0.0258) for IUS+OA and 0.0205 (95% CI: 0.0191, 0.0219) for IUS alone, a difference of 0.0039.

CLINICAL RELEVANCE/APPLICATION

IUS+OA provides useful diagnostic information and, with AI-DST, has the potential to reduce false positives, and thus biopsies of benign masses, versus IUS alone without sacrificing sensitivity.

BR03-D8   3D Imaging For Intraoperative Breast Lumpectomy Specimen Assessment: A Feasibility Study During The Surgery

Participants
Mauro Hanaoka, MD, Lexington, Kentucky (*Presenter*) Nothing to Disclose

PURPOSE

Currently used 2D radiographic imaging during breast-conserving surgery (BCS) is limited in assessing positive margins in surgical specimens (reported margin sensitivity, 36-58%). Emerging volumetric specimen imager (VSI) with 3D imaging has a better correlation with pathology, but no VSI has been implemented or evaluated in the OR. Therefore, we aimed to assess the feasibility of implementing a VSI as a potential method for intraoperative specimen assessment during BCS.*Methods and Materials 21 consecutive female patients who underwent BCS for breast cancer were prospectively included (Preliminary data). Patients who had prior BCS and radiation therapy are excluded. All patients underwent ultrasound/mammography-guided localization of the lesions. After excision, each specimen was marked for orientation and imaged using 2D radiography first and then VSI during surgery. VSI imaging time and effect on clinical flow were recorded. One blinded radiologist retrospectively analyzed images acquired with both modalities. The lesion maximal dimension was measured and compared with the diagnostic images and pathology reports. Specimen margin on 3D images was marked as negative or positive and findings were compared with the final histopathological analysis. Positive margin status was defined as a tumor on ink margin for invasive cancer and <1mm for ductal carcinoma in situ (DCIS) at both imaging and pathology. Statistical analyses of the present study were performed using SPSS

software (version 22.0; IBM Corp., Armonk, NY, USA).*Results 21 subjects (age range 39-77) underwent BCT; 6 had positive margins. VSI detected all 6 positive margins (sensitivity 80%, specificity 50%, PPV 33%, NPV 88%, Accuracy 57%). Tumor size measured with VSI showed moderate correlation with pathological measurement (r=0.62, p=0.002). VSI imaging time was approximately 6 minutes and no impact on OR workflow was observed.*Conclusions VSI is a promising new technique that could potentially be used in the OR for specimen assessment during BCS without interrupting the workflow. It has better margin sensitivity than the standard 2D image. More prospective data will be collected from this ongoing study to assess VSI performance in margin assessment and its impact on surgical time and re-excision rates.*Clinical Relevance/Application VSI provides full-3D and thin-slice cross-sectional images, allowing more precise localization and orientation of the lesion and specimen margins than the commonly used 2D images. This is the first study reporting on the feasibility of implementing the VSI for breast specimen assessment during surgery. The protocol established from this study defines the guideline for a full-scale, prospective clinical trial to evaluate the VIS clinical application.

RESULTS

21 subjects (age range 39-77) underwent BCT; 6 had positive margins. VSI detected all 6 positive margins (sensitivity 80%, specificity 50%, PPV 33%, NPV 88%, Accuracy 57%). Tumor size measured with VSI showed moderate correlation with pathological measurement (r=0.62, p=0.002). VSI imaging time was approximately 6 minutes and no impact on OR workflow was observed.

CLINICAL RELEVANCE/APPLICATION

VSI provides full-3D and thin-slice cross-sectional images, allowing more precise localization and orientation of the lesion and specimen margins than the commonly used 2D images. This is the first study reporting on the feasibility of implementing the VSI for breast specimen assessment during surgery. The protocol established from this study defines the guideline for a full-scale, prospective clinical trial to evaluate the VIS clinical application.

BR03-D9   **Breast Cancer Patients Undergoing Neoadjuvant Chemotherapy; Is Axillary Response Determined By The Initial Nodal Burden?**

Participants
Ali Sever, MD, Orpington, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

Axillary management in node positive breast cancer patients following neoadjuvant chemotherapy (NAC) is controversial. Depending on the baseline imaging, and response to treatment, patients with limited axillary involvement can be offered sentinel node biopsy alongside with targeted axillary dissection of the biopsy proven positive node(s). However in heavy nodal disease this is often avoided regardless post treatment response and patients undergo axillary clearance as first line treatment. The purpose of this study is to identify the role of baseline axillary imaging in biopsy-proven node positive breast cancer patients prior to NAC and to investigate the importance of initial staging in HER2-positive and HER2-negative cases.*Methods and Materials Breast cancer patients between 2017 and 2020, who were diagnosed with axillary nodal involvement following ultrasound-guided core biopsy were retrospectively identified. Breast tumor HER2 status was already determined. As per unit's protocol, all patients received baseline staging MRI and ultrasound prior to NAC and number of abnormal nodes were registered. Patients with three or less abnormal nodes (putative N1) had marker insertion into the biopsied node for eventual sentinel node biopsy and targeted axillary dissection. Axillary nodal clearance was planned for patients with four or more abnormal nodes (putative =N2) regardless their response to treatment.*Results There were 121 biopsy-proven axillary node positive patients who received NAC. Fifty patients were HER2-positive and remaining 71 patients were HER2-negative. Of the 33 N1, HER2-positive cases, 18 (55%) had complete pathological axillary response in their surgical specimen. In remaining 17 N2 cases, 9 (53%) had complete pathological response. In the 71 HER2-negative patients, 49 had N1 disease and 18 (37%) of them had complete pathological response. Only 5 of the 22 (23%) N2 cases showed complete response.*Conclusions Patients with HER2-positive tumors, axillary response is not directly determined by the initial nodal status. Depending on post treatment breast and axillary response, these patients may still benefit sentinel node biopsy (+/- targeted axillary dissection) regardless their advanced nodal involvement at initial presentation.*Clinical Relevance/Application Axillary response is not directly related to initial heavy nodal burden. In selected cases, especially in patients with HER2-positive tumors, sentinel node biopsy may still be an option.

RESULTS

There were 121 biopsy-proven axillary node positive patients who received NAC. Fifty patients were HER2-positive and remaining 71 patients were HER2-negative. Of the 33 N1, HER2-positive cases, 18 (55%) had complete pathological axillary response in their surgical specimen. In remaining 17 N2 cases, 9 (53%) had complete pathological response. In the 71 HER2-negative patients, 49 had N1 disease and 18 (37%) of them had complete pathological response. Only 5 of the 22 (23%) N2 cases showed complete response.

CLINICAL RELEVANCE/APPLICATION

Axillary response is not directly related to initial heavy nodal burden. In selected cases, especially in patients with HER2-positive tumors, sentinel node biopsy may still be an option.

MS03-D1   **Fluoroscopic Evaluation Of Spontaneous And Blunt Traumatic Pneumomediastinum**

Participants
Clayton Taylor, MD, Indianapolis, Indiana (*Presenter*) Nothing to Disclose

PURPOSE

Fluoroscopic evaluation (FE) of spontaneous and blunt traumatic pneumomediastinum (PM) is frequently performed in the emergency setting. Oral contrasted fluoroscopic studies have been shown to be low yield in specific pediatric and adult patient populations with PM, but they are often still performed given the high morbidity and mortality of a missed esophageal injury. We seek to determine the positivity rate of FE in patients presenting with spontaneous or blunt traumatic PM.*Methods and Materials IRB approved consecutive retrospective chart review was performed on all patients who underwent FE of imaging confirmed spontaneous or blunt traumatic PM between 2001-2019. Patients were excluded if there was a history of prior esophageal surgery, penetrating trauma, esophageal cancer or recent tracheal or recent esophageal instrumentation. For each patient, data regarding demographics, presenting history, physical exam findings, laboratory data, clinical course and imaging findings were collected.*Results A total of 252 patients met inclusion criteria during the 18 year study period, including 170 patients with spontaneous PM and 82 with blunt traumatic PM. A total of 8 fluoroscopic studies showed findings concerning for an esophageal injury, for a total positivity rate of 3.2%. All positive cases occurred in patients with spontaneous PM for a positivity rate of 4.7% in patients presenting with spontaneous PM and 0% in patients presenting with blunt traumatic PM. Of the patients found to have a positive esophagram, 75% presented with either vomiting/retching (N=4) or vomiting/retching with cough (N=2) as their primary symptoms. Pleural effusion was present in 83% (5/6) of these patients. Underlying esophageal injury was confirmed in all patients with positive fluoroscopic study who underwent surgery or endoscopy (N=7). There was one false negative esophagram (1/244, or 0.4%), in a patient who was found to have esophageal injury on subsequent endoscopy.*Conclusions FE is low yield across a broad patient population presenting with spontaneous or blunt traumatic PM. However, emergent FE for spontaneous PM may still be warranted given the positivity rate of 4.7%, especially in the setting of vomiting or retching. The practice of emergency FE of PM in the setting of blunt trauma should be discontinued.*Clinical Relevance/Application The use of FE in patients presenting with blunt traumatic PM should be discontinued. While FE positivity rate is low in patients with spontaneous PM the practice is warranted given the high morbidity and mortality of esophageal injury.

RESULTS

A total of 252 patients met inclusion criteria during the 18 year study period, including 170 patients with spontaneous PM and 82 with blunt traumatic PM. A total of 8 fluoroscopic studies showed findings concerning for an esophageal injury, for a total positivity rate of 3.2%. All positive cases occurred in patients with spontaneous PM for a positivity rate of 4.7% in patients presenting with spontaneous PM and 0% in patients presenting with blunt traumatic PM. Of the patients found to have a positive esophagram, 75% presented with either vomiting/retching (N=4) or vomiting/retching with cough (N=2) as their primary symptoms. Pleural effusion was present in 83% (5/6) of these patients. Underlying esophageal injury was confirmed in all patients with positive fluoroscopic study who underwent surgery or endoscopy (N=7). There was one false negative esophagram (1/244, or 0.4%), in a patient who was found to have esophageal injury on subsequent endoscopy.

CLINICAL RELEVANCE/APPLICATION

The use of FE in patients presenting with blunt traumatic PM should be discontinued. While FE positivity rate is low in patients with spontaneous PM the practice is warranted given the high morbidity and mortality of esophageal injury.

IN03-B1 **Accelerating Training Data Annotation Via A Continuous AI-assisted, Human-supervised Feedback Loop In Kidney Segmentation In CT**

Participants
Gabriel Melendez-Corres, BS, Los Angeles, California (*Presenter*) Nothing to Disclose

PURPOSE

A common issue present with AI in medical imaging is the lack of ample, curated data for training predictive models, as annotation generation is often prohibitively resource-intensive. We propose the implementation of a continuous AI-assisted feedback loop to accelerate image annotation generation, in which a starter AI model, trained on limited data, provides annotation initializations to human annotators to accelerate annotation, and the subsequent human-corrected annotations are sent back to update the AI model. This loop is run continuously with small batches of data, with each iteration improving the AI-initialized annotation, and thereby requiring even less time for human annotation. Eventually, minimal annotation is needed, requiring only a fraction of resources to generate well-annotated data. We demonstrate the utility of this approach, even with small batches (n < 10), in an initial implementation for kidney segmentation in CT images.*Methods and Materials An off-the-shelf 3D U-Net was trained on an initial set of 8 CT images with kidney annotations from an expert image analyst. This initial model was used to generate initial segmentations on unannotated images, which were sent back the analyst to aid them in annotating the kidneys. The newly annotated images were added to the training data for subsequent updating of the model. This feedback loop was repeated for 2 iterations, for a total of 16 images added to the training set. To measure performance, the median dice coefficient (DCE) was used to compare the model's predicted segmentation to the analyst corrected annotation. The analyst provided estimates for annotation times.*Results Model performance increased from 92% to 98% DCE from the first iteration to the second iteration. Analyst annotation time decreased by approximately 20% and 35%, respectively, for images with model segmentations similar to the reference truth. Annotation time doubled for images where the model yielded a poor segmentation.*Conclusions Preliminary results suggest that the feedback loop accelerates the generation of well-curated training data. With each iteration, even building a model from scratch with few cases, we see improvements in the model's segmentations and reduction in annotation times. However, more iterations, and optimized processing techniques or model architectures, are needed to maintain a consistent performance throughout all images.*Clinical Relevance/Application A continuous feedback loop approach, iterating a continuous stream of data batches, can be used to build annotated training sets at a faster rate for training AI algorithms. This in turn aids in building more robust models for computer aided diagnosis tasks, or even tasks outside of medical imaging.

RESULTS

Model performance increased from 92% to 98% DCE from the first iteration to the second iteration. Analyst annotation time decreased by approximately 20% and 35%, respectively, for images with model segmentations similar to the reference truth. Annotation time doubled for images where the model yielded a poor segmentation.

CLINICAL RELEVANCE/APPLICATION

A continuous feedback loop approach, iterating a continuous stream of data batches, can be used to build annotated training sets at a faster rate for training AI algorithms. This in turn aids in building more robust models for computer aided diagnosis tasks, or even tasks outside of medical imaging.

NPM03-B2 **Developing A Community-based Lung Cancer Screening Digital Outreach Intervention Tailored For Low Socioeconomic Status Communities**

Participants
Efren J. Flores, MD, Boston, Massachusetts (*Presenter*) 1. Speaker Honorarium, Medscape2. Speaker Honoraria, Grand Rounds presentations (non-profit organizations)

PURPOSE

Individuals from low socioeconomic status (SES) communities experience worse lung cancer (LC) outcomes and multilevel barriers to digital health. Community-based lung cancer screening (LCS) outreach can assist in overcoming these gaps and promote trust. The purpose of this study was to use mixed-methods research to develop a tailored digital health outreach intervention to promote LCS and understand related social needs among low SES communities.*Methods and Materials Focus Groups (FG) were conducted at an urban academic medical center with affiliated community health centers with representative PCPs (n=12), advocates (n=8), and LCS (n=7) and non-LCS (n=8) patients. Qualitative analysis guided development of 3 tailored LCS outreach videos with messaging by a: Radiologist, Patient, and Patient/Radiologist together. A national sample of 315 LCS-eligible, current smokers with Medicaid were randomized to 1 of 3 video conditions to determine satisfaction, preferred source, intent to screen, and attitudes about LC. ANOVA examined the main effect of video condition on continuous variables and bivariate correlations examined associations with a composite social needs assessment score.*Results FG with PCPs, advocates, and LCS and non-LCS patients cited transportation and fear about LC as major barriers to LCS. Patients reported confusion about LCS eligibility criteria, the LCS process, and insurance coverage. The outreach video was modified to emphasize the treatability of early LC, adopted clear language for eligibility and insurance coverage, and displayed a patient undergoing LCS and receiving results. For national testing, 67% (210/315) reported satisfaction with the video. Participants in the Patient condition reported the greatest intent to speak to a PCP about LCS, $F(2,312)=3.65=.027$. Participants reported limited social needs (M=2.09, IQR=3). However, greater social need was significantly associated with lower health literacy $r(315)=-.18$, $p=.001$, smoking-related stigma $r(315)=.22$, $p<.000$, lower confidence in arranging transport to LCS, $r(313)=-.34$, $p<.000$, greater cost concerns about LCS, $r(315)=.14$, $p=.01$, perceived severity of LC $r(315)=.12$, $p=.03$, and greater worry about developing LC $r(315)=.14$, $p=.01$.*Conclusions A community-based outreach intervention was effective at addressing salient barriers to LCS. Cost concerns, lower literacy levels, and fear of LC diagnosis from FG discussions mapped onto concerns from a national representative sample.*Clinical Relevance/Application Radiologists can partner with patients and key community stakeholders in the development of effective LCS outreach interventions aimed to increase equitable LCS participation among low SES communities.

RESULTS

FG with PCPs, advocates, and LCS and non-LCS patients cited transportation and fear about LC as major barriers to LCS. Patients reported confusion about LCS eligibility criteria, the LCS process, and insurance coverage. The outreach video was modified to emphasize the treatability of early LC, adopted clear language for eligibility and insurance coverage, and displayed a patient undergoing LCS and receiving results. For national testing, 67% (210/315) reported satisfaction with the video. Participants in the Patient condition reported the greatest intent to speak to a PCP about LCS, $F(2,312)=3.65=.027$. Participants reported limited social needs (M=2.09, IQR=3). However, greater social need was significantly associated with lower health literacy $r(315)=-.18$, $p=.001$, smoking-related stigma $r(315)=.22$, $p<.000$, lower confidence in arranging transport to LCS, $r(313)=-.34$, $p<.000$, greater cost concerns about LCS, $r(315)=.14$, $p=.01$, perceived severity of LC $r(315)=.12$, $p=.03$, and greater worry about developing LC $r(315)=.14$, $p=.01$.

CLINICAL RELEVANCE/APPLICATION

Radiologists can partner with patients and key community stakeholders in the development of effective LCS outreach interventions aimed to increase equitable LCS participation among low SES communities.

RI03-B2   **Added Value Of Diffusion-weighted Imaging And Delayed Gadolinium-enhanced Mri For Staging Of Ib-iib Cervical Cancer Treated With Neo-adjuvant Chemotherapy**

Participants
Frédéric Vanhove, Leuven, Belgium (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the added value of diffusion-weighted magnetic resonance imaging (DWI-MRI) and delayed Gadolinium-enhanced (DGE-)MRI to T2-weighted MRI (T2-MRI) for staging cervical uterine cancer after neo-adjuvant chemotherapy (NACT).*Methods and Materials This retrospective study was approved by the ethics committee and analyzed forty-two cervical cancer patients treated by NACT prior to planned surgery. All patients had received 3 Tesla MRI including T2-MRI, DWI-MRI (b0-1000 sec/mm2) and DGE-MRI [1.1 mm isotropic 3D T1-weighted gradient-echo sequence 17 minutes after Gadobutrol injection (Gadovist®)] . An expert reader scored for presence of vaginal and parametrial invasion, pelvic nodal metastases and FIGO-stage at the post-NACT T2-MRI, T2-MRI+DWI-MRI and T2-MRI+DWI-MRI+DGE-MRI with 2 weeks intervals. Diagnostic performance was compared for the 3 reading sessions in correlation to histopathology after surgery and follow-up.*Results For predicting vaginal invasion, T2-MRI showed 71.43% sensitivity and 88.57% specificity; T2-MRI+DWI-MRI showed 57.14% sensitivity and 88.57% specificity and T2-MRI+DWI-MRI+DGE-MRI showed 71.43% sensitivity and 100% specificity. For predicting parametrial invasion, T2-MRI showed 54.55% sensitivity and 93.55% specificity; T2-MRI+DWI-MRI showed 72.73% sensitivity and 100% specificity and T2-MRI+DWI-MRI+DGE-MRI showed 90.91% sensitivity and 100% specificity. For predicting pelvic nodal metastases, T2-MRI showed 7.14% sensitivity and 92.86 % specificity; T2-MRI+DWI-MRI showed 13.79% sensitivity and 76.92% specificity and T2-MRI+DWI-MRI+DGE-MRI showed 71.43% sensitivity and 92.86% specificity. T2-MRI+DWI-MRI+DGE-MRI showed higher accuracy over T2-MRI and T2+DWI-MRI for predicting parametrial invasion (97.62% versus 83.33% versus 92.86%), vaginal invasion (95.24% versus 85.71% versus 83.33%) and nodal metastases (85.71% versus 64.29% versus 64.29%) and assigned the highest number of patients to the correct FIGO stage (33 of 42 versus 13 of 42 versus 23 of 42).*Conclusions Adding delayed Gadolinium-enhanced MRI to T2-MRI and DWI-MRI improves diagnostic performance for locoregional staging of cervical cancer after NACT prior to surgery.*Clinical Relevance/Application Better detection of locoregional tumor extent after neoadjuvant chemotherapy by delayed Gadolinium-enhanced MRI may improve therapeutic decision making towards operability.

RESULTS

For predicting vaginal invasion, T2-MRI showed 71.43% sensitivity and 88.57% specificity; T2-MRI+DWI-MRI showed 57.14% sensitivity and 88.57% specificity and T2-MRI+DWI-MRI+DGE-MRI showed 71.43% sensitivity and 100% specificity. For predicting parametrial invasion, T2-MRI showed 54.55% sensitivity and 93.55% specificity; T2-MRI+DWI-MRI showed 72.73% sensitivity and 100% specificity and T2-MRI+DWI-MRI+DGE-MRI showed 90.91% sensitivity and 100% specificity. For predicting pelvic nodal metastases, T2-MRI showed 7.14% sensitivity and 92.86 % specificity; T2-MRI+DWI-MRI showed 13.79% sensitivity and 76.92% specificity and T2-MRI+DWI-MRI+DGE-MRI showed 71.43% sensitivity and 92.86% specificity. T2-MRI+DWI-MRI+DGE-MRI showed higher accuracy over T2-MRI and T2+DWI-MRI for predicting parametrial invasion (97.62% versus 83.33% versus 92.86%), vaginal invasion (95.24% versus 85.71% versus 83.33%) and nodal metastases (85.71% versus 64.29% versus 64.29%) and assigned the highest number of patients to the correct FIGO stage (33 of 42 versus 13 of 42 versus 23 of 42).

CLINICAL RELEVANCE/APPLICATION

Better detection of locoregional tumor extent after neoadjuvant chemotherapy by delayed Gadolinium-enhanced MRI may improve therapeutic decision making towards operability.

PH04-D1   Comparison Of Acoustic Noise Between Silent Sequence And Conventional Sequence MRI In Head Examinations

Participants
Shumeng Zhu, Xi'an, China (*Presenter*) Nothing to Disclose

PURPOSE

To measure the acoustic noise level of each sequence in conventional and silent MRI at 3.0T scanner (Discovery 750W; GE Medical system, Milwaukee, WI), and compare the difference between them.*Methods and Materials The acoustic noise level was detected in different locations, including the locations of the patient head, foot, and the scanner operator, and the area near the patient table where often a family member of the patient stands. The protocol package of head scan of conventional sequences includes T2 Flair Propeller, T2 Propeller, and 3D-T1 FSPGR; while the silent sequences contain Silent T2 Flair, Silent T2 Propeller, and Silent MR T1. The former two T2 sequences reduced acoustic noise by derating gradient slew rate and optimized gradient wave form of PROPELLER sequence, while the latter T1 sequence uses a different approach by eliminating the noise at the source: silent technique. Silent technique is a novel data acquisition method in which the gradients are used continuously, but are not rapidly switched on or off. Since the gradients are no longer switched on and off, mechanical vibration is eliminated and much reduced noise is generated during the acquisition. We measured the peak and equivalent of sound pressure level (SPL) of each sequence at the locations mentioned above using a special noise meter (BSWA 801; Beijing Shengwang Acoustic and Electromagnetic Technology), each of which was tested for 20 seconds and measured continuously for 3 times, and the average was measured as the result. The acoustic noise levels between conventional and silent MRI were evaluated quantitatively.*Results The peak-SPL of the silent sequence(94.87 ± 7.45dBA) is obviously lower than that of the conventional sequence noise(130.13 ± 0.40dBA), $p<0.05$. The equivalent-SPL of the silent sequence(81.57 ± 7.10dBA) is obviously lower than that of the conventional sequence noise(116.67 ± 2.72dBA), $p<0.05$. The maximum difference of peak-SPL between the two sequence is 42.7dBA and the maximum difference of equivalent-SPL between the two sequence is 45.1dBA.*Conclusions The silent sequence can significantly reduce the acoustic noise in the head MRI at 3.0T. Consequently, it should reduce the physical or psychological discomfort caused by high acoustic noise and improve the success rate of MRI scans.*Clinical Relevance/Application Reducing noise, reducing the physical or psychological discomfort and improving the success rate of MRI scans.

RESULTS

The peak-SPL of the silent sequence(94.87 ± 7.45dBA) is obviously lower than that of the conventional sequence noise(130.13 ± 0.40dBA), $p<0.05$. The equivalent-SPL of the silent sequence(81.57 ± 7.10dBA) is obviously lower than that of the conventional sequence noise(116.67 ± 2.72dBA), $p<0.05$. The maximum difference of peak-SPL between the two sequence is 42.7dBA and the maximum difference of equivalent-SPL between the two sequence is 45.1dBA.

CLINICAL RELEVANCE/APPLICATION

Reducing noise, reducing the physical or psychological discomfort and improving the success rate of MRI scans.

PH04-D11   Deep Learning-Based Motion-Resolved 4D MRI

Participants
Ramin Jafari, BS, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Free-breathing MR imaging is an emerging technique with important clinical relevance to address limitations of breath-hold sequences and enable access to motion information. Recently, there has been interest in real-time motion-resolved free-breathing MR imaging with application in MRI-guided radiation therapy. This work proposes to use a deep learning approach named XD-Net to replace the iterative XD-GRASP reconstruction algorithm by a neural network and enable reconstruction of motion-resolved 4D MR images in seconds rather than tens of minutes.*Methods and Materials Free-breathing 3D abdominal imaging was performed on seven healthy volunteers (without contrast injection) and seven patients (post-contrast injection) on 3T scanners (Discovery MR750 and Signa Premier, GE Healthcare, Waukesha, WI). A prototype T1-weighted golden-angle stack-of-stars pulse sequence was used and a total of 900 spokes were acquired, with a total scan time of approximately 2 minutes.XD-GRASP reconstruction: Ten respiratory motion-states (90 spokes in each state) were generated by sorting the continuously acquired data and iterative XD-GRASP reconstruction was performed to generate motion-resolved artifact-free images from undersampled multi-coil radial data.XD-Net reconstruction: A 2D convolutional neural network was designed with 10 layers and the network was trained using XD-GRASP reconstruction as a reference. Several runs were performed, where one subject was selected as a test set, and the remaining cases were augmented and split into training (80%) and validation (20%).*Results Reconstruction time for XD-GRASP (60 slices) was approximately 138 minutes. Reconstruction time for the proposed XD-Net was only 10 seconds, which represents an 800-fold reduction in reconstruction time. Comparison of the proposed XD-Net with the reference XD-GRASP in a healthy subject (Fig1., left) and metastasis patient (Fig.1, right) demonstrates good qualitative and quantitative agreement.*Conclusions The proposed XD-Net can achieve an 800-fold reduction in reconstruction time compared to the current XD-GRASP reconstruction for motion-resolved 4D imaging without image quality degradation. Future work will be focused to use deep learning for the motion

sorting component and clinical application of the technique to various motion prone dynamic imaging scenarios.*Clinical Relevance/Application XD-Net is a promising approach to almost real-time reconstruction of motion-resolved data, which will enable robust clinical translation in cases where MRI results are needed shortly after finishing acquisition, including MRI-guided radiotherapy.

RESULTS

Reconstruction time for XD-GRASP (60 slices) was approximately 138 minutes. Reconstruction time for the proposed XD-Net was only 10 seconds, which represents an 800-fold reduction in reconstruction time. Comparison of the proposed XD-Net with the reference XD-GRASP in a healthy subject (Fig1., left) and metastasis patient (Fig.1, right) demonstrates good qualitative and quantitative agreement.

CLINICAL RELEVANCE/APPLICATION

XD-Net is a promising approach to almost real-time reconstruction of motion-resolved data, which will enable robust clinical translation in cases where MRI results are needed shortly after finishing acquisition, including MRI-guided radiotherapy.

PH04-D12   Research On The Application Value Of Revolution 256-slice Spectrum CT Optimal Single Energy Imaging In Hepatic Portal Vein Imaging

Participants
Junli Ma, Shizuishan, China (*Presenter*) Nothing to Disclose

PURPOSE

To Investigation of optimal monoenergetic energy image in hepatic portal vein (HPV) imaging using 256-row spectral CT.*Methods and Materials A total of 60 patients underwent enhanced upper abdominal examination were selected, 37 males and 23 females, with an average age of 59.18±16.72 years. All patients were scanned using the wide-body detector Revolution 256-row CT spectral imaging mode (GSI). The CT value and SD value of hepatic portal vein and subcutaneous fat were measured every 1 keV at the level of 40-140 keV (a total of 101 keV single energy levels) in the portal phase. CT value, SD value and signal-to-noise ratio (SNR=CTHPV/SDfat) of 101 groups of monoenergetic image (40keV-140keV) hepatic portal veins and fat were measured. SD of fat were used as background noise. Two senior physicians used double-blind methods to evaluate the portal phase single energy level images of 40-140keV on the AW workstation (GE Healthcare), fixed the window width and window level (WW=400, WL=40).*Results Two senior doctors used double-blind method to evaluate the optimal single energy of the images respectively. The consistency test was performed with the ICC intra-group correlation coefficient, ICC=0.810 (p<0.001). Taking the average value of the best monoenergetic image evaluated by two radiologists, the optimal single energy range is 62-73 keV, and the median is 68 keV. The SNR curve shows that the SNR gradually decreases with the increase of single energy 40-140kev. The CT value for HPV at 40, 62, 68, 74, 100 keV was 453.02, 207.13, 174.60, 149.43 and 90.81 HU, SD for fat was 35.92, 19.08,16.85, 15.16 and 11.23 HU,and SNR was 13.37,11.53,11.03,10.50,8.67, respectively. That is, at 40keV, the image has good signal-to-noise ratio, but high image noise is the largest, and the quality is poor; at 140keV, the image noise is low, but the image signal-to-noise ratio is poor, combined with the optimal monoenergetic energy range obtained by subjective evaluation the optimal single energy is 68 keV.*Conclusions Revolution 256-row energy spectrum CT hepatic portal vein imaging has the optimal single energy median of 68 keV (the optimal monoenergetic image range is about 62-73 keV), which significantly improves the image quality.*Clinical Relevance/Application When the optimal single energy 68keV is used for hepatic portal vein imaging, the image quality can be significantly improved, which is beneficial to observe whether the portal vein has thrombosis, cancer thrombus, and collateral circulation. In this study, the optimal single energy median of energy spectrum CT hepatic portal vein imaging is 68 keV (the optimal monoenergetic range is about 62-73 keV), which has guiding significance for the clinical application of energy spectrum in the abdomen.

RESULTS

Two senior doctors used double-blind method to evaluate the optimal single energy of the images respectively. The consistency test was performed with the ICC intra-group correlation coefficient, ICC=0.810 (p<0.001). Taking the average value of the best monoenergetic image evaluated by two radiologists, the optimal single energy range is 62-73 keV, and the median is 68 keV. The SNR curve shows that the SNR gradually decreases with the increase of single energy 40-140kev. The CT value for HPV at 40, 62, 68, 74, 100 keV was 453.02, 207.13, 174.60, 149.43 and 90.81 HU, SD for fat was 35.92, 19.08,16.85, 15.16 and 11.23 HU,and SNR was 13.37,11.53,11.03,10.50,8.67, respectively. That is, at 40keV, the image has good signal-to-noise ratio, but high image noise is the largest, and the quality is poor; at 140keV, the image noise is low, but the image signal-to-noise ratio is poor, combined with the optimal monoenergetic energy range obtained by subjective evaluation the optimal single energy is 68 keV.

CLINICAL RELEVANCE/APPLICATION

When the optimal single energy 68keV is used for hepatic portal vein imaging, the image quality can be significantly improved, which is beneficial to observe whether the portal vein has thrombosis, cancer thrombus, and collateral circulation. In this study, the optimal single energy median of energy spectrum CT hepatic portal vein imaging is 68 keV (the optimal monoenergetic range is about 62-73 keV), which has guiding significance for the clinical application of energy spectrum in the abdomen.

PH04-D3   Pulmonary Z-score: A New CT Imaging Biomarker For Quantifying Pulmonary Perfusion Defects

Participants
Ke Li, PhD, Madison, Wisconsin (*Presenter*) Research Consultant, Pulmera Inc.

PURPOSE

Iodine basis images generated from dual-energy CT (DECT) have been used to assess lung perfusion defects. The underlying assumption is that the amount of iodine signal is correlated with the amount of perfused blood volume in the lung. However, the amount of iodine measured in the iodine basis image is often confounded by the presence of high-density materials, not necessarily iodine, in the lung. As a result, the quantification accuracy of lung perfusion defects using DECT is limited. The purpose of this work was to develop and validate a new DECT-derived biomarker (Z-score) to achieve quantitative pulmonary perfusion assessment.*Methods and Materials A first-principle analysis was performed to discover a quantitative relationship between the pulmonary perfusion blood volume (PBV) and a new quantitative biomarker, i.e., Z-score value, which is defined as a power function of the effective atomic number. The proposed Z-score method was compared against the corresponding iodine quantification analysis and the results were benchmarked by the ground truth clinical diagnosis.*Results For patients with both acute pulmonary embolism (PE) and virus pneumonia, the Z-score maps clearly demonstrated regional perfusion defects in the area supplied by the embolized vessels, while the iodine images failed to demonstrate the defects because pneumonia-induced consolidations elevated

the local tissue density and counteracted the reduction of iodine uptake in the area. For patients with chronic PE or pulmonary hypertension, Z-score maps provide a much clearer depiction of the global or regional perfusion defects (mean PBV: 25 [20, 30] ml/100g). For a patient with atelectasis and pleural effusion but normal perfusion, Z-score maps show normal perfusion while the iodine basis images erroneously show an apparent perfusion disparity. For healthy control subjects, Z-score maps show uniform and normal perfusion with a mean PBV value of 40 [37, 43] ml/100g.*Conclusions The Z-score is a sensitive and specific imaging biomarker for detecting and quantifying potential pulmonary perfusion defects.*Clinical Relevance/Application The method directly benefits the diagnosis and prognosis of PE and other pulmonary diseases by enabling simultaneous vessel morphology and perfusion assessment with a single DECT acquisition.

RESULTS

For patients with both acute pulmonary embolism (PE) and virus pneumonia, the Z-score maps clearly demonstrated regional perfusion defects in the area supplied by the embolized vessels, while the iodine images failed to demonstrate the defects because pneumonia-induced consolidations elevated the local tissue density and counteracted the reduction of iodine uptake in the area. For patients with chronic PE or pulmonary hypertension, Z-score maps provide a much clearer depiction of the global or regional perfusion defects (mean PBV: 25 [20, 30] ml/100g). For a patient with atelectasis and pleural effusion but normal perfusion, Z-score maps show normal perfusion while the iodine basis images erroneously show an apparent perfusion disparity. For healthy control subjects, Z-score maps show uniform and normal perfusion with a mean PBV value of 40 [37, 43] ml/100g.

CLINICAL RELEVANCE/APPLICATION

The method directly benefits the diagnosis and prognosis of PE and other pulmonary diseases by enabling simultaneous vessel morphology and perfusion assessment with a single DECT acquisition.

PH04-D4 Evaluation Of The Chemical Composition Of Kidney Stones Using Dual-energy Spectral CT In Gout Patients

Participants
Xiaohu Li, MD, Hefei, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the prevalence of uric acid(UA) kidney stones with dual-energy spectral CT (DESCT) and explore the risk factors for nephrolithiasis in primary gout patients.*Methods and Materials 152 consecutive gout patients underwent urinary ultrasound or DESCT to confirm the existence of nephrolithiasis. Urinalysis and Blood analysis were also taken.*Results Fifty patients(32.9%)were diagnosed as urolithiasis. Fifty patients of the 152 patients underwent a DESCT scan, and 43 patients had urinary stones in DESCT. Twenty-nine patients had multiple calculi. The mean size of the calculi was 8.3 mm (range, 1.2-24.0 mm). Among them, 27.9% (12/43) of the patients had pure UA, 39.5% (17/43) of the patients had UA-based mixed stone and 32.6%(14/43) had Calcium oxalate or Calcium phosphate compositions in the stone.Gout patients with urinary stones suffered from more frequency of acute gout attacks and had longer symptom duration of gout. DESCT Shows the accumulation of MSU in jointspoly arthritis(=5joints) 32(74.4%). 39(90.7%) of all patients had at least one bone erosion in the feet/ankles. 78.9% of patients had at least one biochemical abnormality. 74 (48.7%) patients presented hypomagnesuria. 23 (15.1%) patients presented hypercalciuria. 23 (15.1%) patients presented hyperuricosuiria. 44 (28.9%) had UAU. Among two groups, lithiasic patients were more likely to have hyperuricosuiria, while other abnormities were not significantly different(P>0.05).*Conclusions Our results indicated that urinary stones were more common in gout patients, especially UA stones, which was primarily due to low urine pH. DESCT can discriminate UA stones in vivo. Higher frequency of acute gout attacks and long symptom duration more often in gout-lithiasic.*Clinical Relevance/Application UA Urinary stones with DESCT and explore the risk factors for nephrolithiasis in primary gout patients.

RESULTS

Fifty patients(32.9%)were diagnosed as urolithiasis. Fifty patients of the 152 patients underwent a DESCT scan, and 43 patients had urinary stones in DESCT. Twenty-nine patients had multiple calculi. The mean size of the calculi was 8.3 mm (range, 1.2-24.0 mm). Among them, 27.9% (12/43) of the patients had pure UA, 39.5% (17/43) of the patients had UA-based mixed stone and 32.6%(14/43) had Calcium oxalate or Calcium phosphate compositions in the stone.Gout patients with urinary stones suffered from more frequency of acute gout attacks and had longer symptom duration of gout. UA Urinary stones with DESCT and explore the risk factors for nephrolithiasis in primary gout patients.

PH04-D9 Noise Suppression In Dual-energy Material Decomposition Using Total-variation Regularization

Participants
Qinghao Chen, PhD, St. Louis, Missouri (*Presenter*) Nothing to Disclose

PURPOSE

Dual-energy (DE) decomposition radiography that employs the non-linear model and seeks for the solution of the inverse problem is sensitive to image noise. The material decomposed images are often dominated by image noises especially when the DE x-ray beams have significant spectrum overlap. We developed an iterative DE decomposition method with noise suppression that can reduce the noise level while preserving the edges and contrast in the images.*Methods and Materials We established the non-linear DE decomposition model by the calibration of basis materials and polynomial approximation. The low and high energy x-ray images were acquired at 90 kVp and 140 kVp with a tin filter respectively. Water and bone images were obtained by minimizing a cost function with a fidelity term and a TV regularization term to suppress the noise while preserving the edges of the image feature. A monotone fast iterative shrinkage/thresholding algorithm (MFISTA) was employed to solve the inverse problem.*Results We tested the performance of the method by imaging animal cadaver. Two radiographs consisting of low energy and high energy images were acquired and decomposed to soft-tissue-only and bone-only images. Using TV regularization, the image noise was suppressed while the image edges remained sharp.*Conclusions Iterative DE decomposition based on the non-linear model and TV regularization was able to achieve improved material decomposition results. With the same dose level, the new DE decomposition algorithm is able to achieve improved visibility of anatomical features.*Clinical Relevance/Application The TV-based dual-energy decomposition method may be broadly employed in chest radiography for the diagnosis of cancer and COVID-19, as well as image-guided intervention and

radiotherapy.

RESULTS

We tested the performance of the method by imaging animal cadaver. Two radiographs consisting of low energy and high energy images were acquired and decomposed to soft-tissue-only and bone-only images. Using TV regularization, the image noise was suppressed while the image edges remained sharp.

CLINICAL RELEVANCE/APPLICATION

The TV-based dual-energy decomposition method may be broadly employed in chest radiography for the diagnosis of cancer and COVID-19, as well as image-guided intervention and radiotherapy.

HN03-A2   **Development And Validation Of CT-based Radiomics Nomogram For The Classification Of Benign Parotid Gland Tumors**

Participants

Menglong Zheng, Hefei, China (*Presenter*) Nothing to Disclose

PURPOSE

Accurate preoperative diagnosis of parotid tumor is essential for the formulation of optimal individualized surgical plans. The aim of this study is to investigate the diagnostic performance of radiomics nomogram based on contrast enhanced CT images in the differentiation of the two most common benign parotid gland tumors.*Methods and Materials 110 patients with parotid gland tumors including 76 with pleomorphic adenoma (PA) and 34 with adenolymphoma (AL) confirmed by histopathology were included in this study. Radiomics features were extracted from contrast enhanced CT images of venous phase. A radiomics model was established and a radiomics score (Rad-score) was calculated. Clinical factors including clinical data and CT features were assessed to build a clinical factor model. Finally, a nomogram incorporating the Rad-score and independent clinical factors was constructed. Receiver operator characteristics (ROC) curve was generated and the area under the ROC curve (AUC) was calculated to quantify the discriminative performance of each model on both the training and validation cohorts. Decision curve analysis (DCA) was conducted to evaluate the clinical usefulness of each model.*Results The radiomics model showed good discrimination in the training cohort (AUC 0.89; 95% CI, 0.80-0.98) and validation cohort (AUC 0.89; 95% CI, 0.77-1.00). The radiomics nomogram showed excellent discrimination in the training cohort (AUC, 0.98; 95% CI, 0.96-1.00) and validation cohort (AUC, 0.95; 95% CI, 0.88-1.00) and displayed better discrimination efficacy compared with the clinical factor model (AUC, 0.93; 95% CI, 0.88-0.99) in the training cohort (p < 0.05). The decision curve analysis demonstrated that the combined radiomics nomogram provided superior clinical usefulness than clinical factor model and radiomics model.*Conclusions The CT-based radiomics nomogram combining Rad-score and clinical factors exhibits excellent predictive capability for differentiating parotid PA from AL, which might hold promise in assisting radiologists and clinicians in the exact differential diagnosis and formulation of appropriate treatment strategy.*Clinical Relevance/Application In patients who were diagnosed with benign parotid tumors preoperatively, our nomogram provided a promising tool to assist radiologists and clinicians in exact differential diagnosis and formulation of appropriate treatment strategy. For patients with parotid PA, a partial superficial parotidectomy is recommended. In contrast, enucleation is sufficient for patients with AL.

RESULTS

The radiomics model showed good discrimination in the training cohort (AUC 0.89; 95% CI, 0.80-0.98) and validation cohort (AUC 0.89; 95% CI, 0.77-1.00). The radiomics nomogram showed excellent discrimination in the training cohort (AUC, 0.98; 95% CI, 0.96-1.00) and validation cohort (AUC, 0.95; 95% CI, 0.88-1.00) and displayed better discrimination efficacy compared with the clinical factor model (AUC, 0.93; 95% CI, 0.88-0.99) in the training cohort (p < 0.05). The decision curve analysis demonstrated that the combined radiomics nomogram provided superior clinical usefulness than clinical factor model and radiomics model.

CLINICAL RELEVANCE/APPLICATION

In patients who were diagnosed with benign parotid tumors preoperatively, our nomogram provided a promising tool to assist radiologists and clinicians in exact differential diagnosis and formulation of appropriate treatment strategy. For patients with parotid PA, a partial superficial parotidectomy is recommended. In contrast, enucleation is sufficient for patients with AL.

HN03-A3   **The Reproducibility Of T2 Relaxation Time For Temporomandibular Joint (TMJ) Assessment With A 3.0 T MRI**

Participants

Pongsapak Wongratwanich, DDS, Hiroshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the intra- and inter-examination reproducibility of T2 relaxation time for TMJ at 3.0 Tesla (T).*Methods and Materials Sixteen volunteers, regardless of any TMJ disorders, were enrolled in the study. MRI was performed using a 3.0 T MR imaging scanner equipped with a dStream head 32ch coil (Philips Ingenia, Philips Healthcare, Netherlands). T2 mapping was taken twice in 11 volunteers (>5 minutes between two sessions without repositioning) in the oblique sagittal planes for intra-examination reproducibility evaluation. Seven volunteers underwent two separate examinations more than six months apart for inter-examination reproducibility evaluation. The regions of interest (ROIs) for T2 mapping sequences of articular disc and retrodiscal tissue were manually selected.*Results The mean values of T2 relaxation times of articular disc in 11 volunteers were 23.4 ± 2.1 and 23.7 ± 3.1 ms for the first and second T2 mapping sequences, respectively. Retrodiscal tissue mean values were 29.6 ± 3.3 ms for the first sequence and 29.8 ± 4.2 ms for the second sequence. Intra-examination reproducibility of T2 relaxation times measured in articular disc and retrodiscal tissue showed intraclass correlation coefficients (ICCs) as good (0.707) and strong (0.904) correlation, respectively. Pearson's correlation was also conducted and found no significant differences comparing T2 relaxation times between 2 sessions for both articular disc (r = 0.758) and retrodiscal tissue (r = 0.924) (P < 0.05). Seven volunteers showed mean values of 24.7 ± 3.4 ms for the first examination and 26.4 ± 4.1 ms for the second examination of articular disc. T2 mean values of

retrodiscal tissue were 30.6 ± 4.7 and 29.6 ± 5.1 ms for the first and second examination, respectively. Inter-examination reproducibility demonstrated ICCs as good (0.758, 0.771) on both ROIs. T2 relaxation times between first and second examination were not significantly different (r = 0.745, 0.780) (P < 0.05).*Conclusions Due to good to strong ICCs of intra- and inter-examination reproducibility in volunteers, the 3.0 T MRI machine seems to be a promising tool for T2 mapping regardless of TMJ's condition.*Clinical Relevance/Application T2 relaxation time is a biochemical value used to assess TMJ pathology. A 3.0 T MRI provides a proper selection of ROIs, leading to a more accurate TMJ disorder diagnosis.

RESULTS

The mean values of T2 relaxation times of articular disc in 11 volunteers were 23.4 ± 2.1 and 23.7 ± 3.1 ms for the first and second T2 mapping sequences, respectively. Retrodiscal tissue mean values were 29.6 ± 3.3 ms for the first sequence and 29.8 ± 4.2 ms for the second sequence. Intra-examination reproducibility of T2 relaxation times measured in articular disc and retrodiscal tissue showed intraclass correlation coefficients (ICCs) as good (0.707) and strong (0.904) correlation, respectively. Pearson's correlation was also conducted and found no significant differences comparing T2 relaxation times between 2 sessions for both articular disc (r = 0.758) and retrodiscal tissue (r = 0.924) (P < 0.05). Seven volunteers showed mean values of 24.7 ± 3.4 ms for the first examination and 26.4 ± 4.1 ms for the second examination of articular disc. T2 mean values of retrodiscal tissue were 30.6 ± 4.7 and 29.6 ± 5.1 ms for the first and second examination, respectively. Inter-examination reproducibility demonstrated ICCs as good (0.758, 0.771) on both ROIs. T2 relaxation times between first and second examination were not significantly different (r = 0.745, 0.780) (P < 0.05).

CLINICAL RELEVANCE/APPLICATION

T2 relaxation time is a biochemical value used to assess TMJ pathology. A 3.0 T MRI provides a proper selection of ROIs, leading to a more accurate TMJ disorder diagnosis.

PD05-A1   Automated Bone Age Assessment In A Retrospective Cohort Of German Children From The Clinical Routine: Agreement Between Ai And Expert Readers

Participants
Matthew DiFranco, Vienna, Austria (*Presenter*) Chief Scientific Officer, IB Lab GmbH

PURPOSE

In this study we evaluate the agreement between AI and expert readers for bone age (BA) assessment according to the Greulich & Pyle method.*Methods and Materials Radiographs of 259 patients were analyzed retrospectively (133 males aged 2 to 17 years, 126 females aged 2 to 16 years). Two pediatric radiologists and one pediatric endocrinologist made blind reads of BA using the Greulich & Pyle (GP) method independently, and an AI-software was subsequently used to estimate BA from the same images. Agreement of AI with readers was assessed based on mean absolute deviation (MAD) and root mean squared deviation (RMSD), as well as via comparison of Bland-Altman limits of agreement (LOA).*Results MAD and RMSD of AI vs. reader average (0.51 and 0.66 years) was less than that for the mean of three reader pairs (0.66 and 0.86 years, p<0.05 for each reader pair). Bland-Altman LOA between AI and reader average was (-1.22, 1.35 years), well within the mean LOAs of the three reader pairings (-1.62, 1.75 years).*Conclusions A fully automated AI software shows agreement with expert readers in BA assessment on a cohort of German children and adolescents, suggesting AI integration into the radiology workflow is possible and could lead to more efficient bone age reading.*Clinical Relevance/Application The radiological determination of BA from a left-hand x-ray continues to be the reference standard for skeletal maturity assessment related to short or long stature, premature or delayed puberty, and underlying conditions. Artificial intelligence (AI) algorithms are becoming more prevalent due to the subjectivity and time-consuming nature of BA assessment.

RESULTS

MAD and RMSD of AI vs. reader average (0.51 and 0.66 years) was less than that for the mean of three reader pairs (0.66 and 0.86 years, p<0.05 for each reader pair). Bland-Altman LOA between AI and reader average was (-1.22, 1.35 years), well within the mean LOAs of the three reader pairings (-1.62, 1.75 years).

CLINICAL RELEVANCE/APPLICATION

The radiological determination of BA from a left-hand x-ray continues to be the reference standard for skeletal maturity assessment related to short or long stature, premature or delayed puberty, and underlying conditions. Artificial intelligence (AI) algorithms are becoming more prevalent due to the subjectivity and time-consuming nature of BA assessment.

PD05-A2   Impact Of Patient Shielding Discontinuation On Repeat Rates And Speed Of Service In Pediatric Digital Radiography

Participants
Jan Pachon, chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study is to compare clinical repeat rates (RR) and speed of service of pediatric digital radiography before and after discontinuing the routine use of patient shielding. Many years of research have shown that shields provide negligible benefits to patients while the associated risks of shielding can be substantial. It is for this reason that the AAPM and other professional societies have recommended to eliminate the routine use of patient shields. In October 2020, we implemented this recommendation and only provided a shield at the request of the patient. We assess how the discontinuation of all routine patient shielding has impacted RR and speed of service.*Methods and Materials The RR and reasons for repeated digital radiographs were documented over the course of 19 months, 12 months during which patient shielding was routinely used and 7 months after shields were discontinued. Shielding related repeats were documented as either patient motion or artifacts whenever a shield interfered with the exam quality. We compared the RR of these repeat reasons with and without routine shielding for abdomen and pelvis exams. We also evaluated speed of service before and after shielding discontinuation by getting the difference between exam time as stamped in the RIS to the time of image availability on PACS. To minimize the time technologists spend explaining the change in practice, we developed a patient awareness campaign called "So long Shields!".*Results The average RR of digital radiographs with routine shielding due to patient motion was 10.06%±0.34 and 7.7%±0.25 due to artifacts. In the span of seven months after shielding was discontinued, the average patient motion related RR was 7.43%±0.37 and 5.84%±0.36 from artifacts. These results indicate a ~2.6% and 1.9% decrease (p<0.05) in patient motion and artifact related repeats, respectively, without shielding (figure. 1). A comparison of RR for abdomen and pelvis exams before and after shielding discontinuation shows a decrease in motion related repeats of ~9% and ~1.8% for abdomen and pelvis exams, respectively. An evaluation of speed of service indicates negligible differences (p>0.05) when shielding was discontinued (figure. 2).*Conclusions We found the overall RR without routine patient shielding significantly lower than when shielding was routinely used. This is particularly true for abdomen and pelvis exams where patient motion could cause a shield to move and obscure anatomy. We were also able to show that through a patient awareness campaign on the rationale for not shielding, speed of service was not impacted.*Clinical Relevance/Application Based on our findings, we encourage other institutions to assess their own departmental RRs and consider discontinuing all routine patient

shielding.

RESULTS

The average RR of digital radiographs with routine shielding due to patient motion was 10.06%±0.34 and 7.7%±0.25 due to artifacts. In the span of seven months after shielding was discontinued, the average patient motion related RR was 7.43%±0.37 and 5.84%±0.36 from artifacts. These results indicate a ~2.6% and 1.9% decrease (p<0.05) in patient motion and artifact related repeats, respectively, without shielding (figure. 1). A comparison of RR for abdomen and pelvis exams before and after shielding discontinuation shows a decrease in motion related repeats of ~9% and ~1.8% for abdomen and pelvis exams, respectively. An evaluation of speed of service indicates negligible differences (p>0.05) when shielding was discontinued (figure. 2).

CLINICAL RELEVANCE/APPLICATION

Based on our findings, we encourage other institutions to assess their own departmental RRs and consider discontinuing all routine patient shielding.

SDP-IR-10   **Comparing Midterm Clinical Outcomes Of Subintimal Angioplasty Vs Primary Stenting In TASC C And D Superficial Femoral Artery Disease**

Participants
Ansan Joseph, MD, Ahmedabad, India (*Presenter*) Nothing to Disclose

PURPOSE

There is still no definitive consensus regarding primary or selective stenting in TASC C and D lesions superficial femoral arterial disease (SFAD). The aim of this study was to compare clinical outcomes of subintimal angioplasty vs primary stenting in TASC C AND D SFAD.*Methods and Materials A single centre retrospective analysis was performed of all consecutive patients undergoing endovascular treatment for TASC C and D SFAD from 2018 to 2021. Primary endpoints were primary and secondary clinical patency rates. Secondary endpoints were ulcer healing, amputation free survival rate, limb salvage rate, improvement in ABPI, rest and claudication pain and occurrence of major adverse cardiac events, Kaplan-Meier curves were used to compare patency rates. Multivariable Cox regression analysis was performed to adjust for confounding variables which may affect patency rates*Results A total of 55 patients were analysed with a median follow up of 30 months. 17 patients (30.9%) were stented(PTA-S group). Primary clinical patency rates at 12,18 and 24 months were 88%, 85%, and 82% after subintimal angioplasty (PTA group)and 90%, 88%, and 86% after stent placement(PTA-S group) respectively. Secondary patency rates were also comparable for the PTA and PTA-S group. Multivariable analysis showed comparable primary and secondary clinical patency between both the groups. The re-intervention rate, amputation free survival rate, limb salvage rate did not significantly differ between the two groups.*Conclusions The clinical outcomes of patients with TASC C AND D Superficial Femoral artery disease treated with subitimal angioplasty alone is comparable with primary stenting in mid term followup. So an approach of optional stenting can be followed in these patients with cost effectiveness and good clinical outcomes.*Clinical Relevance/Application There is still no definitive consensus regarding primary or selective stenting in TASC C and D lesions superficial femoral arterial disease (SFAD). Our study suggests that by performing optional stenting only in cases with residual dissections/stenosis post angioplasty will lead to good clinical outcomes and bring down the treatment cost significantly.

RESULTS

A total of 55 patients were analysed with a median follow up of 30 months. 17 patients (30.9%) were stented(PTA-S group). Primary clinical patency rates at 12,18 and 24 months were 88%, 85%, and 82% after subintimal angioplasty (PTA group)and 90%, 88%, and 86% after stent placement(PTA-S group) respectively. Secondary patency rates were also comparable for the PTA and PTA-S group. Multivariable analysis showed comparable primary and secondary clinical patency between both the groups. The re-intervention rate, amputation free survival rate, limb salvage rate did not significantly differ between the two groups.

CLINICAL RELEVANCE/APPLICATION

There is still no definitive consensus regarding primary or selective stenting in TASC C and D lesions superficial femoral arterial disease (SFAD). Our study suggests that by performing optional stenting only in cases with residual dissections/stenosis post angioplasty will lead to good clinical outcomes and bring down the treatment cost significantly.

SDP-IR-11   **Interventional Oncolytic Therapy For Residual Tumor After Incomplete Radiofrequency Ablation**

Participants
Guanhui Zhou, MD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the feasibility of interventional oncolytic therapy for residual tumor after incomplete radiofrequency ablation (iRFA).*Methods and Materials This study included in vitro experiments using VX2 tumor cells and in vivo validation experiments on rabbit models with VX2 liver cancer. The content included (1) optimizing ICG dose and ICG time-window for intracellular uptake by VX2 tumor cells;; and (2) validating the feasibility using ICG-based OI to assess efficacy of RFH-enhanced oncolytic therapy (LTX-315) for treatment of same cancers. The cells treatment was divided into four groups: (1) RFH alone at 42?°C for 30?min; (2) oncolytic therapy with LTX-315 alone; (3) combination therapy of oncolytic therapy plus RFH; and (4) saline to serve as a control group. The residual tumor treatment of rabbits in three group (n=6/group) were were treated by:(1) 2-mg LTX-315; (2) 4-mg LTX-315; and (3) saline to serve as a control group. MTS assay, fluorescence microscopy, and flow cytometry were used to compare cell viabilities and apoptosis. Optical imaging of ICG was performed using Bruker optical/x-ray imaging system. For in vivo validation, LTX-315 was directly infused into rabbit residual liver cancer after iRFA treatment through a multi-functional perfusion-thermal RF electrode. Ultrasound were used to follow up size of tumors overtime, which were correlated with subsequent histology.*Results For in vitro experiments, ICG taken up by tumor cells was linearly increased from 0 to 100 μg/mL with the optimized concentration at 100 μg/mL, while ICG-SI reached the peak at 24 hours. MTS assay and apoptosis analysis demonstrated the lowest cell viability and highest apoptosis in combination therapy, compared to other three groups (p<0.001). ICG-enhanced interventional optical imaging showed a significantly decreased SI in combination therapy, which was confirmed by the optical/x-ray imaging. For in vivo experiments, ultrasound imaging showed the smaller tumor volume in 2-mg LTX-315 therapy group compared to control group (p < .05), and all the tumors were observed to disappear in the 4-mg LTX-315 treatment group, which were well correlated with

pathologic analysis.*Conclusions It is feasible of interventional oncolytic therapy of residual liver cancer after iRFA through RFH-enhanced effect and apoptotic/anti-tumor immunity pathways, which may open new avenues to prevent residual or recurrent disease of thermally ablated intermediate-to-large liver cancer.*Clinical Relevance/Application Interventional oncolytic therapy can be used for treatment of residual tumor after incomplete radiofrequency ablation (iRFA)

RESULTS

For in vitro experiments, ICG taken up by tumor cells was linearly increased from 0 to 100 μg/mL with the optimized concentration at 100 μg/mL, while ICG-SI reached the peak at 24 hours. MTS assay and apoptosis analysis demonstrated the lowest cell viability and highest apoptosis in combination therapy, compared to other three groups (p<0.001). ICG-enhanced interventional optical imaging showed a significantly decreased SI in combination therapy, which was confirmed by the optical/x-ray imaging. For in vivo experiments, ultrasound imaging showed the smaller tumor volume in 2-mg LTX-315 therapy group compared to control group (p < .05), and all the tumors were observed to disappear in the 4-mg LTX-315 treatment group, which were well correlated with pathologic analysis.

CLINICAL RELEVANCE/APPLICATION

Interventional oncolytic therapy can be used for treatment of residual tumor after incomplete radiofrequency ablation (iRFA)

SDP-IR-12   Creation Of A Novel 3D-Printed Benchtop Simulator For Percutaneous Transhepatic Cholangioscopy

Participants
David Gullotti, MD, Baltimore, Maryland (*Presenter*) Co-founder, SpineAlign Medical, Inc

PURPOSE

To create a 3D-printed benchtop simulator that enables trainees to practice endoscopic manipulation and interventions such as stone retrieval under ether direct or fluoroscopic visualization.*Methods and Materials A 3D model representing the gallbladder, cystic, hepatic, and common bile ducts was created using Solidworks computer aided design software. A hobbyist-grade 3D printer (Prusa i3 MKSS, Czech Republic) was used to print the two-part model using Prusament Polylactic Acid (PLA) filament. Screw holes were tapped to accommodate 10-32 radiolucent nylon screws . A laser cutter (Universal Laser systems, USA) cut ¼" acrylic sheets with a matching contour to the underlying 3D-printed model. A cholangioscope (Boston Scientific, USA) was used within the channels of the printed model, and fluoroscopic images were obtained.*Results The benchtop model accommodated the cholangioscope throughout its intraluminal channels and an introducer sheath within the gallbladder access site. Both anterograde and retrograde ductal access was obtained. The multiple branch design of the hepatic ducts enabled the user to practice scope location awareness and targeted navigation. The disassembling, two-part design allowed for placement of simulated obstructing stones with which retrieval could be practiced. The radiolucent build materials allowed for visualization with fluoroscopic imaging and the optional clear acrylic top allowed for direct visualization, although this resulted in minor glare from reflected light.*Conclusions This work presents the design and successful use of a novel tool for trainees to practice scope positional awareness, manipulation, and associated biliary interventions with either direct or fluoroscopic visualization.*Clinical Relevance/Application The applications of percutaneous transhepatic cholangioscopy (PTCS) are expanding within Interventional Radiology. This in-house model enables trainees to practice endoscope manipulation and treatment maneuvers.

RESULTS

The benchtop model accommodated the cholangioscope throughout its intraluminal channels and an introducer sheath within the gallbladder access site. Both anterograde and retrograde ductal access was obtained. The multiple branch design of the hepatic ducts enabled the user to practice scope location awareness and targeted navigation. The disassembling, two-part design allowed for placement of simulated obstructing stones with which retrieval could be practiced. The radiolucent build materials allowed for visualization with fluoroscopic imaging and the optional clear acrylic top allowed for direct visualization, although this resulted in minor glare from reflected light.

CLINICAL RELEVANCE/APPLICATION

The applications of percutaneous transhepatic cholangioscopy (PTCS) are expanding within Interventional Radiology. This in-house model enables trainees to practice endoscope manipulation and treatment maneuvers.

SDP-IR-13   Downstaging Locally Advanced Pancreatic Cancer To Resectability: Perivascular Ablation Using An Intra-arterial Balloon Laser Catheter In Pigs

Participants
Franz E. Boas, MD,PhD, Duarte, California (*Presenter*) Co-founder, CLARIPACS, LLC;Investor, Labdoor;Investor, Qventus, Inc;Investor, CloudMedx;Investor, Notable Labs;Investor, XGenomes Corp;Research support, Bayer AG;Research support, General Electric Company;Speaker, Guerbet SA;Research Grant, Guerbet SA;Research support, Guerbet SA;Research support, STEBA Biotech NV;Research support, Terumo Corporation

PURPOSE

In 20-30% of non-metastatic pancreatic cancer, surgical resection is not possible because of involvement of crucial arteries such as the superior mesenteric artery (SMA). Ablation of perivascular tumor could potentially downstage these patients to allow pancreatectomy. Here, we present initial pre-clinical safety data on intra-arterial vascular targeted photodynamic therapy (VTP), using a balloon laser catheter to illuminate the perivascular tissues and activate the VTP agent.*Methods and Materials Percutaneous intra-arterial VTP was performed in 2 pigs, using a balloon laser catheter. From femoral artery access, an 8 F clear silicone balloon catheter was advanced into the right external iliac artery (which is the same size as the human SMA). A laser fiber with a 1 cm cylindrical diffuser was advanced into the balloon catheter. Heparin (100 U/kg) and a photosensitizer (WST-11, 4 mg/kg) were infused intravenously. The balloon was inflated with 1 ml of 50% contrast, and the laser fiber was illuminated (753 nm, 300 mW) for 20 minutes. The balloon was periodically deflated (1 minute every 5 minutes), and the catheter was flushed, to prevent clot formation and distal ischemia. Safety was evaluated by catheter angiography and necropsy after VTP ablation. Light delivery was evaluated with the balloon laser catheter placed in either saline or the common femoral artery (1 pig).*Results Catheter angiography after intra-arterial VTP showed no thrombus or arterial injury. Gross pathology showed no injury to the arterial wall. 82% of light energy was delivered 5 mm outside the balloon in the femoral artery, compared to saline.*Conclusions Endovascular VTP can be safely performed using a balloon laser catheter. Laser energy is delivered 360° around the artery, to a depth of at least 5 mm outside the artery.*Clinical Relevance/Application An intra-arterial balloon laser catheter, combined with an intravenous photosensitizer, could be used for non-thermal ablation of pancreatic tumors encasing the SMA, to downstage to resectability.

RESULTS

Catheter angiography after intra-arterial VTP showed no thrombus or arterial injury. Gross pathology showed no injury to the arterial wall. 82% of light energy was delivered 5 mm outside the balloon in the femoral artery, compared to saline.

CLINICAL RELEVANCE/APPLICATION

An intra-arterial balloon laser catheter, combined with an intravenous photosensitizer, could be used for non-thermal ablation of pancreatic tumors encasing the SMA, to downstage to resectability.

SDP-IR-14 Effect Timing Of Endovascular Repair On Long-term Outcomes Of Uncomplicated Acute Type B Aortic Dissection

Participants
Dongqiao Xiang, MD, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare 5-year outcomes of acute versus subacute thoracic endovascular aortic repair (TEVAR) in patients with uncomplicated acute type B aortic dissection (ATBAD).*Methods and Materials Between March 2008 and September 2018, 238 consecutive patients with uncomplicated ATBAD received the TEVAR treatment in the acute or subacute phase were retrospectively analyzed. The primary endpoints were all-cause death and aortic-related death. The second endpoint was composite outcomes of death from any cause or dissection-related severe complications. Inverse probability treatment weighting (IPTW) was used to balance baseline characteristics. Weight-adjusted Kaplan-Meier estimate with landmark analysis and weighted Cox model were performed to assess time-to-event outcomes.*Results In the IPTW-adjusted population, the 30-day mortality was 1.5% in the acute group and 0% in the subacute group (P = 0.24). The incidence of 30-day adverse events occurred in 16.8% and 6.9% patients in the acute and subacute group, respectively (P = 0.13). At 5 years, there was no statistically significant difference in all-cause death (hazard ratio [HR], 1.50; 95% confidence interval [CI], 0.59-3.81; P = 0.39) and aortic-related death (HR, 1.11; 95% CI, 0.34-3.60; P = 0.86) between two groups. The composite outcomes occurred in 30 (23.0%) patients in the acute group and 18 (22.3%) patients in the subacute group, respectively (HR, 0.67; 95% CI, 0.36-1.25; P = 0.20). There was a significant interaction between treatment effect and time (Pinteraction = 0.01), with a significantly higher incidence of the composite outcomes in the acute group at 1 year (HR, 0.25; 95% CI, 0.08-0.79; P = 0.02) but a lower incidence between 1 and 5 years (HR, 1.25; 95% CI, 0.56-2.76; P = 0.59).*Conclusions At 5-year follow-up, no significant differences exist in the all-cause death and aortic-related death between acute and subacute TEVAR. However, acute TEVAR is associated with an increased rate of severe complications within 1 year. Waiting until the subacute stage to perform TEVAR treatment may be the best option with a low risk of early complications and a favorable long-term prognosis.*Clinical Relevance/Application TEVAR in the subacute phase was associated with lower early complications and similar long-term survival compared with acute TEVAR in patients with uncomplicated acute type B aortic dissection. Waiting until the subacute stage to perform TEVAR treatment may be the best option.

RESULTS

In the IPTW-adjusted population, the 30-day mortality was 1.5% in the acute group and 0% in the subacute group (P = 0.24). The incidence of 30-day adverse events occurred in 16.8% and 6.9% patients in the acute and subacute group, respectively (P = 0.13). At 5 years, there was no statistically significant difference in all-cause death (hazard ratio [HR], 1.50; 95% confidence interval [CI], 0.59-3.81; P = 0.39) and aortic-related death (HR, 1.11; 95% CI, 0.34-3.60; P = 0.86) between two groups. The composite outcomes occurred in 30 (23.0%) patients in the acute group and 18 (22.3%) patients in the subacute group, respectively (HR, 0.67; 95% CI, 0.36-1.25; P = 0.20). There was a significant interaction between treatment effect and time (Pinteraction = 0.01), with a significantly higher incidence of the composite outcomes in the acute group at 1 year (HR, 0.25; 95% CI, 0.08-0.79; P = 0.02) but a lower incidence between 1 and 5 years (HR, 1.25; 95% CI, 0.56-2.76; P = 0.59).

CLINICAL RELEVANCE/APPLICATION

TEVAR in the subacute phase was associated with lower early complications and similar long-term survival compared with acute TEVAR in patients with uncomplicated acute type B aortic dissection. Waiting until the subacute stage to perform TEVAR treatment may be the best option.

SDP-IR-15 Long Term Improvement In Body Composition Of Cirrhotic Patients With Sarcopenia After Transjugular Intrahepatic Portosystemic Shunt Creation

Participants
Jiacheng Liu, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

Sarcopenia is a frequent complication in patients with cirrhosis. This study was aimed to evaluate the time-course changes of CT-based body composition in cirrhotic patients after transjugular intrahepatic portosystemic shunt (TIPS) placement.*Methods and Materials We retrospectively analyzed 224 patients who underwent TIPS procedure between August 2016 and May 2020. Skeletal muscle area (SMA), skeletal muscle index (SMI), subcutaneous fat area (SFA) and subcutaneous fat thickness (SFT) were evaluated through CT images at baseline and at 1-3, 3-6 and 9-12 months after TIPS placement.*Results After TIPS insertion, increasing age (HR 1.049, 95%CI 1.023-1.077), higher model for end-stage liver disease (MELD) score (HR 1.118, 95%CI 1.055-1.186) and lower SMI (HR 0.895, 95%CI 0.849-0.945) were identified as independent risk factors for mortality. In patients with sarcopenia, SMA and SMI increased significantly at 3-6 months post-TIPS and maintained a constant level at 9-12 months post-TIPS, while SFA and SFT increased significantly in males but not in females. However, in patients without sarcopenia, no significant difference was found in the variation tendency of SMA, SMI, SFA and SFT. Additionally, the mean ascitic-free weight and body mass index (BMI) increased significantly in sarcopenia patients but nonsignificantly in non-sarcopenia patients at 12 months after TIPS placement.*Conclusions Sarcopenia was independently associated with the risk of death and could be reversed after TIPS creation. The improvement of weight, BMI, skeletal muscle and subcutaneous fat mass following TIPS was more pronounced in sarcopenia patients compared with non-sarcopenia patients.*Clinical Relevance/Application In this work, we evaluated the time-course changes of CT-based body composition included skeletal muscle area (SMA), skeletal muscle index (SMI), subcutaneous fat area (SFA), subcutaneous fat thickness (SFT), weight and body mass index (BMI) in cirrhotic patients after transjugular intrahepatic portosystemic shunt (TIPS) placement. We found that sarcopenia was independently associated with the risk of death and could be reversed after TIPS creation. Additionally, the improvement of weight, BMI, skeletal muscle and subcutaneous fat mass following TIPS was more pronounced in sarcopenia patients compared with non-sarcopenia patients.

RESULTS

After TIPS insertion, increasing age (HR 1.049, 95%CI 1.023-1.077), higher model for end-stage liver disease (MELD) score (HR 1.118, 95%CI 1.055-1.186) and lower SMI (HR 0.895, 95%CI 0.849-0.945) were identified as independent risk factors for mortality. In patients with sarcopenia, SMA and SMI increased significantly at 3-6 months post-TIPS and maintained a constant level at 9-12 months post-TIPS, while SFA and SFT increased significantly in males but not in females. However, in patients without sarcopenia, no significant difference was found in the variation tendency of SMA, SMI, SFA and SFT. Additionally, the mean ascitic-free weight and body mass index (BMI) increased significantly in sarcopenia patients but nonsignificantly in non-sarcopenia patients at 12 months after TIPS placement.

CLINICAL RELEVANCE/APPLICATION

In this work, we evaluated the time-course changes of CT-based body composition included skeletal muscle area (SMA), skeletal muscle index (SMI), subcutaneous fat area (SFA), subcutaneous fat thickness (SFT), weight and body mass index (BMI) in cirrhotic patients after transjugular intrahepatic portosystemic shunt (TIPS) placement. We found that sarcopenia was independently associated with the risk of death and could be reversed after TIPS creation. Additionally, the improvement of weight, BMI, skeletal muscle and subcutaneous fat mass following TIPS was more pronounced in sarcopenia patients compared with non-sarcopenia patients.

SDP-IR-16   Percutaneous Transesophageal Gastric-tube Placement As A Viable Option For Patients Who Cannot Receive Conventional Enteral Access

Participants
Lisa Rotellini-Coltvet, Phoenix, Arizona (*Presenter*) Nothing to Disclose

PURPOSE

Percutaneous transesophageal gastric-tube (PTEG) placement is performed by interventional radiologists in patients with a contraindication to percutaneous gastrostomy.*Methods and Materials We retrospectively reviewed the medical records and imaging of patients who underwent PTEG placement within our multisite institution from 2014 to 2021. Demographics, clinical history, imaging, and outcomes for each patient were obtained and reviewed via electronic medical records to determine technical success rate, major and minor complications related to the procedure, relief of symptoms, time to discharge, PTEG associated readmissions, and catheter longevity.*Results Between 2014-2020, forty-six PTEG procedures were attempted. There were 23 males, 23 females with an average age of 56.3 years (range 22-83 years). Gastric venting from malignant bowel obstruction (42/46, 91.3%) was the most common indication for the procedure. The most common contraindication for percutaneous gastrostomy was peritoneal carcinomatosis (25/46, 54%) followed by ascites (23/46, 50%) and invasive gastric cancer (6/46, 13%). Median ECOG scores were 2.5 (range 1-4). Technical success in the placement of a PTEG was 44/46, 95.7%. In 1 patient, fibrosis due to radiation therapy precluded percutaneous access to the esophagus . Intraprocedural aspiration resulting from emesis during balloon inflation was reported (n=1; (2.2%)). The most common immediate post procedural issues reported were mild throat pain (n=1; 2.2%) which was resolved with oral viscous lidocaine. The most common delayed issue was migration of the PTEG (n=2). There was 1 death resulting from aspiration pneumonitis. Using the Edmonton Symptom Assessment Scale (ESAS) and the Karnofsky Performance Scale (KPS), patency rates and relief of obstructive symptoms were 100% at 0, 7, and 14 days on average post procedure.*Conclusions PTEG placement can provide symptomatic relief to terminally ill patients; ESAS and KPS scores were 100% up to 14 days post-placement. No association was identified between ECOG score and major/minor complication rates (p>0.05). PTEG is a viable option for venting given staff and patients are educated appropriately to prevent misuse.*Clinical Relevance/Application This study has introduced a novel technique to help patients gain symptomatic control of malignant small bowel obstruction who otherwise would not meet conventional criteria for traditional approaches.

RESULTS

Between 2014-2020, forty-six PTEG procedures were attempted. There were 23 males, 23 females with an average age of 56.3 years (range 22-83 years). Gastric venting from malignant bowel obstruction (42/46, 91.3%) was the most common indication for the procedure. The most common contraindication for percutaneous gastrostomy was peritoneal carcinomatosis (25/46, 54%) followed by ascites (23/46, 50%) and invasive gastric cancer (6/46, 13%). Median ECOG scores were 2.5 (range 1-4). Technical success in the placement of a PTEG was 44/46, 95.7%. In 1 patient, fibrosis due to radiation therapy precluded percutaneous access to the esophagus . Intraprocedural aspiration resulting from emesis during balloon inflation was reported (n=1; (2.2%)). The most common immediate post procedural issues reported were mild throat pain (n=1; 2.2%) which was resolved with oral viscous lidocaine. The most common delayed issue was migration of the PTEG (n=2). There was 1 death resulting from aspiration pneumonitis. Using the Edmonton Symptom Assessment Scale (ESAS) and the Karnofsky Performance Scale (KPS), patency rates and relief of obstructive symptoms were 100% at 0, 7, and 14 days on average post procedure.

CLINICAL RELEVANCE/APPLICATION

This study has introduced a novel technique to help patients gain symptomatic control of malignant small bowel obstruction who otherwise would not meet conventional criteria for traditional approaches.

SDP-IR-17   Semi-automatic MRI Feature Assessment In Small- And Medium Volume Benign Prostatic Hyperplasia After Prostatic Artery Embolization

Participants
Vanessa Schmidt, MD, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To assess the treatment response of benign prostatic syndrome (BPS) following prostatic artery embolization (PAE) using a semi-automatic analysis of magnetic resonance imaging (MRI) features and clinical indexes.*Methods and Materials In this prospective monocenter trial we analyzed MR and clinical data of n=20 patients with symptomatic BPS before and after (1, 6, 12 months) PAE. MR image analysis was performed using a dedicated semi-automatic software for segmentation of the central and the total gland (CG, TG), respectively: signal intensities (SI) of T1-weighted (T1w), T2-weighted (T2w), and diffusion weighted images (DWI), intravesical prostatic protrusion (IPP), and prostatic volumes (CGV, TGV) were evaluated at each time point. The semi-automatic calculation of TGV was compared to the conventional calculation of TGV by the ellipse formula. International prostate symptom score (IPSS) and international consultation on incontinence questionnaire-urinary incontinence short form (ICIQ-UI SF) were used as clinical indexes. Substratification analysis by baseline TGV =60 mL and >60 mL was performed. Statistical testing in form of ANOVA, pairwise comparisons using Bonferroni correction, and multiple linear correlations were conducted using SPSS with p<0.05 considered significant.*Results TGV was significantly reduced at 1, 6, and 12 months after PAE assessed by the semi-automatic approach and the conventional ellipse formula (p=0.005; p=0.025). CGV presented significantly decreased 1 month after

embolization (p=0.038). There were no significant differences in CGV before and 6 and 12 months after PAE (p=0.191; p=0.283). 90 % of the patients demonstrated IPP at baseline with a significant decrease at 1, 6, and 12 months after treatment (p=0.028; p=0.010; p=0.008). ADC values of CG significantly decreased 1 month after embolization (p<0.001). There were no significant differences in T1w- and T2w-SI before and after treatment at each time point. All patients showed significant improvement in IPSS and ICIQ-UI SF 1 (p=0.002; p=0.016) and 6 months (p<0.001; p=0.020) after embolization compared to baseline values.*Conclusions MRI is an adequate method for assessing morphological and functional changes of the prostate gland following PAE confirming the concept that PAE leads to significant reduction in TGV and CGV and a decreased IPP already 1 month after therapy.*Clinical Relevance/Application The minimal increase of prostatic volume and IPP as well as the recurrence of clinical symptoms at 12 months indicate a slightly decreased long-term success compared to the short-term results.

RESULTS

TGV was significantly reduced at 1, 6, and 12 months after PAE assessed by the semi-automatic approach and the conventional ellipse formula (p=0.005; p=0.025). CGV presented significantly decreased 1 month after embolization (p=0.038). There were no significant differences in CGV before and 6 and 12 months after PAE (p=0.191; p=0.283). 90 % of the patients demonstrated IPP at baseline with a significant decrease at 1, 6, and 12 months after treatment (p=0.028; p=0.010; p=0.008). ADC values of CG significantly decreased 1 month after embolization (p<0.001). There were no significant differences in T1w- and T2w-SI before and after treatment at each time point. All patients showed significant improvement in IPSS and ICIQ-UI SF 1 (p=0.002; p=0.016) and 6 months (p<0.001; p=0.020) after embolization compared to baseline values.

CLINICAL RELEVANCE/APPLICATION

The minimal increase of prostatic volume and IPP as well as the recurrence of clinical symptoms at 12 months indicate a slightly decreased long-term success compared to the short-term results.

SDP-IR-18 Lower Gastrointestinal Bleeding: Differences In Outcomes Between Patients Undergoing Primary Endovascular Vs Primary Endoscopic Interventions

Participants
Alexander Villalobos, MD, Atlanta, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

To compare mortality and hospital length of stay (LOS) for patients with lower gastrointestinal bleeding (LGIB) treated with primary endovascular intervention (PEI) versus primary gastroenterology endoscopic intervention (PGEI).*Methods and Materials Using ICD codes, all LGIB encounters and associated diagnostic and therapeutic procedures were identified using 2005-2015 United States National Inpatient Sample databases. LGIB encounters first treated with angiography and/or embolization were classified as PEI; those first treated with diagnostic and/or therapeutic endoscopy were classified as PGEI. To reduce treatment selection bias during statistical analysis, remaining LGIB encounters first treated with surgery or conservative management were excluded. Prolonged LOS was defined as >7 inpatient days. Odds ratios (OR) for mortality and prolonged LOS were evaluated using multivariate logistic regression after propensity score matching of multiple clinically relevant baseline covariates.*Results Of the 617,735 LGIB encounters identified, PEI and PGEI were used in 4,702 and 143,718 encounters, respectively. The mean age, gender, and ethnicity of the overall study cohort was 69 ± 16 years old, 54% female, and 73% Caucasian, respectively. With PGEI set as the reference treatment group, PEI was associated with increased risk of mortality (OR=3.16 [95% CI 2.97-3.36], p<0.001) and prolonged LOS (OR=3.57 [95% CI 3.05-4.18], p<0.001).*Conclusions Compared to primary endoscopic intervention, inpatients with LGIB initially treated with primary endovascular intervention were associated with increased risk of both mortality and prolonged hospital length of stay.*Clinical Relevance/Application Inpatients with LGIB treated with primary endovascular intervention are associated with increased risk of mortality and prolonged hospital length of stay as compared to inpatients treated with primary endoscopic intervention, suggesting that primary endoscopic intervention should take precedence over primary endovascular intervention when such interventions are being considered.

RESULTS

Of the 617,735 LGIB encounters identified, PEI and PGEI were used in 4,702 and 143,718 encounters, respectively. The mean age, gender, and ethnicity of the overall study cohort was 69 ± 16 years old, 54% female, and 73% Caucasian, respectively. With PGEI set as the reference treatment group, PEI was associated with increased risk of mortality (OR=3.16 [95% CI 2.97-3.36], p<0.001) and prolonged LOS (OR=3.57 [95% CI 3.05-4.18], p<0.001).

CLINICAL RELEVANCE/APPLICATION

Inpatients with LGIB treated with primary endovascular intervention are associated with increased risk of mortality and prolonged hospital length of stay as compared to inpatients treated with primary endoscopic intervention, suggesting that primary endoscopic intervention should take precedence over primary endovascular intervention when such interventions are being considered.

SDP-IR-19 Patient Outcomes Following Upper Gastrointestinal Bleeding Vessel Embolization

Participants
J. Reed McGraw, BS, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Transcatheter arterial embolization (TAE) is frequently performed for patients with non-variceal upper gastrointestinal bleeding (UGIB) refractory to medical and endoscopic therapy. The purpose of this study was to evaluate the safety and efficacy of TAE with a particular focus on mucosal changes on post-embolization endoscopy.*Methods and Materials A retrospective review of patients undergoing arteriography for refractory non-variceal UGIB from 12/2003 - 8/2019 was performed. Patients less than 18 years old or those with UGIB secondary to acute trauma were excluded. Etiology of bleeding, embolization technique, pre- and post-embolization endoscopy results, and mortality were collected from the medical record and analyzed using multivariate logistic regressions.*Results A total of 283 patients underwent arteriography for UGIB. Of those, 277 patients underwent TAE. The most commonly treated etiologies of UGIB were ulcer (132) and bleeding mass (46). Post-TAE 30-day mortality was 26.5% (75/283). Intra-procedure complication rate was 6.4% (18/283) and was predominantly related to maldeployment. Rebleeding rate within the same admission was 22.2% (63/283). There was no correlation between the type of embolic used and mortality. Ninety-nine (99) patients underwent post-TAE endoscopy. Of those patients, 38 demonstrated new findings including 23 with macroscopic ulcer and 15 with mucosal inflammation. Sixty-one patients had no new findings in the vascular distribution of TAE. There was no correlation between the type of embolic used, performance of empiric embolization (i.e. embolization without arteriographic evidence of hemorrhage), and the vascular territory involved with post-TAE endoscopy findings. Interestingly, UGIB in the setting of bleeding

ulcer was significantly correlated with post-TAE macroscopic findings of inflammation (OR 5.32, p = .04). No patients in the study were found to have small bowel stenosis at the time of post-TAE endoscopy.*Conclusions TAE is a safe and effective intervention for patients with life-threatening UGIB. In our cohort, there were no differences in mortality or follow-up endoscopy findings based on the use of permanent (e.g. coils) or transient (e.g. Gelfoam) embolic. Further, TAE in the setting of bleeding ulcer was associated with mucosal healing as it was correlated with regression from ulcer to inflammation of the mucosa.*Clinical Relevance/Application Endoscopy findings following TAE for UGIB has remain underreported. The results of the presented study underscore the safety of TAE demonstrating that the type of embolic used and the location of embolization are not correlated with deleterious mucosal changes on endoscopic follow-up after intervention and may promote healing in some cases.

RESULTS

A total of 283 patients underwent arteriography for UGIB. Of those, 277 patients underwent TAE. The most commonly treated etiologies of UGIB were ulcer (132) and bleeding mass (46). Post-TAE 30-day mortality was 26.5% (75/283). Intra-procedure complication rate was 6.4% (18/283) and was predominantly related to maldeployment. Rebleeding rate within the same admission was 22.2% (63/283). There was no correlation between the type of embolic used and mortality. Ninety-nine (99) patients underwent post-TAE endoscopy. Of those patients, 38 demonstrated new findings including 23 with macroscopic ulcer and 15 with mucosal inflammation. Sixty-one patients had no new findings in the vascular distribution of TAE. There was no correlation between the type of embolic used, performance of empiric embolization (i.e. embolization without arteriographic evidence of hemorrhage), and the vascular territory involved with post-TAE endoscopy findings. Interestingly, UGIB in the setting of bleeding ulcer was significantly correlated with post-TAE macroscopic findings of inflammation (OR 5.32, p = .04). No patients in the study were found to have small bowel stenosis at the time of post-TAE endoscopy.

CLINICAL RELEVANCE/APPLICATION

Endoscopy findings following TAE for UGIB has remain underreported. The results of the presented study underscore the safety of TAE demonstrating that the type of embolic used and the location of embolization are not correlated with deleterious mucosal changes on endoscopic follow-up after intervention and may promote healing in some cases.

SDP-IR-2   Outpatient Percutaneous Radiofrequency Ablation Of Large, Benign, Symptomatic Thyroid Nodules: Preliminary Safety And Early Outcomes.

Participants
Michael L. Douek, MD, MBA, Santa Monica, California (*Presenter*) Nothing to Disclose

PURPOSE

To describe safety and outcomes in outpatient treatment of large, symptomatic thyroid nodules with radiofrequency ablation (RFA).*Methods and Materials Large, benign thyroid nodules (defined as nodules with estimated volumes of 20 cc or greater) were treated in 10 patients with radiofrequency ablation (RFA) between 2015 and 2021. All patients had biopsy-proven benign thyroid nodules which were causing cosmetic issues or compressive symptom and all patients declined surgery. Estimated nodule volumes, vascularity, and composition, and patient symptom and cosmetic scores were obtained on initial and follow-up visits. Number of ablation sessions, ablation technique, electrode size, and energy utilized were analyzed. Thyroid function before and after ablation and minor and major complications were recorded.*Results 11 large thyroid nodules were treated in 10 patients between 2015 and 2021. Mean pre-ablation nodule size was 54 cc (range 20 to 101 cc). In some cases, a staged, multisession approach, depending on nodule size, was used, allowing all except one case to be performed as a same-day outpatient procedure with local anesthesia only. The mean number of ablation sessions was 1.6 (range 1 to 3). All nodules were treated with real-time ultrasound guidance and the "moving shot" technique with specific avoidance and/or hydroprotection of peri-neural locations. Mean nodule volume reduction at 1, 6, and 12 months were 51%, 62%, and 86% respectively. All patients had cosmetic and/or symptomatic improvements, examples of which included improvement in hoarseness, breathing, and dysphagia. There were no minor or major complications, and no patient required thyroid hormone replacement.*Conclusions In conclusion, RFA of large thyroid nodules is technically feasible as a staged, outpatient-based procedure requiring only local anesthesia, yielding significant improvements in nodule size and patient symptoms, with a favorable risk profile. Outcomes in this series parallel those reported internationally and in other small U.S. case series.*Clinical Relevance/Application As has been seen in other countries, radiofrequency ablation is a viable, low-risk alternative to surgery for treating large symptomatic, benign thyroid nodules.

RESULTS

11 large thyroid nodules were treated in 10 patients between 2015 and 2021. Mean pre-ablation nodule size was 54 cc (range 20 to 101 cc). In some cases, a staged, multisession approach, depending on nodule size, was used, allowing all except one case to be performed as a same-day outpatient procedure with local anesthesia only. The mean number of ablation sessions was 1.6 (range 1 to 3). All nodules were treated with real-time ultrasound guidance and the "moving shot" technique with specific avoidance and/or hydroprotection of peri-neural locations. Mean nodule volume reduction at 1, 6, and 12 months were 51%, 62%, and 86% respectively. All patients had cosmetic and/or symptomatic improvements, examples of which included improvement in hoarseness, breathing, and dysphagia. There were no minor or major complications, and no patient required thyroid hormone replacement.

CLINICAL RELEVANCE/APPLICATION

As has been seen in other countries, radiofrequency ablation is a viable, low-risk alternative to surgery for treating large symptomatic, benign thyroid nodules.

SDP-IR-20   Evaluation Of Transarterial Radioembolization With Iodine-131 Lipiodol For Hepatic Metastases

Participants
Vineel Inampudi I, MD, Vijayawada, India (*Presenter*) Nothing to Disclose

PURPOSE

To analyse the response and survival benefits of TARE with Iodine- 131 Lipiodol for hepatic metastases.*Methods and Materials Prospective study of 600 patients between May 2015 to December 2020 with pathologically proven hepatic metastases referred for palliative therapy with transarterial radioembolization. At baseline (the day of the first session of intraarterial treatment), standard laboratory data including tumour marker levels and imaging characteristics of the liver and hepatic lesions from cross-sectional imaging(CT or MRI) , prior treatment history were recorded. Post procedure the patients were reviewed after one month with a follow up PET CT and tumour marker levels to evaluate response of treatment.*Results At the end of follow up period 84 patients died. The mean overall survival after TARE was 34.415±3.0 months. The mean duration of survival was found to be 38.88±5 months in patients with NET, 35.118±3.95 months in patients with GI malignancies, 27.21±8.3 months for patients with pancreatico-biliary

malignancies and 20.685±5.2 months for patients with other malignancies. (p=0.17). Overall survival after 45 months was 70%. 45 months survival in NET patients was 76% and 75% in GI malignancies, 57% in pancreatico-biliary and 50% in other malignancies. Response evaluation could not be done in 27 patients as they did not undergo follow up imaging. In the rest of the 489 patients, 266 patients showed a partial response, 155 patients showed stable disease and 66 patients showed progressive diseases. In 222 patients with NET, 169 patients showed a partial response, 30 patients showed stable disease and 23 patients showed progressive diseases. In 133 patients with GI malignancies, 95 patients showed a partial response, 25 patients showed stable disease and 13 patients showed progressive diseases. In 88 patients with pancreatico-biliary malignancies, 61 patients showed a partial response, 18 patients showed stable disease and 9 patients showed progressive diseases. All 46 patients with other malignancies showed stable disease.*Conclusions Transarterial radioembolization with I131-Lipiodol is highly effective in patients with hepatic metastases, especially in those with poor response to other treatments and has shown significant survival benefit and better quality of life. TARE with 131I-Lipiodol has an added advantage of being cost effective compared to TARE with 90Yttrium embedded microspheres in developing countries like India.*Clinical Relevance/Application All patients with hepatic metastases underwent multiple cycles of chemotherapy and other treatments with poor response / progressive disease . In this background , the treatment with 131I Lipiodol has shown improved response both clinically, biochemically and radiologically.

RESULTS

At the end of follow up period 84 patients died. The mean overall survival after TARE was 34.415±3.0 months. The mean duration of survival was found to be 38.88±5 months in patients with NET, 35.118±3.95 months in patients with GI malignancies, 27.21±8.3 months for patients with pancreatico-biliary malignancies and 20.685±5.2 months for patients with other malignancies. (p=0.17). Overall survival after 45 months was 70%. 45 months survival in NET patients was 76% and 75% in GI malignancies, 57% in pancreatico-biliary and 50% in other malignancies. Response evaluation could not be done in 27 patients as they did not undergo follow up imaging. In the rest of the 489 patients, 266 patients showed a partial response, 155 patients showed stable disease and 66 patients showed progressive diseases. In 222 patients with NET, 169 patients showed a partial response, 30 patients showed stable disease and 23 patients showed progressive diseases. In 133 patients with GI malignancies, 95 patients showed a partial response, 25 patients showed stable disease and 13 patients showed progressive diseases. In 88 patients with pancreatico-biliary malignancies, 61 patients showed a partial response, 18 patients showed stable disease and 9 patients showed progressive diseases. All 46 patients with other malignancies showed stable disease.

CLINICAL RELEVANCE/APPLICATION

All patients with hepatic metastases underwent multiple cycles of chemotherapy and other treatments with poor response / progressive disease . In this background , the treatment with 131I Lipiodol has shown improved response both clinically, biochemically and radiologically.

SDP-IR-21 Machine Learning-based Radiomic Features On Pre-ablation MRI As Predictors Of Pathologic Response In Patients With Hepatocellular Carcinoma (HCC) Who Underwent Hepatic Transplant

Participants
Azadeh Tabari, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this research was to develop a machine learning model to predict response to ablation therapy in patients with HCC, using pre-ablation MRI radiomics.*Methods and Materials This retrospective study was approved by IRB. From 2005 to 2015, 97 patients with HCC who underwent liver transplant were identified. A total of 112 radiomic features (shape, first-order, and texture) were extracted from each tumor, using contrast-enhanced MRIs that were performed within 3 months prior to ablation. Pathologic response was determined at liver transplant. The dataset was randomly partitioned into training and testing cohorts based on a 20% holdout validation. A kernel naïve bayes model was developed using minimum redundancy maximum relevance (mRMR) for feature selection. The final model included the top 46 features based on mRMR and performance was tested on the 20% holdout validation cohort. Univariate logistic regression (UVR) and ROC analysis was used to determine statistically significant features in predicting treatment response.*Results Ninety-seven patients (117 tumors, 31 (32%) microwave ablation, 66 (68%) radiofrequency ablation) were included. The mean model for end-stage liver disease (MELD) score was 10.5±3. Mean follow-up was 336.2±179 days. 38% of patients did not exhibit complete pathologic response on pathology review at the time of transplant. Two first-order and 2 GLRM features were associated with incomplete pathologic response on UVR analysis (P<0.05). The final machine-learning model included the top 46 radiomic features was predictive of incomplete pathologic response with the best AUC of 0.77, sensitivity of 100%, and specificity of 69%.*Conclusions The use of MRI radiomics with machine learning may enhance the ability to predict pathologic response to ablation therapy in patients with HCC underwent liver transplant.*Clinical Relevance/Application The machine learning based radiomics features analysis could provide a prediction model, and non-invasively explore the association between pre-ablation MRI images and pathological response in patients with HCC listed for hepatic transplant. This will allow us to personalize treatment for these patients and predict who will benefit from ablation therapy.

RESULTS

Ninety-seven patients (117 tumors, 31 (32%) microwave ablation, 66 (68%) radiofrequency ablation) were included. The mean model for end-stage liver disease (MELD) score was 10.5±3. Mean follow-up was 336.2±179 days. 38% of patients did not exhibit complete pathologic response on pathology review at the time of transplant. Two first-order and 2 GLRM features were associated with incomplete pathologic response on UVR analysis (P<0.05). The final machine-learning model included the top 46 radiomic features was predictive of incomplete pathologic response with the best AUC of 0.77, sensitivity of 100%, and specificity of 69%.

CLINICAL RELEVANCE/APPLICATION

The machine learning based radiomics features analysis could provide a prediction model, and non-invasively explore the association between pre-ablation MRI images and pathological response in patients with HCC listed for hepatic transplant. This will allow us to personalize treatment for these patients and predict who will benefit from ablation therapy.

SDP-IR-22 The Role Of Intra-arterial 177Lu-Dotatate Therapy In The Treatment Of Hepatic Metastasis From Neuroendocrine Tumors

Participants
Vineel Inampudi I, MD, Vijayawada, India (*Presenter*) Nothing to Disclose

PURPOSE

The propensity of currently practiced intravenous 177Lu therapy to produce side-effects warrants any novel techniques to reduce

the side-effects without compromising the dose delivered to the target areas. GEP-NETs have the tendency to metastasize to the liver, but seldomly to other organs. We have postulated the selective intra-arterial administration of 177Lu-DOTATATE to hepatic arteries will reduce unwanted side-effects and increasing the dose delivered to target areas due to the first-pass extraction of the radiopeptides by the tumor.*Methods and Materials A prospective evaluation of 654 patients who underwent intra-arterial Lu-177 DOTATATE therapy for hepatic neuroendocrine metastasis in our institution from June 2014 - January 2021 was done. CAPTEM-PRRT regimen based on Columbia university protocol as adopted in our study. RECIST and PERCIST crieterias were used to response evaluation based on pre-procedure and follow-up 68Ga-DOTANOC PET-CT.*Results We found that 88% (CR+PR) of patients had a significant radiological tumour response and 12% showed a stabilization of the disease. No patients were found to have progressive disease. All patients tolerated the procedure well, with none experiencing any significant procedure related acute side effects. None of the patients developed acute radiation induced liver disease or renal toxicity. Only 14 patients developed grade 1 to 2 hematological toxicity. Only 10 patients developed transient increase of hepatic enzymes, which normalized subsequently with no decrease in the total bilirubin levels. 50% patients showed partial response to therapy according to RECIST criteria and patients showed stable disease. All patients reported significant improvement in symptoms and sense of well-being after treatment initiation.*Conclusions Our initial experience of intra arterial administration of 177Lu-DOTATATE therapy in patients with liver dominant metastases from NET is promising, feasible, safe and tolerable. The preliminary therapeutic potential of this therapy is encouraging. However, further prospective studies are needed to show its impact in improving clinical outcomes, median survival and progression free survival.*Clinical Relevance/Application Intra-arterial 177Lu DOTATATE Therapy for hepatic metastases of neuroendocrine tumors is a well-tolerated treatment option in patients suffering from multiple, non-resectable hepatic metastases from NET. Since both loco-regional and systemic effects can be achieved by intra-arterial application of peptide-labeled radioactive isotopes, notably symptom control and treatment response seem to be superior to systemic intravenous protocols.

RESULTS

We found that 88% (CR+PR) of patients had a significant radiological tumour response and 12% showed a stabilization of the disease. No patients were found to have progressive disease. All patients tolerated the procedure well, with none experiencing any significant procedure related acute side effects. None of the patients developed acute radiation induced liver disease or renal toxicity. Only 14 patients developed grade 1 to 2 hematological toxicity. Only 10 patients developed transient increase of hepatic enzymes, which normalized subsequently with no decrease in the total bilirubin levels. 50% patients showed partial response to therapy according to RECIST criteria and patients showed stable disease. All patients reported significant improvement in symptoms and sense of well-being after treatment initiation.

CLINICAL RELEVANCE/APPLICATION

Intra-arterial 177Lu DOTATATE Therapy for hepatic metastases of neuroendocrine tumors is a well-tolerated treatment option in patients suffering from multiple, non-resectable hepatic metastases from NET. Since both loco-regional and systemic effects can be achieved by intra-arterial application of peptide-labeled radioactive isotopes, notably symptom control and treatment response seem to be superior to systemic intravenous protocols.

SDP-IR-23 Advanced Hepatocellular Carcinoma Treated By Transcatheter Arterial Chemoembolization With Drug-eluting Beads Plus Tyrosine Kinase Inhibitor: Lenvatinib Or Sorafenib?

Participants
Jiaping Li, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to investigate the safety and efficacy of DEB-TACE plus lenvatinib in comparison with that of DEB-TACE plus sorafenib for advanced HCC.*Methods and Materials The medical records of consecutive patients with advanced HCC who underwent DEB-TACE plus lenvatinib (DEB-TACE+LEN) or DEB-TACE plus sorafenib (DEB-TACE+SOR) between January 2017 and December 2020 were retrospectively reviewed. All patients were started on sorafenib (800mg/day) or lenvatinib (8mg/day (<60kg) or 12mg/day (=60kg)) 2-3 weeks prior to the first DEB-TACE session. Propensity score matching was performed to fit the baseline characteristics between the two groups. Adverse events (AEs), objective response rate (ORR), disease control rate (DCR), overall survival (OS) and time to progression (TTP) were compared between patients who underwent DEB-TACE+LEN and DEB-TACE+SOR.*Results A total of 150 patients were enrolled in this study. The patients in DEB-TACE+LEN group (n=50) showed significantly better ORR (64.0% vs. 33.3%; P=0.008), OS (hazard ratio [HR] =0.63, 95% confidence interval (CI): 0.41-0.98; P=0.043) and TTP (HR=0.65, 95%CI: 0.45-0.94; P=0.023) than that in DEB-TACE+SOR group (n=100). Subgroup analyses showed that in patients with portal vein tumor thrombus (PVTT), median OS and TTP were significantly longer in the DEB-TACE+LEN group than did the DEB-TACE+SOR group (HR=0.59, 95%CI: 0.36-0.98; P=0.043; HR=0.89, 95%CI: 0.35-2.29; P=0.035). The patients in DEB-TACE+LEN group had a significantly lower incidence of hand-foot skin reaction (32.0% vs. 49.0%; P=0.048), but a higher incidence of proteinuria (26.0% vs. 10.0%; P=0.010) than that in the DEB-TACE+SOR group. There was no significant difference in the rate of grade 3-4 AEs between the two groups.*Conclusions DEB-TACE combined with lenvatinib confers better ORR, OS and TTP than does DEB-TACE combined with sorafenib in patients with advanced HCC, especially patients with PVTT, with acceptable DEB-TACE-related and tyrosine kinase inhibitor (TKI)-related AEs, thus making it a superior treatment modality for these patients.*Clinical Relevance/Application Oral tyrosine kinase inhibitors (TKIs), including lenvatinib and sorafenib, are recommended as a standard therapy for advanced HCC. Recently, there were many results suggesting that DEB-TACE plus sorafenib is an effective and promising treatment for patients with advanced HCC. However, no studies on DEB-TACE plus lenvatinib for advanced HCC patients have been reported to date. The results of our study suggested that lenvatinib plus DEB-TACE is a potential therapeutic option for advanced HCC.

RESULTS

A total of 150 patients were enrolled in this study. The patients in DEB-TACE+LEN group (n=50) showed significantly better ORR (64.0% vs. 33.3%; P=0.008), OS (hazard ratio [HR] =0.63, 95% confidence interval (CI): 0.41-0.98; P=0.043) and TTP (HR=0.65, 95%CI: 0.45-0.94; P=0.023) than that in DEB-TACE+SOR group (n=100). Subgroup analyses showed that in patients with portal vein tumor thrombus (PVTT), median OS and TTP were significantly longer in the DEB-TACE+LEN group than did the DEB-TACE+SOR group (HR=0.59, 95%CI: 0.36-0.98; P=0.043; HR=0.89, 95%CI: 0.35-2.29; P=0.035). The patients in DEB-TACE+LEN group had a significantly lower incidence of hand-foot skin reaction (32.0% vs. 49.0%; P=0.048), but a higher incidence of proteinuria (26.0% vs. 10.0%; P=0.010) than that in the DEB-TACE+SOR group. There was no significant difference in the rate of grade 3-4 AEs between the two groups.

CLINICAL RELEVANCE/APPLICATION

Oral tyrosine kinase inhibitors (TKIs), including lenvatinib and sorafenib, are recommended as a standard therapy for advanced HCC. Recently, there were many results suggesting that DEB-TACE plus sorafenib is an effective and promising treatment for patients

with advanced HCC. However, no studies on DEB-TACE plus lenvatinib for advanced HCC patients have been reported to date. The results of our study suggested that lenvatinib plus DEB-TACE is a potential therapeutic option for advanced HCC.

SDP-IR-24 Prognostic Tool For HCC Beyond Milan Criteria Undergoing Transarterial Chemoembolization After Transjugular Intrahepatic Portosystemic Shunt

Participants
Wenzhe Fan, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Currently, there is a need for a model that can predict the outcome of transarterial chemoembolization (TACE) in patients with hepatocellular carcinoma (HCC) beyond the Milan criteria after transjugular intrahepatic portosystemic shunt (TIPS). This study aimed to develop an easy-to-use tool specifically for such patients.*Methods and Materials From January 2013 to January 2019, 160 consecutive patients with HCC exceeding the Milan criteria underwent TIPS and TACE. Univariate and multivariate analyses were performed to explore the clinical factors independently correlated with overall survival (OS). A prognostic score was then developed to identify different prognoses in an initial cohort and validated in an external cohort (n = 72).*Results In the multivariate analysis, the presence of portal vein tumor thrombus (PVTT), alpha-fetoprotein (AFP), extrahepatic spread (EHS), alanine aminotransferase (ALT), and red blood cell (RBC) count were identified as predictors of OS. These factors were used to develop a prognostic score (TAMAR score, range: 0-6). The median survival was found to decrease with an increase in TAMAR score, and patients were stratified into favorable (0-2 points), intermediate (3-4 points), and dismal (>4 points) groups with the corresponding median survival values of 17.3, 8.7, and 4.3 months, respectively (P < 0.001). Additionally, the time to progression (TTP) (P < 0.001) and tumor response were also stratified into the same prognostic groups. An external validation cohort was used to confirm the prognostic scores.*Conclusions The proposed scoring system can accurately stratify the outcomes of patients with HCC beyond the Milan criteria who underwent TACE after TIPS; it helps identify the patients who may benefit from this treatment approach.*Clinical Relevance/Application The results of this study may be of great significance for guiding individual treatment of patients with HCC after TIPS in clinical practice. The proposed scoring system is able to stratify the outcomes of patients with HCC beyond the Milan criteria who underwent TACE after TIPS.

RESULTS

In the multivariate analysis, the presence of portal vein tumor thrombus (PVTT), alpha-fetoprotein (AFP), extrahepatic spread (EHS), alanine aminotransferase (ALT), and red blood cell (RBC) count were identified as predictors of OS. These factors were used to develop a prognostic score (TAMAR score, range: 0-6). The median survival was found to decrease with an increase in TAMAR score, and patients were stratified into favorable (0-2 points), intermediate (3-4 points), and dismal (>4 points) groups with the corresponding median survival values of 17.3, 8.7, and 4.3 months, respectively (P < 0.001). Additionally, the time to progression (TTP) (P < 0.001) and tumor response were also stratified into the same prognostic groups. An external validation cohort was used to confirm the prognostic scores.

CLINICAL RELEVANCE/APPLICATION

The results of this study may be of great significance for guiding individual treatment of patients with HCC after TIPS in clinical practice. The proposed scoring system is able to stratify the outcomes of patients with HCC beyond the Milan criteria who underwent TACE after TIPS.

SDP-IR-25 Lipiodol As An Intra-procedural Imaging Biomarker For Liver Tumor Response To Transarterial Chemoembolization: Post-hoc Analysis Of A Prospective Clinical Trial

Participants
Christopher Petty, BS, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

To prospectively evaluate the role of a 3D quantitative assessment of intra-procedural Lipiodol deposition on cone-beam CT (CBCT) as a predictive biomarker of outcome in patients with primary or metastatic liver cancer undergoing cTACE.*Methods and Materials This was a post-hoc analysis of data from an IRB-approved prospective clinical trial. Thirty-two patients with hepatocellular carcinoma or liver metastases underwent contrast-enhanced CBCT obtained immediately after cTACE, unenhanced MDCT at 24 hours after cTACE, and follow-up imaging 30-, 90- and 180-days post-procedure. Lipiodol deposition was quantified on intra-procedural CBCT and was characterized by 4 ordinal levels: =25%, >25-50%, >50-75%, >75%. Tumor response was assessed on follow-up MRI (Figure 1). Lipiodol deposition on imaging, the correlation between Lipiodol deposition and tumor response criteria, and correlation between Lipiodol coverage and median overall survival (MOS) were evaluated.*Results A Bland-Altman plot of Lipiodol deposition on imaging demonstrated a bias of 2.75, with 95%-limits-of-agreement: - 16.6 to 22.1%. Correlation between relative Lipiodol deposition and change in enhancing tumor volume showed a negative association post-cTACE (30-day: p<0.001; rho=-0.63). Comparing Lipiodol mRECIST responders versus non-responders showed statistically significant higher volumetric deposition in responders for EASL-30d, EASL-90d, and quantitative EASL-180d. An inverse relationship between Lipiodol deposition in responders versus non-responders for two-dimensional EASL reached statistical significance at 30 days (p=0.02) and 90 days (p=0.05). Kaplan-Meier analysis for patients with high vs. low Lipiodol deposition showed a MOS of 46 vs. 33 months (p=0.05).*Conclusions 3D quantification of Lipiodol deposition on intra-procedural CBCT is a predictive biomarker of outcome in patients with primary or metastatic liver cancer undergoing cTACE. There are spatial and volumetric agreements between 3D quantification of Lipiodol deposition on intra-procedural CBCT and 24h post-cTACE MDCT. More Lipiodol tumor coverage is associated with improved and sustained tumor response post-cTACE.*Clinical Relevance/Application The spatial and volumetric agreement between Lipiodol deposition on intra-procedural CBCT and 24hr post-cTACE MDCT could suggest that acquiring MDCT 24 hours after cTACE is redundant. Importantly, the demonstrated relationship between levels of tumor coverage with Lipiodol and degree of tumor response after cTACE underline the role of Lipiodol as an intra-procedural surrogate for tumor response, with potential implications for the prediction of survival.

RESULTS

A Bland-Altman plot of Lipiodol deposition on imaging demonstrated a bias of 2.75, with 95%-limits-of-agreement: -16.6 to 22.1%. Correlation between relative Lipiodol deposition and change in enhancing tumor volume showed a negative association post-cTACE (30-day: p<0.001; rho=-0.63). Comparing Lipiodol mRECIST responders versus non-responders showed statistically significant higher volumetric deposition in responders for EASL-30d, EASL-90d, and quantitative EASL-180d. An inverse relationship between Lipiodol deposition in responders versus non-responders for two-dimensional EASL reached statistical significance at 30 days (p=0.02) and 90 days (p=0.05). Kaplan-Meier analysis for patients with high vs. low Lipiodol deposition showed a MOS of 46 vs. 33

months (p=0.05).

The spatial and volumetric agreement between Lipiodol deposition on intra-procedural CBCT and 24hr post-cTACE MDCT could suggest that acquiring MDCT 24 hours after cTACE is redundant. Importantly, the demonstrated relationship between levels of tumor coverage with Lipiodol and degree of tumor response after cTACE underline the role of Lipiodol as an intra-procedural surrogate for tumor response, with potential implications for the prediction of survival.

SDP-IR-3 Safety And Efficacy Of Chemosaturation With Percutaneoushepatic Perfusion Of Melphalan For Metastatic Uveal Melanoma: An 8-year Retrospective Study Of 250 Interventions In 81 Patients.

Participants
Tom Gibson, MBBCHIR, Romsey, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

Uveal melanoma, the most common primary ocular malignancy in adults, carries a poor prognosis: 50% of patients develop metastatic disease with a 10-25% 1-year survival and no established standard of care treatment. Prior studies of melphalan percutaneous hepatic perfusion (M-PHP) have shown promise in metastatic UM (mUM) patients with liver predominant disease but are limited by small sample sizes. We contribute our single centre findings on the safety and efficacy of the procedure in the largest sample population to date.*Methods and Materials We performed a retrospective analysis of outcome and safety data for all mUM patients receiving M-PHP at our institutions. Tumour response and treatment toxicity were evaluated using RECIST 1.1 and Common Terminology Criteria for Adverse Events (CTCAE) v5.03, respectively.*Results A total of 250 M-PHP procedures were performed in 81 patients (median of 3 per patient). Analysis demonstrated a hepatic disease control rate of 88.9% (72/81), hepatic response rate of 66.7% (54/81), and overall response rate (ORR) of 60.5% (49/81). After median follow-up of 12.9 months, median overall progression-free (PFS) and median overall survival (OS) were 8.4 months and 14.9 months, respectively. There were no fatal treatment-related adverse events (TRAE). Forty-three grade 3 (29) or 4 (14) TRAE occurred in 23 (28.4%) patients with a significant reduction in such events between procedures performed in 2016-20 vs 2012-16 (0.17 per patient vs 0.90 per patient, p<0.001).*Conclusions M-PHP provides excellent response rates and PFS compared with other available treatments. With a decreasing side effect profile with experience, combination therapy with systemic agents may be viable to further advance OS.*Clinical Relevance/Application There is currently no standard of care for patients with mUM. Hepatic involvement is common and a key determinant of survival. M-PHP can treat the entire liver and has previously been shown to be effective and safe in the relatively small cohort studies to date. We provide, to our knowledge, the largest single centre experience to date that indicates excellent ORR, good PFS, reduced complications with experience, and raises the idea that combination therapy with systemic agents may be feasible and necessary to further OS in this disease.

RESULTS

A total of 250 M-PHP procedures were performed in 81 patients (median of 3 per patient). Analysis demonstrated a hepatic disease control rate of 88.9% (72/81), hepatic response rate of 66.7% (54/81), and overall response rate (ORR) of 60.5% (49/81). After median follow-up of 12.9 months, median overall progression-free (PFS) and median overall survival (OS) were 8.4 months and 14.9 months, respectively. There were no fatal treatment-related adverse events (TRAE). Forty-three grade 3 (29) or 4 (14) TRAE occurred in 23 (28.4%) patients with a significant reduction in such events between procedures performed in 2016-20 vs 2012-16 (0.17 per patient vs 0.90 per patient, p<0.001).

There is currently no standard of care for patients with mUM. Hepatic involvement is common and a key determinant of survival. M-PHP can treat the entire liver and has previously been shown to be effective and safe in the relatively small cohort studies to date. We provide, to our knowledge, the largest single centre experience to date that indicates excellent ORR, good PFS, reduced complications with experience, and raises the idea that combination therapy with systemic agents may be feasible and necessary to further OS in this disease.

SDP-IR-4 Effects Of Particle Density On Outcomes After Lobar Radioembolization

Participants
Franz E. Boas, MD,PhD, Duarte, California (*Presenter*) Co-founder, CLARIPACS, LLC;Investor, Labdoor;Investor, Qventus, Inc;Investor, CloudMedx;Investor, Notable Labs;Investor, XGenomes Corp;Research support, Bayer AG;Research support, General Electric Company;Speaker, Guerbet SA;Research Grant, Guerbet SA;Research support, Guerbet SA;Research support, STEBA Biotech NV;Research support, Terumo Corporation

PURPOSE

To determine if larger or more vascular tumors benefit from more particles during lobar radioembolization.*Methods and Materials Propensity score matching was used to select 57 pairs of patients that received lobar radioembolization. In each matched pair, one patient was treated using glass microspheres (120 Gy), and the other patient was treated using resin microspheres (BSA method). For each patient, tumor and liver volumes, tumor-to-normal ratio, number of particles delivered, dose (Gy), and particle density (particles/ml) were determined. Tumor-to-normal ratio was measured on both 99mTc-MAA SPECT/CT and post-90Y bremsstrahlung SPECT/CT. Response, local progression-free survival, and REILD were analyzed.*Results Overall, there was no difference between glass and resin microspheres, in terms of response, local progression-free survival, overall survival, or REILD. Glass microspheres had a stronger correlation between tumor-to-normal ratio on 99mTc-MAA versus 90Y SPECT/CT, compared to resin microspheres. For hypervascular tumors (tumor-to-normal ratio = 2.6), delivering fewer particles (< 6000 particles/ml treatment volume) was associated with better local progression-free survival (p=0.03). For less vascular tumors (tumor-to-normal ratio < 2.6), delivering more particles (= 6000 particles/ml) was associated with better local progression-free survival (p=0.02). In rare cases, with hypovascular tumors and low tumor volume, gaps larger than 0.39 cm were predicted between particles.*Conclusions The original hypothesis was not supported by the data. For hypervascular tumors, fewer particles was associated with improved tumor-to-normal ratio, and improved local progression-free survival. For less vascular tumors, more particles was associated with improved tumor-to-normal ratio, and improved local progression-free survival.*Clinical Relevance/Application Optimizing the number of particles delivered, based on tumor vascularity, can improve outcomes after radioembolization.

RESULTS

Overall, there was no difference between glass and resin microspheres, in terms of response, local progression-free survival, overall survival, or REILD. Glass microspheres had a stronger correlation between tumor-to-normal ratio on 99mTc-MAA versus 90Y

SPECT/CT, compared to resin microspheres. For hypervascular tumors (tumor-to-normal ratio = 2.6), delivering fewer particles (< 6000 particles/ml treatment volume) was associated with better local progression-free survival (p=0.03). For less vascular tumors (tumor-to-normal ratio < 2.6), delivering more particles (= 6000 particles/ml) was associated with better local progression-free survival (p=0.02). In rare cases, with hypovascular tumors and low tumor volume, gaps larger than 0.39 cm were predicted between particles.

CLINICAL RELEVANCE/APPLICATION

Optimizing the number of particles delivered, based on tumor vascularity, can improve outcomes after radioembolization.

SDP-IR-5   Clinical And Imaging Outcomes After Transjugular Intrahepatic Portosystemic Shunt Reduction For Over Shunting Complications

Participants
Raj Shah, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

To assess clinical and imaging outcomes after transjugular intrahepatic portosystemic shunt (TIPS) reduction for over shunting complications.*Methods and Materials This investigation was an IRB-approved multi-institution retrospective observational cohort study. Thirty-three patients (M:F 20:13, median age 61 years, median MELD score 13) underwent TIPS reduction between 2007-2020. Procedure indications included medically refractory hepatic encephalopathy (HE) (n=28, 85%), post-TIPS liver failure (PTLF) (n=4, 12%), and heart failure (n=1, 3%). Measured clinical outcomes included improvement in HE (persistent, improved, resolved; classified using the West-Haven system) and PTLF (persistent, improved, or resolved) after TIPS reduction, and transplant free survival (TFS). Measured imaging outcomes included patency of reduced TIPS, assessed by surveillance ultrasound.*Results TIPS reductions were successfully performed using the parallel stent (n=31, 94%) or hourglass (n=2, 6%) techniques at median 120 days after TIPS creation (median 164 days for HE, median 5 days for PTLF). Portosystemic pressure gradient (PSG) increased from median 9 to 15 mm Hg (P<0.001). Overall HE rate after TIPS reduction was 54% (15/28); HE was persistent, improved, and resolved in 6 (21%), 9 (32%), and 13 (46%) cases, respectively. In PTLF patients, MELD score significantly increased from median 23 pre-TIPS to median 35 post-TIPS (P=0.008), but there was no improvement (0/4, 0%) in PTLF after TIPS reduction (median MELD 31, P=0.414). Median TFS was not reached. 30-day, 6-month, 1-year, and 3-year survival rates were 97%, 90%, 81%, and 60%. Median shunt patency was 961 days (95% CI 476-1,447). 30-day, 6-month, 1-year, and 3-year shunt patency rates were 92%, 81%, 74%, and 37%.*Conclusions While TIPS reduction may be an effective and durable approach to treat post-TIPS medically refractory HE, shunt reduction may not achieve a meaningful therapeutic benefit for PTLF, although more research is needed.*Clinical Relevance/Application TIPS is often used in the management of portal hypertension complications. However, increased shunting can lead to adverse events, including HE and PTLF. TIPS reduction may be considered in cases refractory to medical management. While published literature has described the technical outcomes and short-term results of TIPS reduction, data regarding longer term clinical and imaging (patency) outcomes of reduced shunts is scarce. Better understanding of TIPS reduction outcomes could help in the management of TIPS-related adverse events.

RESULTS

TIPS reductions were successfully performed using the parallel stent (n=31, 94%) or hourglass (n=2, 6%) techniques at median 120 days after TIPS creation (median 164 days for HE, median 5 days for PTLF). Portosystemic pressure gradient (PSG) increased from median 9 to 15 mm Hg (P<0.001). Overall HE rate after TIPS reduction was 54% (15/28); HE was persistent, improved, and resolved in 6 (21%), 9 (32%), and 13 (46%) cases, respectively. In PTLF patients, MELD score significantly increased from median 23 pre-TIPS to median 35 post-TIPS (P=0.008), but there was no improvement (0/4, 0%) in PTLF after TIPS reduction (median MELD 31, P=0.414). Median TFS was not reached. 30-day, 6-month, 1-year, and 3-year survival rates were 97%, 90%, 81%, and 60%. Median shunt patency was 961 days (95% CI 476-1,447). 30-day, 6-month, 1-year, and 3-year shunt patency rates were 92%, 81%, 74%, and 37%.

CLINICAL RELEVANCE/APPLICATION

TIPS is often used in the management of portal hypertension complications. However, increased shunting can lead to adverse events, including HE and PTLF. TIPS reduction may be considered in cases refractory to medical management. While published literature has described the technical outcomes and short-term results of TIPS reduction, data regarding longer term clinical and imaging (patency) outcomes of reduced shunts is scarce. Better understanding of TIPS reduction outcomes could help in the management of TIPS-related adverse events.

SDP-IR-6   Utilization Of Cooled Radiofrequency Ablation For The Treatment Of Uncomplicated Total Knee Arthroplasty Chronic Pain And Stiffness: Initial Single Institution Pilot Study

Participants
Felix Gonzalez, MD, Roswell, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

To introduce percutaneous image-guided cooled radiofrequency ablation for the treatment of chronic pain and stiffness after total knee arthroplasty with no hardware complication and to establish the clinical efficacy, technical feasibility, and safety profile of this technique.*Methods and Materials This retrospective pilot study includes a total of 19 consecutive patients experiencing persistent chronic pain after total knee arthroplasty, without underlying hardware complications, that failed conservative care. Patients initially underwent anesthetic blocks of the genicular nerve branches to determine C-RFA candidacy. After adequate response to the anesthetic blocks consistent of >50% immediate pain relief, patients were subjected to cooled radiofrequency ablations 2-3 weeks later. Treatment response was evaluated utilizing clinically validated questionnaires (KOOS: Knee injury and Osteoarthritis Outcome Score) and Visual Analog Score (VAS) in order to assess pain severity, stiffness, functional activities of daily living and use of pain medication. Follow-up outcome scores were collected up to 1 year after C-RFA procedure.*Results A total of 19 knees were treated consecutively between 4/2019 and 1/2020 (mean patient age 70.5 years; 5M:14F). The mean total KOOS score improved significantly from baseline at 36.2 ±?14.1 to 61.9?±?26.5 at a mean of 10.2 months after treatment (p?<?0.0001), with significant improvement in mean pain score from 36.5?±?15.2 to 72.45?±?25.2 (p?<?0.0001) and mean stiffness score from 47?±?21.9 to 68.5?±?24.9 (p?<?0.0001). No major complications were encountered. No patients went on to re-treatment, surgical revision, or other intervention.*Conclusions Image-guided genicular nerve cooled radiofrequency ablation is a safe and effective treatment method for chronic pain/stiffness, which can be seen after TKA with an intact hardware.*Clinical Relevance/Application Currently, there is no effective way to treat symptoms such as pain and stiffness in patients status post TKA with an intact harward refractory to conservative interventions. Cooled radiofrequency ablation offers an alternative treatment methodology for

these symptoms without significant complications.

RESULTS

A total of 19 knees were treated consecutively between 4/2019 and 1/2020 (mean patient age 70.5 years; 5M:14F). The mean total KOOS score improved significantly from baseline at 36.2 ±?14.1 to 61.9?±?26.5 at a mean of 10.2 months after treatment (p? <?0.0001), with significant improvement in mean pain score from 36.5?±?15.2 to 72.45?±?25.2 (p?<?0.0001) and mean stiffness score from 47?±?21.9 to 68.5?±?24.9 (p?<?0.0001). No major complications were encountered. No patients went on to re-treatment, surgical revision, or other intervention.

CLINICAL RELEVANCE/APPLICATION

Currently, there is no effective way to treat symptoms such as pain and stiffness in patients status post TKA with an intact harward refractory to conservative interventions. Cooled radiofrequency ablation offers an alternative treatment methodology for these symptoms without significant complications.

SDP-IR-7   Shear Wave Elastography For Tennis Elbow: Quantitative Outcome Measure To Track Healing Changes Of The Common Extensor Tendon After PRP Treatment Compared To Corticosteroid At 1 Year.

Participants
Grant M. Quilling, BS, Madison, Wisconsin (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the efficacy of a single platelet-rich-plasma (PRP) injection to a single corticosteroid (CS) injection at 1 year for the treatment of lateral epicondylosis and correlate morphologic and quantitative ultrasound (US) changes to clinical outcomes.*Methods and Materials IRB approval and informed consent obtained. 47 subjects with a mean age of 48 years old (range, 31-63) who had common extensor tendon pain for at least 3 consecutive months with US or MRI confirmation of chronic lateral epicondylosis that had failed conservative therapy. Subjects were block randomized into either a PRP or CS treatment groups and completed clinical surveys at 0, 4, 8, 12, 16, 26 and 52 weeks. Patient surveys consisted of VAS pain scores, QuickDASH, PRTEE, SANE, SF-12 and satisfaction surveys. Grip strength tests performed at 0, 26 and 52 weeks and underwent conventional US and shear wave speed (SWS) assessment at 0, 26 and 52 weeks. Tendon morphology on US was characterized by thickness, hyperemia and echogenicity.*Results There was no statistically significant difference in the PRP and CS found at 52-weeks for VAS pain, QuickDASH total, PRTEE, SANE, SF-12 and satisfaction scores. PRP injections were found to be a significant improvement to CS injections for QuickDASH work module scores at 26 weeks (p=0.01) and 52 weeks (p=0.001). There was no statistically significant improvement at 26 weeks for the PRP injection group (p=0.158) but statistically significant improved grip strength was present at 52 weeks (p=0.027). No significant difference was found in conventional US thickness, echogenicity and hyperemia at 26-weeks and 52-weeks. The PRP injection group had a significantly improved SWS at 52 weeks (p=0.023).*Conclusions PRP injection led to improvements in QuickDASH work module at 26-week and 52-weeks, grip strength at 52-weeks and SWS at 52-weeks but no significant improvements in other clinical surveys or conventional US. Increase in SWS correlated with significant improvement in pain and function in the PRP group.*Clinical Relevance/Application PRP is an effective treatment alternative for refractory lateral epicondylosis with an increased grip strength and QuickDASH work module score and SWS may be an acceptable quantitative biomarker for tendon healing.

RESULTS

There was no statistically significant difference in the PRP and CS found at 52-weeks for VAS pain, QuickDASH total, PRTEE, SANE, SF-12 and satisfaction scores. PRP injections were found to be a significant improvement to CS injections for QuickDASH work module scores at 26 weeks (p=0.01) and 52 weeks (p=0.001). There was no statistically significant improvement at 26 weeks for the PRP injection group (p=0.158) but statistically significant improved grip strength was present at 52 weeks (p=0.027). No significant difference was found in conventional US thickness, echogenicity and hyperemia at 26-weeks and 52-weeks. The PRP injection group had a significantly improved SWS at 52 weeks (p=0.023).

CLINICAL RELEVANCE/APPLICATION

PRP is an effective treatment alternative for refractory lateral epicondylosis with an increased grip strength and QuickDASH work module score and SWS may be an acceptable quantitative biomarker for tendon healing.

SDP-IR-8   Potential Of Pre-interventional Magnetic Resonance Angiography For Optimization Of Workflow And Clinical Outcome Of Prostatic Arterial Embolization

Participants
Leona Alizadeh, MD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

PURPOSE

We evaluated the impact of pre-interventional magnetic resonance angiography (MRA) on prostatic artery embolization (PAE) regarding workflow, radiation dose, and clinical outcome.*Methods and Materials 259 patients (mean age 68.28 ± 8.69, range 41-92) with benign prostatic hypertrophy (BPS) who had undergone PAE between January 2017 and December 2020 were retrospectively evaluated. Pre-interventional MRA was performed in 137 cases. In 122 patients, no pre-interventional MRA was performed. MR-images were evaluated regarding origin of the PA, volumetry of the prostatic gland and ADC values. Impact of MRA on PAE workflow and Radiation-dose was examined.International Prostate Symptom Score (IPSS), Quality of Life (QoL) and International Index of Erectile Function (IIEF) were evaluated before and after PAE to examine clinical improvement.*Results Significant differences regarding volume reduction (-20 ± 13 ml with MRA vs. -17 ± 9 ml without MRA) and ADC value reduction were found (-78 ± 111 10-6 mm2/s with MRA vs. -45 ± 99 10-6 mm2/s without MRA). Workflow during PAE was altered because of pathological findings in MRA in 16 patients. Radiation dose (5518.54 ± 6677.97 µGym2 with MRA vs. 23963.50 ± 19792.25 µGym2 without MRA) and fluoroscopy times (19.35 ± 9.01 min. with MRA vs. 27.45 ± 12.54 min. without MRA) were significantly lower with MRA. The MRA-group showed significantly higher improvement in IPSS reduction (-11 ± 8 points with MRA vs. -7 ± 9 points without MRA, p<0.001), while QOL and IEF showed no significant differences (p>0.05).*Conclusions Pre-interventional MRA significantly improves workflow and clinical outcome of PAE while significantly reducing radiation dose. Therefore, we recommend performance of MRA for pre-interventional planning in patients undergoing PAE.*Clinical Relevance/Application Improvement of patient safety and radiation dose reduction during PAE.

RESULTS

Significant differences regarding volume reduction (-20 ± 13 ml with MRA vs. -17 ± 9 ml without MRA) and ADC value reduction were found (-78 ± 111 10-6 mm2/s with MRA vs. -45 ± 99 10-6 mm2/s without MRA). Workflow during PAE was altered because of pathological findings in MRA in 16 patients. Radiation dose (5518.54 ± 6677.97 µGym2 with MRA vs. 23963.50 ± 19792.25 µGym2 without MRA) and fluoroscopy times (19.35 ± 9.01 min. with MRA vs. 27.45 ± 12.54 min. without MRA) were significantly lower with MRA. The MRA-group showed significantly higher improvement in IPSS reduction (-11 ± 8 points with MRA vs. -7 ± 9 points without MRA, p<0.001), while QOL and IEF showed no significant differences (p>0.05).

CLINICAL RELEVANCE/APPLICATION

Improvement of patient safety and radiation dose reduction during PAE.

SDP-IR-9   Experimental Study On Transarterial Administration Of Bevacizumab Combined With Transarterial Chemoembolization In Rats With Hepatocellular Carcinoma.

Participants
shen zhang, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the effects of transarterial administration of Bevacizumab (Avastin), an inhibitor of vascular endothelial growth factor (VEGF), combined with transarterial chemoembolization (TACE) in the treatment of hepatocellular carcinoma in rats. *Methods and Materials Subcapsular implantation of solid Morris hepatoma 3924A (2 mm3) was performed in the livers of 20 male ACI rats. Animal subjects were assigned to the group based on which treatment drugs were injected into the hepatic artery: Group A: TACE (mitomycin C + lipiodol + degradable starch microspheres) + bevacizumab; Group B: TACE alone. Post-treatment (V2) and pre-treatment (V1) tumor volumes were assessed by magnetic resonance imaging (MRI) and the mean proportion (V2/V1) was calculated. Immunohistochemical expression of MMP-9 and VEGF in tumors was semi-quantitative in all rats.*Results The ratios of the post-treatment to pretreatment tumor volumes (V2/V1) in groups A and B were 1.6649 ± 0.1255 and 3.0061 ± 0.1910 respectively. Significant difference was observed between group A and group B (P<0.0001). Higher expression of MMP-9 and VEGF in hepatocellular carcinoma was demonstrated in the control group (TACE alone) than group A (TACE + Bevacizumab) (both P<0.0020).*Conclusions Transarterial administration of bevacizumab combined with TACE noticeably inhibits the growth of hepatic carcinoma and intrahepatic metastases in rats.*Clinical Relevance/Application To explore the effect of transcatheter arterial chemoembolization (TACE) combined with bevacizumab in the treatment of liver cancer.

RESULTS

The ratios of the post-treatment to pretreatment tumor volumes (V2/V1) in groups A and B were 1.6649 ± 0.1255 and 3.0061 ± 0.1910 respectively. Significant difference was observed between group A and group B (P<0.0001). Higher expression of MMP-9 and VEGF in hepatocellular carcinoma was demonstrated in the control group (TACE alone) than group A (TACE + Bevacizumab) (both P<0.0020).

CLINICAL RELEVANCE/APPLICATION

To explore the effect of transcatheter arterial chemoembolization (TACE) combined with bevacizumab in the treatment of liver cancer.

IR04-A2   **Safety And Efficacy Of CT-Guided Percutaneous Biopsy Of Suspicious Sub-Centimeter Retroperitoneal Lymph Nodes Detected By Metabolic Imaging For The Diagnosis Of Metastatic Prostate Cancer**

Participants
Jamie Kapplinger, MD,PhD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

Greater than 20% of patients with treated prostate cancer will have recurrent disease within 10 years of treatment. Early and accurate diagnosis is key to the management of recurrent prostate cancer. While elevated PSA remains the major clinical indicator, increasingly imaging plays an important role in the evaluation for metastatic prostate cancer. Advances in molecular imaging, such as 11C-choline PET/CT (Chol/PET), have led to earlier detection of smaller sites of recurrence. As tissue diagnosis remains the gold standard for confirmation of recurrent prostate cancer, the purpose of this study was to evaluate the efficacy and risk profile of CT-guided biopsies of small (=1cm) retroperitoneal lymph nodes (rLN) detected with metabolic imaging.*Methods and Materials Retrospective review was performed of prostate cancer patients who had undergone CT-guided core biopsy of suspicious or indeterminate rLN detected by Chol/PET between 6/1/2012 and 3/20/2020. Patient, rLN size and location, Chol/PET, procedural, complication and pathologic data was recorded. The biopsy length was measured as the rLN short axis length along the path of the biopsy device.*Results A total of 290 biopsies were performed in 269 patients. Of these, 152 (52.4%) were done on rLN =1 cm (4-10mm, mean 8±1 mm) and 138 were >1 cm (11-54mm, mean 16±6mm). There was no difference in the technical success rate between biopsies of rLN =1 cm and >1 cm with a diagnostic rate of 91.4% (139/152) and 95.7% (132/138), respectively (p=0.16). A diagnosis of malignancy was made in 50.0% (76/152) of the =1 cm biopsies and 54.3% (75/138) for biopsies >1 cm. Considering the smallest rLNs, diagnostic samples were obtained from nodes of 4, 5 and 6 mm diameter in 50% (1/2), 100% (5/5), and 86.7% (13/15), respectively. There was no significant difference in bleeding complications (major: 1.3 vs. 1.5%; minor: 13.8 vs. 6.5% (p=0.05), lesion location or prostate specific antigen values (4.4±6.5 vs.10.9±48.9, p=0.12) between patients with rLN =1 cm and >1 cm, respectively. Not unexpectedly, rLN =1 cm had lower lesion maximum standardized uptake value (p<0.001) on Chol/PET.*Conclusions New techniques in metabolic imaging can identify suspected metastatic disease in tiny (4-10mm) retroperitoneal lymph nodes that could be overlooked by conventional imaging. We show that CT-guided percutaneous biopsy of these tiny nodes is safe and effective for diagnosis of metastatic prostate cancer.*Clinical Relevance/Application New techniques in metabolic imaging can identify suspected metastatic disease in tiny (4-10mm) retroperitoneal lymph nodes that could be overlooked by conventional imaging; we show that CT-guided percutaneous biopsy of these tiny nodes is safe and effective for diagnosis of metastatic prostate cancer.

RESULTS

A total of 290 biopsies were performed in 269 patients. Of these, 152 (52.4%) were done on rLN =1 cm (4-10mm, mean 8±1 mm) and 138 were >1 cm (11-54mm, mean 16±6mm). There was no difference in the technical success rate between biopsies of rLN =1 cm and >1 cm with a diagnostic rate of 91.4% (139/152) and 95.7% (132/138), respectively (p=0.16). A diagnosis of malignancy was made in 50.0% (76/152) of the =1 cm biopsies and 54.3% (75/138) for biopsies >1 cm. Considering the smallest rLNs, diagnostic samples were obtained from nodes of 4, 5 and 6 mm diameter in 50% (1/2), 100% (5/5), and 86.7% (13/15), respectively. There was no significant difference in bleeding complications (major: 1.3 vs. 1.5%; minor: 13.8 vs. 6.5% (p=0.05), lesion location or prostate specific antigen values (4.4±6.5 vs.10.9±48.9, p=0.12) between patients with rLN =1 cm and >1 cm, respectively. Not unexpectedly, rLN =1 cm had lower lesion maximum standardized uptake value (p<0.001) on Chol/PET.

CLINICAL RELEVANCE/APPLICATION

New techniques in metabolic imaging can identify suspected metastatic disease in tiny (4-10mm) retroperitoneal lymph nodes that could be overlooked by conventional imaging; we show that CT-guided percutaneous biopsy of these tiny nodes is safe and effective for diagnosis of metastatic prostate cancer.

IR04-A3   **Ultrasound-triggered Release Of Vancomycin From Prophylactic Spinal Device**

Participants
Flemming Forsberg, PhD, Philadelphia, Pennsylvania (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research support, Canon Medical Systems Corporation;Research support, General Electric Company;Speaker, General Electric Company;Research support, Siemens AG;Research Grant, Butterfly Network, Inc;Research support, Lantheus Medical Imaging, Inc;Research support, Bracco Group

PURPOSE

Bacterial infection following spinal fusion surgery is a major clinical concern, with up to 10% incidence despite aggressive peri-operative antibiotic treatments. We have designed an ultrasound-triggered drug release system to combat post-surgical bacterial survival. This study quantified the long-term stability and ultrasound-triggered vancomycin (VAN) release from this system.*Methods and Materials Polylactic acid (PLA) clips with a 0.79cm3 drug-loading reservoir were 3D printed and loaded with ~150-180µL of VAN solution (400mg/mL, ~60-80mg total, Athenex) and 50µL of Sonazoid microbubbles (GE Healthcare), then sealed with a PLA film (0.05±0.01mm thick). Clips were then submerged in 37°C water and insonated in Doppler mode at 1.8MHz for

10min using a Logiq E9 scanner (GE Healthcare) with a C6 probe (6.5kHz PRF, ISPTA 146.2±1.4mW/cm2) to rupture the PLA seal for VAN release. VAN release was quantified in triplicate using spectrophotometry (Tecan, 281nm absorbance) at t=0, 10, 20, ? 60min, then at 2, 4, 6, 12, 24, 36, 48, and 72h. Long-term stability of Sonazoid was determined over a 14-day incubation at 4°C. Reconstituted microbubbles (50μL) were added to 150μL of either distilled water or VAN solution (400mg/mL). Microbubble counts were obtained in triplicate after 0, 1, 3, 6, 8, 10, and 14 days using a BD LSR II flow cytometer (BD Biosciences), while enhancement of the Sonazoid solutions was visualized in contrast mode on days 0, 3, 8, and 14.*Results After the 14 day incubation, Sonazoid in water had reduced by ~90% (from 7.3±1.4x107 to 7.3±1.6x106), while those in VAN reduced by ~60% (from 8.9±6.7x106 to 3.3±9.3x106). VAN appears to have a slightly conservatory effect on Sonazoid (p=0.0073). Marked contrast enhancement was observed from both solutions at all 4 time points, indicating the remaining microbubbles were still acoustically active. Rupture of the PLA seal was observed in all 5 insonated clips with a cumulative VAN release of 81.4±2.8mg at 72h. The majority of the VAN was released within the first hour post-insonation, which is ideal for delivering a supratherapeutic bolus and preventing development of bacterial resistance. None of the 5 uninsonated controls showed any significant leakage or rupture, with only a nominal amount of VAN detectable in the media (0.3±0.1mg at 72h), indicating that the PLA seals sufficiently contain the payload within the device until ultrasound triggering.*Conclusions Overall, these results demonstrate the ability to produce ultrasound-triggered release of an encapsulated prophylactic solution.*Clinical Relevance/Application This system will aggressively combat post-surgical bacterial infection with great versatility in applications for wide clinical impact.

RESULTS

After the 14 day incubation, Sonazoid in water had reduced by ~90% (from 7.3±1.4x107 to 7.3±1.6x106), while those in VAN reduced by ~60% (from 8.9±6.7x106 to 3.3±9.3x106). VAN appears to have a slightly conservatory effect on Sonazoid (p=0.0073). Marked contrast enhancement was observed from both solutions at all 4 time points, indicating the remaining microbubbles were still acoustically active. Rupture of the PLA seal was observed in all 5 insonated clips with a cumulative VAN release of 81.4±2.8mg at 72h. The majority of the VAN was released within the first hour post-insonation, which is ideal for delivering a supratherapeutic bolus and preventing development of bacterial resistance. None of the 5 uninsonated controls showed any significant leakage or rupture, with only a nominal amount of VAN detectable in the media (0.3±0.1mg at 72h), indicating that the PLA seals sufficiently contain the payload within the device until ultrasound triggering.

CLINICAL RELEVANCE/APPLICATION

This system will aggressively combat post-surgical bacterial infection with great versatility in applications for wide clinical impact.

IR04-A4   Effect Of Aspirin Administration On Transplant-free Survival After Transjugular Intrahepatic Portosystemic Shunt (TIPS) Placement: A Retrospective Multicenter Analysis

Participants
Philipp Schindler, MD, Muenster, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the effect of aspirin (acetylsalicylic acid) administration on transplant-free survival in patients with transjugular intrahepatic portosystemic shunt (TIPS).*Methods and Materials Data from all patients receiving TIPS at three university liver centers between 2013 and 2018 (n=814) were retrospectively reviewed. N=587 patients were stratified depending on aspirin administration after TIPS (aspirin cohort, n=163; no-aspirin cohort, n=424) and subdivided into two matched cohorts after propensity score matching. Primary endpoint of the study was transplant-free survival at 12 months after TIPS. Secondary endpoints included occurrence of hepatic encephalopathy (HE), recurrence of primary TIPS indication and TIPS re-intervention rates in 12-months follow-up.*Results Aspirin administration improved transplant-free survival 12 months after TIPS (aspirin cohort, 90.8% vs. no-aspirin cohort, 76.6%; p<0.001). HE occurred more frequently in the aspirin cohort (p=0.014). Frequency of recurrence of primary TIPS-indication (p=0.612) and TIPS re-intervention rates (p=0.406) were not affected by aspirin administration.*Conclusions This retrospective multicenter study provides first data demonstrating a beneficial effect of aspirin administration on transplant-free survival in TIPS patients without impairment of TIPS function.*Clinical Relevance/Application Aspirin administration after TIPS placement has a substantial effect on the transplant-free survival. These findings support the necessity for prospective randomized clinical trials to investigate the effects of aspirin in TIPS patients.

RESULTS

Aspirin administration improved transplant-free survival 12 months after TIPS (aspirin cohort, 90.8% vs. no-aspirin cohort, 76.6%; p<0.001). HE occurred more frequently in the aspirin cohort (p=0.014). Frequency of recurrence of primary TIPS-indication (p=0.612) and TIPS re-intervention rates (p=0.406) were not affected by aspirin administration.

CLINICAL RELEVANCE/APPLICATION

Aspirin administration after TIPS placement has a substantial effect on the transplant-free survival. These findings support the necessity for prospective randomized clinical trials to investigate the effects of aspirin in TIPS patients.

IR02-B2   **Splenic Artery Steal Syndrome In Patients With Orthotopic Liver Transplant: Where To Embolize The Splenic Artery?**

Participants
Florian Fleckenstein, MS, Berlin, Germany (*Presenter*) Nothing to Disclose

PURPOSE

This study compared proximal and distal splenic artery embolization (SAE) in patients with splenic artery steal syndrome (SASS) after orthotopic liver transplantation (OLT) regarding post interventional changes of liver function to identify an ideal location of embolization.*Methods and Materials 80 patients with SASS after OLT treated with SAE between 2007 and 2017 were retrospectively reviewed. Periinterventional DSA was used to assess treatment success and to stratify patients according to the site of embolization. Liver function was assessed using following laboratory values: bilirubin (TBIL), albumin, gamma-glutamyl transferase (GGT), glutamat-pyruvat-transaminase (GPT), glutamic-oxaloacetic transaminase (GOT), Aspartate-transaminase (AST), aPTT, INR and thrombocyte count. Descriptive statistics were used to summarize the data. Median laboratory values of pre, 1- and 3-days, as well as 1-week and 1-month post-embolization were compared using linear mixed model regression analysis.*Results All procedures were technically successful and showed an improved blood flow in the hepatic artery post-embolization. Five Patients were excluded. Pairwise comparison using linear mixed model regression analysis could showed a significant difference between proximal and distal embolization for GPT (57.0 (IQR 107.5) vs. 118.0 (IQR 254.0) U/l, p=0.002) and GOT (48.0 (IQR 48.0) vs. 81.0 (IQR 115.0) U/l, p=0.008) 3-days after embolization as well as median thrombocyte counts 7-days after embolization (122 (IQR 108) vs. 83 (IQR 74) in thousands, p=0.014). For all other laboratory values, no statistically significant difference could be shown between both groups stratified regarding the site of embolization.*Conclusions In conclusion no clinical relevant difference could be detected between a proximal and distal SAE. We conclude that a successful SAE is independent of the site of embolization.*Clinical Relevance/Application Choice of SAE technique in patients suffering from SASS after OLT might solely be based on interventionalists preferences and anatomical conditions.

RESULTS

All procedures were technically successful and showed an improved blood flow in the hepatic artery post-embolization. Five Patients were excluded. Pairwise comparison using linear mixed model regression analysis could showed a significant difference between proximal and distal embolization for GPT (57.0 (IQR 107.5) vs. 118.0 (IQR 254.0) U/l, p=0.002) and GOT (48.0 (IQR 48.0) vs. 81.0 (IQR 115.0) U/l, p=0.008) 3-days after embolization as well as median thrombocyte counts 7-days after embolization (122 (IQR 108) vs. 83 (IQR 74) in thousands, p=0.014). For all other laboratory values, no statistically significant difference could be shown between both groups stratified regarding the site of embolization.

CLINICAL RELEVANCE/APPLICATION

Choice of SAE technique in patients suffering from SASS after OLT might solely be based on interventionalists preferences and anatomical conditions.

PH03-B1   Deep Learning Based Semantic Segmentation Of Intracranial Aneurysm With 3d Patches For Overcoming Imbalance In Brain TOF-MRA

Participants
Sungwon Ham, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop a semantic segmentation on an intracranial aneurysm with 3D patches in brain time-of-flight (TOF)-MR angiography (MRA) with convolutional neural net (CNN).*Methods and Materials Total 154 3D TOF-MRA datasets with intracranial aneurysm were acquired from XX center and YY hospital, which was split into 124, 14 and 16 patients as a training, validation, and test sets, respectively. The gold standard of ????the intracranial aneurysm was manually drawn by an expert neuroradiologist with more than 10 years' experience. These MRAs were pre-processed by using the skull-stripping, the signal intensity normalization and N4 bias correction. In addition, they were resampled into a 0.3mm isotropic voxel size. The 3D patches with 64x64x64 size along the vessel skeleton from MRA were extracted. Various kinds of ratios between normal vs aneurysm patches including 1:1, 2:1, and 3:1 were evaluated. 3200 normal patches and 1100 aneurysm patches were used for training, tuning, and validation sets as 8:1:1. These patches were augmented by flip, zoom, gaussian noise and rotation, etc. The sematic segmentation on intracranial aneurysm was trained using 3D U-Net with auxiliary classifier to differentiate each patch as normal or aneurysm, which could be useful to overcome the extreme imbalance of normal or aneurysm patches. To evaluate segment performance, Dice similarity coefficient (DSC), sensitivity and false positives (FP) per patient were evaluated.*Results The overall mean DSC of our model was 0.705 ± 0.09, the sensitivity per lesion was 0.88, and the FP per patient was 0.31.*Conclusions This 3D patch-level method, showed performance of aneurysms segmentation sufficiently in viewpoint of good sensitivity and small FP, which can be helpful in actual clinical setting.*Clinical Relevance/Application Segmentation of intracranial aneurysms, especially in smaller cases, is very difficult and a misdiagnosis may result in poor clinical outcomes. Therefore, our deep learning model that automatic intracranial aneurysms segmentation will be of valuable aid to radiologists. This is especially important due to the increased workload and consequent fatigue of the radiologist.

RESULTS

The overall mean DSC of our model was 0.705 ± 0.09, the sensitivity per lesion was 0.88, and the FP per patient was 0.31.

CLINICAL RELEVANCE/APPLICATION

Segmentation of intracranial aneurysms, especially in smaller cases, is very difficult and a misdiagnosis may result in poor clinical outcomes. Therefore, our deep learning model that automatic intracranial aneurysms segmentation will be of valuable aid to radiologists. This is especially important due to the increased workload and consequent fatigue of the radiologist.

PH03-B10   In Silico Imaging Trials With Unknown Lesion Location: Initial Results For A Search Task On The Victre Pipeline

Participants
Miguel Angel Lago Angel, PhD, Silver Spring, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the effect of visual search (or location uncertainty) on the outcome of an in silico imaging trial and to compare it to the location-known exactly paradigm.*Methods and Materials We generated 1000 computational images using the VICTRE pipeline corresponding to a Siemens Mammomat Inspiration system. Half of the virtual patients had an inserted simulated spiculated mass in a random location within the breast volume. Breast models were projected using a GPU-accelerated Monte Carlo simulation to generate a Digital Mammography (DM). This process was repeated for 7 mass sizes from 250 mm3 to 85,000 mm3. We analyzed the detectability using a Channelized Hotelling Observer with convolutional channels and a search paradigm of scanning all pixels in the image. The model calculated the likelihood ratio of the presence of the signal at each pixel, taking the maximum value as the response for each case. An analysis was then performed for all trials and the Area Under the ROC (AUC) was calculated for each size. For the search model, we used a mass material with a higher x-ray attenuation to compensate for task difficulty.*Results The use of the VICTRE pipeline in a parallel cluster allowed us to generate 1000 digital mammograms per day, averaging one every 1.5 minutes. Detectability results show a steady increase in the AUC with size and a rapid increase on sizes less than 10,000 mm3 finally saturating at 1 at around 30,000 mm3. The AUC obtained with the search task will be compared with results obtained for a location-known exactly detection task using the same VICTRE methodology.*Conclusions We show the potential of in silico imaging trials to analyze large amounts of images to investigate the effect of unknown lesion location in search tasks. Model observer training strategies for search tasks need to differ from location-known-exactly tasks to allow for the detection of subtle lesions in the presence of anatomical background noise.*Clinical Relevance/Application We show that in silico imaging trials are feasible and could provide additional insight into the performance comparison considering search tasks between imaging technologies. This is of particular relevance for the understanding of the differences between DM and DBT in terms of 2d and 3d search strategies and efficiency in a screening setting.

RESULTS

The use of the VICTRE pipeline in a parallel cluster allowed us to generate 1000 digital mammograms per day, averaging one every 1.5 minutes. Detectability results show a steady increase in the AUC with size and a rapid increase on sizes less than 10,000 mm3 finally saturating at 1 at around 30,000 mm3. The AUC obtained with the search task will be compared with results obtained for a location-known exactly detection task using the same VICTRE methodology.

CLINICAL RELEVANCE/APPLICATION

We show that in silico imaging trials are feasible and could provide additional insight into the performance comparison considering search tasks between imaging technologies. This is of particular relevance for the understanding of the differences between DM and DBT in terms of 2d and 3d search strategies and efficiency in a screening setting.

PH03-B12   Survival Outcome Prediction Following Risk-adaptive Chemoradiation For Unresectable Non-small Cell Lung Cancer Using Machine Learning Of Single / Multimodality Radiomics

Participants
Parisa Forouzannezhad, PhD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

We evaluated whether single / multimodality radiomics can improve survival outcome prediction relative to published prognostic clinical factors and quantitative imaging biomarkers in patients with unresectable locally advanced non-small cell lung cancer (LA-NSCLC).*Methods and Materials Survival outcomes were modeled for 45 patients with LA-NSCLC enrolled on a trial of risk-adaptive chemoradiation and optional consolidation PD-L1 checkpoint blockade. Semi-automatic gradient-based tumor segmentations on pre-treatment CT, FDG-PET, and MAA-SPECT perfusion imaging were passed to IBSI-compliant Pyradiomics to extract 110 intensity, shape, and texture features. Fixed bin width discretization of 0.25 SUV, 25 HU, and 25 CNTS was consistently applied to ensure sufficient gray-level sampling of PET, CT, and SPECT radiomics, respectively. Least Absolute Shrinkage and Selection Operator (LASSO) dimensionality reduction of each radiomics modality was applied to 10-fold cross-validation training sets. Stratified resampling minimized imbalances in survival event proportion between training and testing sets. Ensemble component-wise gradient boosting survival trees with LASSO-selected features were grown using the same training folds and a nested grid search for hyperparameter tuning. Concordance index (c-index) and 95% confidence intervals of survival prediction models were computed on 10-fold cross-validation testing sets using single-modality and multimodality radiomics.*Results Median follow-up was 19 months [3-50 months] with 18 overall survival (OS) events. OS prediction models achieved stratified resampled 10-fold cross-validated c-index of 0.70 [0.63-0.76], 0.63 [0.57-0.68], and 0.62 [0.55-0.66] using PET, CT, and SPECT radiomics, respectively. Multimodality PET/CT/SPECT radiomics achieved c-index of 0.72 [0.66-0.76] for predicting OS, significantly outperforming (p<0.001) the benchmark clinical-imaging model c-index of 0.64 [0.58-0.69], which consisted of LASSO-selected CT planning target volume, PET SUVmax, PET metabolic tumor volume, and PET total lesion glycolysis.*Conclusions A multimodality framework of gradient boosting survival trees was successfully implemented with pre-treatment PET, CT, and SPECT radiomics to predict survival outcomes of patients with unresectable NSCLC. PET radiomics had the highest prognostic value for OS, with incremental gains using multimodality PET/CT/SPECT radiomics.*Clinical Relevance/Application Multimodality radiomics outcome modeling can provide decision support for precise therapy combinations and adaptive treatment intensification based on risk stratification.

RESULTS

Median follow-up was 19 months [3-50 months] with 18 overall survival (OS) events. OS prediction models achieved stratified resampled 10-fold cross-validated c-index of 0.70 [0.63-0.76], 0.63 [0.57-0.68], and 0.62 [0.55-0.66] using PET, CT, and SPECT radiomics, respectively. Multimodality PET/CT/SPECT radiomics achieved c-index of 0.72 [0.66-0.76] for predicting OS, significantly outperforming (p<0.001) the benchmark clinical-imaging model c-index of 0.64 [0.58-0.69], which consisted of LASSO-selected CT planning target volume, PET SUVmax, PET metabolic tumor volume, and PET total lesion glycolysis.

CLINICAL RELEVANCE/APPLICATION

Multimodality radiomics outcome modeling can provide decision support for precise therapy combinations and adaptive treatment intensification based on risk stratification.

PH03-B2   The Effect Of A Z-axis Dynamic Collimation System On Organ Equivalent Dose In Thorax CT

Participants
Antonios Papadakis, MSc, PhD, Heraklion, Greece (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to investigate the effect of a z-axis dynamic collimation (DC) system on organ equivalent dose in pediatric and adult thorax CT.*Methods and Materials Five physical anthropomorphic phantoms that simulate the average individual as a neonate, 1-, 5-, 10-years-old child and female adult were employed. Thorax acquisitions were performed on a Revolution HD GE CT scanner. Acquisitions were performed first with the DC system disabled and then with the DC system enabled. z-axis exposure profiles were recorded using a solid state point detector. Whole body axial image series of the phantoms were used to generate age-specific voxelized phantoms, which were input to a Monte Carlo based simulation tool to generate three-dimensional radiation dose image maps. DC disabled and DC enabled acquisitions were simulated by applying material segmentation and using the scanner geometry, filtration, photon energy spectrum and recorded z-axis exposure profiles. The dose image maps were used to estimate thyroid, breast, lung, and liver equivalent doses. Percent reduction in organ equivalent dose achieved with DC was determined. Image noise was measured as the standard deviation of the Hounsfield unit value at selected anatomical sites along the z-axis.*Results In DC disabled acquisitions, thyroid equivalent dose ranged from 0.5 mGy in neonate to 4.1 mGy in adult. The corresponding organ equivalent doses for breast, lung and liver ranged from 1.2 mGy to 5.5 mGy, 1.5 mGy to 6.5 mGy, and 4.1 mGy to 4.7 mGy, respectively. In DC enabled acquisitions, equivalent dose was reduced for organs located beyond or close to the boundaries of the planned imaged volume, i.e. up to 16% for thyroid and 8% for liver. DC did not modify equivalent dose for breast and lung. Image noise was not significantly affected in DC enabled acquisitions (P < 0.01).*Conclusions z-axis dynamic collimation reduces the equivalent dose to organs located beyond the boundaries of the planned imaged volume. CT operators should be aware that this reduction is moderate and that they should still be careful when setting the boundaries of the planned imaged volume to limit exposure of radiosensitive organs.This work has received funding from the Euratom research and training programme 2014-2018 under grant agreement No 755523 (MEDIRAD).*Clinical Relevance/Application The results presented in this study demonstrate that although the reduction of equivalent dose in organs located beyond the boundaries of the planned image volume is moderate, the use of the z-axis collimation system is important to optimize radiation dose in thorax CT.

RESULTS

In DC disabled acquisitions, thyroid equivalent dose ranged from 0.5 mGy in neonate to 4.1 mGy in adult. The corresponding organ equivalent doses for breast, lung and liver ranged from 1.2 mGy to 5.5 mGy, 1.5 mGy to 6.5 mGy, and 4.1 mGy to 4.7 mGy, respectively. In DC enabled acquisitions, equivalent dose was reduced for organs located beyond or close to the boundaries of the planned imaged volume, i.e. up to 16% for thyroid and 8% for liver. DC did not modify equivalent dose for breast and lung. Image noise was not significantly affected in DC enabled acquisitions (P < 0.01).

CLINICAL RELEVANCE/APPLICATION

The results presented in this study demonstrate that although the reduction of equivalent dose in organs located beyond the boundaries of the planned image volume is moderate, the use of the z-axis collimation system is important to optimize radiation dose in thorax CT.

PH03-B8　Utility Of High-resolution CT For The Detection And Characterization Of Stenotic Lesions: A Phantom Study Using Model Observers

Participants
Andrew Hernandez, PHD, Sacramento, California (*Presenter*) Research funded, Canon Medical Systems Corporation

PURPOSE

The accurate detection and grading of atheromatous stenotic lesions within the cardiacand intracranial vasculature is imperative for early recognition of disease and guiding treatmentstrategies. In this work, a novel stenotic lesion phantom was used to evaluate a high-resolution CTscanner in terms of disk detection and size discrimination performance.*Methods and Materials The phantom is comprised of three acrylic cylinders (15 cm in diameter and 1.3 cm thick) with matching array of holes machined in each module (1.32-10.08 mm in physical diameter). The outer two modules contain holes that are slightly larger than the corresponding hole in the central module. The stack of three modules was submerged in iodine solution emulating contrast-enhanced stenotic lesions with a range of five nominal diameters (2.95-10.08 mm) and stenosis severity (0, 50%, 60%, 70%, and 80%). The phantom was imaged on the Canon Aquilion Precision high-resolution CT scanner in high-resolution "HR" mode (0.25x0.50 mm detector size) and normal-resolution "NR" (0.50x0.50 mm) with 30 repeat scans acquired for each mode using 120 kV and 14 mGy CTDIvol. Both FBP and an iterative algorithm (AIDR3D) were used for reconstruction with the smooth FC18 kernel. A non-prewhitening model observer with an eye filter was implemented for both a disk detection task and a size discrimination task.*Results HR mode resulted in higher detectability in comparison with NR for disk diameters up to 4.0 and 2.8 mm for FBP and AIDR, respectively. For the size discrimination task, the larger the difference in stenosis severity the higher the detectability. For FBP, differences in detectability were all within 10% except for the 2.95 mm nominal diameter lesion comparing 50%vs. 80% (termed 50v80) stenosis severity where HR was 13% higher than NR. Differences in detectability for AIDR were within 10% except for the 2.95 mm nominal diameter where HR resulted in 12%, 17%, and 22% higher detectability in comparison to NR for 50v60, 50v70, and50v80 stenosis, respectively, and the 4 mm nominal diameter where HR resulted in 11% higher detectability in comparison to NR for 50v80.*Conclusions A stenotic lesion phantom and model observer methodology demonstrated the value of high-resolution imaging for fine size discrimination tasks simulating stenotic severity. It is anticipated that this methodology will be used to optimize the acquisition and reconstruction parameters on this new CT scanner technology for quantifying stenotic lesion detection and severity.*Clinical Relevance/Application The advantage of HR mode in comparison to NR was demonstrated in the size discrimination task. The accurate quantification of stenosis in atheromatous disease is clinically important for optimal patient risk stratification and treatment.

RESULTS

HR mode resulted in higher detectability in comparison with NR for disk diameters up to 4.0 and 2.8 mm for FBP and AIDR, respectively. For the size discrimination task, the larger the difference in stenosis severity the higher the detectability. For FBP, differences in detectability were all within 10% except for the 2.95 mm nominal diameter lesion comparing 50%vs. 80% (termed 50v80) stenosis severity where HR was 13% higher than NR. Differences in detectability for AIDR were within 10% except for the 2.95 mm nominal diameter where HR resulted in 12%, 17%, and 22% higher detectability in comparison to NR for 50v60, 50v70, and50v80 stenosis, respectively, and the 4 mm nominal diameter where HR resulted in 11% higher detectability in comparison to NR for 50v80.

CLINICAL RELEVANCE/APPLICATION

The advantage of HR mode in comparison to NR was demonstrated in the size discrimination task. The accurate quantification of stenosis in atheromatous disease is clinically important for optimal patient risk stratification and treatment.

PH03-B9　Key-slice Parsing And Diagnostic Confidence Estimation For Localization And Differentiation Of Liver Lesions Using Multi-phasic MRI

Participants
Yuhsuan Wu, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

Multi-phasic MRI is a key modality to non-invasively discover and diagnose liver lesions. Yet, reported reader specificities remain low, e.g., over-interpreting washout as hepatocellular carcinoma (HCC). Computer-aided diagnosis (CAD) solutions may help boost diagnostic performance, but reported algorithms assume lesions are localized already. As well, they offer no assessment of their diagnostic certainty, i.e., how confident each prediction is. To address this gap, we develop a fully automatic CAD workflow that localizes liver lesions, differentiates them, and outputs the certainty of each prediction.*Methods and Materials We retrospectively enrolled 400 patients, each imaged with multi-phasic MRI. Diagnoses were all histopathologically confirmed: 207 HCC, 83 intrahepatic cholangiocarcinoma (ICC), and 110 secondary metastases. Each present lesion was annotated with RECIST marks on each slice. To robustly localize lesions, we use a physician inspired deep-learning (DL) workflow: (1) identify key slices; (2) rank slices using curve parsing; and (3) localize one key lesion per key slice. A DL classifier then classifies each found lesion as either HCC, ICC, or metastasis, where Monte Carlo dropout provides an assessment of predictive certainty. For comparative human reader performance, an abdominal radiologist with > 20 years of experience diagnosed each patient based on only the MRI studies.*Results Because localization and classification must both succeed, performance demands are high. Using five-fold cross validation and ROC analysis, our model's HCC vs. others area under the curve (AUC) is a high 91.3%. Our model's max Youden index of 0.674 compares well to the senior radiologist's Youden index of 0.731. For categorical predictions, our model reports a mean F1 of 61.3%, Importantly, our model accurately assesses certainty, e.g., only keeping the 75% most certain predictions boosts the AUC and mean F1 to 94.3%. and 70.7%, respectively.*Conclusions We proposed a multi-phasic MRI CAD solution to localize liver lesions,

differentiate their type, and assess predictive certainty. Experiments demonstrate high diagnostic performance and an effective assessment of which patients it is uncertain about.*Clinical Relevance/Application Our CAD solution can support physicians in making more confident radiological liver lesion diagnoses. By providing certainty measurements, it can also help assess when other tests are required.

RESULTS

Because localization and classification must both succeed, performance demands are high. Using five-fold cross validation and ROC analysis, our model's HCC vs. others area under the curve (AUC) is a high 91.3%. Our model's max Youden index of 0.674 compares well to the senior radiologist's Youden index of 0.731. For categorical predictions, our model reports a mean F1 of 61.3%, Importantly, our model accurately assesses certainty, e.g., only keeping the 75% most certain predictions boosts the AUC and mean F1 to 94.3%. and 70.7%, respectively.

CLINICAL RELEVANCE/APPLICATION

Our CAD solution can support physicians in making more confident radiological liver lesion diagnoses. By providing certainty measurements, it can also help assess when other tests are required.

IR03-A2   **Healthcare Disparity: Lack of Access to Embolization Identified for Black Women Affected by Uterine Fibroids in Rural Alabama**

Participants
Cynthia De la Garza Ramos, MD, Jacksonville, Florida (*Presenter*) Nothing to Disclose

PURPOSE

Uterine fibroids are the most common benign tumor in women impacting approximately 70% by the age of 50. Uterine fibroid embolization (UFE) is a viable treatment for symptomatic control for most of these patients; however, access to this procedure is not ubiquitous. An estimated 55,000 African American women living in Alabama between the ages of 35-50 have symptomatic uterine fibroids but live in a county that does not offer UFE. This disparity is even further divided in an area known as the blackbelt, which comprises about 20 counties across nearly 300 miles and is well known for its healthcare scarcity. The purpose of this study is to identify and develop methods to move the needle away from the status quo and improve access to UFE, especially in the black belt region.*Methods and Materials Uterine fibroid burden in Alabama was estimated by extracting county level data based on age, sex and race. Once an unmet need was established, medical centers performing embolization were identified in relationship to each county and population density. With support from Varian Medical Systems, CPT codes from these hospitals were used to determine the volume of embolization procedures performed. These results will guide appropriate intervention in order to increase access to UFE in all counties, but especially in the blackbelt region.*Results There is a strong correlation between population density and embolization procedures (r = 0.83 on Pearson correlation; p = 0.0001). Only 10 medical centers in Alabama offer embolization and 89% of these procedures are performed at only 3 of these 10. In the blackbelt region, there is just one hospital that performs embolization for over 20 counties, which accounts for 3% of all procedures in Alabama.*Conclusions Thousands of women living in Alabama suffer from symptomatic uterine fibroids but do not have access to UFE. This effect is even worse for African American women where an estimated 55,000 have symptomatic fibroids but live in a county that does not offer UFE. The next phase of this project is to implement an outreach program to address this overwhelming need. Telehealth partnerships between university-based health systems and rural hospitals are in development to assuage this disparity.*Clinical Relevance/Application Over 55,000 Black women 35-50 years old in Alabama suffer from uterine fibroids but do not have access to embolization. Implementing telehealth services would address this healthcare disparity.

RESULTS

There is a strong correlation between population density and embolization procedures (r = 0.83 on Pearson correlation; p = 0.0001). Only 10 medical centers in Alabama offer embolization and 89% of these procedures are performed at only 3 of these 10. In the blackbelt region, there is just one hospital that performs embolization for over 20 counties, which accounts for 3% of all procedures in Alabama.

CLINICAL RELEVANCE/APPLICATION

Over 55,000 Black women 35-50 years old in Alabama suffer from uterine fibroids but do not have access to embolization. Implementing telehealth services would address this healthcare disparity.

IR03-A3   **Refining Prognosis In Chemoembolization For Hepatocellular Carcinoma: Immunonutrition And Liver Function.**

Participants
Lukas Mueller, MD, Mainz, Germany (*Presenter*) Nothing to Disclose

PURPOSE

A combination of the Albumin-Bilirubin (ALBI) grading and the Prognostic Nutritional Index (PNI) has recently been identified as a highly predictive scoring system for patients with hepatocellular carcinoma (HCC) undergoing tumor ablation. This study aimed to evaluate this combination's promising results in treatment naïve patients undergoing TACE treatment.*Methods and Materials Between 2010 and 2020, 280 patients who met the inclusion criteria were retrospectively identified at our tertiary care liver center. Lymphocyte count, serum albumin, and bilirubin levels were recorded to calculate both scores; further established risk factors entered multivariate analysis. Influence of ALBI grade and PNI on the median overall survival (OS) was assessed using univariate and multivariate regression analyses. In the next step, ALBI and PNI were combined, and the prognostic ability of this combined approach was compared to existing scoring systems (BCLC, HAP, mHAP-II) regarding their Harrell´s Concordance Index.*Results Both ALBI grade 2-3 and a low PNI were highly predictive for median OS (ALBI grade 1-3: 39.0 vs 16.3 vs 5.4 months, p<0.001; high vs low PNI: 21.4 vs. 7.5, p<0.001). Combination of both and stratification into 4 groups resulted in an OS of 39.0, 20.1, 10.3, and 5.4 months (p<0.001). With a Harrell´s Concordance Index (C-Index) of 0.69, the ALBI-PNI outperformed each individual score (C-Index = 0.65 respectively 0.64) and was also better than BCLC, HAP and mHAP-II (C-Indices 0.66, 0.60 and 0.59).*Conclusions The combination of ALBI and PNI was superior to each score alone and also to other established scoring systems in prognosis prediction. Thus, the easy-to-calculate ALBI-PNI might be a promising stratification tool for patients with HCC undergoing TACE, reflecting both immunonutritive status and liver function.*Clinical Relevance/Application ALBI-PNI might be a promising stratification tool for patients with HCC undergoing TACE and especially, the combination with other established risk factors offers great

potential.

RESULTS

Both ALBI grade 2-3 and a low PNI were highly predictive for median OS (ALBI grade 1-3: 39.0 vs 16.3 vs 5.4 months, p<0.001; high vs low PNI: 21.4 vs. 7.5, p<0.001). Combination of both and stratification into 4 groups resulted in an OS of 39.0, 20.1, 10.3, and 5.4 months (p<0.001). With a Harrell´s Concordance Index (C-Index) of 0.69, the ALBI-PNI outperformed each individual score (C-Index = 0.65 respectively 0.64) and was also better than BCLC, HAP and mHAP-II (C-Indices 0.66, 0.60 and 0.59).

CLINICAL RELEVANCE/APPLICATION

ALBI-PNI might be a promising stratification tool for patients with HCC undergoing TACE and especially, the combination with other established risk factors offers great potential.

IR03-A4   Catheter-directed Thrombolysis Vs. Anticoagulation For The Prevention And Treatment Of Post-thrombotic Syndrome In Deep Vein Thrombosis: A Systematic Review And Meta-analysis

Participants
Ashkan Heshmatzadeh Behzadi, MD, Milford, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

We performed a meta-analysis to assess the benefit of additional ultrasound-accelerated catheter-directed thrombolysis (CDT) for the prevention of post-thrombotic syndrome compared with standard anticoagulation(AC) therapy in patients with iliofemoral deep-vein thrombosis.*Methods and Materials This meta-analysis was performed according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). A search of databases was conducted by 2 researchers independently for clinical trials Medline, Embase , Cochrane CENTRAL and google scholar were reviewed. Outcomes of interest included post-thrombotic syndrome, thromboembolic events, mortality, and bleeding risk. A random effects model meta-analysis was performed. Heterogeneity was reported with the I2 statistic, >50% of I2 was considered to be statistically significant.*Results Five randomized controlled trials (RCTs) including 1157 patients met the inclusion criteria. Our meta-analysis showed additional ultrasound-accelerated catheter-directed thrombolysis does not change the risk of post-thrombotic syndrome 1 year after acute iliofemoral deep-vein thrombosis compared with Standard anticoagulation therapy alone, (OR: 0.5; 95% CI: 0.12-1.1; I2 = 85.1%). Safety outcomes Rates for bleeding were reported in all 5 studies included in the meta-analysis. The overall bleeding rates after a follow-up of 24 months in the CDT Group was 14% (80 out of 568 patients) whereas in the AC only group was 7.0% (40 out of 589 patients). The two groups did not have a statistically significant rate of bleeding (OR: 4.0; 95% CI: 0.80-15.54; I2 = 69.7%). The overall death rate in the whole cohort was 1.5%; 8 patients in the CDT group compared to 11 patients in the AC group. No difference was found between the two groups (OR: 0.99; 95% CI: 0.37- 2.38), I2 (70.7%).*Conclusions Our meta-analysis showed that additional ultrasound-accelerated catheter-directed thrombolysis does not change the risk of post-thrombotic syndrome 1 year after acute iliofemoral deep-vein thrombosis compared with standard therapy alone.*Clinical Relevance/Application Our meta-analysis based on combining data from multiple well designed randomized clinical trials showed that additional ultrasound-accelerated catheter-directed thrombolysis does not change the risk of post-thrombotic syndrome 1 year after acute iliofemoral deep-vein thrombosis compared with standard therapy alone.

RESULTS

Five randomized controlled trials (RCTs) including 1157 patients met the inclusion criteria. Our meta-analysis showed additional ultrasound-accelerated catheter-directed thrombolysis does not change the risk of post-thrombotic syndrome 1 year after acute iliofemoral deep-vein thrombosis compared with Standard anticoagulation therapy alone, (OR: 0.5; 95% CI: 0.12-1.1; I2 = 85.1%). Safety outcomes Rates for bleeding were reported in all 5 studies included in the meta-analysis. The overall bleeding rates after a follow-up of 24 months in the CDT Group was 14% (80 out of 568 patients) whereas in the AC only group was 7.0% (40 out of 589 patients). The two groups did not have a statistically significant rate of bleeding (OR: 4.0; 95% CI: 0.80-15.54; I2 = 69.7%). The overall death rate in the whole cohort was 1.5%; 8 patients in the CDT group compared to 11 patients in the AC group. No difference was found between the two groups (OR: 0.99; 95% CI: 0.37- 2.38), I2 (70.7%).

CLINICAL RELEVANCE/APPLICATION

Our meta-analysis based on combining data from multiple well designed randomized clinical trials showed that additional ultrasound-accelerated catheter-directed thrombolysis does not change the risk of post-thrombotic syndrome 1 year after acute iliofemoral deep-vein thrombosis compared with standard therapy alone.

IR03-A6   Factors Associated With Persistence In Treated Pulmonary Arteriovenous Malformations: A Retrospective, Single-center, Observational Study

Participants
Muhammad Latif, MBBS, Dundalk, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Persistence rates of treated pulmonary AVMs are as high as 25%. Risk factors for persistence have been established based on single timepoint cross-sectional studies. However, no study has analyzed patient, pAVM, and technical risk factors associated with persistence using a survival analysis model.*Methods and Materials We retrospectively analyzed 118 patients with 405 pAVM who underwent embolization with coils or microvascular plugs (MVP™ system) or Amplatzer vascular plug (AVPTM) at an academic tertiary care hospital from 2003 to 2020. We included patients with follow-up chest computed tomography pulmonary angiograms (CTPAs). Patient mean age ± standard deviation was 44 ± 18 years (69% women); range, 3-87 years] with 405 treated pAVMs were included in the analysis. Median follow-up time was 1.6 years (interquartile range 0.3, 5.7). Three experienced radiologist confirmed persistence after reviewing the follow up CTPA images with a general consensus agreement. Persistence was defined as a <70% reduction in pAVM sac size or contrast enhancement of the sac on follow-up CTPA. Forty-one pAVMs (10%) had persistence. Univariable Cox proportional hazard regression was used to determine associations of potential risk factors and embolic agents with persistence, and a multivariable prediction model was developed. A p value of < 0.05 was considered statistically significant.*Results On multivariate analysis, feeding artery diameter (hazard ratio [HR], 1.1; 95% confidence interval [CI], 1.0-1.3; P = .02), number of feeding arteries (HR, 2.0; 95% CI, 1.1-3.65; P = .03), embolic nest to pAVM sac distance (HR, 4.8; 95%CI, 2.0-11; P < .01), and embolic device types were significantly associated with persistence. pAVMs embolized with coils alone had a higher incidence of persistence compared with pAVMs treated with an MVP™ system, AVPTM, or a combination of either plug type with a coil (P = .02) or MVPTM and AVPTM. The persistence rate was 16% (34/207), 8% (7/88) and 0% (0/98) for coil only, AVPTM only and MVPTM only pAVMs respectively.*Conclusions We identified and confirmed several variables associated with persistence,

including type and size of embolic device used, site of deployment, intrinsic morphologic features of pAVM, and BMI. Such findings could have implications for the treatment of patients with pAVMs.*Clinical Relevance/Application As such, pretreatment knowledge of these variables can be used for planning and optimization of successful pAVM embolization. For now, we believe that there is sufficient evidence to encourage the use of either the MVP™ system or a combination of AVPTM and coils as first line agents for the embolization of pAVM.

RESULTS

On multivariate analysis, feeding artery diameter (hazard ratio [HR], 1.1; 95% confidence interval [CI], 1.0-1.3; P = .02), number of feeding arteries (HR, 2.0; 95% CI, 1.1-3.65; P = .03), embolic nest to pAVM sac distance (HR, 4.8; 95%CI, 2.0-11; P < .01), and embolic device types were significantly associated with persistence. pAVMs embolized with coils alone had a higher incidence of persistence compared with pAVMs treated with an MVP™ system, AVPTM, or a combination of either plug type with a coil (P = .02) or MVPTM and AVPTM. The persistence rate was 16% (34/207), 8% (7/88) and 0% (0/98) for coil only, AVPTM only and MVPTM only pAVMs respectively.

CLINICAL RELEVANCE/APPLICATION

As such, pretreatment knowledge of these variables can be used for planning and optimization of successful pAVM embolization. For now, we believe that there is sufficient evidence to encourage the use of either the MVP™ system or a combination of AVPTM and coils as first line agents for the embolization of pAVM.

NMMI03-A2 177Lu-DOTATATE In The Treatment Of Recurrent Meningioma

Participants
Jay Gajera, MD,BSC, Melbourne, Australia (*Presenter*) Nothing to Disclose

PURPOSE

Somatostatin receptor (SSTR)-targeted peptide receptor radionuclide therapy (PRRT) represents a promising approach for treatment-refractory meningiomas. The objective of this study was to perform quantitative analysis to determine the early radiobiological disease response of progressive radiation therapy refractory WHO grade I-III meningiomas following 2 cycles of ^{177}Lu-Dotatate based PRRT.*Methods and Materials We performed a retrospective review of 17 patients with recurrent WHO grade I-III meningiomas (median age 69 years, range 40-80 years). Patients had pre- and post-therapy ^{68}Ga-DOTATATE positron emission tomography (PET) as well as T1 contrast-enhanced MRI. Regions of Interest were drawn on PET images using MIM version 7 (MIM Software Inc.; Beachwood, OH). Post treatment PET indices and volumes were compared with baseline values. Tumor response was classified as progressed for &gt15% volume change, regressed for &lt15% change, and stable for ± 15% of baseline volume. Outcomes on MRI were determined using response assessment in neuro-oncology (RANO) criteria for meningioma.*Results 33 lesions in 17 patients were included in the quantitative analysis. The median follow-up was 5 months (range 3-10 months). 25/33 (75.7%) lesions showed regression or remained stable on serial imaging. 8/33 (24.2%) lesions demonstrate interval progression. These 8 lesions were in 2 patients. The baseline SUVmax had a mean of 11.7 (range 4.1-29.9) and post-treatment SUVmax had a mean of 10.6 (range 1.3-29). The baseline tumour volume had a mean of 8.0ml (range 0.1- 54.5) and post-treatment tumour volume had a mean of 8.8ml (range 0.2- 59.3). We found baseline Max SUV to be a moderate predictor of post treatment PET volumes (R value 0.055). The majority of lesions with early progression had SUVmax at baseline of &lt7. An initial analysis of the MRI response revealed 6/8 lesions were stable on follow up and 2/8 demonstrated progressive disease.*Conclusions Lesions with a higher SUVmax may be more responsive to therapy and baseline SUVmax is a potentially useful criterion when considering patients for PRRT regimens.*Clinical Relevance/Application [177Lu]-Dotatate is a potentially useful management strategy in treatment refractory meningiomas.

RESULTS

33 lesions in 17 patients were included in the quantitative analysis. The median follow-up was 5 months (range 3-10 months). 25/33 (75.7%) lesions showed regression or remained stable on serial imaging. 8/33 (24.2%) lesions demonstrate interval progression. These 8 lesions were in 2 patients. The baseline SUVmax had a mean of 11.7 (range 4.1-29.9) and post-treatment SUVmax had a mean of 10.6 (range 1.3-29). The baseline tumour volume had a mean of 8.0ml (range 0.1- 54.5) and post-treatment tumour volume had a mean of 8.8ml (range 0.2- 59.3). We found baseline Max SUV to be a moderate predictor of post treatment PET volumes (R value 0.055). The majority of lesions with early progression had SUVmax at baseline of &lt7. An initial analysis of the MRI response revealed 6/8 lesions were stable on follow up and 2/8 demonstrated progressive disease.

CLINICAL RELEVANCE/APPLICATION

[177Lu]-Dotatate is a potentially useful management strategy in treatment refractory meningiomas.

NMMI03-A3 A Conjugation Strategy To Modulate Antigen Binding As Well As Fcrn Interaction Lead To Improved Tumor Targeting And Radioimmunotherapy Efficacy With An Antibody Targeting Prostate Specific Antigen

Participants
Joanna Strand, Lund, Sweden (*Presenter*) Nothing to Disclose

PURPOSE

The hu5A10 is a humanized monoclonal antibody (mAb) that specifically targets and internalizes prostate cancer cells by binding to prostate-specific antigen (PSA). Preclinical evaluations have shown that hu5A10 is an excellent vehicle for PCa radiotheranostics. We studied the impact of different chelates and conjugation ratios on hu5A10's target affinity, neonatal fc-receptor interaction on in vivo targeting efficacy and possible enhanced therapeutic efficacy.*Methods and Materials hu5A10 was conjugated with DOTA or DTPA at a molar ratio of 3:1, 6:1, and 12:1. Surface plasmon resonance (SPR) was used to study antigen and FcRn binding to the antibody conjugates. [111In]hu5A10 radio-immunoconjugates were administered intravenously into BALB/c mice carrying subcutaneous LNCaP xenografts. Serial SPECT images were obtained during the first week. Tumors were harvested and radionuclide distribution was analyzed by autoradiography along with microanatomy and immunohistochemistry.*Results As seen by SPR, the binding to PSA was clearly affected by the chelate-to-antibody ratio Similarly, FcRn interacted less with antibodies conjugated at high ratios of chelator which was more pronounced for DOTA conjugates. The autoradiography data indicated a higher distribution of radioactivity to the rim of the tumor which was more pronounced for DOTA conjugates. The autoradiography data indicated a higher distribution of radioactivity to the rim of the tumor for lower ratios and a more homogenous distribution at higher ratios. Mice injected with ratio 3:1 111In-DOTA-hu5A10 showed no significant difference in tumor volume when compared to mice given vehicle over a time period of 3 weeks. Mice given a similar activity of the ratio 6:1 111In-DOTA-hu5A10 or 6:1 111In-DTPA-hu5A10 or 12:1 111In-DTPA-hu5A10 showed significant tumor growth retardation.*Conclusions The present study demonstrates that the radiolabeling strategy can positively modify the hu5A10's capacity to bind PSA and complex with the FcRn-receptor, which results in more homogenous

activity distribution in tumors and enhanced therapy efficacy.*Clinical Relevance/Application The present study demonstrates that the radiolabeling strategy can positively modify the hu5A10's capacity to bind PSA and complex with the FcRn-receptor, which results in more homogenous activity distribution in tumors and enhanced therapy efficacy. These new innovative radiochemistry ideas could potentially decrease relapse of tumors in patients treated with internalizing antibodies.

RESULTS

As seen by SPR, the binding to PSA was clearly affected by the chelate-to-antibody ratio Similarly, FcRn interacted less with antibodies conjugated at high ratios of chelator which was more pronounced for DOTA conjugates. The autoradiography data indicated a higher distribution of radioactivity to the rim of the tumor for lower ratios and a more homogenous distribution at higher ratios. Mice injected with ratio 3:1 111In-DOTA-hu5A10 showed no significant difference in tumor volume when compared to mice given vehicle over a time period of 3 weeks. Mice given a similar activity of the ratio 6:1 111In-DOTA-hu5A10 or 6:1 111In-DTPA-hu5A10 or 12:1 111In-DTPA-hu5A10 showed significant tumor growth retardation.

CLINICAL RELEVANCE/APPLICATION

The present study demonstrates that the radiolabeling strategy can positively modify the hu5A10's capacity to bind PSA and complex with the FcRn-receptor, which results in more homogenous activity distribution in tumors and enhanced therapy efficacy. These new innovative radiochemistry ideas could potentially decrease relapse of tumors in patients treated with internalizing antibodies.

MS03-B1   Imaging Features Of Beirut Blast Injuries: Distribution Of Patterns And Radiological Imaging

Participants
Caline Azzi, MD, Beirut, Lebanon (*Presenter*) Nothing to Disclose

PURPOSE

To determine imaging utilization and describe the range of radiologic findings and outcomes of immediate (within 30 hours) injuries following the August 4 Beirut blast that is considered one of the largest non-nuclear blasts in history and comprised 2 successive explosions, approximately 35 seconds apart.*Methods and Materials An Institutional Review Board approved retrospective analysis of the radiographic findings and outcomes of all patients who underwent imaging at the American University of Beirut Medical Center because of trauma from the blast was performed. Images were identified by searching the radiology PACS system for studies performed within 30 hours from the blast. Imaging findings extracted from the radiology reports were documented and analyzed. Patients' demographics, types of interventions and outcomes were determined by reviewing the Electronic Medical Records.*Results Within 30 hours of the second explosion, a total of 213 patients underwent 512 imaging studies (radiographs n=302 (59%), CT n=204 (40%), ultrasounds n=5 (1%) and MRI n=1), in addition to bedside ultrasound examinations in the Emergency Department. The most commonly imaged body parts with plain radiographs were the extremities (upper (47%), lower (31%)), and with CT were the brain (44%), chest (18%), and abdomen/pelvis (18%). The most commonly injured organs were the head and neck (40%) and extremities (40%). The most common injury in the head was skull injury (44%), followed by intracranial bleeding (21%) (subarachnoid hemorrhage (35%), subdural hematoma and hemorrhagic contusions (24% each), and epidural hematomas (17%)). The most common injury in the extremities was blast-related shrapnel injuries, with a total 925 shrapnel in 57 patients, most in the upper extremities (45%).*Conclusions The most common body region injured by the Beirut blast was the head and neck (40%), likely due to mass collapse of buildings. Blast injuries induced by penetrating shrapnel most commonly affected the upper extremity. The primary reason is likely the shockwave from the first smaller explosion that gave patients time to instinctively shield their head with their arms.*Clinical Relevance/Application To familiarize the radiologist with the nature and patterns of blast injury. This should enable the radiologist to seek out injuries that may not be clinically apparent initially.

RESULTS

Within 30 hours of the second explosion, a total of 213 patients underwent 512 imaging studies (radiographs n=302 (59%), CT n=204 (40%), ultrasounds n=5 (1%) and MRI n=1), in addition to bedside ultrasound examinations in the Emergency Department. The most commonly imaged body parts with plain radiographs were the extremities (upper (47%), lower (31%)), and with CT were the brain (44%), chest (18%), and abdomen/pelvis (18%). The most commonly injured organs were the head and neck (40%) and extremities (40%). The most common injury in the head was skull injury (44%), followed by intracranial bleeding (21%) (subarachnoid hemorrhage (35%), subdural hematoma and hemorrhagic contusions (24% each), and epidural hematomas (17%)). The most common injury in the extremities was blast-related shrapnel injuries, with a total 925 shrapnel in 57 patients, most in the upper extremities (45%).

CLINICAL RELEVANCE/APPLICATION

To familiarize the radiologist with the nature and patterns of blast injury. This should enable the radiologist to seek out injuries that may not be clinically apparent initially.

GI03-C2   **Comparison Of Image Quality Of 3D Magnetic Resonance Cholangiopancreatography Performed With Respiratory Triggered (PACE) Versus Breath-Hold Compressed Sensing (BH-CS) Techniques At 1.5T**

Participants
Chenchan Huang, MD, Manhasset, New York (*Presenter*) Nothing to Disclose

PURPOSE

To perform a qualitative and quantitative comparison of image quality of 3D-MRCP imaging of the biliary system and pancreatic duct acquired using respiratory triggered prospective acquisition correction technique (PACE) and breath-hold compressed sensing technique (BH-CS).*Methods and Materials 120 3D-MRCP exams performed with both PACE and BH-CS techniques during a 9 month period at a 1.5T MRI scanner were included. One experienced and one less-experienced radiologists retrospectively assessed duct clarity of extrahepatic bile duct (CHD/CBD), right central intrahepatic duct (IHD), right peripheral IHD, left central IHD, left peripheral IHD, and main pancreatic duct (PD) using a 1-5 scale. Overall image quality (IQ) and motion artifact of the bile ducts and PD were recorded using a 1-5 scale. Quantitative analysis of relative duct-to-periductal contrast ratios (RCs) of the pancreaticobiliary ducts were calculated by a different radiologist. Mean acquisition time of two techniques were recorded. These qualitative and quantitative measurements were compared between the two techniques. A p<0.05 indicated statistical significance.*Results The acquisition time was markedly reduced in BH-CS MRCP compared with PACE-MRCP (mean 17.5 sec versus 6 min 36 sec). RCs of the CHD/CBD, left IHD, right IHD, and PD were significantly higher at BH-CS than PACE MPCP (all p<0.001). Clarity of right peripheral IHD, left peripheral IHD, PD were significantly higher at PACE MRCP for experienced reader (all p<0.05). Clarity of CHD/CBD was significantly higher at CS-BH MRCP for less-experienced reader (p=0.001). Motion artifact of bile ducts was significantly better at BH-CS MRCP for experienced reader (p=0.014). Overall IQ of PD was significantly better at PACE-MRCP for experienced reader (p=0.046). Overall IQ of bile ducts and motion artifact of PD were not significantly different for either reader.*Conclusions Clarity of peripheral IHD was significantly higher at PACE MRCP for experienced reader though overall IQ of biliary tree was not significantly different for either reader. Clarity and overall IQ of PD were significantly better at PACE-MRCP for experienced reader.*Clinical Relevance/Application There is significant time saving using a breath-hold compressed sensing 3D MRCP. Implementing BH-CS MRCP into MRCP protocols should be carefully selected based on the clinical indications.

RESULTS

The acquisition time was markedly reduced in BH-CS MRCP compared with PACE-MRCP (mean 17.5 sec versus 6 min 36 sec). RCs of the CHD/CBD, left IHD, right IHD, and PD were significantly higher at BH-CS than PACE MPCP (all p<0.001). Clarity of right peripheral IHD, left peripheral IHD, PD were significantly higher at PACE MRCP for experienced reader (all p<0.05). Clarity of CHD/CBD was significantly higher at CS-BH MRCP for less-experienced reader (p=0.001). Motion artifact of bile ducts was significantly better at BH-CS MRCP for experienced reader (p=0.014). Overall IQ of PD was significantly better at PACE-MRCP for experienced reader (p=0.046). Overall IQ of bile ducts and motion artifact of PD were not significantly different for either reader.

CLINICAL RELEVANCE/APPLICATION

There is significant time saving using a breath-hold compressed sensing 3D MRCP. Implementing BH-CS MRCP into MRCP protocols should be carefully selected based on the clinical indications.

GI03-C4   **Value Of Dual Energy CT For Assessment Of Fatty Liver Disease: Comparison With Quantitative MRI**

Participants
Pengcheng Zhang, MD, San Francisco, California (*Presenter*) Nothing to Disclose

PURPOSE

To determine if dual-energy virtual non-contrast CT predicts hepatic steatosis measured using MRI proton density fat fraction.*Methods and Materials 128 patients undergoing dual energy CT (DECT) of the abdomen and MRI with proton density fat fraction (PDFF) within 30 days of each other were selected at a single center from 2016-2020. For DECT, both split-beam and dual source scanners were used. MRI PDFF was performed at 3T using 6 echoes. For each patient, DECT VNC attenuation values and MRI-derived PDFF values were measured in similar locations within the right and left hepatic lobes. Pearson correlation coefficients between CT and MRI were computed separately using measurements from each lobe. Patients were separated into steatotic and non-steatotic groups, using FF=6% as a threshold for establishing liver steatosis. Comparison of VNC HU was made between steatotic and non-steatotic groups by chi-square test. Receiver operator characteristic (ROC) curve and area under ROC curve (AUC) were used to establish an optimal HU threshold of VNC CT to determine hepatic steatosis (>6% on PDFF). All tests were performed separately in the right and left lobes.*Results Median interval between CT and MRI was 2 days. VNC and MRI-derived FF were significantly correlated with R = -0.61 and -0.66 for the right and left lobes, respectively (P<0.05). Median VNC HU in the right and left lobes were significantly different in the steatotic and non-steatoic groups (median steatotic vs non-steatotic right: 54.7 vs 70.3 HU, left: 49 vs 63.7 HU, P<0.001). ROC curves established an optimal threshold cutoff for hepatic steatosis on VNC of 54.8 HU (sensitivity 53.3%, specificity 91.8%; AUC 0.799) for the right hepatic lobe and 50.6 HU (sensitivity 60.7%, specificity 94%; AUC 0.853).*Conclusions Attenuation measured using DECT VNC images of the liver is highly specific (>90%) for the diagnosis of hepatic steatosis.*Clinical Relevance/Application Early detection of fatty liver disease could direct patients to medical intervention and

reduced progression to cirrhosis and need for liver transplant.

RESULTS

Median interval between CT and MRI was 2 days. VNC and MRI-derived FF were significantly correlated with R = -0.61 and -0.66 for the right and left lobes, respectively (P<0.05). Median VNC HU in the right and left lobes were significantly different in the steatotic and non-steatoic groups (median steatotic vs non-steatotic right: 54.7 vs 70.3 HU, left: 49 vs 63.7 HU, P<0.001). ROC curves established an optimal threshold cutoff for hepatic steatosis on VNC of 54.8 HU (sensitivity 53.3%, specificity 91.8%; AUC 0.799) for the right hepatic lobe and 50.6 HU (sensitivity 60.7%, specificity 94%; AUC 0.853).

CLINICAL RELEVANCE/APPLICATION

Early detection of fatty liver disease could direct patients to medical intervention and reduced progression to cirrhosis and need for liver transplant.

GI03-C5 Response Assessment Following Yttrium-90 Transarterial Radioembolization For Advanced Hepatocellular Carcinoma: Comparison Of RECIST, MRECIST, And LI-RADS Treatment Response Algorithm

Participants
Madeleine Sertic, MBBCh, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To compare Response Evaluation Criteria in Solid Tumours (RECIST), modified RECIST (mRECIST), and LI-RADS Treatment Response Algorithm (LI-RADS TRA) in treatment evaluation following Yttrium-90 transarterial radioembolization (TARE) for advanced hepatocellular carcinoma (HCC).*Methods and Materials This retrospective single institution study included 80 patients who underwent TARE for management of advanced HCC. The patients undergoing TARE had diagnostic CT or MRI performed at baseline, and post-treatment scans at 1 and 3 months. Evaluation of treatment response was performed by an independent reader according to RECIST, mRECIST and LI-RADS TRA. The patients were categorized as "responders" and "non-responders" as determined by RECIST, mRECIST and LI-RADS TRA criteria on the second post-treatment scan, and the findings were compared.*Results A total of 105 TAREs were performed in 80 patients. At 1 month, a higher proportion of patients were categorized as responders based on mRECIST (29%, n=30) compared to RECIST (5%, n=5) and LI-RADS TRA (19%, n=20). Similarly, at 3 months 33% (n=35) were categorized as responders based on mRECIST, compared to 12% (n=13) on RECIST and 25% (n=26) on LI-RADS TRA. At 1 and 3 months, 100% of responders per RECIST were also classified as responders by mRECIST. 8/26 (31%) LI-RADS TRA responders were only classified as such on LI-RADS TRA; of these, 7/8 were patients with new metastases. The one-year overall survival rates were 75%, 70% and 82% for responders based on RECIST, mRECIST and LI-RADS TRA, respectively. The one-year overall survival rates were 78%, 81% and 76% for non-responders based on RECIST, mRECIST and LI-RADS TRA, respectively.*Conclusions In patients with advanced HCC undergoing TARE, mRECIST identifies more responders at 1-month and 3-months compared to RECIST and LI-RADS TRA. LI-RADS TRA does not assess non-target lesions and can identify patients as responders despite the presence of new metastatic disease.*Clinical Relevance/Application In patients with advanced HCC, mRECIST identifies more responders at 1- and 3-months post TARE than RECIST or LI-RADS TRA. Accurate identification of responders and non-responders can be used to guide treatment decisions and expedite additional or alternate therapy.

RESULTS

A total of 105 TAREs were performed in 80 patients. At 1 month, a higher proportion of patients were categorized as responders based on mRECIST (29%, n=30) compared to RECIST (5%, n=5) and LI-RADS TRA (19%, n=20). Similarly, at 3 months 33% (n=35) were categorized as responders based on mRECIST, compared to 12% (n=13) on RECIST and 25% (n=26) on LI-RADS TRA. At 1 and 3 months, 100% of responders per RECIST were also classified as responders by mRECIST. 8/26 (31%) LI-RADS TRA responders were only classified as such on LI-RADS TRA; of these, 7/8 were patients with new metastases. The one-year overall survival rates were 75%, 70% and 82% for responders based on RECIST, mRECIST and LI-RADS TRA, respectively. The one-year overall survival rates were 78%, 81% and 76% for non-responders based on RECIST, mRECIST and LI-RADS TRA, respectively.

CLINICAL RELEVANCE/APPLICATION

In patients with advanced HCC, mRECIST identifies more responders at 1- and 3-months post TARE than RECIST or LI-RADS TRA. Accurate identification of responders and non-responders can be used to guide treatment decisions and expedite additional or alternate therapy.

GI03-C7 First In Human Safety Trial Of A Novel Oral Dark Borosilicate Contrast Material In Healthy Volunteers

Participants
Yuxin Sun, BS,MSc, San Francisco, California (*Presenter*) Stockholder, Nextrast, Inc

PURPOSE

To assess the safety and efficacy of a novel oral nonabsorbable Dark Borosilicate Contrast Material (DBCM) for CT in healthy volunteers*Methods and Materials FDA IND and institutional review board approval was obtained. Five groups of 5 to 6 healthy adult volunteers were consented for an escalating dose trial of a new oral DBCM (CT attenuation below -100 HU). Physical exam, hematology, metabolic panel, urinalysis and ECG were done before and 1, 4, and 24 hours after drinking 3% sorbitol placebo (n=2/group) or DBCM (n=3, groups 1-4; n=4, group 5), with each group consuming a progressively larger volume (400, 800, 1200, 1600, or 2000mL). Side effects were recorded on day 1 and 1 week post dosing. For groups 1, 3, and 5, blood at pre, 1, 2, 4, 7, and 24 hours and urine at pre, 4, and 24 hours after dosing were measured for silicon by digestion ICP-MS. Pre and post dose fecal occult blood tests were obtained. Volunteers were scanned by CT before and within 35 to 75 minutes after oral dose completion. Two radiologists independently recorded bowel lumen CT attenuation and rated bowel delineation (5-point Likert)*Results All adverse events were mild and transient, and 1, 2, 2, 4, 3 adverse events were seen in placebo groups 1-5, and 0, 2, 6, 7, 7 in DBCM groups 1-5, respectively. Of these adverse events, 8 of 12 and 10 of 22 total were diarrhea or loose stools in the placebo and DBCM groups respectively. Other side effects included abdominal pain (n=1 placebo, 4 in DBCM), nausea or vomiting (n=1 and 3), or flatulence (n=1 and 4). One event of temporary left ear pain in the DBCM group was judged to be unrelated. No significant changes in hematology, metabolic panel, urinalysis, or ECG were seen. No uptake of DBCM into blood or urine was detected. No nonconfounded fecal occult blood was seen (positive in 1 placebo and 2 DBCM in groups 1 and 2 related to straining at stool or high dietary meat consumption). CT scans showed marking of bowel from the stomach to the terminal ileum in 14 of 16 subjects with DBCM. Superior delineation of bowel wall was seen with DBCM compared to placebo.*Conclusions Novel oral DBCM is tolerated well, shows rapid transit time, no uptake into blood or urine, and excellent marking and delineation of the small bowel at CT.*Clinical

Relevance/Application Novel oral DBCM is well tolerated and provides excellent bowel distension and superior bowel wall delineation compared to neutral contrast at unenhanced CT. Further clinical study is warranted

RESULTS

All adverse events were mild and transient, and 1, 2, 2, 4, 3 adverse events were seen in placebo groups 1-5, and 0, 2, 6, 7, 7 in DBCM groups 1-5, respectively. Of these adverse events, 8 of 12 and 10 of 22 total were diarrhea or loose stools in the placebo and DBCM groups respectively. Other side effects included abdominal pain (n=1 placebo, 4 in DBCM), nausea or vomiting (n=1 and 3), or flatulence (n=1 and 4). One event of temporary left ear pain in the DBCM group was judged to be unrelated. No significant changes in hematology, metabolic panel, urinalysis, or ECG were seen. No uptake of DBCM into blood or urine was detected. No nonconfounded fecal occult blood was seen (positive in 1 placebo and 2 DBCM in groups 1 and 2 related to straining at stool or high dietary meat consumption). CT scans showed marking of bowel from the stomach to the terminal ileum in 14 of 16 subjects with DBCM. Superior delineation of bowel wall was seen with DBCM compared to placebo.

CLINICAL RELEVANCE/APPLICATION

Novel oral DBCM is well tolerated and provides excellent bowel distension and superior bowel wall delineation compared to neutral contrast at unenhanced CT. Further clinical study is warranted

NR01-B10   A Deep Learning Model To Detect Intracranial Hemorrhage In Computed Tomography Scans Without Medical Annotation

Participants
Andre C. Castilla, MD,PhD, Sao Paulo, Brazil (*Presenter*) Stockholder, NeuralMed

PURPOSE

Intracranial hemorrhage, a life-threatening condition, includes several types of bleeding within the intracranial cavity, generally confirmed using Computed Tomography (CT) scans. Previous deep learning algorithms developed to aid the detection of this pathology requires a physician to annotate exams per slice. In this work, we annotated a dataset of head CT exams using Natural Language Processing (NLP) and applied an architecture using convolutional and recurrent neural networks to classify each exam. We also highlight slices where the hemorrhage appears to aid diagnosis.*Methods and Materials We assembled a dataset of head CT exams collected from a group of 6 hospitals and 5 specialized outpatient clinics. The labels were extracted from the written reports using an NLP model previously trained using BERT architecture. From each of the 8432 collected exams, we selected the axial volumetric unenhanced series. Almost 40% of exams had some kind of intracranial hemorrhage. We did not separate the bleeding subtypes. Each exam was processed using brain, blood, and bone windows, resliced to 25 images, cropped, and resized to 300x300. We used a MobileNet network pre-trained with ImageNet weights combined with a Long short-term memory (LSTM) with categorical cross-entropy as loss function. The output of the model was: hemorrhage, no finding, and other pathologies. To identify in which slice and area the hemorrhage was found, we applied the Gradient Class Activation Map (GradCAM) technique.*Results On the validation set, we achieved an AUC of 0.96, 0.87 for recall, and 0.97 for precision. On the external set, validated by a doctor, these were 0.91, 0.85, and 0.86 respectively. Through the GradCAM method, we selected the best slices of each exam, and doctors were able to evaluate the results and indicate with more precision where a hemorrhage was found.*Conclusions Select CT exams using NLP and training classification with a CNN+LSTM architecture improved the classification without the need for a per slice annotation. The identification of the most relevant slices, using the GradCAM technique, alongside clinical information, may help doctors better understand each patient case, accelerating and improving the diagnosis. This method is faster because it removes the need for medical annotation, which can be added later on image errors to improve the model.*Clinical Relevance/Application By detecting 96.6% of the normal exams, we can speed up doctor's work, providing more time for the analysis of the slices with bleeding, increasing the precision of the diagnosis.

RESULTS

On the validation set, we achieved an AUC of 0.96, 0.87 for recall, and 0.97 for precision. On the external set, validated by a doctor, these were 0.91, 0.85, and 0.86 respectively. Through the GradCAM method, we selected the best slices of each exam, and doctors were able to evaluate the results and indicate with more precision where a hemorrhage was found.

CLINICAL RELEVANCE/APPLICATION

By detecting 96.6% of the normal exams, we can speed up doctor's work, providing more time for the analysis of the slices with bleeding, increasing the precision of the diagnosis.

NR01-B3   Addressing Intra- And Inter-rater Variability Within Response Assessment Of Pediatric Medulloblastomas And Leptomeningeal Seeding Tumors Using A Deep-learning Based Automatic Tumor Segmentation And Response Assessment Model

Participants
Daniel Kim, Hudson, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

Longitudinal measurement of tumor burden with MRI is an essential component of response assessment in pediatric brain tumors but is vulnerable to inter- and intra-rater variability in clinical practice. We developed a fully automated pipeline for (1) the segmentation of tumors in pediatric medulloblastomas and leptomeningeal seeding tumors and (2) automatic 2D and 3D measurements of tumors.*Methods and Materials A preoperative and postoperative cohort were randomly split into training and testing sets in a 4:1 ratio. A 3D U-Net neural network was trained to automatically segment the enhancing tumor and T2/FLAIR hyperintensity regions on T1 contrast-enhanced (T1ce) and T2/FLAIR images, respectively. The product of the maximum bidimensional diameters according to the RAPNO criteria (AutoRAPNO) was determined. Performance was compared to that of two expert human raters who performed assessments independently. Volumetric measurements of predicted and expert segmentations were computationally derived and compared.*Results Our preoperative cohort consisted of 794 T2 and 638 T1ce MRIs from 794 patients. Our postoperative cohort consisted of 492 FLAIR and 511 T1ce MRIs from 122 patients. There was excellent agreement of volumes between preoperative and postoperative predicted and manual segmentations, with ICCs of 0.912 and 0.960 for the two preoperative and 0.947 and 0.896 for the two postoperative models. While there was high agreement between AutoRAPNO scores on predicted segmentations and manually calculated scores (Rater 2 ICC=0.909; Rater 3 ICC=0.851), there was higher agreement between AutoRAPNO scores on predicted segmentations and AutoRAPNO scores on manual segmentations (ICC = 0.933). Lastly, the performance of AutoRAPNO was superior in repeatability to that of human raters for MRIs with multiple lesions.*Conclusions Our

automated deep learning pipeline demonstrated tumor segmentation and size calculation performance comparable to that of human experts. More importantly, higher agreement of AutoRAPNO scores on predicted segmentations with AutoRAPNO scores on manual segmentations vs. with manually calculated scores demonstrates that automatic pipelines can reduce inter- and intra-rater variability in response assessment for pediatric brain tumors.*Clinical Relevance/Application A deep learning segmentation pipeline is more cost-effective than increasing volume of highly specialized human labor, scalable to demand, and excels in its remarkably fast volumetric calculations and robustness to inter and intra-rater variability. Incorporating deep learning-based response assessment can improve patient care by allowing medical specialists currently performing response assessment to focus on next steps in treatment.

RESULTS

Our preoperative cohort consisted of 794 T2 and 638 T1ce MRIs from 794 patients. Our postoperative cohort consisted of 492 FLAIR and 511 T1ce MRIs from 122 patients. There was excellent agreement of volumes between preoperative and postoperative predicted and manual segmentations, with ICCs of 0.912 and 0.960 for the two preoperative and 0.947 and 0.896 for the two postoperative models. While there was high agreement between AutoRAPNO scores on predicted segmentations and manually calculated scores (Rater 2 ICC=0.909; Rater 3 ICC=0.851), there was higher agreement between AutoRAPNO scores on predicted segmentations and AutoRAPNO scores on manual segmentations (ICC = 0.933). Lastly, the performance of AutoRAPNO was superior in repeatability to that of human raters for MRIs with multiple lesions.

CLINICAL RELEVANCE/APPLICATION

A deep learning segmentation pipeline is more cost-effective than increasing volume of highly specialized human labor, scalable to demand, and excels in its remarkably fast volumetric calculations and robustness to inter and intra-rater variability. Incorporating deep learning-based response assessment can improve patient care by allowing medical specialists currently performing response assessment to focus on next steps in treatment.

NR01-B5 Amplitude Synchronization Of Spontaneous Brain Activity Of Medial And Lateral Temporal Gyri In Epilepsy Patients With Mesial Temporal Sclerosis

Participants
Mahdi Alizadeh, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

In this study, we examine whether amplitude synchronization of medial and lateral temporal gyri can detect unique alterations in left temporal lobe epilepsy (TLE) patients with mesial temporal sclerosis (MTS).*Methods and Materials This is a retrospective study of preoperative rsfMRI data from 26 MTS patients (age 23-69) and 16 controls (age 21-35). fMRI data were preprocessed and registered to a standard space. Using each subject's T1 scan, medial and lateral temporal regions were automatically segmented, manually revised and then fit to a standard space using a symmetric normalization (SyN) registration algorithm. For each subject, we used dual regression analysis to detect amplitude synchronization of medial and lateral temporal segments with the rest of the brain. We calculated the overlapped volume ratio of synchronized voxels within target regions including the thalamus (total and bilateral), insula (bilateral), cerebellum (bilateral), brainstem, total gray matter, medial and lateral gyri (bilateral) and supratentorial. Two-sample student's t-tests (DoF = 15) were used for statistical comparison of synchronization in MTS patients and controls.*Results In MTS patients, the ipsilateral lateral temporal lobe demonstrated hyperactive connections with the thalamus bilaterally (ipsilateral: $p = 0.02$, t-score = -2.67; contralateral $p = 0.02$, t = -2.69; total thalamus: $p = 0.01$, t = -3.12) and the brainstem ($p < 0.01$, t = -5.06). The contralateral lateral temporal lobe also showed hyperactivity with the contralateral thalamus ($p = 0.05$, t = -2.17) and the brainstem ($p < 0.01$, t = -4.68). The contralateral medial temporal lobe showed hypoactivity with the ipsilateral medial temporal lobe ($p = 0.02$, t = 2.59).*Conclusions We found increased synchronization between lateral temporal lobes and the thalamus and brainstem, suggesting that hyperactivity in ascending arousal systems involving these structures may constitute a component of abnormal functional networks in MTS. Furthermore, we saw reduced synchronization between the ipsilateral and contralateral medial temporal lobes, indicating less intra-temporal lobe connectivity in MTS. Our results demonstrate amplitude synchronization as an effective method to detect functional connectivity alterations in MTS.*Clinical Relevance/Application Elucidating regions with altered functional connectivity to temporal regions can improve understanding of TLE networks, pathology and treatment. Future studies can examine the effectiveness of using patient-specific abnormal patterns to tailor targeted therapies such as guided surgical resection.

RESULTS

In MTS patients, the ipsilateral lateral temporal lobe demonstrated hyperactive connections with the thalamus bilaterally (ipsilateral: $p = 0.02$, t-score = -2.67; contralateral $p = 0.02$, t = -2.69; total thalamus: $p = 0.01$, t = -3.12) and the brainstem ($p < 0.01$, t = -5.06). The contralateral lateral temporal lobe also showed hyperactivity with the contralateral thalamus ($p = 0.05$, t = -2.17) and the brainstem ($p < 0.01$, t = -4.68). The contralateral medial temporal lobe showed hypoactivity with the ipsilateral medial temporal lobe ($p = 0.02$, t = 2.59).

CLINICAL RELEVANCE/APPLICATION

Elucidating regions with altered functional connectivity to temporal regions can improve understanding of TLE networks, pathology and treatment. Future studies can examine the effectiveness of using patient-specific abnormal patterns to tailor targeted therapies such as guided surgical resection.

NR01-B7 A Meta-stacked Ensemble Model: Classification Of Cognitive Decline Using Structural MRI

Participants
Emily Yunha Shin, MS,BEng, Seoul, Korea, Republic Of (*Presenter*) Employee, NEUROPHET, Inc

PURPOSE

Dementia is a neurodegenerative disorder that causes a wide range of decline in brain function. Although many studies explored various MRI properties, most of them focused on Alzheimer's disease (AD), a particular type of dementia. In this study, we propose a meta-stacked ensemble model (meta-SEM) that performs two-class classification of a wide range of cognitive decline (CD), including mild cognitive impairment (MCI) and multiple dementia (D) subtypes, from healthy controls (HC).*Methods and Materials A total of 1344 participants (CD=736, HC=608) were included from the Catholic Aging Brain Imaging (CABI) database. T1-weighted brain MRIs were processed using a deep learning-based multi-label segmentation model developed by our research group. Demographic data (age, gender, year of education), regional brain volumes, and T1 brain images were used for our meta-SEM. Our model consisted of three distinct modules. (1) Three machine learning (ML) models (including logistic regression, ridge classifier, and

linear discriminant analysis) were trained on demographic data and volumes of regions of interest. Each ML model was trained to classify four multi targets, (i) HC/CD, (ii) HC/MCI/D, (iii) MCI/D, and (iv) 8-class auxiliary subtypes. (2) Single deep learning (DL) VGGNet was trained using 32 axial 2D slices selected through entropy method from each brain image. The DL model was trained to classify three multi-labels except for MCI/D. (3) The outcomes from (1) and (2) were provided to a meta learner, which produced the final results of classification. For comparison, we also trained a standard SEM with only HC/CD estimators.*Results Our meta-SEM resulted in the following metrics: accuracy=0.836; sensitivity=0.788; specificity=0.885; and AUC=0.893. The result of meta-SEM showed better performance than the standard SEM (accuracy=0.828). To evaluate generalizing ability, we divided the test results into auxiliary subtypes. Except for early MCI (sensitivity=0.660) and late MCI (sensitivity=0.900), all other dementia subtypes showed sensitivities of 1.0.*Conclusions As suggested by the generalizing ability of our meta-SEM, using various targets containing a wide range of information appears to help learn diverse patterns of different dementia subtypes.*Clinical Relevance/Application Our generalizable classification model for cognitive decline may help distinguish cases requiring detailed clinical examinations as an auxiliary diagnostic tool.

RESULTS

Our meta-SEM resulted in the following metrics: accuracy=0.836; sensitivity=0.788; specificity=0.885; and AUC=0.893. The result of meta-SEM showed better performance than the standard SEM (accuracy=0.828). To evaluate generalizing ability, we divided the test results into auxiliary subtypes. Except for early MCI (sensitivity=0.660) and late MCI (sensitivity=0.900), all other dementia subtypes showed sensitivities of 1.0.

CLINICAL RELEVANCE/APPLICATION

Our generalizable classification model for cognitive decline may help distinguish cases requiring detailed clinical examinations as an auxiliary diagnostic tool.

NR01-B9   Adapting The RSNA Challenge-winner's Deep Learning Model To A Korean Population Dataset: Intracranial Hemorrhage Detection On Low Dose Scans

Participants
Changwon Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To enable the RSNA 2019-challenge-winner deep learning model (RSNA DLM) for intracranial hemorrhage detection (ICH) to adapt to and ensure to yield its proven performance in a different scan setting especially on low dose scan condition.*Methods and Materials Our prior study found that the RSNA DLM for ICH detection produced much low performance for an independent Korean population (Korea University Medical Center, KUMC) dataset obtained with low dose scan settings. Under an assumption that the strong image noise on the KUMC dataset owing to reduced photon flux disturbed the behavior of DLM, we applied an AI-based CT denoising solution (ClariCT.AI, ClariPi, Seoul, Korea) to the KUMC dataset as an off-the-shelf tool to adapt the RSNA DLM to the unseen low dose scan setting. In order to confirm the noise reduction effect, the image noise was measured on an ROI on ventricle from the RSNA dataset, and the KUMC dataset without and with denoising. The RSNA DLM was trained only with the challenge training dataset and not retrained with any other dataset. Finally, sensitivity and specificity were compared to see the adaptation effect.*Results Our prior study found that the RSNA DLM for ICH detection produced much low performance for an independent Korean population (Korea University Medical Center, KUMC) dataset obtained with low dose scan settings. Under an assumption that the strong image noise on the KUMC dataset owing to reduced photon flux disturbed the behavior of DLM, we applied an AI-based CT denoising solution (ClariCT.AI, ClariPi, Seoul, Korea) to the KUMC dataset as an off-the-shelf tool to adapt the RSNA DLM to the unseen low dose scan setting. In order to confirm the noise reduction effect, the image noise was measured on an ROI on ventricle from the RSNA dataset, and the KUMC dataset without and with denoising. The RSNA DLM was trained only with the challenge training dataset and not retrained with any other dataset. Finally, sensitivity and specificity were compared to see the adaptation effect.*Conclusions We were able to adapt the RSNA DLM to an independent Korean population dataset obtained with a low dose scan setting by applying an AI-based CT denoising solution. ICH detection performance was shown to recover after denoising of the low dose scan dataset.*Clinical Relevance/Application This study can be applied to construct a pre-processing procedure in intracranial hemorrhage detection software using a non-contrast enhanced head CT image.

RESULTS

Our prior study found that the RSNA DLM for ICH detection produced much low performance for an independent Korean population (Korea University Medical Center, KUMC) dataset obtained with low dose scan settings. Under an assumption that the strong image noise on the KUMC dataset owing to reduced photon flux disturbed the behavior of DLM, we applied an AI-based CT denoising solution (ClariCT.AI, ClariPi, Seoul, Korea) to the KUMC dataset as an off-the-shelf tool to adapt the RSNA DLM to the unseen low dose scan setting. In order to confirm the noise reduction effect, the image noise was measured on an ROI on ventricle from the RSNA dataset, and the KUMC dataset without and with denoising. The RSNA DLM was trained only with the challenge training dataset and not retrained with any other dataset. Finally, sensitivity and specificity were compared to see the adaptation effect.

CLINICAL RELEVANCE/APPLICATION

This study can be applied to construct a pre-processing procedure in intracranial hemorrhage detection software using a non-contrast enhanced head CT image.

NPM03-D1 Wide State By State Variations Exist In The Number Of Imaging Services Performed Per Medicare Beneficiary

Participants
Aditya Khurana, BS, Scottsdale, Arizona (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate geographic variations over time in the number of imaging services performed per Medicare beneficiary per year.*Methods and Materials CMS Physician and Other Supplier Public Use File Database of Medicare Part B claims submitted from 2012 to 2018 was utilized. The number of imaging services performed per radiologist and the number of unique beneficiaries served per radiologist were extracted for each radiologist and a corresponding ratio (the number of services performed per unique beneficiary) was calculated for each radiologist. Ratios were tabulated by state and year.*Results In 2012, 3,574.6 claims for imaging services were submitted per radiologist, which decreased to 3,393.4 in 2018 (-5.1%). By US state, the number of imaging services submitted per radiologist ranged from 3,426.8 in Hawaii to 13,483.6 in Maryland. In 2012, there were on average 2033.3 unique Medicare beneficiaries seen per radiologist, which increased to 2124.7 in 2018 (4.5%). By US state, the number of unique beneficiaries seen per radiologist in 2018 ranged from 1,378.1 in Minnesota to 3,716.9 in Mississippi.Annual imaging services performed per Medicare beneficiary was 3.1 in 2012, and increased to 3.4 in 2018 (+10.4%). By US state in 2018, the ratio ranged from 1.8 in Maine to 8.2 in Minnesota. From 2012 to 2018, the ratio demonstrated the largest decrease in Alabama (3.4, 2.4, -29.9%) and the largest increase in Maryland (3.8, 5.7, 49.8%).*Conclusions Annual imaging services performed per Medicare beneficiary increased over the study period, and varies more than four fold across states. These findings raise concern for variable quality and potential unwarranted variations, such as access limitations for Medicare patients in some states and over- or inappropriate utilization in others.*Clinical Relevance/Application Varied utilization patterns of imaging services per beneficiary across US states suggest Medicare resources could be better optimized to ensure high quality care for the Medicare population.

RESULTS

In 2012, 3,574.6 claims for imaging services were submitted per radiologist, which decreased to 3,393.4 in 2018 (-5.1%). By US state, the number of imaging services submitted per radiologist ranged from 3,426.8 in Hawaii to 13,483.6 in Maryland. In 2012, there were on average 2033.3 unique Medicare beneficiaries seen per radiologist, which increased to 2124.7 in 2018 (4.5%). By US state, the number of unique beneficiaries seen per radiologist in 2018 ranged from 1,378.1 in Minnesota to 3,716.9 in Mississippi.Annual imaging services performed per Medicare beneficiary was 3.1 in 2012, and increased to 3.4 in 2018 (+10.4%). By US state in 2018, the ratio ranged from 1.8 in Maine to 8.2 in Minnesota. From 2012 to 2018, the ratio demonstrated the largest decrease in Alabama (3.4, 2.4, -29.9%) and the largest increase in Maryland (3.8, 5.7, 49.8%).

CLINICAL RELEVANCE/APPLICATION

Varied utilization patterns of imaging services per beneficiary across US states suggest Medicare resources could be better optimized to ensure high quality care for the Medicare population.

NPM03-D2 The Applicant's Perspective On A Dedicated DEI Discussion On Radiology Interview Day

Participants
Abdullah Memon, Northbrook, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

In the US, diversity, equity and inclusion (DEI) is a growing priority for both residency programs and applicants alike. The racially disparate workforce in medicine can exacerbate health inequities by providing less culturally competent care to minorities. To highlight the importance of DEI, residency programs can discuss the topic on interview day within the program's general presentation. At our institution, we partitioned a session on each DR and IR residency interview day to emphasize our DEI mission and promote student dialogue around DEI topics, demonstrating to students that our department is committed to becoming a leader in this work. We assessed applicants' outlooks on the session and if it will attract those committed to this mission to join our program.*Methods and Materials A 25-minute interactive DEI session led by departmental DEI leadership was presented on each interview day, which included icebreakers by way of radiology DEI statistics, an overview of institutional patient demographics, description of DEI initiatives the program is pursuing, and an open dialogue with candidates. Applicants then completed a voluntary, anonymous, 10-question survey between the deadline for Rank Order List entry and Match Day. Questions included demographics, such as gender and URiM status, and specifics of the session on a five-point Likert scale. T-tests were used to compare the responses of male to females and URiM to non-URiM applicants. Cronbach's alpha was calculated to measure internal consistency.*Results In the 2020-2021 application cycle, 31% of applicants who interviewed at our program completed the survey. 35% of male interviewees and 26% of female interviewees completed the survey. Of those applicants within the interviewee cohort self-identifying as URiM, 63% completed the survey. On average, applicants had mostly neutral to positive experiences, with comments noting the open nature of the discussion and that DEI seems to be emphasized by the program. Non-URiM applicants agreed more than URiM applicants ($p = 0.047$) that the session demonstrated DEI is an active priority for the program. Cronbach's alpha for all applicants, males, females, URiM, and non-URiM was between 0.94-0.97, indicating excellent internal

consistency.*Conclusions Overall, this study demonstrated that an independent DEI session was well received by applicants, and a dedicated but brief discussion on the topic within the interview day can help highlight a program's commitment to DEI. Further assessment is required to identify areas where the session can be improved.*Clinical Relevance/Application With DEI becoming an essential topic in medicine, residency programs can incorporate a dedicated session on this subject to demonstrate to applicants their mission of DEI.

RESULTS

In the 2020-2021 application cycle, 31% of applicants who interviewed at our program completed the survey. 35% of male interviewees and 26% of female interviewees completed the survey. Of those applicants within the interviewee cohort self-identifying as URiM, 63% completed the survey. On average, applicants had mostly neutral to positive experiences, with comments noting the open nature of the discussion and that DEI seems to be emphasized by the program. Non-URiM applicants agreed more than URiM applicants (p = 0.047) that the session demonstrated DEI is an active priority for the program. Cronbach's alpha for all applicants, males, females, URiM, and non-URiM was between 0.94-0.97, indicating excellent internal consistency.

CLINICAL RELEVANCE/APPLICATION

With DEI becoming an essential topic in medicine, residency programs can incorporate a dedicated session on this subject to demonstrate to applicants their mission of DEI.

SDP-MK-1   Prevalence And Risk Factors Of T-score Discordance Between Lumbar Spine And Hip Bone Mineral Density Using Dual-energy X-ray Absorptiometry In The Hong Kong Chinese Population: A Pilot Study

Participants
Kwan Wai Li, Hong Kong, Hong Kong (*Presenter*) Nothing to Disclose

PURPOSE

T-score discordance between lumbar spine and hip bone mineral density (BMD) using Dual-energy absorptiometry (DXA) could affect the therapeutic plan for patients. The aim of this study is to investigate the prevalence and risk factors of such discordance in the Hong Kong Chinese population.*Methods and Materials In this retrospective study, a total of 403 subjects (86.4% female) with a mean age of 67.7 ± 10.4 years, who underwent DXA using Hologic Horizon A in our center from January 2020 to February 2021 were reviewed. Patients with spinal and femoral fixation devices were excluded. BMD was measured to calculate the T-score at L1-L4 lumbar spine and left hip for all subjects. If degenerative changes were observed in any of the vertebrae, that specific vertebrae were excluded for lumbar spine analysis. Classification of T-scores (osteoporosis, osteopenia and normal) were identified at the two sites according to the World Health Organization classification. Statistical analysis was performed using IBM SPSS version 26.*Results Concordance, minor discordance and major discordance of T-scores were observed in 63.3%, 34.7% and 2% of the subjects, respectively. Since there was a significant difference between the null hypothesis and the general model (P = 0.042) in the test of parallelism, multinomial logistic regression was used instead of ordinal regression. Multicollinearity between independent variables (age, body mass index (BMI) and gender) was checked using tolerance and variance inflation factor. Box-Tidwell test was used to verify the linear relationship between continuous independent variables (age and BMI) and the logit transformation of the dependent variable (discordance). Concordance was chosen as the reference group for comparison. BMI (Adjusted odds ratio (AOR) = 1.061, 95% confidence interval (CI): 1.006 - 1.118, P = 0.028) and males (AOR = 3.086, 95% CI: 1.704 - 5.587, P < 0.001) were found to be the risk factor of minor T-score discordance, while age (AOR = 1.073, 95% CI: 1.002 - 1.149, P = 0.045) was found to be the risk factor of major T-score discordance.*Conclusions Although major discordance is uncommon, nearly 37% of the sample population shows diagnostic discordance. Yet, the subjects in this study were referred for osteoporosis assessment in a single center and hence the results might not be generalized to the whole Hong Kong Chinese population. Future studies with larger sample sizes including more independent variables such as fat and muscle mass, menopause, age at menopause and menarche, medical and drug history would be conducted.*Clinical Relevance/Application In case of T-score discordance, radiologists should consider including an additional site such as forearm for BMD measurement to improve the diagnosis of osteoporosis.

RESULTS

Concordance, minor discordance and major discordance of T-scores were observed in 63.3%, 34.7% and 2% of the subjects, respectively. Since there was a significant difference between the null hypothesis and the general model (P = 0.042) in the test of parallelism, multinomial logistic regression was used instead of ordinal regression. Multicollinearity between independent variables (age, body mass index (BMI) and gender) was checked using tolerance and variance inflation factor. Box-Tidwell test was used to verify the linear relationship between continuous independent variables (age and BMI) and the logit transformation of the dependent variable (discordance). Concordance was chosen as the reference group for comparison. BMI (Adjusted odds ratio (AOR) = 1.061, 95% confidence interval (CI): 1.006 - 1.118, P = 0.028) and males (AOR = 3.086, 95% CI: 1.704 - 5.587, P < 0.001) were found to be the risk factor of minor T-score discordance, while age (AOR = 1.073, 95% CI: 1.002 - 1.149, P = 0.045) was found to be the risk factor of major T-score discordance.

CLINICAL RELEVANCE/APPLICATION

In case of T-score discordance, radiologists should consider including an additional site such as forearm for BMD measurement to improve the diagnosis of osteoporosis.

SDP-MK-10   MRI Evaluation Of Soft Tissue Tumors: Is A Fast Isotropic T2-weighted 3D Sequence Suitable?

Participants
Laura M. Fayad, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

To test whether a 4-fold accelerated 3-dimensional (3D) T2-weighted (T2) CAIPIRINHA SPACE turbo spin-echo (TSE) sequence with isotropic voxel size offers at least equivalent performance to conventional 2DT2 TSE for the evaluation of intrinsic and perilesional soft tissue tumors (STT) characteristics.*Methods and Materials 108 patients with histologically proven STTs underwent MRI, including 3DT2 (CAIPIRINHA SPACE TSE) and 2DT2 (TSE) sequences at 3T. Two radiologists independently evaluated each technique for quality (diagnostic, non-diagnostic), tumor characteristics (heterogeneity, signal intensity, tumor margin), and the presence or absence of cortex involvement, bone marrow edema, joint extension, neurovascular encasement, and perilesional edema; tumor size and perilesional edema extent were measured. Signal-to-noise (SNR) and contrast-to-noise (CNR) ratios and acquisition times for 2DT2 in two planes and isotropic 3DT2 sequences were reported. Descriptive statistics, inter-

method agreement, and intraclass correlation (ICC) were applied.*Results The image quality was rated as diagnostic for all 2DT2 and 3DT2 sequences (100% [108/108]). No difference was observed between the 3DT2 and 2DT2 qualitative parameters evaluated by the two readers (p>0.05). There was no difference in tumor size (3DT2: mean largest size, 2.9±2.5cm (range, 0.3-19 cm), 2DT: 22.8±2.6cm (range, 0.3-18.2cm) p=0.4) or perilesional edema extent between the sequences (3DT2: mean extent 0.5±1.2 cm (range, 0.2-7cm), 2DT2: 0.5±1.0cm (range, 0.3-6.3cm), p=0.9). Interobserver reliability for measurements was high (ICC range 0.7-1) for both sequences. There was no difference in the SNR of tumors, bone marrow, and fat between the sequences, whereas the SNR of muscle was higher (p<0.05) on 3DT2 compared with 2DT2. CNR measures on 3DT2 were similar to 2DT2 (p>0.1). The average 3DT2 acquisition time was 5:43min±2:07min (range,3:04min-8:36min), whereas the 2DT2 acquisition in two planes was 7:55min±2:42min(range,5:32min-12:30min).*Conclusions Isotropic 3DT2 CAIPIRINHA SPACE MRI offers higher spatial resolution and faster acquisition times and comparable assessments of soft tissue tumor characteristics than conventional 2DT2 TSE MRI in two planes. 3DT2 CAIPIRINHA SPACE TSE can substitute 2DT2 TSE in tumor protocols.*Clinical Relevance/Application Isotropic 3DT2 CAIPIRINHA SPACE TSE has higher spatial resolution and is comparable for assessments of soft tissue tumor characteristics compared to conventional 2DT2 TSE.Multiplanar reformats of 3DT2 CAIPIRINHA SPACE TSE can substitute 2DT2 TSE acquired in multiple planes, thereby reducing the acquisition time of MRI tumor protocols.

RESULTS

The image quality was rated as diagnostic for all 2DT2 and 3DT2 sequences (100% [108/108]). No difference was observed between the 3DT2 and 2DT2 qualitative parameters evaluated by the two readers (p>0.05). There was no difference in tumor size (3DT2: mean largest size, 2.9±2.5cm (range, 0.3-19 cm), 2DT: 22.8±2.6cm (range, 0.3-18.2cm) p=0.4) or perilesional edema extent between the sequences (3DT2: mean extent 0.5±1.2 cm (range, 0.2-7cm), 2DT2: 0.5±1.0cm (range, 0.3-6.3cm), p=0.9). Interobserver reliability for measurements was high (ICC range 0.7-1) for both sequences. There was no difference in the SNR of tumors, bone marrow, and fat between the sequences, whereas the SNR of muscle was higher (p<0.05) on 3DT2 compared with 2DT2. CNR measures on 3DT2 were similar to 2DT2 (p>0.1). The average 3DT2 acquisition time was 5:43min±2:07min (range,3:04min-8:36min), whereas the 2DT2 acquisition in two planes was 7:55min±2:42min(range,5:32min-12:30min).

CLINICAL RELEVANCE/APPLICATION

Isotropic 3DT2 CAIPIRINHA SPACE TSE has higher spatial resolution and is comparable for assessments of soft tissue tumor characteristics compared to conventional 2DT2 TSE.Multiplanar reformats of 3DT2 CAIPIRINHA SPACE TSE can substitute 2DT2 TSE acquired in multiple planes, thereby reducing the acquisition time of MRI tumor protocols.

SDP-MK-11 Non-neoplastic Outcomes From The Oxford Sarcoma MDT

Participants
Faheem Malik, MA,MBBCHIR, Oxford, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

Bone and soft tissue tumours (BST) can give similar clinical and radiological findings as non-neoplastic lesions. One of the objectives of the Oxford Sarcoma Multidisciplinary Team (OSMDT) meeting is to distinguish true BST from non-neoplastic tumour-mimicking pathologies. In this poster, we present cases referred to the OSMDT in the last year that received an outcome of non-neoplastic lesion. Our primary outcome measure is the incidence of non-neoplastic lesions presenting as suspected sarcoma to the OSMDT. Our secondary outcome measure is the spectrum of conditions comprising these non-neoplastic lesions. We will discuss some specific examples, and outline their radiological features. We hope this gives other clinicians an insight into the tumour-mimicking pathologies encountered by a tertiary centre.*Methods and Materials We conducted a retrospective observational study compiling the non-neoplastic outcomes from the OSMDT in the last year. We identified all referrals made to our service between 1st January 2020 and 31st December 2020, and matched patient details from these referrals to our Electronic Patient Record (EPR) and Picture Archiving and Communication System (PACS).*Results The total number of case discussion events in the Oxford Bone and Soft Tissue Service MDT was 2337. The total number of new cases discussed at least once between 1st January 2020 and 31st December 2020 was 976; 958 from the UK, 17 from Malta, and 1 from Jamaica. Of these new cases, 84/976 (8.61%) received an outcome of non-neoplastic lesion. This gives a primary outcome incidence of 8.61% for seriously-suspected sarcomas receiving an outcome of non-neoplastic lesion at our MDT. These non-neoplastic outcomes can be categorised into the following types of pathologies: 32.1% vascular, 31.0% inflammatory, 14.3% traumatic, 6.0% degenerative, 6% idiopathic, 3.8% infective, 3.6% metabolic, 1.2% autoimmune, and 1% genetic. The most common specific diagnosis was vascular malformation, comprising 31.0% of all non-neoplastic outcomes.*Conclusions The incidence of non-neoplastic lesions presenting to our tertiary sarcoma MDT as suspected sarcoma is 8.61%. These lesions are made up of a number of pathologies, with vascular and inflammatory conditions being the most common.*Clinical Relevance/Application We hope that this poster gives clinicians an insight into the incidence of non-neoplastic conditions presenting to a tertiary centre as seriously-suspected sarcoma. We also hope to demonstrate the spectrum of radiological presentations of these conditions.

RESULTS

The total number of case discussion events in the Oxford Bone and Soft Tissue Service MDT was 2337. The total number of new cases discussed at least once between 1st January 2020 and 31st December 2020 was 976; 958 from the UK, 17 from Malta, and 1 from Jamaica. Of these new cases, 84/976 (8.61%) received an outcome of non-neoplastic lesion. This gives a primary outcome incidence of 8.61% for seriously-suspected sarcomas receiving an outcome of non-neoplastic lesion at our MDT. These non-neoplastic outcomes can be categorised into the following types of pathologies: 32.1% vascular, 31.0% inflammatory, 14.3% traumatic, 6.0% degenerative, 6% idiopathic, 3.8% infective, 3.6% metabolic, 1.2% autoimmune, and 1% genetic. The most common specific diagnosis was vascular malformation, comprising 31.0% of all non-neoplastic outcomes.

CLINICAL RELEVANCE/APPLICATION

We hope that this poster gives clinicians an insight into the incidence of non-neoplastic conditions presenting to a tertiary centre as seriously-suspected sarcoma. We also hope to demonstrate the spectrum of radiological presentations of these conditions.

SDP-MK-12 The Configuration Of Soft Tissue Sarcoma As A Valuable Feature On Mri

Participants
Sam Sedaghat, MD, Kiel, Germany (*Presenter*) Nothing to Disclose

PURPOSE

A new morphological aspect is to characterize soft tissue sarcomas (STS) by their configurations on MRI. The purpose of this multicenter study was to determine the value of STS configurations on MRI for use in the routine radiological setting.*Methods and

Materials 345 patients with STS were identified. Patients with other examinations than MRI and patients with lipo-, angio- and retroperitoneal sarcomas were excluded. 131 primary STS were included. Histological STS grades were derived from all available pathological reports and primary STS were divided into three groups according to the FNCLCC grading system: G1 (low-grade), G2 (intermediate) and G3 (high-grade). According to recent studies, the tumor configuration was divided into polycyclic/multilobulated, fascicular, ovoid/nodular, streaky, and fusiform. For imaging, 1.5-Tesla MRI systems were used.*Results 55 high-grade, 41 intermediate-grade and 35 low-grade primary STS lesions were identified. Primary STS significantly most often occurred in the extremities (p<0.001). Polycyclic/multilobulated, ovoid/nodular and streaky were the most common configurations. Most of the high-grade (G3) and intermediate-grade (G2) primary STS showed a polycyclic/multilobulated configuration (p<0.001), while low-grade primary STS (G1) were mostly ovoid/nodular. G3 polycyclic/multilobulated STS were significantly more often infiltrative, compared to G2 polycyclic/multilobulated STS (p<0.05). Most ovoid/nodular primary STS were well-defined (p<0.001). Streaky G3 and G2 sarcoma were all infiltrative, while streaky G1 sarcoma mostly showed well-defined borders. Additionally, high-grade streaky and polycyclic/multilobulated STS were significantly larger in size, compared to intermediate- and low-grade STS.*Conclusions Configuration of STS on MRI can indicate the grade of malignancy, as higher-grade (G2/3) STS significantly most often show a polycyclic/multilobulated configuration, while low-grade STS (G1) are mainly ovoid/nodular. Furthermore, infiltrative behavior might suggest higher-grade STS in streaky and polycyclic/multilobulated configured STS. Therefore, the configuration of STS is a valuable feature on MRI.*Clinical Relevance/Application The configuration is a long overlooked feature of STS on MRI and there are only a few studies dealing with this feature. Our study showed that the configuration of STS has the potential to predict the grade of malignancy and consecutively evaluate the therapy. Therefore, the configuration of STS should be implemented in MRI reports on STS.

RESULTS

55 high-grade, 41 intermediate-grade and 35 low-grade primary STS lesions were identified. Primary STS significantly most often occurred in the extremities (p<0.001). Polycyclic/multilobulated, ovoid/nodular and streaky were the most common configurations. Most of the high-grade (G3) and intermediate-grade (G2) primary STS showed a polycyclic/multilobulated configuration (p<0.001), while low-grade primary STS (G1) were mostly ovoid/nodular. G3 polycyclic/multilobulated STS were significantly more often infiltrative, compared to G2 polycyclic/multilobulated STS (p<0.05). Most ovoid/nodular primary STS were well-defined (p<0.001). Streaky G3 and G2 sarcoma were all infiltrative, while streaky G1 sarcoma mostly showed well-defined borders. Additionally, high-grade streaky and polycyclic/multilobulated STS were significantly larger in size, compared to intermediate- and low-grade STS.

CLINICAL RELEVANCE/APPLICATION

The configuration is a long overlooked feature of STS on MRI and there are only a few studies dealing with this feature. Our study showed that the configuration of STS has the potential to predict the grade of malignancy and consecutively evaluate the therapy. Therefore, the configuration of STS should be implemented in MRI reports on STS.

SDP-MK-13 Whole-body MR Imaging In Limb Girdle Muscular Dystrophy Type R1/2A (LGMDR1/LGMD2A): A Multicenter Study

Participants
Lais Aivazoglou, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

To provide a detailed description and define a characteristic WBMRI pattern of involvement in LGMDR1 patients with correlation to clinical and functional data.*Methods and Materials Patients with a confirmed diagnosis of LGMDR1 under follow-up in three neuromuscular disorder centers were recruited. Institutional ethical committee authorization and written informed consent of all patients were obtained. The study group consisted of 18 patients. Clinical and epidemiological data were collected and a functional evaluation was performed, consisting of the&9; Gardner-Medwin and Walton (GMW) scale to evaluate lower limb functionality and the Brooke scale to evaluate upper limb functionality.All patients underwent a WBMRI protocol (1.5T) consisting of axial T1 and STIR images. Fifty one different muscles were assessed regarding fatty infiltration (5-point scale) and muscle edema (4-point scale). The results were evaluated with non-parametric statistical analysis using the software R.*Results All patients showed strikingly symmetrical T1 abnormalities. The highest fatty infiltration scores involved the serratus anterior and the long head of the biceps femoris, adductor magnus and lumbar erector spinae. The most spared muscle bellies overall were cervical paraspinal muscles, sternocleidomastoid, thoracic transversospinal and popliteus.There was a mediolateral gradient of involvement of the posterior paraspinal muscles, in which the erector spinae muscles (the more lateral muscles) were more affected than the transversospinalis muscles (the more medial muscles), with p 0.0026 in the thoracic segment and p 0.0090 in the lumbar segment.In the thighs, the posterior compartment was preferentially involved in comparison to the anterior compartment. A striped pattern of involvement of the vastus lateralis was present in 13 of the 18 patients (72%): the "pseudocollagen sign".There was a strong correlation between the lower limbs MR score to the functional GMW score (Spearman's correlation coefficient: 0.8285) and a moderate correlation between the upper limbs MR score with the Brooke score (Spearman's correlation coefficient: 0.5396).*Conclusions We present a detailed description of the characteristic WBMRI pattern of involvement in LGMDR1 patients with the highlights of the mediolateral gradient of involvement of the posterior paraspinal muscles, the "pseudocollagen sign" and the strong correlation between the lower limbs MR score to the functional GMW score.*Clinical Relevance/Application Knowledge of the whole-body MR pattern of involvement of LGMDR1 patients adds to the diagnostic workup of myopathies in clinical practice and broadens the possibilities of different muscles to be used in the future as an outcome measure in clinical trials.

RESULTS

All patients showed strikingly symmetrical T1 abnormalities. The highest fatty infiltration scores involved the serratus anterior and the long head of the biceps femoris, adductor magnus and lumbar erector spinae. The most spared muscle bellies overall were cervical paraspinal muscles, sternocleidomastoid, thoracic transversospinal and popliteus.There was a mediolateral gradient of involvement of the posterior paraspinal muscles, in which the erector spinae muscles (the more lateral muscles) were more affected than the transversospinalis muscles (the more medial muscles), with p 0.0026 in the thoracic segment and p 0.0090 in the lumbar segment.In the thighs, the posterior compartment was preferentially involved in comparison to the anterior compartment. A striped pattern of involvement of the vastus lateralis was present in 13 of the 18 patients (72%): the "pseudocollagen sign".There was a strong correlation between the lower limbs MR score to the functional GMW score (Spearman's correlation coefficient: 0.8285) and a moderate correlation between the upper limbs MR score with the Brooke score (Spearman's correlation coefficient: 0.5396).

CLINICAL RELEVANCE/APPLICATION

Knowledge of the whole-body MR pattern of involvement of LGMDR1 patients adds to the diagnostic workup of myopathies in clinical practice and broadens the possibilities of different muscles to be used in the future as an outcome measure in clinical trials.

SDP-MK-14 Compression Of Nerve Roots May Increase The Degree Of Fat Infiltration Of Multifidus Muscle

Participants
Hui Hao, Xi'an, China (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to find the relationship between the degree of nerve root compression and the degree of multifidus muscle lipidization using conventional MRI images.*Methods and Materials Images of all patients undergoing lumbar MRI in our center from January to April 2019 were retrospectively analyzed, and T2 Sag and T2 Ax images were selected.The level of intervertebral disc herniation was determined in sagittal position, and Priffman grading and Kader grading of intervertebral disc herniation in transverse position were conducted.(Table 1 and Fig 1)Basic information such as name, gender and age were collected.All statistical analysis were performed by using SPSS 20.0 (SPSS, Chicago, IL, USA); p<0.05 was considered as statistically significant difference.*Results A total of 244 (110 male and 134 female) patients with the age(51±16)were enrolled in this study. Lumbar magnetic resonance imaging was performed in all patients , some patients had herniated discs at more than one vertebral level. So we analyzed a total of 453 problematic vertebral levels. According to the situation of disc herniation can be divided into central type and lateral recess type.Priffman grading and Kader grading were related to the central type. The degree of compression was correlated with the degree of aliphatization, and both sides were correlated, indicating that the higher the degree of compression was, the higher the degree of aliphatization was (the correlation coefficient r=0.207 on the left , r=0.195 on the right). (Table 2)A herniated disc to the left had the same result (left correlation coefficient r=0.289,and the right r=0.200). (Table 3)Disc herniation to the right can also indicate the correlation between degree of compression and degree of steatosis (left correlation coefficient r=-.050;right Correlation coefficient r=.292)(Table 4).*Conclusions The nerve root compression quantified by Priffman grading is correlated the degree of lipidization, also the inconsistently distributed degree of lipidization is higher in compression side. Those observations strongly support the hypothesis that nerve root compression is the reason of multifidus muscle fat infiltration.*Clinical Relevance/Application The increase of multifidus muscle fat infiltration will affect the postoperative rehabilitation of patients with lumbar spine surgery. In this study, reasons for fat infiltration on both sides of multifidus muscles were analyzed retrospectively.In our study, nerve root compression was found to be correlated with degree of multifidus muscle fat infiltration. This correlation support the hyposis that nerve root compression would result in an increase in the adiposity of multifarious muscles.

RESULTS

A total of 244 (110 male and 134 female) patients with the age(51±16)were enrolled in this study. Lumbar magnetic resonance imaging was performed in all patients , some patients had herniated discs at more than one vertebral level. So we analyzed a total of 453 problematic vertebral levels. According to the situation of disc herniation can be divided into central type and lateral recess type.Priffman grading and Kader grading were related to the central type. The degree of compression was correlated with the degree of aliphatization, and both sides were correlated, indicating that the higher the degree of compression was, the higher the degree of aliphatization was (the correlation coefficient r=0.207 on the left , r=0.195 on the right). (Table 2)A herniated disc to the left had the same result (left correlation coefficient r=0.289,and the right r=0.200). (Table 3)Disc herniation to the right can also indicate the correlation between degree of compression and degree of steatosis (left correlation coefficient r=-.050;right Correlation coefficient r=.292)(Table 4).

CLINICAL RELEVANCE/APPLICATION

The increase of multifidus muscle fat infiltration will affect the postoperative rehabilitation of patients with lumbar spine surgery. In this study, reasons for fat infiltration on both sides of multifidus muscles were analyzed retrospectively.In our study, nerve root compression was found to be correlated with degree of multifidus muscle fat infiltration. This correlation support the hyposis that nerve root compression would result in an increase in the adiposity of multifarious muscles.

SDP-MK-15 Achilles Tendon Changes Detected With Magnetization Transfer Of Ultrashort Echo Time Magnetic Resonance Imaging After Long-distance Running

Participants
Yijie Fang, Zhuhai, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the value of magnetization transfer of ultrashort echo time magnetic resonance imaging (UTE-MT) in demonstrate feasibility of detection of subclinical sports-related achilles tendon changes in athletes after the marathon.*Methods and Materials The research was approved by the institutional ethics committee review board, and the volunteers provided written consent before the study. Twenty-nine amateur long-distance runners underwent an MR examination (UTE-MT, T1-weighted MR imaging, and T2-weighted MR imaging with fat suppression) of both achilles tendon 1 week before, 2 days after, and 4 weeks after they participated in a marathon. The four regions was divided into 4 subregions: insertion, middle, muscle-tendon junction and whole achilles tendon. The MTR were derived from the UTE-MT data by 2 radiologists independently. Data per achilles tendon from the three time-points were compared by using a two-way mixed-design analysis of variance with a Bonferroni posthoc test.*Results The 2 radiologists had good consistency in the measurement of MTR of achilles tendon with the ICC values of 0.892 to 0.934. This study also revealed injured in UTE-MT that over time were not revealed by qualitative T2WI imaging with fat suppression. The MTR were significantly decreased (P <0.05) in the middle, muscle-tendon junction and whole achilles tendon 2 days after running, and the MTR was recovered 4 weeks after running.*Conclusions After a single marathon, the changes of achilles tendon in amateur marathon runners are reversible. In the absence of positive findings in conventional MRI, UTE-MT can indirectly reflect changes in biochemical composition of the achilles tendon during exercise.*Clinical Relevance/Application UTE-MT reflects the content of macromolecules and may be used as a technique for detecting Achilles tendon injury.

RESULTS

The 2 radiologists had good consistency in the measurement of MTR of achilles tendon with the ICC values of 0.892 to 0.934. This study also revealed injured in UTE-MT that over time were not revealed by qualitative T2WI imaging with fat suppression. The MTR were significantly decreased (P <0.05) in the middle, muscle-tendon junction and whole achilles tendon 2 days after running, and the MTR was recovered 4 weeks after running.

CLINICAL RELEVANCE/APPLICATION

UTE-MT reflects the content of macromolecules and may be used as a technique for detecting Achilles tendon injury.

SDP-MK-16 Comprehensive Assessment Of Ultrasound's Role For Carpal Tunnel Syndrome In Reference To

Electromyography In A Tertiary Hospital.

Participants
Yaman M. Alahmad, Doha, Qatar (*Presenter*) Nothing to Disclose

PURPOSE

Carpal Tunnel Syndrome (CTS) is the most common peripheral mononeuropathy related to entrapment syndrome. Although it is a clinical diagnosis, a confirmatory test is usually needed for uncertain cases. An increase in the median nerve cross-sectional area (CSA) is seen using ultrasound (US) imaging for CTS patients. However, the optimal cutoffs for the diagnosis and classification of CTS using the US are controversial. Several studies used cutoffs of 8.5 to 10.0 mm2 for the diagnosis, with various ranges for the severity indices. We aimed to study the correlation between the findings of US imaging and electromyography (EMG) in patient with CTS for diagnostic and classification purposes.*Methods and Materials We conducted a retrospective cross-sectional study for the period between 2014 and 2020 to identify CTS patients who are above eighteen-year-old and had both US and EMG studies. We excluded patient who had median nerve trauma or neoplasm and those who had US without EMG. For patients with bilateral ultrasound wrist assessment, each hand was considered as a separate image to be compared with EMG. Data were analyzed using SPSS 64-bit version 25. Shapiro-Wilk test was used to assess for distribution normality. Levene's test was performed to assess for homogeneity of variance. EMG findings were classified into: normal, mild, moderate, severe CTS (independent variable). US CSA used as dependent variable. One-way Analysis of Variance (ANOVA) test and Post Hoc analysis were used to assess for difference. US's sensitivity and specificity were calculated for CTS, when compared to EMG (gold standard).*Results Our final sample was 99 subjects; 81 females and 18 males. Their age range was between 24 to 87 years; with mean of 49 ± 3 years. CTS classification using the median nerve CSA reported by US, when compared to EMG, was as following (95% confidence interval of the mean): normal: 8.7 - 10.8 mm2, mild CTS: 10.6 - 16.5 mm2, moderate CTS: 15.4 - 18.1 mm2, severe CTS: 19.1 - 23.1 mm2. There was a statistically significant difference between groups as determined by one-way ANOVA (p<0.001). A Scheffe Post Hoc test revealed no statistical difference between normal and mild CTS groups (p=0.08). There was statistical difference between mild and moderate groups (p=0.006) and moderate and severe groups (p<0.001). Our data showed US sensitivity for CTS of 73.8% and specificity of 76.3%.*Conclusions Sonography seems unable to differentiate some normal from mild CTS cases. However, median nerve CSA of =10 mm2 are suggestive of normal EMG. Nevertheless, sonography appears to be excellent in diagnosing and classifying moderate and severe CTS cases.*Clinical Relevance/Application US can be used as a screening tool in patients with suspected CTS. More studies are needed to assure external validity.

RESULTS

Our final sample was 99 subjects; 81 females and 18 males. Their age range was between 24 to 87 years; with mean of 49 ± 3 years. CTS classification using the median nerve CSA reported by US, when compared to EMG, was as following (95% confidence interval of the mean): normal: 8.7 - 10.8 mm2, mild CTS: 10.6 - 16.5 mm2, moderate CTS: 15.4 - 18.1 mm2, severe CTS: 19.1 - 23.1 mm2. There was a statistically significant difference between groups as determined by one-way ANOVA (p<0.001). A Scheffe Post Hoc test revealed no statistical difference between normal and mild CTS groups (p=0.08). There was statistical difference between mild and moderate groups (p=0.006) and moderate and severe groups (p<0.001). Our data showed US sensitivity for CTS of 73.8% and specificity of 76.3%.

CLINICAL RELEVANCE/APPLICATION

US can be used as a screening tool in patients with suspected CTS. More studies are needed to assure external validity.

SDP-MK-17 Diagnostic Performance Of Mr Arthrogram In Abduction And External Rotation For Detection Of Glenoid Labral Lesions: A Systematic Review And Meta-analysis

Participants
Mehrzad Shafiei, MD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

To compare the diagnostic performance of direct magnetic resonance (MR) arthrography for labral lesions during conventional positioning, abduction and external rotation (ABER), and abduction and external rotation (ABER) plus conventional positioning by using a systematic review and meta-analysis.*Methods and Materials A comprehensive literature search was performed on the two main concepts of magnetic resonance arthrography position (Abduction and External rotation) and labral lesions. Inclusion criteria consisted of original studies that assessed the diagnostic accuracy of MR arthrography in ABER and conventional position for the diagnosis of labral lesions, by using surgical findings as the reference standard. The Quality Assessment of Diagnostic Accuracy Studies 2 (QUADAS-2) tool was used to assess methodologic quality. Meta-analyses were performed that compared MR arthrography during conventional positioning, abduction and external rotation (ABER), and abduction and external rotation (ABER) plus conventional positioning.*Results Seven studies met inclusion and exclusion criteria. Total of 695, 504, and 195 lesions assessed by conventional MRA, ABER MRA, and ABER MRA plus conventional MRA, respectively, were included in our analysis. Pooled sensitivities of MRA in conventional, ABER, and ABER plus conventional position for diagnosis of labral tear were 80.5%, 81.61%, and 94.47%, respectively. Pooled specificities of MRA in conventional, ABER, and ABER plus conventional position for diagnosis of labral tear were 88.52%, 85.56%, and 90.1%, respectively. Summary receiver operator characteristic (ROC) curve demonstrated improved accuracy of ABER plus conventional MRA compared with conventional MRA and ABER MRA with area under the curve (AUC) of 0.99, 0.89, and 0.88, respectively.*Conclusions ABER plus conventional MRA showed substantial superiority compared to both ABER MRA and conventional MRA alone for diagnosis of labral lesions. ABER MRA alone has a diagnostic value comparable to conventional MRA for depicting glenoid labral lesions.*Clinical Relevance/Application The addition of ABER position to conventional MRA could improve diagnostic accuracy for depicting labral tears.

RESULTS

Seven studies met inclusion and exclusion criteria. Total of 695, 504, and 195 lesions assessed by conventional MRA, ABER MRA, and ABER MRA plus conventional MRA, respectively, were included in our analysis. Pooled sensitivities of MRA in conventional, ABER, and ABER plus conventional position for diagnosis of labral tear were 80.5%, 81.61%, and 94.47%, respectively. Pooled specificities of MRA in conventional, ABER, and ABER plus conventional position for diagnosis of labral tear were 88.52%, 85.56%, and 90.1%, respectively. Summary receiver operator characteristic (ROC) curve demonstrated improved accuracy of ABER plus conventional MRA compared with conventional MRA and ABER MRA with area under the curve (AUC) of 0.99, 0.89, and 0.88, respectively.

CLINICAL RELEVANCE/APPLICATION

The addition of ABER position to conventional MRA could improve diagnostic accuracy for depicting labral tears.

SDP-MK-18 Improved Delineation Of Bone Structures In The Wrist Using Photon-counting CT

Participants
Nina Kammerling, MD, Motala, Sweden (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate diagnostic image quality of wrist images obtained using a prototype photon-counting detector (PCD) computed tomography (CT) and to compare it to a state-of-the-art conventional energy-integrating detector CT (EID-CT).*Methods and Materials Twelve human wrist specimens were scanned with EID-CT (SOMATOM Force; Siemens Healthineers, Forchheim, Germany) and PCD-CT (SOMATOM Count Plus; Siemens Healthineers, Forchheim, Germany) at comparable patient dose levels (CTDI 5.3 mGy) and similar technique parameters (120 kV, rotation time 1 s, pitch 0.85). Axial images were reconstructed using the thinnest possible slice thickness, i.e. 0.4 mm on EID-CT and 0.2 mm on PCD-CT (UHR-mode) at 50% overlap, with the largest image matrix size possible (512 x 512 on EID-CT and 2048 x 2048 on PCD-CT). Reconstruction kernels with different sharpness, optimized for imaging of skeletal structures, were used. Noise levels were assessed using the standard deviation of the CT number of the image pixels in fat tissue. Contrast-to-noise ratios (CNR) were calculated for bone structures. Spatial resolution was evaluated by quantifying the separation of trabecular bone and bone marrow using 3D histogram analysis.*Results Bone CNR was lower for PCD-CT using a relatively sharp bone kernel (Br89u), compared to EID-CT (PCD-CT: 11.5 ± 1.2; EID-CT: 18.8 ± 3.4). The 3D histogram analysis, however, showed a better delineation of trabecular bone structure for PCD-CT reconstructed with the sharper bone kernel. The relative number of unsharp voxels was significantly lower for PCD-CT for both the radius (27 ± 3 %) and the scaphoideum (26 ± 4 %) compared to EID-CT (radius: 48 ± 11%; scaphoideum: 45 ± 13 %; p < 0.001), despite a 63% decrease in CNR for the sharper bone kernel.*Conclusions Computed tomography of the wrist using a prototype photon-counting CT scanner provides superior delineation of trabecular bone compared to conventional CT at comparable patient doses and despite using a sharper reconstruction kernel with a higher level of image noise. This is due to better detector dose efficiency, smaller detector elements allowing for thinner slice thickness and a large image matrix of 2048 x 2048 pixels.*Clinical Relevance/Application This study shows an improved visibility of bone structures using PCD-CT, which may lead to a better diagnosis of fractures, as well as more individualized and targeted treatment measures.

RESULTS

Bone CNR was lower for PCD-CT using a relatively sharp bone kernel (Br89u), compared to EID-CT (PCD-CT: 11.5 ± 1.2; EID-CT: 18.8 ± 3.4). The 3D histogram analysis, however, showed a better delineation of trabecular bone structure for PCD-CT reconstructed with the sharper bone kernel. The relative number of unsharp voxels was significantly lower for PCD-CT for both the radius (27 ± 3 %) and the scaphoideum (26 ± 4 %) compared to EID-CT (radius: 48 ± 11%; scaphoideum: 45 ± 13 %; p < 0.001), despite a 63% decrease in CNR for the sharper bone kernel.

CLINICAL RELEVANCE/APPLICATION

This study shows an improved visibility of bone structures using PCD-CT, which may lead to a better diagnosis of fractures, as well as more individualized and targeted treatment measures.

SDP-MK-19 Quantitative MRI Depicts Abnormal EMG Motor Unit Recruitment And Spontaneous Activity In Muscle Denervation

Participants
Kenneth Serrano, BA, Port Jefferson, New York (*Presenter*) Nothing to Disclose

PURPOSE

While MRI qualitatively depicts muscle denervation, electromyography (EMG) is used to grade its severity. This study elevated the role of quantitative MRI (qMRI) techniques (T2-mapping and diffusion tensor imaging-based apparent fiber diameter (AFD)) in denervation assessment. We hypothesized that qMRI can discriminate between different grades in severity of muscle denervation.*Methods and Materials 31 subjects (age=38.6+/-19.1, 22M/9F) undergoing brachial plexus MRI and EMG (mean=9.0 days apart) for suspected plexopathy were prospectively recruited for qMRI. A 10-minute qMRI included T2-mapping and multi-b-valued DTI. A novel AFD metric, using cylinders to model muscle fiber cross-section, was derived from DTI data. Five muscles (supraspinatus, infraspinatus, and deltoid anterior/middle/posterior heads) were manually segmented on 3 representative axial slices (superior, middle, and inferior). EMG measures included motor unit recruitment (MUR), from greatest to least: 'full', 'decreased', 'discrete', and 'none', and abnormal spontaneous activity: fibrillations and positive sharp waves (PSWs) ('0', '1+', '2+', '3+'). Parametric t-tests (a=0.05) with Holm-Bonferroni correction of T2 and AFD were performed between EMG grades.*Results 129 muscles (88 denervated, confirmed by EMG) were analyzed. Mean T2 (ms) was significantly (p<0.01) higher in more severe MUR denervation grades ('decreased': 45.7, 'discrete': 52.3, 'none':56.6) than non-denervated (38.6). Mean AFD (um) was significantly (p<0.01) lower in denervated (63.6, 60.4, 59.3) than non-denervated muscles (77.8). Significant mean T2 increases (p<0.01) and AFD decreases (p<0.02) existed between fibrillation grades of '2+' and '0' (by +5.7ms and -10.3um) and between '3+' and '0' (by +13.2ms and -8.9um). For PSWs, significant mean T2 (ms) increases ('1+':+14.0, '2+': +6.0, '3+': +14.4, p<0.01) and AFD (um) decreases ('2+':-11.3, '3+': -10.7 only, p<0.01) were observed.*Conclusions qMRI can discriminate between EMG severity grades. Future work will involve longitudinal imaging, analyzing other anatomies and disease processes, and validating the AFD metric with human muscle biopsy.*Clinical Relevance/Application Quantitative MRI (T2-mapping and diffusion diameter) may provide non-invasive depiction of muscle denervation severity.

RESULTS

129 muscles (88 denervated, confirmed by EMG) were analyzed. Mean T2 (ms) was significantly (p<0.01) higher in more severe MUR denervation grades ('decreased': 45.7, 'discrete': 52.3, 'none':56.6) than non-denervated (38.6). Mean AFD (um) was significantly (p<0.01) lower in denervated (63.6, 60.4, 59.3) than non-denervated muscles (77.8). Significant mean T2 increases (p<0.01) and AFD decreases (p<0.02) existed between fibrillation grades of '2+' and '0' (by +5.7ms and -10.3um) and between '3+' and '0' (by +13.2ms and -8.9um). For PSWs, significant mean T2 (ms) increases ('1+':+14.0, '2+': +6.0, '3+': +14.4, p<0.01) and AFD (um) decreases ('2+':-11.3, '3+': -10.7 only, p<0.01) were observed.

CLINICAL RELEVANCE/APPLICATION

Quantitative MRI (T2-mapping and diffusion diameter) may provide non-invasive depiction of muscle denervation severity.

SDP-MK-2 Quantitative Shear Wave Elastography Evaluation Of Rectus Femoris Muscle In Healthy Adults

Participants

Jisook Yi, MD, Busan, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study is (1) to investigate the reliability of shear wave ultrasonography of rectus femoris (RF) muscle according to locations and (2) to compare the measurements of rectus femoris muscle between SWE and CT in healthy adults.*Methods and Materials Seventy (30 men, 40 women; mean age, 45.7 years) with healthy body mass index (BMI < 25) were included between June 2019 and January 2020. SWE of right RF muscle of subjects was performed by one musculoskeletal radiologist. Qualitative muscle visual grade was performed using 4 grades. SWE findings (stiffness and shear wave velocity [SWV]) of RF muscle were measured on proximal, mid, and distal 1/3 portion of RF muscle. Measurements were repeated 10 minutes after the first measurement. CT without contrast enhancement of RF muscle was performed the same day of SWE and RF muscle density (MD) was measured on mid 1/3 portion. The reliability of SWE measurements was assessed by using intraclass correlation coefficient (ICC). The correlation between SWE measurements and MD on CT was analyzed using Pearson's correlation.*Results The interobserver agreements for SWE findings were almost perfect for mid-RF muscle (k=0.831 for stiffness, k=0.822 for SWV) and substantial for proximal (k=0.775 for stiffness, k=0.770 for SWV) and distal (k=0.771 for stiffness, k=0.795 for SWV) RF muscle. There were negative moderate correlations in visual grade/velocity (r=-0.478, p<0.001) and visual grade/stiffness (r=-0.489, p<0.001). There were very weak to weak correlations between CT MD and SWE findings (r=-0.265-0.392).*Conclusions SWE findings of RF muscle demonstrated the highest reliability in mid-portion of thigh. SWE findings showed moderate correlation with visual grade of USG and very weak to weak correlation to muscle density on CT.*Clinical Relevance/Application SWE of muscle might be detected the early change of muscle degeneration compared to CT. And it could be used as an objective method to evaluate the quality of muscle and might promote precision medicine.

RESULTS

The interobserver agreements for SWE findings were almost perfect for mid-RF muscle (k=0.831 for stiffness, k=0.822 for SWV) and substantial for proximal (k=0.775 for stiffness, k=0.770 for SWV) and distal (k=0.771 for stiffness, k=0.795 for SWV) RF muscle. There were negative moderate correlations in visual grade/velocity (r=-0.478, p<0.001) and visual grade/stiffness (r=-0.489, p<0.001). There were very weak to weak correlations between CT MD and SWE findings (r=-0.265-0.392).

CLINICAL RELEVANCE/APPLICATION

SWE of muscle might be detected the early change of muscle degeneration compared to CT. And it could be used as an objective method to evaluate the quality of muscle and might promote precision medicine.

SDP-MK-20 Combination Use Of Compressed Sensing And Deep Learning For Shoulder MRI: Stability In Various Sequences

Participants
Takeshi Nakaura, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning-based reconstruction (DLR) has been reported to be effective in improving the image quality of magnetic resonance imaging (MRI), but almost no previous reports evaluated its stability for various sequences. This study aimed to evaluate the usefulness of the combined use of compressed sensing and DLR for various sequences in shoulder MRI.*Methods and Materials This retrospective study included 37 consecutive patients who underwent under-sampled shoulder MRI, including coronal short T1 inversion recovery (STIR) sequences, T1-weighted images (T1WI), and T2-weighted images (T2WI). Images were reconstructed using the conventional Wavelet-based denoising method (Wavelet method) or the combination of Wavelet and DLR-based denoising method (hybrid-DLR method) for each sequence. The signal-to-noise ratio (SNR) and the contrast-to-noise ratio (CNR) of bone, muscle, and fat and half width at half maximum (FWHM) of the shoulder joint were compared between the two image reconstruction methods. Two board-certified radiologists scored for image noise, contrast, sharpness, artifacts, and overall image quality of the two image types using a 4-point scale.*Results The SNRs and CNRs of bone, muscle, and fat in STIR, T1WI, and T2WI from the hybrid-DLR method were significantly higher than those of Wavelet method (p < 0.001). No significant differences were found in the FWHM of the shoulder joint among all sequences (p > 0.05). The image noise, sharpness, artifacts, and overall image quality in all sequences reconstructed using the hybrid-DLR method were significantly higher than those of the Wavelet method (p < 0.001). No significant differences were observed in the contrast between the two methods (p > 0.05).*Conclusions The hybrid-DLR method can improve the image quality of compressed sensing in STIR, T1WI, and T2WI of the shoulder relative to the Wavelet method.*Clinical Relevance/Application The hybrid-DLR method with compressed sensing can offer high-quality and fast scanning protocols for various sequences in shoulder MRI.

RESULTS

The SNRs and CNRs of bone, muscle, and fat in STIR, T1WI, and T2WI from the hybrid-DLR method were significantly higher than those of Wavelet method (p < 0.001). No significant differences were found in the FWHM of the shoulder joint among all sequences (p > 0.05). The image noise, sharpness, artifacts, and overall image quality in all sequences reconstructed using the hybrid-DLR method were significantly higher than those of the Wavelet method (p < 0.001). No significant differences were observed in the contrast between the two methods (p > 0.05).

CLINICAL RELEVANCE/APPLICATION

The hybrid-DLR method with compressed sensing can offer high-quality and fast scanning protocols for various sequences in shoulder MRI.

SDP-MK-21 Histopathologic And Radiologic Assessment Of Chemotherapeutic Response In Osteosarcoma: Correlation Of Adc With Huvos Grading

Participants
Himansu S. Mohanty, MBBS, New Delhi, India (*Presenter*) Nothing to Disclose

PURPOSE

Histological necrosis, the current standard for response evaluation in osteosarcoma, is attainable after chemotherapy. To establish therole of surrogate markers of response prediction and evaluation using MRI in the pre-surgical assessment.*Methods and Materials In a retrospective analysis MRI images of newly diagnosed osteosarcoma patients who received more than threecycles of neo-adjuvant chemotherapy or high dose methotrexate followed by surgery during 2012-2018 were analysed. All patients

hadundergone post-chemotherapy conventional, diffusion-weighted and contrast-enhanced MRI. Classifying histological response in post-surgicalspecimens according to Huvos grading of necrosis as the reference standard, ADC was measured in pre-surgical DW MRI study and comparedto it. ADC was measured separately in soft tissues and bony component of tumor or only in the bone/soft tissue whichever feasible in the sampleand it was compared with Huvos grading of necrosis.*Results Mean ADC for soft tissue component in 28 samples was 2068.3±382.5 and mean ADC for 55 samples of bony component was 1866.6± 357.6. The ADC measured in bony samples of osteosarcoma is significantly correlating with Huvos grading with P value <0.05. However theADC of soft tissue component is not correlating significantly with Huvos grading.*Conclusions In osteosarcoma, chemotherapy related grade of bony necrosis can be predicted with the help of DW MRI.*Clinical Relevance/Application DWI allows assessment of tumor necrosis after neoadjuvant chemotherapy by ADC measurement.It can give an information of tumor burden before limb salvage surgery. It also helps in response evaluation who are continued on chemotherapy

RESULTS

Mean ADC for soft tissue component in 28 samples was 2068.3±382.5 and mean ADC for 55 samples of bony component was 1866.6± 357.6. The ADC measured in bony samples of osteosarcoma is significantly correlating with Huvos grading with P value <0.05. However theADC of soft tissue component is not correlating significantly with Huvos grading.

CLINICAL RELEVANCE/APPLICATION

DWI allows assessment of tumor necrosis after neoadjuvant chemotherapy by ADC measurement.It can give an information of tumor burden before limb salvage surgery. It also helps in response evaluation who are continued on chemotherapy

SDP-MK-22 High-resolution Imaging Of Large Joints Using Photon-counting Detector (PCD) CT

Participants
Francis Baffour, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To demonstrate improved spatial resolution of shoulder and pelvis CT exams using a photon-counting detector (PCD) CT compared to conventional energy-integrating detector (EID) CT.*Methods and Materials Patients who underwent clinically-indicated shoulder or pelvis/hip EID-CT exams were recruited to undergo the same exam on an investigational research whole-body PCD-CT system (SOMATOM Count Plus, Siemens Healthineers) using its non-comb-based high resolution (HR) mode. EID-CT images were reconstructed following routine clinical protocol (Br62/Br64 kernel, 1mm thickness). PCD-CT images were reconstructed using a HR kernel (Br76) at 0.6 mm thickness. Two musculoskeletal radiologists blindly evaluated randomized EID-CT and PCD-CT images, rating critical joint structure visualization using a 5-point Likert scale. Readers compared images from the same patient in a side-by side fashion, assigning a score to images on the left monitor in comparison to the right (1- worse visualization and diagnostic confidence; 2 - worse visualization, no change in diagnostic confidence; 3 - comparable visualization and diagnostic confidence; 4 - improved visualization, no change in diagnostic confidence; 5 - improved confidence and visualization). A post-hoc assignment of reader scores was performed such that they reflected PCD-CT visualization relative to that of EID-CT. Wilcoxon signed-rank test was used for statistical analysis.*Results 17 patients underwent shoulder CT (EID-CT: mean CTDIvol = 33.8 mGy; PCD-CT mean CTDIvol = 18.0 mGy) and 15 patients underwent pelvis/hip CT (EID-CT: mean CTDIvol = 15.2 mGy; PCD-CT: mean CTDIvol = 11.5 mGy). Both readers rated PCD-CT images significantly better than EID-CT for critical joint structure visualization (mean scores; Reader 1: shoulder 3.6, hip 3.5; Reader 2: shoulder 4.1, hip 3.7. shoulders; p<0.001; hips, p<0.05).*Conclusions PCD-CT in HR mode has better visualization of critical structures in the shoulder and pelvis/hip compared to conventional EID-CT. PCD-CT doses were 25-47% lower than EID-CT doses.*Clinical Relevance/Application Unlike EID-CT, where comb-based HR scans are limited to extremities, PCD-CT allows reduced dose and higher resolution imaging of large joints for better visualization of critical joint structures.

RESULTS

17 patients underwent shoulder CT (EID-CT: mean CTDIvol = 33.8 mGy; PCD-CT mean CTDIvol = 18.0 mGy) and 15 patients underwent pelvis/hip CT (EID-CT: mean CTDIvol = 15.2 mGy; PCD-CT: mean CTDIvol = 11.5 mGy). Both readers rated PCD-CT images significantly better than EID-CT for critical joint structure visualization (mean scores; Reader 1: shoulder 3.6, hip 3.5; Reader 2: shoulder 4.1, hip 3.7. shoulders; p<0.001; hips, p<0.05).

CLINICAL RELEVANCE/APPLICATION

Unlike EID-CT, where comb-based HR scans are limited to extremities, PCD-CT allows reduced dose and higher resolution imaging of large joints for better visualization of critical joint structures.

SDP-MK-23 Development And Operationalization Of An Automated Workflow For Correlation Of Knee MRI And Arthroscopy Findings

Participants
Naveen Subhas, MD, Cleveland, Ohio (*Presenter*) Research support, Siemens AG;

PURPOSE

To evaluate and assess the accuracy of an automated workflow developed at our institution to prospectively capture and correlate knee MRI results with surgical findings.*Methods and Materials Discrete data were extracted using a text search algorithm from a structured dictation macro with picklists implemented for knee MRI. Patients who underwent arthroscopic knee surgery in 2019-2020 and had undergone knee MRI within the 6 months before surgery were identified with Teradata. Operative findings were recorded discretely by surgeons using a custom-built iPhone application. Findings were classified as positive, negative, or other for tear in the medial meniscus (MM), lateral meniscus (LM), and anterior cruciate ligament (ACL). An automated Tableau dashboard displaying concordance and individual and group accuracy (sensitivity [Sn]/specificity [Sp]/positive predictive value [PPV]/negative predictive value [NPV]) for each structure was enabled for each radiologist, with updates provided via automated monthly emails. Manual correlation was performed on a random sample of 10% of cases for comparison with automatically derived values.*Results Data from 3287 patients (1569 women, 1718 men; mean age, 44) with MRI results (3472 exams) were analyzed. Automatic correlation was available for more than half of MRI exams (MM, 2074 [59.7%]; LM, 2143 [61.7%]; ACL, 2171 [62.5%]), with most cases (MM, 1888 [54.4%]; LM, 1890 [54.4%]; ACL, 2129 [61.3%]) demonstrating concordant imaging and operative findings. For cases with automatic correlation, the automatically calculated metrics were similar to those reported in the literature (highest Sn, Sp, PPV, and NPV for the ACL, followed by the MM and LM). For cases without automatic correlation, nearly 40% were missing both MRI and surgical data; roughly equal numbers of cases were missing either MRI or surgical data or were excluded from correlation (eg, because of previous surgery). Among the manual correlation cases, we found only 5 discordances, all due to entry error. For all

3 structures, Sn and Sp values for the manually labelled dataset were identical or almost identical to those of the automatically labelled dataset. We calculated that manual concordance analysis would take 12 days of continuous work by an MSK fellow.*Conclusions We have created, implemented, and verified the accuracy of an automated system that provides surgical correlation for knee MRI exams to each radiologist and allows radiologists to quickly review the images and their metrics.*Clinical Relevance/Application This system allows us to identify misses and good calls, facilitate peer learning by identifying common misses, increase the accuracy of image interpretation, improve patient outcomes, and provide a dataset for research and education.

RESULTS

Data from 3287 patients (1569 women, 1718 men; mean age, 44) with MRI results (3472 exams) were analyzed. Automatic correlation was available for more than half of MRI exams (MM, 2074 [59.7%]; LM, 2143 [61.7%]; ACL, 2171 [62.5%]), with most cases (MM, 1888 [54.4%]; LM, 1890 [54.4%]; ACL, 2129 [61.3%]) demonstrating concordant imaging and operative findings. For cases with automatic correlation, the automatically calculated metrics were similar to those reported in the literature (highest Sn, Sp, PPV, and NPV for the ACL, followed by the MM and LM). For cases without automatic correlation, nearly 40% were missing both MRI and surgical data; roughly equal numbers of cases were missing either MRI or surgical data or were excluded from correlation (eg, because of previous surgery). Among the manual correlation cases, we found only 5 discordances, all due to entry error. For all 3 structures, Sn and Sp values for the manually labelled dataset were identical or almost identical to those of the automatically labelled dataset. We calculated that manual concordance analysis would take 12 days of continuous work by an MSK fellow.

CLINICAL RELEVANCE/APPLICATION

This system allows us to identify misses and good calls, facilitate peer learning by identifying common misses, increase the accuracy of image interpretation, improve patient outcomes, and provide a dataset for research and education.

SDP-MK-24 Mri Of The Popliteus Tendon: Age-related Changes In Size And Signal In Asymptomatic Patients And Association With Osteoarthrosis

Participants
Barry Hansford, MD, Lake Oswego, Oregon (*Presenter*) Nothing to Disclose

PURPOSE

The popliteus tendon (PT) is often intermediate to high signal intensity (SI) on PD MRI, mimicking tendinosis. Little has been written on isolated PT pathology or normal MRI PT appearance. Aims: 1) describe normal size, SI and age-related changes of PT in asymptomatic patients (pts); 2) correlate PT size and SI changes to osteoarthrosis (OA); 3) correlate MRI diagnosis of PT pathology with pt symptoms.*Methods and Materials IRB approved retrospective study of pts without trauma/surgery history who had knee MRI from 01-12/2018. Weight-bearing knee radiographs and clinic visits in 150 patients were performed within 2 weeks of MRI. Pts divided by age into 3 cohorts of 50 (1-17y, 18-64y, > 65y). Variables included: PT size on T2/PDWI coronal and axial images; PT SI on T2/PD/T1; PT striations on T2/PD; Kellgren-Lawrence (KL) grade of OA; pt demographics and symptoms. A 2nd sub-analysis was performed for the MRI diagnosis of PT pathology (PACS search 1/2013-12/2018 yielded 38 pts) with the same variables, and whether PT pathology was called as isolated clinical or MRI findings.*Results Analyses of 150 MRIs without PT symptoms showed significant differences in PT thickness in the 3 age cohorts (ANOVA p < 0.0001; post hoc pair-wise p < 0.0001). T1/T2 SI change and striation on T2/PDWI increased in older pts (p < 0.0001). Positive correlation between PT size and KL grade was found (p < 0.0001). Analysis of 38 PT pathology pts showed lower % of female patients (p = 0.03), trend of increasing age (p = 0.08), and higher KL grade (p=0.0004) compared to the 150 knee MRI cohort. Generalized linear regression model trained on the combined dataset with dummy variable denoting PT pathology on MRI showed non-significant coefficients associated with the dummy variable and its interaction terms with age, gender, and KL grade (p > 0.05). Adjusting for age, gender, and KL grade, there was no significant difference in PT thickness between the groups with and without MRI PT pathology. Statistical analyses done in R and Prism.*Conclusions PT increases in size and striations with aging, and enlarges with increasing OA severity. If PT pathology on MRI is suspected, clinical notes should be reviewed to avoid over-diagnosis.*Clinical Relevance/Application Awareness of the normal changes in PT size and SI with aging and OA is important in order to prevent the over-diagnosis of PT pathology on routine knee MRI.

RESULTS

Analyses of 150 MRIs without PT symptoms showed significant differences in PT thickness in the 3 age cohorts (ANOVA p < 0.0001; post hoc pair-wise p < 0.0001). T1/T2 SI change and striation on T2/PDWI increased in older pts (p < 0.0001). Positive correlation between PT size and KL grade was found (p < 0.0001). Analysis of 38 PT pathology pts showed lower % of female patients (p = 0.03), trend of increasing age (p = 0.08), and higher KL grade (p=0.0004) compared to the 150 knee MRI cohort. Generalized linear regression model trained on the combined dataset with dummy variable denoting PT pathology on MRI showed non-significant coefficients associated with the dummy variable and its interaction terms with age, gender, and KL grade (p > 0.05). Adjusting for age, gender, and KL grade, there was no significant difference in PT thickness between the groups with and without MRI PT pathology. Statistical analyses done in R and Prism.

CLINICAL RELEVANCE/APPLICATION

Awareness of the normal changes in PT size and SI with aging and OA is important in order to prevent the over-diagnosis of PT pathology on routine knee MRI.

SDP-MK-25 Quickly Scan In Foot Dixon Using AI Based CS Technology

Participants
Wen Zeng, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

To study the ability of ACS - based Dixon sequence in shortening time in foot MR examination. At the same time, it is discussed whether the Dixon image can maintain good image quality after shortening time.*Methods and Materials A total of 20 patients underwent magnetic resonance foot examination in the Department of Radiology, West China Hospital, Sichuan University. Each patient underwent routine T2 scan, Dixon scan and Dixon-ACS scan. Record the scan time for each sequence. ROI was delineated in the bone, muscle, ligament and air areas on Dixon and Dixon-ACS water charts, signal values and noise values were recorded, and the SNR was calculated. The images were also subjectively evaluated by two experienced radiologists on four aspects, including overall quality, sharpness, detail display, and fake film review scores.*Results The average scanning time of Dixon was 2 minutes 17 seconds, and that of Dixon-ACS was 4 minutes 2 seconds. SNR of bone, muscle and ligament in Dixon and Dixon-ACS water maps were different (P =0.002; P < 0.001; P <0.001), there was no significant difference in SNR in air (P =0.233). In

subjective evaluation, the overall quality and artifacts of Dixon and Dixon-ACS water maps were different (P =0.026; P =0.024), there was no significant difference in image sharpness and detail display (P =0.059).*Conclusions Dixon-ACS can greatly reduce the scanning time, improve the image quality and reduce the image motion artifacts to some extent.*Clinical Relevance/Application Shortening scan events can improve patient cooperation, reduce motion artifacts and improve clinical work efficiency.

RESULTS

The average scanning time of Dixon was 2 minutes 17 seconds, and that of Dixon-ACS was 4 minutes 2 seconds. SNR of bone, muscle and ligament in Dixon and Dixon-ACS water maps were different (P =0.002; P < 0.001; P <0.001), there was no significant difference in SNR in air (P =0.233). In subjective evaluation, the overall quality and artifacts of Dixon and Dixon-ACS water maps were different (P =0.026; P =0.024), there was no significant difference in image sharpness and detail display (P =0.059).

CLINICAL RELEVANCE/APPLICATION

Shortening scan events can improve patient cooperation, reduce motion artifacts and improve clinical work efficiency.

SDP-MK-3   Posterior Capsule Edema: An Ancillary Finding Of Adhesive Capsulitis

Participants
Rajdeep Kapoor, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To determine the value of analyzing the posterior joint capsule of the shoulder on MRI in patients suspected of having adhesive capsulitis.*Methods and Materials The MRI of 57 patients with the presumed diagnosis of adhesive capsulitis were identified retrospectively and matched to control patients (n=57) from 2010-2018. The posterior joint capsule was evaluated in both groups of patients independently by two attending MSK radiologists to determine the clinical significance of this finding in the setting of adhesive capsulitis. Specifically, the posterior capsule was qualitatively evaluated on the sagittal, oblique, T2-weighted, fat suppression sequence for pericapsular edema. Several other variables including the axillary pouch, the coracohumeral ligament (CHL), the rotator interval (RI), the subcoracoid fat triangle, and the teres minor, which have all shown to aid in identification of individuals with adhesive capsulitis, were also evaluated on MRI.*Results Posterior capsule edema was statistically significant (p <0.001) between patients with capsulitis versus the control group with substantial interobserver variability (Kappa 0.66). Both axillary pouch edema and CHL edema were present to a greater degree in the patient group (p<0.001). Axillary pouch and CHL thickness were also increased in the patient group compared to the control group. RI thickness and edema were seen more frequently in patients suspected of having capsulitis. Lastly, teres minor edema and atrophy along with subcoracoid fat obliteration were not statistically different between the case subjects and the control group (p > 0.05).*Conclusions Abnormal signal intensity involving the posterior shoulder capsule can reliably be used for the diagnosis of adhesive capsulitis of the shoulder. Additional MRI findings which provide strong diagnostic value include axillary pouch thickness and increased signal intensity, fatty replacement and abnormal signal in the rotator interval, and thickening and abnormal signal of the CHL. Together, these findings can increase the confidence of diagnosing adhesive capsulitis through imaging.*Clinical Relevance/Application Posterior joint capsule evaluation is a useful adjunct to identify patients with capsulitis and should be routinely assessed on individuals presenting with unknown etiology of shoulder pain.

RESULTS

Posterior capsule edema was statistically significant (p <0.001) between patients with capsulitis versus the control group with substantial interobserver variability (Kappa 0.66). Both axillary pouch edema and CHL edema were present to a greater degree in the patient group (p<0.001). Axillary pouch and CHL thickness were also increased in the patient group compared to the control group. RI thickness and edema were seen more frequently in patients suspected of having capsulitis. Lastly, teres minor edema and atrophy along with subcoracoid fat obliteration were not statistically different between the case subjects and the control group (p > 0.05).

CLINICAL RELEVANCE/APPLICATION

Posterior joint capsule evaluation is a useful adjunct to identify patients with capsulitis and should be routinely assessed on individuals presenting with unknown etiology of shoulder pain.

SDP-MK-4   Deep Interface Changes In Osteonecrosis Of The Femoral Head: Association With ARCO Stage 2 And 3A

Participants
Seul Ki Lee, MD, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to determine the association between deep interface changes and Association Research Circulation Osseous (ARCO) stage 2 and 3A in patients with osteonecrosis of the femoral head (ONFH).*Methods and Materials A retrospective analysis of the deep interface changes of ONFH was conducted 99 cases of ONFH in ARCO stage 2 and 3A according to the 2019 revised ARCO staging system. The imaging findings of the deep interface changes on CT and/or MRI included 1) cystic changes, 2) bone marrow edema (BME), and 3) joint effusion. The characteristics of the deep interface changes were compared between ARCO stage 2 and 3A. Sensitivity and specificity of deep interface changes were estimated with ARCO stages.*Results According to the 2019 revised ARCO staging system, 41 hips were stage 2 and 57 hips were stage 3A. Deep interface changes occurred more frequently in ARCO stage 3A than ARCO stage 2 in terms of cystic changes (68.4% vs. 7.3%, P < 0.001), BME (100.0% vs. 28.9%, P < 0.001), and joint effusion (89.5% vs. 26.8%, P < 0.001). The sensitivity and specificity for ARCO stage 3A were as follows: cystic changes - 68.4% and 92.6%, BME - 100.0% and 71.0%, and joint effusion - 89.4% and 73.1%. The BME and joint effusion were highly sensitive (89.4 - 100.0%) deep interface changes for ARCO stage 3A. For the cystic changes, the sensitivity was not good (14.0 - 68.4%) for ARCO 3A, but the specificity was excellent (92.6 - 100.0%).*Conclusions In the case of ARCO stage 2, cystic change was hardly found, but BME and joint effusion were often found. In the case of ARCO stage 3A, cystic changes were frequently found, and BME and joint effusion almost always occurred.*Clinical Relevance/Application The exact classification between ARCO stage 2 and 3A is important for treatment decisions. However, it is often difficult to distinguish between 2 and 3A only by collapse or crescent sign on imaging studies, especially MRI. Analysis of association between deep interface changes and ARCO stages makes it easier to distinguish between 2 and 3A.

RESULTS

According to the 2019 revised ARCO staging system, 41 hips were stage 2 and 57 hips were stage 3A. Deep interface changes

According to the 2019 revised ARCO staging system, 41 hips were stage 2 and 57 hips were stage 3A. Deep interface changes occurred more frequently in ARCO stage 3A than ARCO stage 2 in terms of cystic changes (68.4% vs. 7.3%, P < 0.001), BME (100.0% vs. 28.9%, P < 0.001), and joint effusion (89.5% vs. 26.8%, P < 0.001). The sensitivity and specificity for ARCO stage 3A were as follows: cystic changes - 68.4% and 92.6%, BME - 100.0% and 71.0%, and joint effusion - 89.4% and 73.1%. The BME and joint effusion were highly sensitive (89.4 - 100.0%) deep interface changes for ARCO stage 3A. For the cystic changes, the sensitivity was not good (14.0 - 68.4%) for ARCO 3A, but the specificity was excellent (92.6 - 100.0%).

CLINICAL RELEVANCE/APPLICATION

The exact classification between ARCO stage 2 and 3A is important for treatment decisions. However, it is often difficult to distinguish between 2 and 3A only by collapse or crescent sign on imaging studies, especially MRI. Analysis of association between deep interface changes and ARCO stages makes it easier to distinguish between 2 and 3A.

SDP-MK-5   Intraneural Ganglion Cysts Around The Hip: Focus On MRI Findings And Clinical Manifestation

Participants
Na Ri Shin, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to describe the cases of intraneural ganglion cysts around the hip based on review of MRI findings and clinical record.*Methods and Materials 15 patients with intraneural ganglion cysts (10 male and 5 female; mean age: 48.4±13.0; age range 22-66 years) were identified from the retrospective search of MRIs obtained in hip and pelvis between January 2013-March 2021. Presence of intraneural ganglion cysts were determined by consensus review of MRIs by two musculoskeletal radiologists for the lesions that met following criteria: 1) tubular of multilobulated fluid signal lesion in continuity with a paralabral cyst that extend along the course of the nerve structure; 2) absence of imaging features suggesting other possible diagnosis, such as neurgenic tumor. Review of medical records and MRI analysis regarding muscle denervation, hip pathology, and contralateral paralabral lesion were done.*Results 11 patients had lesions involving the sciatic nerve with 4 showing extension along the lumbosacral plexus. 3 patients had lesions extending along the obturator nerve and one patient had a lesion involving the superior gluteal nerve. All but one patient (14/15, 93.3%) had clinical symptom related to the lesion including sensory and motor deficit. 7 patients underwent arthroscopic surgery and showed partial improvement of symptom and one of the patient received ultrasound-guided cyst aspiration and steroid injection thereafter, which resulted further improvement of the residual symptom. Sciatic nerve ganglion cysts seemed to arise from the paralabral cyst at the posteroinferior quadrant, while obturator nerve lesions and superior gluteal nerve lesions showed connection with anteroinferior and anterosuperior quadrant of the labrum, respectively, probably representing connection of the articular branch of each nerve with the joint at these locations. Denervation edema of the innervated muscles were found in 3 cases (3/15, 20%). Mean length and diameter of the lesions were 7.96±2.78 cm (range, 3.9-14.5) and 1.85±1.04 cm (range, 0.4-4.6), respectively. One patient had acetabular dysplasia in the affected joint and one had a paralabral cyst at the same labral quadrant in the contralateral hip joint. No patient showed evidence of femoroactabular impingement, full-thickness chondral defect or significant subchondral bone lesion.*Conclusions Our study demonstrates rare cases of intraneural ganglion cysts arising from the hip joint. The lesions share similar MRI findings with specific quadrant of the labrum involved for each nerve.*Clinical Relevance/Application Prior knowledge of these MRI findings may aid in radiologists to diagnose these lesions and lead to early intervention which can improve clinical outcome.

RESULTS

11 patients had lesions involving the sciatic nerve with 4 showing extension along the lumbosacral plexus. 3 patients had lesions extending along the obturator nerve and one patient had a lesion involving the superior gluteal nerve. All but one patient (14/15, 93.3%) had clinical symptom related to the lesion including sensory and motor deficit. 7 patients underwent arthroscopic surgery and showed partial improvement of symptom and one of the patient received ultrasound-guided cyst aspiration and steroid injection thereafter, which resulted further improvement of the residual symptom. Sciatic nerve ganglion cysts seemed to arise from the paralabral cyst at the posteroinferior quadrant, while obturator nerve lesions and superior gluteal nerve lesions showed connection with anteroinferior and anterosuperior quadrant of the labrum, respectively, probably representing connection of the articular branch of each nerve with the joint at these locations. Denervation edema of the innervated muscles were found in 3 cases (3/15, 20%). Mean length and diameter of the lesions were 7.96±2.78 cm (range, 3.9-14.5) and 1.85±1.04 cm (range, 0.4-4.6), respectively. One patient had acetabular dysplasia in the affected joint and one had a paralabral cyst at the same labral quadrant in the contralateral hip joint. No patient showed evidence of femoroactabular impingement, full-thickness chondral defect or significant subchondral bone lesion.

CLINICAL RELEVANCE/APPLICATION

Prior knowledge of these MRI findings may aid in radiologists to diagnose these lesions and lead to early intervention which can improve clinical outcome.

SDP-MK-6   Communication Between The Trochanteric Bursa And Joint Capsule After Total Hip Arthoplasty

Participants
Christopher Watura, FRCR,MBChB, London, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

Peritrochanteric bursal distension on MRI is uncommon (8%) in native hips with greater trochanteric pain syndrome (GTPS) but is often associated with gluteal tendon abnormalities. Furthermore, histological studies find no evidence of primary bursal inflammatory aetiology in GTPS. After total hip arthroplasty (THA), distended peritrochanteric bursae or 'pseudobursae' are common in both asymptomatic (32%) and GTPS patients (62%), suggesting that these are not the symptom generators. Nevertheless, corticosteroid injections into these are common for treating GTPS.Our aim was to investigate (i) the incidence of distended peritrochanteric bursae or pseudobursae after total hip replacement and (ii) the proportion which communicate directly with the hip joint capsule.*Methods and Materials All (1335) MRI hips from between 01/01/2017 to 31/12/2020 were retrieved from the picture archiving system. Only those with a THA were included. Duplicates and repeat studies of the same hip (e.g. performed for follow-up purposes) were excluded.Included cases were retrospectively reviewed by two musculoskeletal radiologists for bursal or pseudobursal distension and the presence of communication with the hip joint capsule, categorised as: "direct communication", "potential communication " or "no communication".*Results A total of 128 MRI hip scans were included.A peritrochanteric fluid-filled space was demonstrated in 23% (30/128) of cases.Direct communication between this and the hip joint capsule was clearly shown in 60% (18/30), potential communication demonstrated in 17% (5/30) and no communication evident in 23% (7/30).In almost all cases, the fluid-filled space demonstrated a thickened low signal wall, more suggestive of post-surgical changes in the soft tissue planes and hence representing a 'pseudobursa' appearance rather than a native bursa.*Conclusions A high proportion of post-THA

peritrocahteric fluid-filled spaces resulted from a direct communication with the hip joint capsule and demonstrated a thicker wall than a typical bursa. As such, these may be better described as pseudobursae relating to post-surgical changes in the soft tissues, rather than being called true native bursae or secondary to a primary bursitis.*Clinical Relevance/Application It is important to recognise pseudobursae on imaging and accurately differentiate them from true bursae in reports. The communication with the hip joint capsule may have implications for corticosteroid steroid injections performed for GTPS post-THA.

RESULTS

A total of 128 MRI hip scans were included.A peritrochanteric fluid-filled space was demonstrated in 23% (30/128) of cases.Direct communication between this and the hip joint capsule was clearly shown in 60% (18/30), potential communication demonstrated in 17% (5/30) and no communication evident in 23% (7/30).In almost all cases, the fluid-filled space demonstrated a thickened low signal wall, more suggestive of post-surgical changes in the soft tissue planes and hence representing a 'pseudobursa' appearance rather than a native bursa.

CLINICAL RELEVANCE/APPLICATION

It is important to recognise pseudobursae on imaging and accurately differentiate them from true bursae in reports. The communication with the hip joint capsule may have implications for corticosteroid steroid injections performed for GTPS post-THA.

SDP-MK-7 A New MRI Technique For The Detailed Inspection Of Compact Bone: Phantom And Preliminary Clinical Study

Participants
Takahiro Sueoka, MD, Hiroshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

On MRI scans the bone structure is a low-intensity area. Our MRI sequence is based on a T2*-weighted sequence; it delineates compact bones. We used a phantom to compare our MRI technique with conventional computed tomography (CT) for their spatial resolution and assessed their diagnostic ability in patients with osteoarthritis.*Methods and Materials We used a 3T MRI scanner (TRILLIUM OVAL, FUJIFILM Healthcare Corp.). The scan parameters were TR 12 ms, TE opposed-phase imaging 6.1 ms, in-phase imaging 7.3 ms, flip angle 40°, band width 150 kHz, FOV 20 cm, acquisition matrix 360, slice thickness and interval 1.5 mm; number of excitations 1. The CT scans were obtained on a 320-detector scanner (Aquilion Precision, Canon Medical Systems) at tube voltage 120 kV, automatic tube current modulation, noise index 7, rotation time 0.75 s, pitch factor 0.569, detector configuration 160 x 0.25 mm, display matrix 512, FOV 30 cm, reconstructed slice thickness and interval 1.5 mm. Using a phantom we measured the modulation transfer function (MTF); cattle bone and lard imitated the human bone and subcutaneous fat contrast. Scans were acquired in 7 patients with osteoarthritis (5 feet, 2 knees). Two board-certified radiologists scored the visibility of the bone cortex, cystic lesions, and osteophytes. They used a 5-point score where 5 = MRI and CT scans are similar, and 1 = MRI and CT scans are dissimilar. Inter-observer agreement was calculated with the kappa-coefficient.*Results In the phantom study the MTF of MRI exceeded that of CT in all spatial frequency ranges. In the clinical study we evaluated 5 distal tibiae, 5 taluses, 2 distal femoral bones, 2 proximal tibiae, 11 cystic lesions, and 12 osteophytes. The mean visual scores assigned by viewer 1 were 4.9 (SD 0.4) for the bone cortex, 4.0 (1.2) for cystic lesions, and 4.8 (0.4) for osteophytes. For viewer 2 they were 4.9 (0.4), 4.1 (1.2), and 4.7 (0.8), respectively. Inter-observer agreement was 0.63.*Conclusions The spatial resolution of phantom scans was higher with MRI than CT. In the clinical study, the diagnostic ability of MRI for the delineation of the bone structure was comparable to CT.*Clinical Relevance/Application The new MRI technique is useful for the morphological evaluation of bone lesions; it may reduce both imaging costs and radiation exposure.

RESULTS

In the phantom study the MTF of MRI exceeded that of CT in all spatial frequency ranges. In the clinical study we evaluated 5 distal tibiae, 5 taluses, 2 distal femoral bones, 2 proximal tibiae, 11 cystic lesions, and 12 osteophytes. The mean visual scores assigned by viewer 1 were 4.9 (SD 0.4) for the bone cortex, 4.0 (1.2) for cystic lesions, and 4.8 (0.4) for osteophytes. For viewer 2 they were 4.9 (0.4), 4.1 (1.2), and 4.7 (0.8), respectively. Inter-observer agreement was 0.63.

CLINICAL RELEVANCE/APPLICATION

The new MRI technique is useful for the morphological evaluation of bone lesions; it may reduce both imaging costs and radiation exposure.

SDP-MK-8 To Evaluate the Diagnostic Value Of18 F FDG PET-CT in Trauma Patients With Suspected Chronic Osteomyelitis

Participants
Sikandar Shaikh, DMRD, Hyderabad, India (*Presenter*) Nothing to Disclose

PURPOSE

To retrospectively evaluate the diagnostic value of 18F-FDG PET/CT in trauma patients with suspected chronic osteomyelitis.*Methods and Materials This was the retrospective study of 66 Limited 18F-FDG PET/CT scans were performed in 66 patients with trauma suspected of having chronic osteomyelitis. In 20 and 46 patients, infection was suspected in the axial and appendicular skeleton, respectively. In 36 patients, PET/CT was performed in the presence of metallic implants. Histopathology or bacteriological culture was used as the standard of reference. For statistical analysis, sensitivity, specificity and accuracy were calculated in relation to findings of the reference standard.*Results Of 66 PET/CT scans, 34 were true positive, 26 true negative, four false positive and one false negative. Eighteen patients had chronic osteomyelitis and 30 had no osseous infection according to the reference standard. Sensitivity, specificity and accuracy for 18F-FDG PET/CT was 94%, 87% and 91% for the whole group, 88%, 100% and 90% for the axial skeleton and 100%, 85% and 91% for the appendicular skeleton, respectively.*Conclusions 18F-FDG PET/CT is a highly sensitive and specific method for the evaluation of chronic infection in the axial and appendicular skeleton in patients with trauma. PET/CT allows precise anatomical localisation and characterisation of the infectious focus and demonstrates the extent of chronic osteomyelitis with a high degree of accuracy*Clinical Relevance/Application 18 FDG PET-CT plays an important role in the evaluation of the Infections like Osteomyelitis

RESULTS

Of 66 PET/CT scans, 34 were true positive, 26 true negative, four false positive and one false negative. Eighteen patients had chronic osteomyelitis and 30 had no osseous infection according to the reference standard. Sensitivity, specificity and accuracy for

18F-FDG PET/CT was 94%, 87% and 91% for the whole group, 88%, 100% and 90% for the axial skeleton and 100%, 85% and 91% for the appendicular skeleton, respectively.

CLINICAL RELEVANCE/APPLICATION

18 FDG PET-CT plays an important role in the evaluation of the Infections like Osteomyelitis

CA05-B1   Comparison Of Agatston Score Derived From An Energy-integrating Detector CT And A Photon-counting Detector CT: An Ex Vivo Study Of Cadaveric Hearts

Participants

Lilian Henriksson, Linkoping, Sweden (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to analyze the correlation and agreement of the Agatston score (AS) between an energy-integrating detector CT (EID-CT) and a photon-counting detector CT (PCD-CT).*Methods and Materials Five cadaveric hearts were positioned in a chest phantom (N1 Lungman; Kyoto Kagaku Co. Ltd, Japan). Each heart was scanned in an EID-CT (SOMATOM Force; Siemens Healthineers, Forchheim, Germany) and a PCD-CT (SOMATOM CounT Plus; Siemens Healthineers, Forchheim, Germany) Examinations were performed according to a clinical calcium score protocol with a standardized slice thickness 3 mm and an increment 1.5 mm. The scans were performed using a spiral protocol at a tube potential of 120 kV. The EID-CT and PCD-CT radiation dose was matched as close as possible (CTDIvol varying between 0.85 and 1.14 mGy). In the PCD-CT reconstructions, a vendor-recommended reconstruction kernel (Qr36) was used, and different monoenergetic energy levels (50-150 keV) were compared to optimize a close match with the prevailing, clinical EID-CT kernel (Sa36). The semi-automatic evaluation of calcium score was performed on a post-processing multimodality workplace (Leonardo MMWP, Siemens, Germany). In total 26 calcified coronary lesions were identified for subsequent inclusion. To analyze the correlation and agreement between AS derived from the EID-CT and PCD-CT, the Pearson correlation (r) and Bland-Altman-plots were applied.*Results The best possible kernel match for Sa36 was Qr36, with a monoenergetic level of 72 keV. The correlation between the PCD-CT and EID-CT with regards to the AS was (r) =0,98 (p<0.001)). Also, a Bland Altman analysis showed mean difference and 1.96 standard deviations upper and lower limits of agreement -7.5 (-31.0 to 16.1), thus with a slight overestimation tendency for the PCD-CT. Fig1.*Conclusions There was an excellent correlation and good agreement between the AS derived from an EID-CT and a PCD-CT. The augmented PCD-CT detector technology, counting every incoming photon, resulted in a slight AS overestimation tendency.*Clinical Relevance/Application The clinically established AS method has excellent possibilities for a conversion to the forthcoming PCD-CT technology. Method dependent PCD-CT overestimation may be compensated for in further mono-energetic development.

RESULTS

The best possible kernel match for Sa36 was Qr36, with a monoenergetic level of 72 keV. The correlation between the PCD-CT and EID-CT with regards to the AS was (r) =0,98 (p<0.001)). Also, a Bland Altman analysis showed mean difference and 1.96 standard deviations upper and lower limits of agreement -7.5 (-31.0 to 16.1), thus with a slight overestimation tendency for the PCD-CT. Fig1.

CLINICAL RELEVANCE/APPLICATION

The clinically established AS method has excellent possibilities for a conversion to the forthcoming PCD-CT technology. Method dependent PCD-CT overestimation may be compensated for in further mono-energetic development.

SDP-IN-1 **Leveraging Predictive "Uncertainty": Assessing Bayesian Convolutional Neural Networks In A Pneumonia-screening Task**

Participants
Tyler Lian, BS, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

Bayesian convolutional neural networks (BCNNs) have emerged in a recent effort to quantify "uncertainty" in machine learning prediction by equipping standard convolutional neural networks with Bayesian posterior inference. In BCNNs, model parameters are represented by updateable probabilistic distributions rather than single point estimates, enabling an incorporation and quantification of uncertainty as probabilistic variance in model prediction. By applying BCNNs to a pneumonia-screening task, this study assessed the behavior and potential clinical utility of model-quantified uncertainty for out-of-sample prediction and within a hypothetical AI-assisted clinical workflow.*Methods and Materials BCNN models (M1, M2) implemented Monte Carlo Dropout in a VGG-19 base and were trained on chest X-rays from one of the NIH CXR14 or CheXpert datasets, respectively. Models were designed as multiclass classifiers to address class imbalance, but only performance on the binary pneumonia-screening task was considered. Both models were evaluated on both validation sets, and model uncertainty was computed as predictive variance over 50 Monte Carlo iterations and plotted. Then, models were evaluated in a mock referral scheme, where 20 percent of the most uncertain of the same-site validation set images were "referred" to a hypothetical clinician and the remaining assessed for model accuracy, compared to a scheme where a random twenty percent were referred out.*Results AUC decreased from 0.606 and 0.697 for same-site sets to 0.533 and 0.641 for opposite-site sets, for M1 and M2 respectively. For both models, distributions of model-quantified uncertainty were more right-skewed (less uncertain) for same-site sets. In the uncertainty-informed referral scheme, model accuracy was 0.185 and 0.143 for M1 and M2 respectively, compared to 0.155 and 0.126 in the random referral scheme.*Conclusions In an applied pneumonia-screening task, higher model-quantified uncertainty was associated with both out-of-distribution prediction and model misclassification error, suggesting the potential of this measure to anticipate these issues in real-world application and promote transparency between clinicians and algorithms in clinical practice.*Clinical Relevance/Application BCNNs supplement model prediction with a quantified measure of prediction uncertainty, which may offer actionable information about model decision-making for clinicians, given more robust development.

RESULTS

AUC decreased from 0.606 and 0.697 for same-site sets to 0.533 and 0.641 for opposite-site sets, for M1 and M2 respectively. For both models, distributions of model-quantified uncertainty were more right-skewed (less uncertain) for same-site sets. In the uncertainty-informed referral scheme, model accuracy was 0.185 and 0.143 for M1 and M2 respectively, compared to 0.155 and 0.126 in the random referral scheme.

CLINICAL RELEVANCE/APPLICATION

BCNNs supplement model prediction with a quantified measure of prediction uncertainty, which may offer actionable information about model decision-making for clinicians, given more robust development.

SDP-IN-10 **Deep Learning For Segmentation Of Veins And Detection Of Deep Vein Thrombosis On Computed Tomography Imaging**

Participants
Anoop Manjunath, Stanford, California (*Presenter*) Nothing to Disclose

PURPOSE

60,000 - 100,000 Americans die annually from complications arising from deep vein thrombosis (DVT), blood clots that form in the veins of the lower extremities and pelvis. Given this condition's nonspecific symptoms and diagnostic difficulty, it remains underdiagnosed, especially in the trauma setting where DVT remains the leading cause of preventable hospital death. An automated warning system for DVTs on Computed Tomography (CT) imaging has the potential to improve the incidental diagnosis of DVTs, especially in the context of trauma, while adding little to no excess burden on the healthcare system.*Methods and Materials 107 CT studies of the lower extremities and pelvis of 86 patients from the Stanford Interventional Radiology Venous InTerventionAL database were used for this study. The dataset consists of 51,451 images, each with hand annotation of veins and DVTs by a trained radiologist. Images were preprocessed and the dataset was split into training, validation, and test sets according to a 70%/10%/20% split on a patient basis. An encoder-decoder convolutional neural network (CNN) model was utilized for vein segmentation. Several CNN architectures for vein segmentation were trained and evaluated using intersection over union (IoU) and Sørensen-Dice coefficient. The predicted vein segmentations in addition to the original images were then used as input to a CNN tasked with determining whether a given CT image contained a DVT. Multiple architectures for DVT classification were evaluated for accuracy, precision, recall, and area under receiver operator curve (AUROC).*Results The best segmentation model, based on the UNet++ architecture, achieved a test set IoU of 0.83 and test set Dice score of 0.79. The best classification model, based on the InceptionNet architecture, achieved a test set AUROC of 0.86, recall of 0.84, precision of 0.86, and accuracy of 0.87. The inclusion of vein segmentation information significantly improved performance for all classification models. The InceptionNet without vein

segmentation had an AUROC of 0.61.*Conclusions We developed a deep neural network system that leverages individual slice-level data for segmentation of deep veins and identification of DVT from CT imaging. Executing this task through an innovative strategy utilizing vein segmentation followed by DVT identification, our system achieves strong performance on both tasks.*Clinical Relevance/Application This automated detection system for DVT will allow for drastically improved incidental diagnosis of DVT, and its interpretable output will minimize clinical burden. In addition to decreasing the incidence and mortality of DVT complications, this algorithm could serve as the foundation for novel systems identifying venous pathology on CT imaging.

RESULTS

The best segmentation model, based on the UNet++ architecture, achieved a test set IoU of 0.83 and test set Dice score of 0.79. The best classification model, based on the InceptionNet architecture, achieved a test set AUROC of 0.86, recall of 0.84, precision of 0.86, and accuracy of 0.87. The inclusion of vein segmentation information significantly improved performance for all classification models. The InceptionNet without vein segmentation had an AUROC of 0.61.

CLINICAL RELEVANCE/APPLICATION

This automated detection system for DVT will allow for drastically improved incidental diagnosis of DVT, and its interpretable output will minimize clinical burden. In addition to decreasing the incidence and mortality of DVT complications, this algorithm could serve as the foundation for novel systems identifying venous pathology on CT imaging.

SDP-IN-11   AI Monitoring In Practice For Bone Age Assessment

Participants
Osvaldo Landi Junior, MD, Sao Paulo, Brazil (*Presenter*) Consultant, Diagnósticos da América SA

PURPOSE

With the increasing number of FDA clearances for artificial intelligence (Ai) models in radiology, we are observing a transition from the field of science to real world applications. These algorithms, now deployed to clinical practice, are exposed to variables that did not exist in the laboratory that could affect its performance in unpredictable ways. The only way to ensure that a model is working as intended in a clinical environment is through ongoing monitoring. The purpose of this study is to describe our results from the prospective surveillance of an Ai model for bone age assessment on hand radiographs on a multi-site healthcare network.*Methods and Materials This model is a convolutional neural network trained on 12611 studies from the RSNA 2017 Pediatric Bone Age Machine Learning Challenge. For the ongoing monitoring, studies were prospectively obtained from the PACs from october 2020 to february 2021, and the ground truth skeletal age was obtained from semi-structured clinical radiology reports using a python script. We also track if radiologists are accessing the Ai results tab by an integration to the radiology information system.*Results In our initial pre-deployment clinical validation using 2835 studies the model achieved a mean average error (MAE) of 11.7 months for females, and 9.36 months for male patients. It was then deployed to the central PACs, reaching 8 different clinical sites and processing 11.900 studies from october 2020 to february 2021, from which 7140 studies were from female patients (60%) and 4760 from male patients (40%). Radiologists accessed the Ai results for 90% of the studies, and the observed MAE was 10.4 for females and 10.2 for males (10.3 months overall) during this timeframe. 10 outlier results were selected for a clinical review which showed that most disagreements between the radiologist and the model were due to asymmetric skeletal maturation of the hand and wrist. Also, while the model training data included only unilateral hand radiographs, one of the clinical sites included both hands in the acquisition protocol. MAE was 10.6 when considering only these studies.*Conclusions This study describes our results from the prospective surveillance of an Ai model for bone age assessment in clinical practice, which has shown acceptable generalization and robustness capabilities, despite variations in input data, such as different acquisition techniques.*Clinical Relevance/Application This research showcases the ongoing monitoring of an Ai model in radiology, which is essencial for its adoption in clinical practice.

RESULTS

In our initial pre-deployment clinical validation using 2835 studies the model achieved a mean average error (MAE) of 11.7 months for females, and 9.36 months for male patients. It was then deployed to the central PACs, reaching 8 different clinical sites and processing 11.900 studies from october 2020 to february 2021, from which 7140 studies were from female patients (60%) and 4760 from male patients (40%). Radiologists accessed the Ai results for 90% of the studies, and the observed MAE was 10.4 for females and 10.2 for males (10.3 months overall) during this timeframe. 10 outlier results were selected for a clinical review which showed that most disagreements between the radiologist and the model were due to asymmetric skeletal maturation of the hand and wrist. Also, while the model training data included only unilateral hand radiographs, one of the clinical sites included both hands in the acquisition protocol. MAE was 10.6 when considering only these studies.

CLINICAL RELEVANCE/APPLICATION

This research showcases the ongoing monitoring of an Ai model in radiology, which is essencial for its adoption in clinical practice.

SDP-IN-12   A Novel Deep Learning-based Iodine Contrast Boosting Algorithm For Reduced-iodine-dose CT Imaging

Participants
Chul Kyun Ahn, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop a novel deep learning (DL)-based iodine contrast boosting algorithm for reduced-iodine-dose CT imaging*Methods and Materials Virtual non-contrast (VNC) and iodine map images were derived from dual-energy liver CT (Somatom Force, Siemens Healthineers AG) of 70 patients (80 kV & 150 kV). In order to generate a training dataset, a paired dataset of 50% iodine map and 50% iodine dose images were generated by multiplying the iodine map image by 0.5 and by summing the VNC with the 50% iodine map images, respectively. A modified U-net was trained by feeding 50% iodine dose images to the input and to predict the corresponding 50% iodine map images. After training, the DL algorithm predicted iodine map image from a new reduced-iodine-dose image. Finally, the predicted iodine map was added to the input image, to produce the contrast-boosted image. Among the 70 patient cases, 50 cases were used for training and the rest 20 cases (10 HCC & 10 non-HCC patients) were used to evaluate the performance of the trained DL algorithm. Intraclass correlation coefficient (ICC3, Two-way mixed effects) was calculated between the predicted iodine map images and the ground-truth iodine map images. Contrast-to-noise ratio (CNR) were measured on HCC lesions and liver vessels in 50% iodine dose, 50% iodine dose after contrast boosting, and 100% iodine dose images.*Results ICCs between the predicted and ground-truth iodine map images of HCC and non-HCC patients were 0.88 and 0.89, respectively. CNR on HCC lesions was 1.6, 4.6, and 4.2 in 50% iodine dose, 50% iodine dose after contrast boosting, and 100% iodine dose images, respectively. CNR on liver vessels was 1.6, 3.6, and 3.3 in 50% iodine dose, 50% iodine dose after contrast boosting, and 100%

iodine dose images, respectively.*Conclusions Our trained DL algorithm has a potential to boost iodine contrast of reduced iodine-dose images to a comparable level of regular iodine-dose images in both HCC and non-HCC patients.*Clinical Relevance/Application Iodine contrast boosting for reduced-iodine-dose CT imaging is feasible with deep learning-based iodine contrast boosting algorithm, which potentially allow reducing iodine dose in clinical practice.

RESULTS

ICCs between the predicted and ground-truth iodine map images of HCC and non-HCC patients were 0.88 and 0.89, respectively. CNR on HCC lesions was 1.6, 4.6, and 4.2 in 50% iodine dose, 50% iodine dose after contrast boosting, and 100% iodine dose images, respectively. CNR on liver vessels was 1.6, 3.6, and 3.3 in 50% iodine dose, 50% iodine dose after contrast boosting, and 100% iodine dose images, respectively.

CLINICAL RELEVANCE/APPLICATION

Iodine contrast boosting for reduced-iodine-dose CT imaging is feasible with deep learning-based iodine contrast boosting algorithm, which potentially allow reducing iodine dose in clinical practice.

SDP-IN-13   Development Of Weakness Compensated-AI Model Of The Maxillary Sinusitis Using Curriculum Learning Algorithm

Participants
Hyug-Gi Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The objective of this study was to develop the minimized over-fitting model using weakness compensated- curriculum learning algorithm and to implement the generalization deep learning model for maxillary sinusitis.*Methods and Materials A total of 3,596 subjects, which included three medical centers, underwent PNS X-ray scan. All subjects were independently labeled as 'normal' and 'sinusitis' by two radiologists. The datasets were split into training (n=2,225), validation (tuning) (588), internal test (n=300), external test #1(n=300), and external test #2 (n=183). Input data was performed three pre-processing steps; extracted maxillary sinus patch, z-score normalization, and data augmentation. We implemented with the ResNet-101 convolutional neural network (CNN) model for classification. First, to minimize the over-fitting between internal and external datasets, the distribution and recognized pattern of predicted results was examined from the learned model - total opacification, air-fluid level, mucosal thickening, and retention cyst. Second, curriculum learning was conducted to compensate weakness data from examined results.*Results Predicted results from learned model was shown over-fitting patterns- external test sets were relative lower performance compared with internal test set (internal test: 80.5 %; external test #1: 69.2%; external test: 63.0%). Especially, air-fluid level, mucosal thickening, and retention cyst data were shown lower performance in external test sets (< 50 %). The external test sets were shown improved performance using weakness compensating curriculum learning (external test #1: 75.1 %; external test #2: 73.2 %). It was significantly different between without and with purposed model (p-value < .05).*Conclusions The proposed weakness compensated curriculum learning algorithm was shown efficient approach to reduce over-fitting between internal and external sets for diagnosis of maxillary sinusitis. Our proposed deep learning method showed potential of the AI system in predicting sinusitis in screening of PNS X-ray.*Clinical Relevance/Application Our method can be explainable the characteristics learned model and it enables generalization. Furthermore, it can be used in other medical imaging diagnostic applications.

RESULTS

Predicted results from learned model was shown over-fitting patterns- external test sets were relative lower performance compared with internal test set (internal test: 80.5 %; external test #1: 69.2%; external test: 63.0%). Especially, air-fluid level, mucosal thickening, and retention cyst data were shown lower performance in external test sets (< 50 %). The external test sets were shown improved performance using weakness compensating curriculum learning (external test #1: 75.1 %; external test #2: 73.2 %). It was significantly different between without and with purposed model (p-value < .05).

CLINICAL RELEVANCE/APPLICATION

Our method can be explainable the characteristics learned model and it enables generalization. Furthermore, it can be used in other medical imaging diagnostic applications.

SDP-IN-14   Automatically, Precisely, And Comprehensively Measuring Tumor Sizes With Minimal Human Effort

Participants
Youbao Tang, PhD, Bethesda, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Precisely measuring the tumor sizes from computed tomography (CT) scans is an indispensable step in oncology image analysis for monitoring disease progression and therapy response. RECIST (Response Evaluation Criteria in Solid Tumors) diameters are adopted widely in clinical practice but imperfect. Although 2D and 3D segmentations prove clinically more valuable, it is not practical to annotate them manually due to time constraints. To address them, we propose a new deep learning system called Prior-guided Dual-path connection Network (PDNet) to measure the tumor sizes automatically, precisely, and comprehensively.*Methods and Materials PDNet consists of an image encoder (IE), a prior encoder (PE), and a decoder (DE). IE extracts highly discriminative multi-scale features from CT images. PE further enhances the features by learning lesion-specific attention matrices in parallel from the click prior information. DE can aggregate the enhanced multi-scale features comprehensively to predict the RECIST diameters and lesion segmentations precisely by introducing top-down and bottom-up connections. Radiologists only need to give a simple click guidance inside the lesion region on any slice. The system is able to segment the lesion slice-by-slice to get its 3D segmentation result and demonstrate the key slice where the lesion has the largest spatial extent. PDNet was trained and tested on the large-scale DeepLesion dataset consisting of 32,735 lesions labeled with RECIST diameters from 10,594 studies of 4,459 patients. 1,000/200 lesions were randomly selected from 500/140 patients and manually annotated their 2D/3D masks as the validation/test set. The remaining patient data served as the training set.*Results For RECIST diameter annotation, compared to the manual reference standard, the diameter differences of long and short axis produced by PDNet were 1.7±1.5 mm and 1.5±1.4 mm, respectively. For lesion segmentation, PDNet achieved a 2D Dice score of 0.924±0.045 on the key slices where lesions have the largest spatial extents and a 3D Dice score of 0.853±0.073.*Conclusions We proposed a deep learning system to automatically annotate tumor sizes with RECIST diameters and segmentations that demonstrate comparable accuracy to experts. It greatly improves the clinical workflow efficiency by using only a click.*Clinical Relevance/Application Our system offers a useful tool for radiologists to get reliable and comprehensive tumor size measurements with minimal effort and may provide high positive clinical values on oncologic imaging analysis workflows and deriving quantitative precision biomarkers.

RESULTS

For RECIST diameter annotation, compared to the manual reference standard, the diameter differences of long and short axis produced by PDNet were 1.7±1.5 mm and 1.5±1.4 mm, respectively. For lesion segmentation, PDNet achieved a 2D Dice score of 0.924±0.045 on the key slices where lesions have the largest spatial extents and a 3D Dice score of 0.853±0.073.

CLINICAL RELEVANCE/APPLICATION

Our system offers a useful tool for radiologists to get reliable and comprehensive tumor size measurements with minimal effort and may provide high positive clinical values on oncologic imaging analysis workflows and deriving quantitative precision biomarkers.

SDP-IN-15 Ct-based Radiomics For The Preoperative Prediction Of The Muscle-invasive Status Of Bladder Cancer And Comparison To Radiologists' Assessment

Participants
Yingpu Cui, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop a radiomics model to predict the muscle-invasive status of bladder cancer (BC) in contrast-enhanced computed tomography (CECT) images, compared with radiologists' interpretations.*Methods and Materials 188 CECT images with pathological confirmed BC were retrospectively archived from November 2018 to December 2019 and were randomly divided into the training (n = 120) and test dataset (n = 68). The BC were manually labeled and validated on the venous phase by a general radiologist and an experienced radiologist, respectively. The radiomics analysis including radiomics feature extraction and model development was completed by the Feature Explorer (FAE) software. The same images were also evaluated by two radiologists. The diagnostic performance of radiomics was evaluated with receiver operating characteristic (ROC). The area under the curve (AUC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated. The predictive performance of radiomics was then compared with visual assessments of the two radiologists.*Results The radiomics model reached an AUC of 0.979 and 0.894 in the training and test dataset, respectively. The radiomics model outperformed the visual assessment (AUC: 0.691-0.775) both in the training and test dataset. Pairwise comparisons showed that the specificities of the radiomics model were higher than the radiologists (85.3-96.7% vs. 47.1-58.3%, all p < 0.05), but the sensitivities were comparable between the radiomics and the radiologists (79.4-90.0% vs. 91.2-96.7%; p range from 0.125-1.000).*Conclusions A radiomics model was developed that outperformed the radiologists' visual assessment in predicting the muscle-invasive status of BC.*Clinical Relevance/Application Distinguishing non-muscle-invasive bladder cancer (non-MIBC) and muscle-invasive bladder cancer (MIBC) is crucial for clinical decision making. Non-MIBC can be managed with less aggressive treatment than MIBC. A preoperative noninvasive tool for detection and staging of BC with high accuracy would be of immense value.

RESULTS

The radiomics model reached an AUC of 0.979 and 0.894 in the training and test dataset, respectively. The radiomics model outperformed the visual assessment (AUC: 0.691-0.775) both in the training and test dataset. Pairwise comparisons showed that the specificities of the radiomics model were higher than the radiologists (85.3-96.7% vs. 47.1-58.3%, all p < 0.05), but the sensitivities were comparable between the radiomics and the radiologists (79.4-90.0% vs. 91.2-96.7%; p range from 0.125-1.000).

CLINICAL RELEVANCE/APPLICATION

Distinguishing non-muscle-invasive bladder cancer (non-MIBC) and muscle-invasive bladder cancer (MIBC) is crucial for clinical decision making. Non-MIBC can be managed with less aggressive treatment than MIBC. A preoperative noninvasive tool for detection and staging of BC with high accuracy would be of immense value.

SDP-IN-16 Construction And Application Of A Patient Derived Hybrid 3d Printing Phantom For Quantitative COVID-19 Imaging

Participants
AHYEONG LEE, SEOUL, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop and construct a patient-derived hybrid 3D anthropomorphic thorax phantom for use in quantitative imaging of COVID-19. We intended to develop a phantom mimicking lung anatomy, HU values, and various lung lesions similar to those of real patients with COVID-19.*Methods and Materials The normal anatomy of the phantom was derived from the chest CT of a 58-year-old woman. The thorax including heart, lungs, and airway were segmented and modeled using a commercial 3D modeling software (AVIEW, CORELINE, Seoul, Korea), and then 3D printed. The lung parenchyma was mimicked by using bead foam with an intent to allow insertion/exchange of fabricated volumetric lesions in the lung parenchyma. COVID-19 lesions in both lungs were also derived from a CT scan of separate patient by using same procedure. Other lung lesions such as emphysema and GGO were spherically fabricated with different sizes by using a casting technique. Polyurethane and PLA were used to reproduce GGO and COVID-19, respectively. After finishing the phantom fabrication, MDCT scanning was made to evaluate its CT imaging appearance. Also we used three COVID-19 quantification software products (LungQuant, VUNO Med, Seoul, Korea; MEDIP COVID19, Medical IP, Seoul, Korea; CAD4COVID-CT, Thirona, Nijmegen, Netherlands) to compare their quantification performance.*Results The HU values of normal anatomy and lung lesions from the phantom were in the similar range of patient CT scans except narrow distribution of HU values owing to the homogenous material. The quantified COVID-19 lesion volume showed significant discrepancy among the three COVID-19 quantification software products ranging from 34.9 ml to 140.28ml and 160ml, with underestimation from the ground truth segmentation of 247.1ml in all three products.*Conclusions Our hybrid anthropomorphic thorax phantom produced the CT image appearance resembling that of patient anatomy and lung lesions including COVID-19 pneumonia. Our phantom has a potential to be used as a platform for simulating lung lesions with known values and performance evaluation of AI-based quantitative imaging software tools.*Clinical Relevance/Application Using a hybrid phantom that reproduces anatomy and lung lesions such as COVID-19, it is possible to generate CT images similar to real patients and evaluate the performance of quantification software tools.

RESULTS

The HU values of normal anatomy and lung lesions from the phantom were in the similar range of patient CT scans except narrow distribution of HU values owing to the homogenous material. The quantified COVID-19 lesion volume showed significant discrepancy among the three COVID-19 quantification software products ranging from 34.9 ml to 140.28ml and 160ml, with underestimation from the ground truth segmentation of 247.1ml in all three products.

SDP-IN-17 Automatic Lung Tumor Segmentation Using Capsule Network Considering The Relationship Between Tumor And Surrounding Structures In Chest Ct Images

Participants
Jumin Lee, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Volumetric lung tumor segmentation is essential for monitoring tumor response to treatment by tracking changes in lung tumor volume. However, it is difficult to segment a lung tumor that is attached to nearby structures that have a shape or intensity similar to that of the lung tumor. Moreover, large tumors have a wide attachment to surrounding structures, making it more difficult to distinguish between the tumor and surrounding structures. The purpose of this study is to accurately segment the lung tumors using Capsule Network, which learns the relative spatial relationship between lung tumor and surrounding structures.*Methods and Materials The dataset used in this study included chest CT images of 256 non-small cell lung cancer (NSCLC) patients consisting of 147 lung squamous cell carcinomas and 109 lung adenocarcinomas. To reduce the occurrence of inter-image differences due to different acquisition protocols among datasets, intensity and pixel spacing normalizations are performed on the input images. To segment lung tumors, a 2D Capsule Network is trained, in which a dynamic routing algorithm enhances specific feature maps with high similarity between lower and upper features to preserve spatial information during convolution.*Results For holdout validation, 256 datasets were randomly divided into 187 training sets, 21 validation sets, and 48 test sets. To evaluate the segmentation accuracy according to the tumor size, the test set was divided into three groups: Group 1 with a size of less than 3cm, Group 2 with a size of 3cm or more and less than 5cm, and Group 3 with a size of more than 5cm. The F1 scores for Group 1, 2, and 3 were 68.52%, 74.89%, and 74.96%, respectively. Although the tumors of Groups 2 and 3 were extensively attached to the surrounding structures, they were found to be accurately segmented in consideration of the relative spatial relationship with the surrounding structures. In whole test set, the F1 score, recall and precision were 71.45%, 76.59% and 73.08%.*Conclusions The lung tumors which are widely attached to surrounding structures were accurately segmented using Capsule Network. (This work was supported by the National Research Foundation of Korea(NRF) grant funded by the Korea government(MSIT) (No. 2020R1A2C1102140) and the Korea Medical Device Development Fund grant funded by the Korea government(the Ministry of Science and ICT, the Ministry of Trade, Industry and Energy, the Ministry of Health and Welfare, the Ministry of Food and Drug Safety)(KMDF PR 20200901 0269).)*Clinical Relevance/Application It can be used to automatically segment lung tumors that are difficult to segment by considering the relationship between lung tumor and surrounding structures and can be utilized for volume measurement for monitoring treatment effects.

RESULTS

For holdout validation, 256 datasets were randomly divided into 187 training sets, 21 validation sets, and 48 test sets. To evaluate the segmentation accuracy according to the tumor size, the test set was divided into three groups: Group 1 with a size of less than 3cm, Group 2 with a size of 3cm or more and less than 5cm, and Group 3 with a size of more than 5cm. The F1 scores for Group 1, 2, and 3 were 68.52%, 74.89%, and 74.96%, respectively. Although the tumors of Groups 2 and 3 were extensively attached to the surrounding structures, they were found to be accurately segmented in consideration of the relative spatial relationship with the surrounding structures. In whole test set, the F1 score, recall and precision were 71.45%, 76.59% and 73.08%.

CLINICAL RELEVANCE/APPLICATION

It can be used to automatically segment lung tumors that are difficult to segment by considering the relationship between lung tumor and surrounding structures and can be utilized for volume measurement for monitoring treatment effects.

SDP-IN-18 All True Positives Are Not Truly Positive - Utility Of Explainability Failure Ratio In A High Sensitivity Screening Setting To Compare Incorrect Localizations Among Algorithms

Participants
Marcela Rosa, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the localization failures of deep learning based Chest Xray classification algorithms on a for detection of consolidationTo compare the localization accuracies of two algorithms in a high sensitivity screening setting by comparing the explainability failure ratios (EFR)*Methods and Materials 632 chest x-rays were randomly collected from an academic centre hospital, read by a chest radiologist, and ground truth for consolidation was established on CARING analytics platform (CARPL), both at study level and at image level by marking bounding box around the lesion. These X-rays were then analysed by tow algorithms , an open-sourced re-implementation of Stanford's baseline X-Ray classification model, CheXpert which uses DenseNet121 as its backbone architecture and by CareXnet, network is trained using the Multi-Task Learning paradigm and uses a Densenet121 backbone. Both provide heat maps corresponding to each class to indicate the confidence of the detected disease using guided GRAD-CAM. The number of true positive cases were estimated at an operating threshold that provides 95% sensitivity. The matching of heat maps and the GT bounding box was done by creating a greedy matching algorithm. EFR is then estimated as the ratio of true positive cases that failed the matching process to the total true positive cases.*Results There were a total of 169 cases of consolidation. The number of true positive cases were 145 and 143 for cheXpert and CareXnet respectively. Upon matching of the localization outputs with GT bounding box, the number of unmatched cases for CheXpert and CareXnet were 41 and 39 respectively, giving an EFR of 28 % and 27 % respectively.*Conclusions In this study, we found that even at high sensitivity operating point with maximum true positive cases, the deep learning algorithms can have a high degree of explainability failures.*Clinical Relevance/Application We present a new clinically acceptable way to compare the localization accuracies of multiple algorithms at high sensitivity operating points using explainability failure ratios.

RESULTS

There were a total of 169 cases of consolidation. The number of true positive cases were 145 and 143 for cheXpert and CareXnet respectively. Upon matching of the localization outputs with GT bounding box, the number of unmatched cases for CheXpert and CareXnet were 41 and 39 respectively, giving an EFR of 28 % and 27 % respectively.

CLINICAL RELEVANCE/APPLICATION

We present a new clinically acceptable way to compare the localization accuracies of multiple algorithms at high sensitivity operating points using explainability failure ratios.

SDP-IN-19   Fully Automatic Detection And Measurement Of Abdominal Aortic Aneurysm Using Artificial Intelligence

Participants
Makoto Orii, Yahaba, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Abdominal aortic aneurysm (AAA) is a life-threatening disease, and the decision to treat relies on the exact detection and size of AAA, which is time-consuming and prone to high inter-reader variability. Artificial intelligence (AI) has revealed new insights into the management of AAA, but it needs large amounts of contrast-enhanced CT data. Moreover, there has been few studies about the fully automatic detection and measurement of AAA. The aim of this study is to evaluate the accuracy of AI for the detection and measurement of AAA using small amounts of non-contrast CT.*Methods and Materials We retrospectively collected 145 non-contrast CT scans of suspected AAA. The first step was to manually segment the 30 non-contrast CT scans to create training data for the AI, and the second step was to improve accuracy using 9 of non-contrast CT scans. The model is then further tested for generalizability on a separate set of 106 examinations with differing patient. Image processing is used to identify the AAA area and automatically measure the size. The AAA region was identified from the amount of change in the minor-axis, and the maximum minor-axis diameter was calculated using elliptical fitting. To evaluate the diagnostic utility of AI for the detection of AAA, the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated referred for the diagnostic report. The reproducibility in the size of AAA was assessed using intraclass correlation coefficients (ICCs) between the diagnostic report and AI.*Results AI achieves high performance for the detection of AAA (sensitivity / specificity / PPV / NPV: 94.6% / 98.7% / 53.8% / 99.9%). The size of AAA calculated by the AI (42.5 ± 8.8 mm) showed a strong correlation with the those of diagnostic reports (44.6 ± 8.4 mm; ICCs = 0.97).*Conclusions AI represents a useful tool in the fully automatic detection and measurement of AAA using small amounts of non-contrast CT.*Clinical Relevance/Application AI will help to accurately detect and measure the size of AAA.

RESULTS

AI achieves high performance for the detection of AAA (sensitivity / specificity / PPV / NPV: 94.6% / 98.7% / 53.8% / 99.9%). The size of AAA calculated by the AI (42.5 ± 8.8 mm) showed a strong correlation with the those of diagnostic reports (44.6 ± 8.4 mm; ICCs = 0.97).

CLINICAL RELEVANCE/APPLICATION

AI will help to accurately detect and measure the size of AAA.

SDP-IN-2   Deep Learning-based Algorithm For Bone Metastasis Detection On Whole-body CT: Evaluation On An Observer Study

Participants
Shunjiro Noguchi, Kyoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To develop and evaluate a deep learning-based algorithm (DLA) for automatic detection of bone metastasis on whole-body CT.*Methods and Materials This retrospective study included CT scans acquired at a single institution between 2009 and 2019. Positive scans with bone metastasis and negative control scans without bone metastasis were collected to train the DLA. Another 50 positive and 50 negative scans were collected separately from the training dataset and were divided into validation and test datasets with a 2:3 split. The DLA was constructed on the training and validation datasets and assessed on the test dataset. The clinical efficacy of the DLA was further evaluated by an observer study with board-certified radiologists. Jackknife alternative free-response receiver operating characteristic analysis was used to evaluate observer performance.*Results A total of 269 positive scans including 1375 bone metastasis lesions and 463 negative scans were collected for the training dataset. The number of lesions identified in the validation and test datasets was 49 and 75, respectively. For the test dataset, the DLA achieved a sensitivity of 89.3% (67 of 75) with 1.5 false positives per case and 82.7% (62 of 75) with 0.617 false positives per case. With the DLA, the overall performance of nine radiologists with reference to the weighted alternative free-response receiver operating characteristic figure of merit improved from 0.746 (95% CI: 0.690, 0.802) to 0.899 (95% CI: 0.865, 0.932) (P < .001). Furthermore, the mean interpretation time per case reduced from 168 to 85 s (P = .004).*Conclusions With the aid of the algorithm, radiologists detected bone metastases on CT with high accuracy and short interpretation time.*Clinical Relevance/Application Bone metastasis detection on CT is a common but challenging task for radiologists. Our algorithm enables radiologists to detect bone metastases with high accuracy and short interpretation time.

RESULTS

A total of 269 positive scans including 1375 bone metastasis lesions and 463 negative scans were collected for the training dataset. The number of lesions identified in the validation and test datasets was 49 and 75, respectively. For the test dataset, the DLA achieved a sensitivity of 89.3% (67 of 75) with 1.5 false positives per case and 82.7% (62 of 75) with 0.617 false positives per case. With the DLA, the overall performance of nine radiologists with reference to the weighted alternative free-response receiver operating characteristic figure of merit improved from 0.746 (95% CI: 0.690, 0.802) to 0.899 (95% CI: 0.865, 0.932) (P < .001). Furthermore, the mean interpretation time per case reduced from 168 to 85 s (P = .004).

CLINICAL RELEVANCE/APPLICATION

Bone metastasis detection on CT is a common but challenging task for radiologists. Our algorithm enables radiologists to detect bone metastases with high accuracy and short interpretation time.

SDP-IN-20   A Machine Learning Model For Automated Selection Of Abdominal MRI Series

Participants
Chad M. Miller, MD, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To develop an automated machine learning (ML) model for accurately identifying abdominal MRI sequence types.*Methods and

To develop an automated machine learning (ML) model for accurately identifying abdominal MRI sequence types. Methods and Materials This retrospective study used a dataset including 2,215 MRI series from 105 examinations. The method described in Gauriau et al. (Journal of Digital Imaging (2020) 33:747-762) for distinguishing brain MRI sequences with a random forest classifier was adapted for abdominal MRI examinations. A subset of DICOM metadata including image acquisition parameters and scanner options were used to train a random forest classifier to predict the sequence type for each series. Ground truth labels were established via review of images by three radiologists with 2-15 years' experience in abdominal imaging. Data were split at the subject level into development and test datasets, and the development set between training and validation datasets. Hyperparameters were optimized using a grid search on the training set.*Results The model performed with high accuracy (98%) in predicting the correct abdominal MRI series on the validation data set (354 series from 17 examinations). A confusion matrix is provided as a Figure, which shows high accuracy for most of the MRI sequences.*Conclusions Our algorithm using DICOM metadata can correctly identify the abdominal MRI series with high accuracy.*Clinical Relevance/Application This random forest classifier could be incorporated into a larger automated pipeline incorporating conditional logic, heuristics, and an image-based deep learning classifier that we have previously developed in order to robustly identify abdominal MRI series for input into pipelines for ML or other post-processing methods, or for development of smart hanging protocols.

RESULTS

The model performed with high accuracy (98%) in predicting the correct abdominal MRI series on the validation data set (354 series from 17 examinations). A confusion matrix is provided as a Figure, which shows high accuracy for most of the MRI sequences.

CLINICAL RELEVANCE/APPLICATION

This random forest classifier could be incorporated into a larger automated pipeline incorporating conditional logic, heuristics, and an image-based deep learning classifier that we have previously developed in order to robustly identify abdominal MRI series for input into pipelines for ML or other post-processing methods, or for development of smart hanging protocols.

SDP-IN-3   Intermediate Slices Generation For Improving Orbital Thin Bone Segmentation Performance In Head CT Images

Participants
Min Jin Lee, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To make customized bone plate model for the reconstruction of fractured orbital bone in craniomaxillofacial surgery, it is necessary to accurately segment the orbital thin bone on head CT images. However, because slice thickness is two to three times larger than pixel spacing, segmentation accuracy is degraded, and reconstructed orbital thin bones show an aliasing effect. The purpose of this study is to improve the inter-slice resolution of head CT images and to validate the effect of improving the inter-slice resolution on the performance of orbital thin bone segmentation.*Methods and Materials We used 355 head CT images with resolution of 512x512, pixel spacing of 0.4~0.619mm, and slice thickness of 1mm. First, to improve the inter-slice resolution using 2D CNN-based OB-SRNET that considers context and area information of labeled orbital bones in multiple view, intermediate slices are generated using images that are down-sampled twice from original CT images. Second, orbital bones with improved inter-slice resolution are segmented using ensemble of two 3D U-Nets. Finally, to validate the effect of the improvement of inter-slice resolution on segmentation, the dataset was randomly divided into 228 training sets, 71 test sets, and 56 validation sets, and original CT image, down-sampled images, and images generated with OB-SRNET are used to compare and analyze segmentation results.*Results Images generated with OB-SRNET over the whole orbital bone area showed 51%, 56%, and 25%, 44% improvement in PSNR, VIF scores, respectively, compared to images generated with bilinear interpolation and 3D SRGAN. Images generated with OB-SRNET have reduced aliasing effects and clear boundaries of thin bones, while images generated with 3D SRGAN have blurry boundaries of thin bones. The orbital bone reconstructed in 3D from images generated by OB-SRNET was similar to the original CT image, and aliasing effect was reduced compared to orbital bone reconstructed in 3D from thick-slice CT. The segmentation performance in F1 score and recall of images generated by OB-SRNET was improved by 10% and 22% in orbital medial wall area, and 25% and 42% in orbital floor area compared to the images with slice thickness of 2mm.*Conclusions Our method improved the inter-slice resolution and validated effect of improving inter-slice resolution on segmentation performance. (Technology Innovation Program (20001811) funded by the Ministry of Trade, Industry & Energy (MOTIE, Korea) and the Korea Medical Device Development Fund grant funded by the Korea government (Ministry of Health & Welfare) (NTIS Number: 9991007552))*Clinical Relevance/Application Our method can be used to provide a customized bone plate for the reconstruction of fractured orbital thin bones in craniomaxillofacial surgery.

RESULTS

Images generated with OB-SRNET over the whole orbital bone area showed 51%, 56%, and 25%, 44% improvement in PSNR, VIF scores, respectively, compared to images generated with bilinear interpolation and 3D SRGAN. Images generated with OB-SRNET have reduced aliasing effects and clear boundaries of thin bones, while images generated with 3D SRGAN have blurry boundaries of thin bones. The orbital bone reconstructed in 3D from images generated by OB-SRNET was similar to the original CT image, and aliasing effect was reduced compared to orbital bone reconstructed in 3D from thick-slice CT. The segmentation performance in F1 score and recall of images generated by OB-SRNET was improved by 10% and 22% in orbital medial wall area, and 25% and 42% in orbital floor area compared to the images with slice thickness of 2mm.

CLINICAL RELEVANCE/APPLICATION

Our method can be used to provide a customized bone plate for the reconstruction of fractured orbital thin bones in craniomaxillofacial surgery.

SDP-IN-4   Cascaded Localization And Segmentation Networks For Renal Parenchymal Segmentation With Self-shape Information For Evaluation Of Contralateral Renal Hypertrophy After Renal Partial Nephrectomy In Abdominal MR Images

Participants
Hyeonjin Kim, MS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Contralateral kidney volume change as a consequence of ipsilateral parenchymal atrophy promotes overall renal function recovery after renal partial nephrectomy (RPN). Segmentation of the renal parenchyma responsible for renal function on abdominal MR images is required to assess contralateral renal hypertrophy and predict renal function after RPN without radiation exposure instead of abdominal CT imaging. The purpose of this study is to segment the renal parenchyma into cascaded localization and segmentation

networks (CLSN) that are less sensitive to outliers by considering its self-shape information.*Methods and Materials The patient's left kidneys were evaluated with 51 abdominal T1-weighted MR images acquired from GE Medical Systems. To localize the kidneys in the abdomen, an ensemble of three 2D U-Nets using attention module is performed individually in the axial, coronal, and sagittal planes with average voting to infer the spatial shape of the kidneys. To segment the renal parenchyma in the localized volume, two 3D U-Nets are individually trained into an image patch and a shape patch and then ensemble, which reduces outliers of the renal parenchyma-like shapes. The image patch is generated by using signal intensity correction to reduce the irregular signal intensity in the localized volume, and the shape patch is generated through convolution of the image patch and the ensemble of three 2D segmentation results.*Results For evaluation, all datasets were trained and tested with 5-fold cross-validation. 2D segmentation results of the axial, coronal and sagittal planes showed under-segmentation and outliers to other organs. The ensemble of three 2D segmentation results avoided outliers and gave the best results in precision, but under-segmentation still occurred. CLSN with image patch avoided under-segmentation and gave the best results in recall, but outliers occurred to nearby organs. CLSN with image and shape patches avoided outliers and showed the best results of 86.75% on an F1-score that combines precision and recall.*Conclusions Our method can be used to predict kidney function after RPN by measuring the volume change in the contralateral renal parenchyma. (This work was supported Basic Science Research Program through the National Research Foundation of Korea(NRF) funded by the Ministry of Science and ICT (NRF-2019R1A2C2004746).*Clinical Relevance/Application The renal parenchymal segmentation results on MR can be used to measure the volume of the contralateral kidney and to analyze the relationship between renal parenchymal volume and renal function.

RESULTS

For evaluation, all datasets were trained and tested with 5-fold cross-validation. 2D segmentation results of the axial, coronal and sagittal planes showed under-segmentation and outliers to other organs. The ensemble of three 2D segmentation results avoided outliers and gave the best results in precision, but under-segmentation still occurred. CLSN with image patch avoided under-segmentation and gave the best results in recall, but outliers occurred to nearby organs. CLSN with image and shape patches avoided outliers and showed the best results of 86.75% on an F1-score that combines precision and recall.

CLINICAL RELEVANCE/APPLICATION

The renal parenchymal segmentation results on MR can be used to measure the volume of the contralateral kidney and to analyze the relationship between renal parenchymal volume and renal function.

SDP-IN-5 Deep Neural Network Augments Performance Of Junior Residents In Diagnosing COVID-19 Pneumonia On Chest Radiographs

Participants
Jordan Sim Zheng Ting, MBBS, Singapore, Singapore (*Presenter*) Nothing to Disclose

PURPOSE

To assess the performance of a deep neural network at differentiating COVID-19 and other pneumonia and evaluate its value in augmenting junior residents' performance.*Methods and Materials A total of 5,125 CXRs were used to develop and evaluate a deep neural network model that was able to perform 3-class classification (Normal, Non-COVID-19 pneumonia and COVID-19 pneumonia). Inputs from two senior radiologists were used as the reference standard. Another independent set of 500 CXRs was used as the external test dataset, which were blindly reviewed by three junior residents with various levels of training without and then with AI assistance.*Results The model achieved an average area under the receiver operating characteristic curve (AUC) of 0.95 with sensitivity of 93% and specificity of 84% on the test set. On the external test dataset, the model achieved AUC of 0.84 with sensitivity of 87% and specificity of 69%. Assisted by the probabilities of the AI model, the performance of the junior residents improved at a degree that is inversely proportionate to their level of training. The junior resident with the least training achieved a 5% improvement in both sensitivity and specificity.*Conclusions Deep neural network model assistance augmented junior residents' performance in diagnosing COVID-19 pneumonia and non-COVID-19 pneumonia on CXRs.*Clinical Relevance/Application Chest X-rays (CXRs) are often the initial radiological investigation in the management of Coronavirus disease-19 (COVID-19). Junior residents may be the first point-of-contact and are thus expected to interpret these CXRs accurately. Artificial intelligence (AI) can potentially improve the performance of junior residents.

RESULTS

The model achieved an average area under the receiver operating characteristic curve (AUC) of 0.95 with sensitivity of 93% and specificity of 84% on the test set. On the external test dataset, the model achieved AUC of 0.84 with sensitivity of 87% and specificity of 69%. Assisted by the probabilities of the AI model, the performance of the junior residents improved at a degree that is inversely proportionate to their level of training. The junior resident with the least training achieved a 5% improvement in both sensitivity and specificity.

CLINICAL RELEVANCE/APPLICATION

Chest X-rays (CXRs) are often the initial radiological investigation in the management of Coronavirus disease-19 (COVID-19). Junior residents may be the first point-of-contact and are thus expected to interpret these CXRs accurately. Artificial intelligence (AI) can potentially improve the performance of junior residents.

SDP-IN-6 Curation Of The CANDID-PTX Dataset With Free-text Reports

Participants
Sijing Feng, MBChB, Mosgiel, New Zealand (*Presenter*) Nothing to Disclose

PURPOSE

Artificial Intelligence (AI) has many potential uses in radiology, but curating the large datasets required to train AI algorithms demands significant time and expertise. This project aims to produce a large chest X-ray (CXR) dataset with segmented annotations of pneumothoraces, acute rib fractures and intercostal chest tubes for use in training and testing AI algorithms.*Methods and Materials 295,613 CXRs were obtained from [Hospital] PACS with radiology reports, with all image and reports data being anonymized algorithmically with manual checking and imported onto the MD.ai image annotation platform. Inclusion criteria was a frontal CXR from a patient over 16 years old. Based on preliminary classifications from a report-based algorithm, all preliminary pneumothorax positive images were reviewed by annotators, along with a selection of approximately five time the number of negative cases.35 doctors were divided into three tiers as per their experience level, with each image being reviewed by multiple doctors including one Tier 3 annotator (a radiology trainee for simple images, or consultant radiologist for difficult images). Cases of significant difficulty were assessed by consultant consensus with the involvement of a thoracic

radiologist. Images were given segmented annotations of any pneumothoraces, acute rib fractures and intercostal chest tubes. After a validation process, a ground truth was established.*Results 26,798 images were reviewed by an appropriate Tier 3 annotator with 7,561 being excluded, leaving 19,237 frontal CXRs in the final dataset. There were 3,196 images with pneumothorax region segmented labels, 1,423 images with intercostal chest tube freeform line labels, and 355 images with acute rib fracture bounding box labels.*Conclusions This study describes the curation of the 19,237-image CANDID-PTX dataset, with segmented annotations of pneumothoraces, acute rib fractures and intercostal chest tubes. This dataset is prepared for the training and testing of AI algorithms in the detection of these features on CXR. Instructions for accessing the CANDID-PTX dataset can be found at DOI: 10.17608/k6.auckland.14173982.*Clinical Relevance/Application This chest X-ray dataset has been curated with segmented pneumothorax, chest tube and rib fracture labels. It can help train artificial intelligence algorithms that can be used in clinical medicine.

RESULTS

26,798 images were reviewed by an appropriate Tier 3 annotator with 7,561 being excluded, leaving 19,237 frontal CXRs in the final dataset. There were 3,196 images with pneumothorax region segmented labels, 1,423 images with intercostal chest tube freeform line labels, and 355 images with acute rib fracture bounding box labels.

CLINICAL RELEVANCE/APPLICATION

This chest X-ray dataset has been curated with segmented pneumothorax, chest tube and rib fracture labels. It can help train artificial intelligence algorithms that can be used in clinical medicine.

SDP-IN-7   Deep Learning Beats Radiologists In Clinical Routine Assessment Of Intensive Care Unit X-rays

Participants
Firas Khader, Aachen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Intensive Care Unit chest radiographs typically serve as the initial imaging step that allow physicians to find pathologic abnormalities. Accurate and timely reading of chest radiographs is of paramount importance. In this study we aim to employ state-of-the-art deep learning methods to detect abnormalities in chest radiographs and compare the results to human raters in a clinical setting.*Methods and Materials Using our in-house dataset comprised of 193,556 chest radiographs that were taken from 2009 until 2020 at a maximum care hospital we trained a ResNet-34 to predict the state of pulmonary infection, effusion, atelectasis (each separately for the left and right lung) as well as the state of congestion and cardiomegaly. For all data the labels were set by experienced radiologists in a structured manner using a dedicated annotation mask. We also calculated Spearman's correlation coefficient between laboratory values of BNP and the predictions of the neural network as well as the archived clinical reports.*Results We compared the results of our neural network (NN) with the archived clinical reports (CR) used to train the neural network, the rating of 6 radiologists (R1-R6) and the rating of an intensive care unit physician (ICU). Cohen's kappa was used to assess the agreement between the raters, using the majority voting of the 6 radiologists as the ground truth. Evaluation was performed on 100 samples. Agreement between the ground truth and the neural network (0.69, 95% interval: [0.63, 0.73]) is significantly higher than that of each single radiologist and the archived clinical reports. Additionally, the ICU has a lower agreement with the ground truth than all the other raters. However, when provided with a prefilled annotation mask with labels predicted by the neural network (ICU+AI), the ICU achieves an agreement that is better than that of the radiologists. We found that in the case of heart size and congestion, the predicted values of the neural network correlated significantly better with the BNP values than those of the CR.*Conclusions In our study we found that neural networks can surpass the performance of experts in the assessment of chest radiographs. Additionally, these predictions also show a better correlation with relevant laboratory values than clinical reports generated by trained radiologists.*Clinical Relevance/Application We demonstrate the superiority of neural networks in a realistic scenario and show that trained physicians can benefit from the preliminary assessment of thoracic radiographs by neural networks. This could help physicians in their initial diagnostic workflow and improve patient care.

RESULTS

We compared the results of our neural network (NN) with the archived clinical reports (CR) used to train the neural network, the rating of 6 radiologists (R1-R6) and the rating of an intensive care unit physician (ICU). Cohen's kappa was used to assess the agreement between the raters, using the majority voting of the 6 radiologists as the ground truth. Evaluation was performed on 100 samples. Agreement between the ground truth and the neural network (0.69, 95% interval: [0.63, 0.73]) is significantly higher than that of each single radiologist and the archived clinical reports. Additionally, the ICU has a lower agreement with the ground truth than all the other raters. However, when provided with a prefilled annotation mask with labels predicted by the neural network (ICU+AI), the ICU achieves an agreement that is better than that of the radiologists. We found that in the case of heart size and congestion, the predicted values of the neural network correlated significantly better with the BNP values than those of the CR.

CLINICAL RELEVANCE/APPLICATION

We demonstrate the superiority of neural networks in a realistic scenario and show that trained physicians can benefit from the preliminary assessment of thoracic radiographs by neural networks. This could help physicians in their initial diagnostic workflow and improve patient care.

SDP-IN-8   Early Detection Of COVID-19 Using Convolutional Neural Networks

Participants
Juana Plasencia-Martinez, MD,PhD, Murcia, Spain (*Presenter*) Nothing to Disclose

PURPOSE

The sensitivity of a chest radiograph for diagnosing COVID-19 is modest at the onset of the disease, even in expert radiological hands. Being able to detect the disease earlier than the radiologist using artificial intelligence tools would allow us to anticipate care and isolation. Our purpose is to evaluate the performance of a deep learning artificial intelligence (AI) algorithm on the first clinical encounter and compare it with several radiologists with different years of experience in chest imaging.*Methods and Materials An ensemble of four deep convolutional networks, Ensemble4Covid, was trained to detect COVID-19 on frontal chest radiographs. The algorithm was tested using images from the first clinical encounter of positive and negative patients over a period of three months. The reference standard for test-positive patients was a positive real-time polymerase chain reaction test, taken within one day of the chest radiograph. The performance of the algorithm was compared with that of 5 radiologists with different years of experience on a smaller test subset of patients. The performance of the deep model training was also validated using the large public dataset COVIDx.*Results A total of 311 positive and 513 negative chest radiographs were used to evaluate the model.

The Ensemble4Covid model achieved an AUC of 85% whereas the radiologists achieved an AUC of 71%. Compared with other models, the performance of a single model of our ensemble achieved non-significant differences on the large public dataset COVIDx.*Conclusions The performance of our Ensemble4Covid on these challenging conditions is significantly higher compared to the assessment of five radiologists. AI can be used for a fast COVID-19 diagnosis.*Clinical Relevance/Application This AI tool can be used for early detection of COVID-19 from conventional chest radiograph taken at the onset of disease before the corresponding density difference is visible to the radiologist.

RESULTS

A total of 311 positive and 513 negative chest radiographs were used to evaluate the model. The Ensemble4Covid model achieved an AUC of 85% whereas the radiologists achieved an AUC of 71%. Compared with other models, the performance of a single model of our ensemble achieved non-significant differences on the large public dataset COVIDx.

CLINICAL RELEVANCE/APPLICATION

This AI tool can be used for early detection of COVID-19 from conventional chest radiograph taken at the onset of disease before the corresponding density difference is visible to the radiologist.

SDP-IN-9   Quantifying Uncertainty In Machine Learning Classifiers For Medical Imaging

Participants
Pascal Tyrrell, PhD, Toronto, Ontario (*Presenter*) Officer, AceAge Inc;Stockholder, AceAge Inc;Investigator, Novo Nordisk AS;Consultant, Novo Nordisk AS;CEO and Co-founder, SofTx Innovations Inc

PURPOSE

Machine learning (ML) models in medical imaging (MI) can be of great value in computer aided diagnostic systems, but little attention is given to the confidence (alternatively, uncertainty) of such models, which may have significant clinical implications. This paper applied, validated, and explored a technique for assessing uncertainty in convolutional neural networks (CNNs) in the context of MI.*Methods and Materials We used a publicly accessible pneumonia chest x-ray dataset with two classes to explore the proposed measure of uncertainty (based on 1. experiments with different class imbalance-sample sizes, 2. experiments with images close to the classification boundary, and 3. the relationship with other performance metrics). A collection of the five most confidently and the five least confidently classified images of the CNN were cross-examined by a radiologist. Additionally, bounds were derived on the uncertainty metric, and recommendations for interpretability were made.*Results With respect to training set class imbalance, the uncertainty metric was minimized when both classes were nearly equal in size (regardless of training set size) and was approximately 17% smaller than the maximum uncertainty resulting from greater imbalance. We found that less-obvious test images (those closer to the classification boundary) produced higher classification uncertainty, about 10-15 times greater than images further from the boundary. Relevant MI performance metrics like accuracy, sensitivity, and sensibility showed seemingly negative correlations, though none were statistically significant (p= 0.05). An expert radiologist and our CNN demonstrated good agreement on a collection of chest exams with respect to confidence in classification.*Conclusions This paper demonstrated the importance of uncertainty reporting alongside predictions in medical imaging. Results demonstrate considerable potential from automatically assessing classifier reliability on each prediction with the proposed uncertainty metric. Going forward, radiologists using ML technologies can more closely examine the prediction quality of these methods, automating workflow and providing richer context with model outputs.*Clinical Relevance/Application The ability for informed decision making based on AI technology is not fully developed without any meaningful measure of uncertainty. In much the same way that a human radiologist may assign a subjective confidence score to their diagnoses, the machine too, should be able to mimic this process. In doing so, radiologists will be able to identify machine classifications that are more uncertain and provide a human interpretation.

RESULTS

With respect to training set class imbalance, the uncertainty metric was minimized when both classes were nearly equal in size (regardless of training set size) and was approximately 17% smaller than the maximum uncertainty resulting from greater imbalance. We found that less-obvious test images (those closer to the classification boundary) produced higher classification uncertainty, about 10-15 times greater than images further from the boundary. Relevant MI performance metrics like accuracy, sensitivity, and sensibility showed seemingly negative correlations, though none were statistically significant (p= 0.05). An expert radiologist and our CNN demonstrated good agreement on a collection of chest exams with respect to confidence in classification.

CLINICAL RELEVANCE/APPLICATION

The ability for informed decision making based on AI technology is not fully developed without any meaningful measure of uncertainty. In much the same way that a human radiologist may assign a subjective confidence score to their diagnoses, the machine too, should be able to mimic this process. In doing so, radiologists will be able to identify machine classifications that are more uncertain and provide a human interpretation.

CA01-B2 Reproducibility Of Quantitative Thoracic 4D Flow MRI: Physiological Variability Of Hemodynamics Due To Circadian Rhythm And Food Intake

Participants
Thekla Helene Oechtering, MD, Madison, Wisconsin (*Presenter*) Research Grant, German Research Foundation (OE 746/1-1)

PURPOSE

To characterize the physiological variability of hemodynamics measured with 4D flow MRI in the thoracic aorta of young, healthy volunteers depending on time of day and food intake.*Methods and Materials 4D flow MRI of the thoracic aorta in 37 healthy volunteers (25±3years, 19 females; no shift work, fasting =5hrs prior to MRI) was acquired at 3T at 7AM and 7PM to evaluate possible circadian changes. 19 subjects were examined a third time after a standardized meal challenge. Typical acquisition parameters included Cartesian sampling, acquired voxel size 2.5x2.5x2.0-2.5mm reconstructed to 2.0x2.0x2.0mm, FOV 28x28x6.4 cm, venc 180 cm/s, 24±3 acquired cardiac phases, and acquisition time 11±3min. Stroke volume (SV), peak flow (Q) and peak velocity (V) were analyzed with GTFlow (Gyrotools, CH) at 8 standardized aortic planes. Statistics included t-test, calculation of relative difference, and Pearson correlation.*Results Peak flow differed significantly in every analysis plane and peak velocity in most planes with higher values in the evening and after a meal compared to the morning and fasting exams (Figure). Circadian differences were less pronounced for stroke volume. Combining the results for ascending aorta, descending aorta, and total thoracic aorta, respectively, all differences proved significant with higher values in the evening and after a meal. AM- and PM-results as well as pre- and postprandial findings showed strong to very strong correlation (SV: r=0.76-0.91; Q: r=0.85-0.94; V: r=0.63-0.95, for all p<0.001). Blood pressure and cardiac frequency were normal and did not differ significantly between exams (p<0.05).*Conclusions For the first time, this study demonstrated that 4D flow MRI can detect circadian hemodynamic changes in the thoracic aorta of young, healthy volunteers. We found significantly higher peak flow, peak velocity, and stroke volume in PM measurements compared to AM acquisitions. Circadian rhythm can be deranged in cardiovascular disease, potentially making 4D flow MRI a non-invasive cardiovascular risk-stratification tool. Our results in the thoracic aorta agree with findings of increased flow in the abdominal aorta in response to a meal challenge described in the literature.*Clinical Relevance/Application 4D flow MRI can detect the variability of thoracic aortic hemodynamics due to circadian rhythm and food intake. If confirmed, this might necessitate consistent timing of 4D flow MRI follow up studies.

RESULTS

Peak flow differed significantly in every analysis plane and peak velocity in most planes with higher values in the evening and after a meal compared to the morning and fasting exams (Figure). Circadian differences were less pronounced for stroke volume. Combining the results for ascending aorta, descending aorta, and total thoracic aorta, respectively, all differences proved significant with higher values in the evening and after a meal. AM- and PM-results as well as pre- and postprandial findings showed strong to very strong correlation (SV: r=0.76-0.91; Q: r=0.85-0.94; V: r=0.63-0.95, for all p<0.001). Blood pressure and cardiac frequency were normal and did not differ significantly between exams (p<0.05).

CLINICAL RELEVANCE/APPLICATION

4D flow MRI can detect the variability of thoracic aortic hemodynamics due to circadian rhythm and food intake. If confirmed, this might necessitate consistent timing of 4D flow MRI follow up studies.

IR03-D2   Preliminary Assessment Of Intraoperative Neuromonitoring Equipment For MRI-guided Ablations: RF-heating And Image Quality

Participants
Christopher Favazza, PhD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate RF heating risks and image degradation associated with use of intraoperative neuromonitoring equipment during interventional MRI.*Methods and Materials Monopolar and bipolar electrodes each connected to separate stimulator systems and two receiver electrode pairs were inserted into opposite ends of a ~50 cm long porcine tissue phantom. Six fiberoptic thermometers were placed at electrode tips. Saline bags were positioned next to the phantom for coil loading and SNR measurements. Bipolar stimulator and receiver electrode wires were routed directly out of the scanner along the shortest pathlength. Monopolar stimulator electrode wires were routed through the length of the bore to reach the stimulator on the opposite side of the scanner. The neuromonitoring computer system was located outside of the scanner room and connected through a waveguide. Two pulse sequences used to monitor ablations, T2-TSE (B1+rms= 3.52μT) for iceball monitoring and T1 SPGR (B1+rms=0.32μT) for thermometry, were executed with different electrode connection configurations: (1) all connected, (2) bipolar + receivers only (3) monopolar + receivers only,(4) receivers only, and none connected with monopolar wires exiting (5) opposite and (6) proximal bore opening. For each of these connection configurations, temperatures were continually measured during MRI. SNR measurements were obtained from saline images.*Results Temperature data showed no heating during the T1 SPGR sequence for all configurations. During T2 imaging, the monopolar electrode's temperature rose ~9°C; all other electrodes showed =2°C temperature rise—for configurations (1)-(5). For configuration (6), a maximum temperature rise of ~3.5°C was measured. Notably, there was visual evidence of a burn at one of the monopolar electrodes with a large wire section coiled within the bore. However, temperature was not monitored out of concern for potential damage to the thermometer. Image quality was severely corrupted with all electrodes connected but increasingly improved with disconnecting stimulator electrodes. SNR values increased maximally by factors of ~50 and 300 for T1 SPGR and T2 TSE sequences, respectively.*Conclusions Neuromonitoring electrodes can substantially heat during MRI, dependent on exact wire placement. However, data suggest heating can be reduced through minimizing wire pathlength in the bore. With a single set of stimulators connected, image quality was sufficient for procedural monitoring, thereby permitting imaging with intermittent neurostimulation and monitoring.*Clinical Relevance/Application Facilitating intraoperative neuromonitoring during MRI-guided ablations could improve patient safety and permit more aggressive treatments.

RESULTS

Temperature data showed no heating during the T1 SPGR sequence for all configurations. During T2 imaging, the monopolar electrode's temperature rose ~9°C; all other electrodes showed =2°C temperature rise—for configurations (1)-(5). For configuration (6), a maximum temperature rise of ~3.5°C was measured. Notably, there was visual evidence of a burn at one of the monopolar electrodes with a large wire section coiled within the bore. However, temperature was not monitored out of concern for potential damage to the thermometer. Image quality was severely corrupted with all electrodes connected but increasingly improved with disconnecting stimulator electrodes. SNR values increased maximally by factors of ~50 and 300 for T1 SPGR and T2 TSE sequences, respectively.

CLINICAL RELEVANCE/APPLICATION

Facilitating intraoperative neuromonitoring during MRI-guided ablations could improve patient safety and permit more aggressive treatments.

IR03-D4   Long-term Follow-up After Image-guided Percutaneous Pancreatic Duct Drainage

Participants
Malkhaz Mizandari, PhD, Tbilisi, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

To introduce a new technical development - steering using a coaxial large gauge needle to avoid critical structures in a percutaneous image-guided pancreatic duct (PD) access. Also, we prospectively review of efficacy and long-term outcomes of percutaneous image-guided PD drainage for treating benign or malignant pathologies with PD obstruction.*Methods and Materials Out of 85 patients with PD duct obstruction, percutaneous drainages were performed in 73 cases under CT, combined ultrasound and fluoroscopy or CT and fluoroscopy guidance in our center during the last 10-years. The technical and clinical success rate, adverse events based on the SIR scale, and survival rate were evaluated.*Results Final cases included acute and chronic pancreatitis (25) or postoperative stricture (1), pancreatic head tumors (42), and papilla of Vater tumors (5). We revealed that image-guided PD drainage was considered a highly feasible therapeutic intervention with an overall success rate of 98.6%. More than 15% of the patients remained alive after 4 years of follow-up. One patient had pancreatic cutaneous fistula, the PD was not dilated and was accessed under CT guidance using a 22 ga needle. Finally, The patient died 5 months later because of tumor progression, with no cutaneous fistula. No major complications occurred in all included cases.*Conclusions Image-guided PD drainage had significant additional benefits in managing cases of PD obstruction due to both benign or malignant

pathologies.*Clinical Relevance/Application The direct PD decompression provided by the image-guided PD drainage procedure may be more effective than commonly used pancreatic fluid collection drainage procedures in terms of lower complication rates and acceptable outcomes.

RESULTS

Final cases included acute and chronic pancreatitis (25) or postoperative stricture (1), pancreatic head tumors (42), and papilla of Vater tumors (5). We revealed that image-guided PD drainage was considered a highly feasible therapeutic intervention with an overall success rate of 98.6%. More than 15% of the patients remained alive after 4 years of follow-up. One patient had pancreatic cutaneous fistula, the PD was not dilated and was accessed under CT guidance using a 22 ga needle. Finally, The patient died 5 months later because of tumor progression, with no cutaneous fistula. No major complications occurred in all included cases.

CLINICAL RELEVANCE/APPLICATION

The direct PD decompression provided by the image-guided PD drainage procedure may be more effective than commonly used pancreatic fluid collection drainage procedures in terms of lower complication rates and acceptable outcomes.

GI02-B1   **Analysis Of CT Findings In Patients With Different Serum Pancreatic Amylase Trends After Major Pancreatic Resections**

Participants
Francesca Mambrin, MD, Verona, Italy (*Presenter*) Nothing to Disclose

PURPOSE

A recent study has demonstrated that a dynamic evaluation of serum pancreatic amylase (spAMY) trends is a more proper predictor of severe early morbidity after partial pancreatectomy than a single postoperative evaluation. We, therefore, sought to analyze the CT features that correlate with early spAMY trends after partial pancreatic resections.*Methods and Materials This is a retrospective study from an IRB-approved prospectively collected register. We included patients who underwent major pancreatic resections between 2016 and 2019 and had a contrast-enhanced postoperative MDCT between postoperative day (POD) 3 and POD 15. Patients were divided into 3 groups based on their patterns of spAMY: (1) spAMY values always< the lower limit of normal/within the reference range /a single increase in spAMY >upper limit of normal at any POD; (2) Sustained increase in spAMY activity on POD 0+1; (3) Sustained increase in spAMY activity including POD 1+2. Two readers in consensus, blinded to spAMY trend, analyzed the exams and logged arterial enhancement homogeneity, MPD diameter, peripancreatic edema, fluid collections, non-enhanced densities of liver, paraspinal and ileo-psoas muscles, and retrorenal fat thickness.*Results 383 patients were included in the study (230 males, 153 females, mean age 62,51 years). A inhomogeneous pancreatic enhancement was more commonly observed in spAMY-3 patients (47%) than in spAMY-2 or spAMY-1 patients (38% and 30%, respectively; p=0.0081). The main pancreatic duct (MPD) was larger in spAMY-1 (mean caliber 2.31±1.66 mm) than in the other groups (p=0.0011). Peripancreatic fat stranding was significantly more common in spAMY-3 than in spAMY-1 and -2 (p=0.0047). Fluid collections were more common in spAMY-3 (p<0.0001).No statistically significant correlations were found between spAMY trends and non-enhanced density of liver (p=0.4043), paraspinal (p=0.3989) and ileo-psoas (p=0.4092) muscles, or between spAMY trends and retrorenal fat thickness (p=0.6281).*Conclusions A correlation was observed between the spAMY-3 trend and the presence of inhomogeneous pancreatic enhancement, MPD dilation, presence of peripancreatic fat stranding, and fluid collections.*Clinical Relevance/Application A clear definition of the CT features of postoperative acute pancreatitis is the base for the radiological description of this entity, which will lead to its accurate and early diagnosis and thus to a proper treatment.

RESULTS

383 patients were included in the study (230 males, 153 females, mean age 62,51 years). A inhomogeneous pancreatic enhancement was more commonly observed in spAMY-3 patients (47%) than in spAMY-2 or spAMY-1 patients (38% and 30%, respectively; p=0.0081). The main pancreatic duct (MPD) was larger in spAMY-1 (mean caliber 2.31±1.66 mm) than in the other groups (p=0.0011). Peripancreatic fat stranding was significantly more common in spAMY-3 than in spAMY-1 and -2 (p=0.0047). Fluid collections were more common in spAMY-3 (p<0.0001).No statistically significant correlations were found between spAMY trends and non-enhanced density of liver (p=0.4043), paraspinal (p=0.3989) and ileo-psoas (p=0.4092) muscles, or between spAMY trends and retrorenal fat thickness (p=0.6281).

CLINICAL RELEVANCE/APPLICATION

A clear definition of the CT features of postoperative acute pancreatitis is the base for the radiological description of this entity, which will lead to its accurate and early diagnosis and thus to a proper treatment.

GI02-B2   **Whole-abdomen Metabolic Imaging In Healthy Volunteers Using Hyperpolarized 13C-Pyruvate MRI**

Participants
Philip Lee, BS, San Francisco, California (*Presenter*) Nothing to Disclose

PURPOSE

Hyperpolarized (HP) 13C MRI is a novel metabolic imaging technique enabling real-time characterization of LDH-catalyzed pyruvate metabolism. It is a promising biomarker of early-stage diffuse liver diseases and therapeutic response in abdominal malignancies. Human clinical studies are now underway at several sites around the world. However, whole-abdomen coverage remains a challenge and little is known about normal HP 13C metabolite levels in humans. To investigate baseline energetics and demonstrate feasibility of whole-abdomen coverage, we investigated HP 13C-pyruvate metabolism in multiple organs of healthy volunteers.*Methods and Materials After IRB approval, 5 healthy subjects underwent HP 13C MRI on a clinical 3 T scanner with volumetric transmitter and an 8-channel receiver array. T1- and T2-weighted images were acquired for anatomic reference. After injection of 0.43 mL/kg of 250 mM HP [1-13C]pyruvate, signals from [1-13C]pyruvate and its downstream metabolites, [1-13C]lactate and [1-13C]alanine, were acquired using a multi-slice echo planar imaging acquisition with flip angles of 30° for pyruvate, 60° for lactate and alanine. Temporal resolution was 3 s, with total scan time 1 minute. Voxel size was 2×2×2 cm3. Data were phase corrected, Fourier transformed, pre-whitened and coil-combined using pyruvate to estimate the coil weights. Metabolite signals were summed throughout the entire time course and ROIs selected within each organ.*Results Metabolite signals (pyruvate, lactate) from kidney and spleen were 3-6 times higher than those from liver and pancreas, reflecting differences in overall perfusion. Although absolute metabolite signals were lower in the liver, lactate:pyruvate and alanine:pyruvate ratios were both higher (L/P: 0.38 vs 0.17-0.21,

A/P: 0.25 vs 0.02-0.10), indicating higher production of these metabolites. Right and left kidney metabolism were symmetric as expected. The pancreas showed higher levels of alanine production relative to other organs, possibly due to high levels of protein synthesis. *Conclusions We successfully acquired HP 13C metabolic images in multiple organs throughout the abdomen with excellent spatial and temporal resolution. This broad spatial coverage will be valuable in developing novel applications of HP 13C MRI. Establishing normal values for metabolite levels will serve as an important baseline for imaging cancer as well as metabolic liver diseases.*Clinical Relevance/Application Whole abdomen HP 13C MRI is technically feasible with metabolite-specific images of pyruvate and downstream metabolites lactate and alanine. Understanding the metabolism in the whole abdomen will be crucial for the characterization of disease states in the liver, spleen, pancreas, and kidneys.

RESULTS

Metabolite signals (pyruvate, lactate) from kidney and spleen were 3-6 times higher than those from liver and pancreas, reflecting differences in overall perfusion. Although absolute metabolite signals were lower in the liver, lactate:pyruvate and alanine:pyruvate ratios were both higher (L/P: 0.38 vs 0.17-0.21, A/P: 0.25 vs 0.02-0.10), indicating higher production of these metabolites. Right and left kidney metabolism were symmetric as expected. The pancreas showed higher levels of alanine production relative to other organs, possibly due to high levels of protein synthesis.

CLINICAL RELEVANCE/APPLICATION

Whole abdomen HP 13C MRI is technically feasible with metabolite-specific images of pyruvate and downstream metabolites lactate and alanine. Understanding the metabolism in the whole abdomen will be crucial for the characterization of disease states in the liver, spleen, pancreas, and kidneys.

GI02-B4   Nodules Identified On Surveillance Ultrasound: CEUS Or MRI As The Initial Test

Participants
Stephanie Wilson, MD, Calgary, Alberta (*Presenter*) Equipment support, Koninklijke Philips NV;Equipment support, Siemens AG;Equipment support, Samsung Electronics Co, Ltd;Research support, Samsung Electronics Co, Ltd;

PURPOSE

Patients at-risk for HCC undergo surveillance ultrasound (US) every 6 months. MRI is the modality of choice to characterize positive ultrasound findings. In our institution, CEUS is well integrated into the surveillance diagnostic pathway. We aim to show equivalence of CEUS as the first step in evaluating lesions from surveillance US.*Methods and Materials This prospective IRB approved study recruited 250 high risk patients for HCC from those referred with a positive surveillance US. We report the first 105 patients, recruited between July 2019 and March 2020. All patients were referred for CEUS and MRI. Biopsy (n=26) and follow-up (n=50) were used as gold standard. MRI and CEUS lesions are classified according to enhancement features and their Liver Imaging and Reporting Data System (LI-RADS) category. A non-blinded research student reviewed all results to show concordance and discordance between CEUS and CEMRI, LI-RADS categorization and resolution of clinical problems posed by surveillance US.*Results The first 105 surveillance US include 37 confirmed HCC. 19/37 were concordant LR-5 on CEUS and MRI, 11/37 cases were concordant LR-4, and 3/37 were concordant LR-M. Additionally, two LR-4 on MRI were upgraded to LR-5 on CEUS, and 2 cases without an MR correlate for the surveillance US observation were LR-4 and LR-5 on CEUS (both biopsy-confirmed HCC). We document 7 concordant LR-M: including the three aforementioned HCC, two intrahepatic cholangiocarcinoma (ICC), one melanoma metastasis, and one benign inflammatory tumor. One patient with tumor-in-vein (LR-TIV) showed concordant CEUS and MRI. All malignancies (n=38) were categorized appropriately on CEUS, and had high agreement with MR exams (36/38 cases = 95%). Additionally, we document 13 benign hepatocellular lesions (LR-3 / LR-4) showing concordance between CEUS and MR exams, 22 cases with concordant benign LR-1. Lastly, 9/105 cases (8.5%) are concordant negative scans, and 20/105 (19%) in which CEUS identifies the surveillance US correlate and MRI does not. Of these 20 patients, two were biopsy-confirmed HCC, correctly categorized on CEUS, and 18 patients had focal fatty sparing/pseudolesion on CEUS.*Conclusions For diagnosis of benign and malignant pathology, CEUS performs equivalent and sometimes superior to MRI in resolving of nodules from surveillance US. Pseudolesions are more easily explained with selection of the same modality and misregistration between modalities doesn't occur with CEUS.*Clinical Relevance/Application US with CEUS is a readily available, less expensive choice for first examination resolution of positive surveillance US scans, accurately diagnosing benign and malignant pathology, and accurately excluding pseudolesions from further evaluation.

RESULTS

The first 105 surveillance US include 37 confirmed HCC. 19/37 were concordant LR-5 on CEUS and MRI, 11/37 cases were concordant LR-4, and 3/37 were concordant LR-M. Additionally, two LR-4 on MRI were upgraded to LR-5 on CEUS, and 2 cases without an MR correlate for the surveillance US observation were LR-4 and LR-5 on CEUS (both biopsy-confirmed HCC). We document 7 concordant LR-M: including the three aforementioned HCC, two intrahepatic cholangiocarcinoma (ICC), one melanoma metastasis, and one benign inflammatory tumor. One patient with tumor-in-vein (LR-TIV) showed concordant CEUS and MRI. All malignancies (n=38) were categorized appropriately on CEUS, and had high agreement with MR exams (36/38 cases = 95%). Additionally, we document 13 benign hepatocellular lesions (LR-3 / LR-4) showing concordance between CEUS and MR exams, 22 cases with concordant benign LR-1. Lastly, 9/105 cases (8.5%) are concordant negative scans, and 20/105 (19%) in which CEUS identifies the surveillance US correlate and MRI does not. Of these 20 patients, two were biopsy-confirmed HCC, correctly categorized on CEUS, and 18 patients had focal fatty sparing/pseudolesion on CEUS.

CLINICAL RELEVANCE/APPLICATION

US with CEUS is a readily available, less expensive choice for first examination resolution of positive surveillance US scans, accurately diagnosing benign and malignant pathology, and accurately excluding pseudolesions from further evaluation.

GI02-B7   Mri Features Of Primary Liver Cancer With Biliary Invasion: The Biliary Involvement Pattern Is A Possible Differential Clue And Prognosis Prediction

Participants
Kenichiro Okumura, Kanazawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To reveal MR Imaging features of hepatocellular carcinoma with imaged bile duct dilation (HCC w/ imgBD) compared to other liver malignancies with imaged bile duct dilatation and HCC without imaged bile duct dilatation (HCC w/o imgBD).*Methods and Materials This retrospective single-institutional study included consecutive 482 patients (337men, mean age 66 +/- 9.8 years) of hepatectomy due to primary liver tumor between January 1, 2008, and December 31, 2018, who received dynamic CT. Among the

tumors with imaged bile duct dilatation (n = 77), the cases that had apparent mass were extracted (n = 53), which included (HCC (n = 21), intrahepatic cholangiocarcinoma (IMCC) (n = 29), combined or mixed hepatocellular cholangiocarcinoma (cHCC-CC) (n = 3). We compared MR imaging findings including non-rim arterial phase hyperenhancement (APHE) and washout, any targetoid appearance (DWI, rim APHE, and central hyperenhancement), pattern of bile duct involvement (compressive or convergent), pathological and imaged bile duct tumor thrombi (BDTT) between HCC w/ imgBD and other malignancies w/ imgBD, or size-matched HCC subcohort w/o BD (n = 42) using chi2-test. The decision tree induction model was built using selected important variables for differential diagnosis of the tumors w/ imgBD. The Kaplan-Meier method was used to estimate overall survival (OS) between HCC patients with and without BDTT.*Results There was no significant difference between size-matched HCC w/ and w/o imgBD in all MRI findings. Among the tumors with imaged bile duct dilatation, a total of 9 cases showed imaged BDTT and 7 of them (78%) were HCC. The Wilcoxon test showed that the overall survival rates were significantly worse for HCC patients with imaged BDTT than for HCC patients without (P = 0.02). The pattern of bile duct involvement (compressive or convergent) was a significant finding for the differentiation of HCC from other malignancies (P < .0001). Decision-tree analysis was built using non-rim APHE with washout and pattern of biliary involvement, and it showed 87% accuracy for diagnosis of the intrahepatic mass with bile duct dilatation.*Conclusions Among MR imaging features of HCC w/ imgBD, a pattern of bile duct involvement (compressive or convergent) and the imaged BDTT, which involved overall survival, could be helpful in differential diagnosis from other primary liver malignancies with bile duct dilatation.*Clinical Relevance/Application Hepatocellular carcinoma sometimes presents with bile duct dilatation in imaging. In this study, we revealed two findings i.e., i) bile duct tumor thrombi in the dilated bile duct and ii) the pattern of bile duct involvement (compressive or convergent) are helpful for differentially diagnosing HCC from other tumors.

RESULTS

There was no significant difference between size-matched HCC w/ and w/o imgBD in all MRI findings. Among the tumors with imaged bile duct dilatation, a total of 9 cases showed imaged BDTT and 7 of them (78%) were HCC. The Wilcoxon test showed that the overall survival rates were significantly worse for HCC patients with imaged BDTT than for HCC patients without (P = 0.02). The pattern of bile duct involvement (compressive or convergent) was a significant finding for the differentiation of HCC from other malignancies (P < .0001). Decision-tree analysis was built using non-rim APHE with washout and pattern of biliary involvement, and it showed 87% accuracy for diagnosis of the intrahepatic mass with bile duct dilatation.

CLINICAL RELEVANCE/APPLICATION

Hepatocellular carcinoma sometimes presents with bile duct dilatation in imaging. In this study, we revealed two findings i.e., i) bile duct tumor thrombi in the dilated bile duct and ii) the pattern of bile duct involvement (compressive or convergent) are helpful for differentially diagnosing HCC from other tumors.

MK05-A1 The Role Of A Virtual Noncalcium Dual-energy CT Application In Osteomyelitis

Participants
Mayuran Saththianathan, MBChB,MS, Westmead, Australia (*Presenter*) Nothing to Disclose

PURPOSE

To determine the sensitivity and specificity of dual-energy CT (DECT) virtual noncalcium images with bone and soft tissue reconstructions in the diagnosis of osteomyelitis.*Methods and Materials Between 1 December 2014 to 1 December 2020, 91 patients who had 99 DECT performed for a clinical indication of osteomyelitis with corresponding MRI, triphasic bone scan and/or white blood cell scintigraphy with CT/SPECT performed either 2 weeks before or 1 month after the DECT were retrospectively identified. Two radiologists interpreted DECT virtual noncalcium images alone for bone marrow edema and with bone and soft tissue reconstructions for osteomyelitis. Fleiss k statistics was used to assess inter-level agreement.*Results Osteomyelitis was present in 25 cases (25%), of which 4 cases (4%) had co-existing septic arthritis, and absent in 74 cases (75%). DECT was performed at the following sites: ankle/foot (n=59), calf (n=12), knee (n=3), thigh (n=7), hip (n=9), pelvis (n=6), wrist/hand (n=1) and shoulder (n=2). Sensitivity with virtual non-calcium images alone was 64% and 76% and specificity was 85.1 and 71.6%. Sensitivity with virtual non-calcium images and bone and soft tissue reconstructions was 72% and 84% and specificity was 81.1% and 73.0%. Interobserver agreement was 76.7% (76 of 99 cases), for virtual noncalcium images alone (k = 0.487), 84.8% (84 of 99 patients) for bone and soft tissue reconstructions with virtual noncalcium images together (k = 0.677).*Conclusions When DECT virtual noncalcium images were combined with standard bone and soft tissue reconstructions, there is improved sensitivity in the diagnosis of osteomyelitis.*Clinical Relevance/Application There is little knowledge on the utility of DECT virtual noncalcium application in the diagnosis of osteomyelitis. To the authors' knowledge, this will be the first study assessing the sensitivity and specificity of DECT in the diagnosis of osteomyelitis.

RESULTS

Osteomyelitis was present in 25 cases (25%), of which 4 cases (4%) had co-existing septic arthritis, and absent in 74 cases (75%). DECT was performed at the following sites: ankle/foot (n=59), calf (n=12), knee (n=3), thigh (n=7), hip (n=9), pelvis (n=6), wrist/hand (n=1) and shoulder (n=2). Sensitivity with virtual non-calcium images alone was 64% and 76% and specificity was 85.1 and 71.6%. Sensitivity with virtual non-calcium images and bone and soft tissue reconstructions was 72% and 84% and specificity was 81.1% and 73.0%. Interobserver agreement was 76.7% (76 of 99 cases), for virtual noncalcium images alone (k = 0.487), 84.8% (84 of 99 patients) for bone and soft tissue reconstructions with virtual noncalcium images together (k = 0.677).

CLINICAL RELEVANCE/APPLICATION

There is little knowledge on the utility of DECT virtual noncalcium application in the diagnosis of osteomyelitis. To the authors' knowledge, this will be the first study assessing the sensitivity and specificity of DECT in the diagnosis of osteomyelitis.

MK05-A3 Artificial Intelligence In Orthopaedic Implant Model Classification: A Systematic Review

Participants
Paul Yi, MD, Baltimore, Maryland (*Presenter*) Consultant, FH Orthopedics SAS;Consultant, BunkerHill Health

PURPOSE

Artificial intelligence (AI) algorithms have demonstrated the ability to accurately and rapidly identify orthopedic implant models on radiographs, which could facilitate preoperative planning and development of large-scale joint replacement registries. However, the scope and performance of AI algorithms in classifying orthopedic implant models has not been systematically evaluated.We performed a systematic review of research studies developing AI algorithms to identify orthopedic implant models on medical images to determine: (1) How well does AI perform in identifying the model of a given orthopedic implant, and (2) What is the performance of deep learning algorithms compared with clinicians?*Methods and Materials We performed a systematic literature search according to PRISMA guidelines in PubMed, EMBASE, and the Cochrane Library for studies published up to March 10, 2021 using search terms related to "artificial intelligence", "orthopaedic", "implant", and "arthroplasty." Inclusion criteria were an original scientific study describing performance of at least one AI algorithm for identification of a specific orthopedic implant on any imaging modality. We summarized performance of AI models for implant identification and comparisons to clinicians.*Results From 2,689 potential publications, 11 were included in the final review (Figure 1). The majority (10, 90.1%) of studies used deep learning models for identification of implants, with one exception using support vector machine. Most studies identified arthroplasty implants for hips, knees, and shoulders (9, 81.8%) with the remaining two identifying spine implants. The number of implant models evaluated/identified ranged from 2 to 27. All studies used radiographs of the extremities or spine with datasets ranging from 170 to 2894 images.Five studies reported overall AUC across all included models ranging from 0.94 - 1.0. Overall accuracy values reported across all studies ranged from 0.804 - 1.0. Only one study compared an AI with clinicians, reporting no statistically significant difference in its performance for identification of THA model compared to three orthopedic surgeons.*Conclusions AI algorithms have demonstrated strong performance in classifying orthopedic implant models from radiographs, particularly for arthroplasty of the hip and knee. Comparison to human experts has been seldom performed, however, highlighting the need for further research to evaluate potential benefit of AI algorithms to human observers.*Clinical Relevance/Application AI algorithms show high performance

to identify specific orthopedic implant models, which could facilitate preoperative planning and curation of large-scale joint replacement registries.

RESULTS

From 2,689 potential publications, 11 were included in the final review (Figure 1). The majority (10, 90.1%) of studies used deep learning models for identification of implants, with one exception using support vector machine. Most studies identified arthroplasty implants for hips, knees, and shoulders (9, 81.8%) with the remaining two identifying spine implants. The number of implant models evaluated/identified ranged from 2 to 27. All studies used radiographs of the extremities or spine with datasets ranging from 170 to 2894 images.Five studies reported overall AUC across all included models ranging from 0.94 - 1.0. Overall accuracy values reported across all studies ranged from 0.804 - 1.0. Only one study compared an AI with clinicians, reporting no statistically significant difference in its performance for identification of THA model compared to three orthopedic surgeons.

CLINICAL RELEVANCE/APPLICATION

AI algorithms show high performance to identify specific orthopedic implant models, which could facilitate preoperative planning and curation of large-scale joint replacement registries.

PHEE-1 The Physics Of Yttrium-90 Radiopharmaceuticals: History ; Review Of Current Industrial Production Methods

Participants
Daniel Braga, MD, Miami Beach, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Provide a brief history of Yttrium and its uses2. Outline Yttrium's geology and main sources worldwide3. Summarize the medical physics of Yttrium-90 (Y-90)4. Analyze the different modes of producing the Y-90 isotope5. Review company-specific manufacturing methods6. Examine the physics regarding the logistics of distribution

TABLE OF CONTENTS/OUTLINE

Yttrium is transitional rare earth metal, first discovered in mineral form in 1787 by the Swedish chemist Carl Arrhenius, with a breadth of industrial applications from lasers to thermal barrier coatings on jet engines. The vast majority of Yttrium is currently sourced from ion-adsorption ore deposits located in several southern Chinese provinces. Early research regarding the vascularity of hepatic neoplasms led to initial reports of a radioactive isotope of Yttrium, called Yttrium-90, being used as a radiopharmaceutical. Y-90 primarily undergoes ß- decay to stable Zirconium-90 with a half-life of 64 hours, and average energy of 0.9367MeV. The dominant manufacturing modes of Y-90 will be reviewed and include (1) Theraspheres produced by melting Y-89 together with filtered aluminum and silicate oxide into glass beads followed by neutron activation of Y-89 to Y-90 in a nuclear reactor, and (2) Sir-Spheres produced by coating Y-90 onto the surface of a microsphere via a cation exchange polystyrene resin. Both require appropriate handling and preparation at the hospital level to ensure consistent delivery of a planned specified dose that is then ultimately administered to the patient.

PHEE-10 Various Applications Of Deep Learning-based Reconstruction At CT: Denoise, Dual-energy CT, And Super-resolution

Participants
Toru Higaki, PhD, Minami-ku, Hiroshima, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Deep learning-based reconstruction (DLR) is becoming popular as a new CT image reconstruction method after hybrid iterative reconstruction (hybrid IR) and model-based IR (MBIR). Since DLR can significantly reduce image noise while preserving image texture, it is expected to reduce radiation exposure in CT scans. Also, DLRs trained with images reconstructed with advanced reconstruction methods can reduce artifacts such as blur. The DLR, which can reduce such noise/artifact, has recently been applied to dual-energy CT (DECT). In addition, super-resolution deep learning reconstruction (SR-DLR) is being developed as a new application of DLR. The SR-DLR increases the matrix of conventional CT images and enhances their spatial resolution. In this presentation, we will first explain the basics of DLR and then introduce various DLR applications and future prospects.

TABLE OF CONTENTS/OUTLINE

1. Basics of deep neural networks2. Denoising deep learning reconstruction: DN-DLR3. DLR for dual-energy CT3.1 Image-based approach3.2 Sinogram-based approach4. Super-resolution deep learning reconstruction: SR-DLR

PHEE-11 Easy Introduction Of The Photon Counting Detector CT (PCD-CT) For Radiologists

Participants
Shota Kondo, Hiroshima, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Unlike conventional (energy-integrated detector [EID]) CT, photon counting detector CT (PCD-CT) measures the photon energy as height of the pulse wave for each x-ray photon. Therefore, PCD-CT can collect X-ray data at multiple energies, and it can achieve CT images with lower noise and higher spatial resolution than conventional CT. On the other hand, there are some phenomena inducing inaccurate pulse counting and energy measurement such as charge sharing, K-escape, Compton scattering at PCD-CT and it is necessary to implement solutions of these issues like simultaneity (coincidence) check to realize a clinically practical PCD-CT scanner. In this educational exhibit, we will easily describe the principle, scan modes, technical issues, physical properties, and potential clinical applications of PCD-CT for radiologists.

TABLE OF CONTENTS/OUTLINE

1. Structure of detector of the PCD-CT 2. Data collection at the PCD-CT 3. Scan mode of the PCD-CT 1) Multiple energy discrimination mode (utilizing energy information) 2) Ultra high resolution mode (higher spatial resolution than conventional CT) 4. Technical issues to be solved to achieve clinically practical PCD-CT scanners 5. Comparison of physical characteristics between the

PCD-CT and conventional CT 1) Noise characteristics 2) Contrast characteristics 3) Spatial resolution 6. Potential clinical applications of PCD-CT 1) Improvement of low contrast detectability 2) High resolution images for lung 3) Accurate measurement of CT number 4) Accurate material decomposition

PHEE-13 "To Scan Or Not To Scan" MRI Safety Questions And Answers To The Various Implanted Electronic Devices.

Participants
Sangam G. Kanekar, MD, Hershey, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

To discuss the safety challenges of MR and scanning active implanted electronic devices.Discuss the important points to remember while screening the patient safety with the various common and less common AIMDs, before the patient is subjected to MRI examination. Discuss the ACR safety guidelines and approach to the various AIMDs

TABLE OF CONTENTS/OUTLINE

The MR environment is associated with multiple challenges to safe scanning in patients with active implanted medical devices (AIMDs). A variety of AIMDs is implanted for the treatment of multiple conditions. These patients are likely to require advanced imaging, including MR imaging to follow up on their disease conditions. These devices under exposure to the MR environment may cause heating of leads and burns to the surrounding vital tissues, device malfunction (eg, infusion pump failure to restart; damaged circuitry in a cardiac pacemaker). In this exhibit, we discuss the approach to investigate the safety of the various Implanted electronic devices include cardiac devices (pacemakers and defibrillators) and neurostimulators (deep brain, auditory brainstem implant, spinal cord, vagal nerve, sacral nerve, hypoglossal nerve, phrenic nerve, peripheral nerve, and auditory nerve/cochlear implants), as well as implantable medication pumps.

PHEE-14 Main Magnetic Field Homogeneity Measurement For MRI Quality Control

Participants
Teresa M. Peterson, Rochester, Minnesota (*Presenter*) Nothing to Disclose

TEACHING POINTS

Understand the importance of main magnetic field homogeneity measurement on diagnostic and interventional MRI quality control.Learn the basic principles of measuring main magnetic field homogeneity and the potential practical challenges of measuring it.Learn the workflow, imaging protocols and technical measures used at our practice to ensure consistent measurement of the main magnetic field homogeneity across multiple MRI vendors.

TABLE OF CONTENTS/OUTLINE

1. Impact of main magnetic field homogeneity measurement on MR image qualitySources of main magnetic field inhomogeneityEffects of main magnetic field inhomogeneity on image quality2. Main magnetic field homogeneity measurement approaches and the practical challengesMagnetic field homogeneity specifications and ACR requirementsField homogeneity measurement by service engineersACR recommended measurement methods Practical challenges3. Automated tool for magnetic field homogeneity measurement used in our institutionImaging protocols based on basic sequences widely available on scannersPhantom and shimming option considerations during imaging for homogeneity measurementsAutomatic conversion of images into proper format and unit for B0 mappingAutomatic phase unwrappingAutomatic detection of phantom center and reporting homogeneity measurements

PHEE-15 Simple Approach To MR Parameters Adjustments For Radiologists

Participants
Matthew Holbrook, MD, Albuquerque, New Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

The aim of this workshop is to introduce a simplified, radiologist-relevant approach to learning the effects of different MR parameters on the signal to noise ratio, to briefly review the relevant background MR physics, and to provide case examples of tuning MR sequences to obtain better quality images. The audience member should leave the workshop feeling confident that they can quickly recognize the effects of different MR parameters and adjust the sequences in a decisive manner.

TABLE OF CONTENTS/OUTLINE

Increasing the signal to noise ratio (SNR) is better for image interpretation. The SNR is affected by the following parameters: 1. Magnetic field strength 2. Number of acquisitions 3. TR, TE, and flip angle 4. Slice thickness and receiver bandwidth 5. Field of view 6. Size of matrix 7. RF coil selection. These parameters can be hard to remember in terms of their effect on SNR and we will present a novel way to tackle the memorization of this learning. Finally, we will present common examples to demonstrate the effects and trade-offs of adjusting these parameters, which will solidify the newly learned material.

PHEE-16 Decoding The Labyrinth Of ASL: A Primer For Radiology Residents

Awards
Certificate of Merit

Participants
Sabha Ahmed, MBBS, Jodhpur, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

To address the complexity of ASL physics with illustrations.To prime the residents with the basics of functional imaging applications of ASL.To elaborate on the applications with emphasis on oncology and neurodegeneration.To illustrate with examples the applications in neuroradiology.

TABLE OF CONTENTS/OUTLINE

Introduction Illustration of the basic technique of ASL Illustrate the various labeling techniques of ASL Limitations and pit falls of

introduction.Illustration of the basic technique of ASL.Illustrate the various labeling techniques of ASL.Limitations and pit falls of each labeling technique .Discussion the applications of ASL in neuroimaging.Case illustrations.

PHEE-17   Impact Of Deep Learning-based Adaptive Noise Reduction For MR Imaging.

Awards
Identified for RadioGraphics

Participants
Shigeru Kiryu, MD, Tokyo, Japan (*Presenter*) Research collaboration, Canon Medical Systems Corporation

TEACHING POINTS

Denoising approach that incorporates deep learning-based reconstruction (dDLR) has improved MR image quality compared with previous reported filtering methods and is the earliest application using deep learning technique brought in clinical practice. In this educational exhibit, we show the concept of dDLR and our experience in this field. While dDLR enables efficient noise reduction, noise issue in MR images has become more prominent. We will present our approaches to deal with this issue.To know the basic concept of dDLR for denoising of MR images. To know current dDLR applications in clinical MRI. To know the noise issue of MR images in the application of dDLR and its solutions.

TABLE OF CONTENTS/OUTLINE

Basic concepts of dDLR for denoising of MR images Our experience in applying dDLR in clinical MRI -Brain MR imaging -MR angiography -MRCP -Musculoskeletal imaging Noise issues and solutions.

PHEE-18   Clinical Implementation Of A First-generation Dual Source Photon Counting Detector CT: First Experience And Perspective For Clinical Use

Participants
Marcel L. Dijkshoorn, Rotterdam, Netherlands (*Presenter*) Consultant, Siemens AG;Research collaboration, Siemens AG;

TEACHING POINTS

To understand the technical differences between a conventional energy integrating detector (EID) CT versus a novel photon counting detector (PCD) CT.To explain the benefits of dual source PCD CT for radiation dose, contrast media usage, image quality and spectral information optimization.To provide an overview and explanation of clinical exam types where photon counting technology changes the scan protocol, image interpretation and reporting approach.To demonstrate how PCD technology affects clinical workflow, education & training and IT infrastructure requirements.

TABLE OF CONTENTS/OUTLINE

Technical backgroundDetector characteristics and data acquisition comparison between PCD CT and EID CT.General spatial resolution improvementSpectral data acquisition and processingDual source specific characteristicsClinical potentialRadiation dose reductionIncreased iodine enhancementImproved spatial resolutionBroader spectral data availabilitySpecific impact on dual source applicationsPitfalls and potential barriersData size handlingServer-thin client software vs PACS readingTraining of your staffClinical examplesNeuroChestAbdomenCardiovascularCT-AngiographyMusculoskeletal

PHEE-19   Direct MR-guidance Of Brachytherapy In Gynecologic Cancers: Workflow Considerations, Technical Development, And Clinical Benefits

Participants
Megan Jacobsen, PhD, Houston, Texas (*Presenter*) Research Grant, Siemens AG

TEACHING POINTS

1. Explain the benefits of direct magnetic resonance (MR) guidance for gynecologic brachytherapy 2. Discuss steps required for imaging physics evaluation of the program, including development of MR safety procedures and pulse sequence optimization. 3. Describe procedural workflow for direct MR guidance of brachytherapy applicator and interstitial needle placement.

TABLE OF CONTENTS/OUTLINE

1. Benefits of MR-guided gynecologic brachytherapy over CT. a. Tumor differentiation from background. b. Segmentation of organs at risk (OAR). c. Clinical benefits and role for direct MR guidance. 2. Introduction to direct MR guidance of gynecologic brachytherapy. a. In-suite applicator placement. b. Specialized equipment. c. Workflow in the MR suite. 3. Imaging physics requirements. a. MR safety evaluation of all equipment. b. MR safety training and verification of personnel. c. Hardware evaluation with transfer table. i. Magnetic field homogeneity. ii. Geometric accuracy. d. Protocol optimization. i. Pulse sequences. ii. Phantom image quality. iii. Volunteer scanning. 4. Case studies demonstrating benefits of direct MR-guidance. a. Reduction in returns to operating room for repositioning. b. Dosimetric benefits. 5. Conclusions.

PHEE-2   Characteristics Of Deep Learning Reconstruction: Application In Clinical Practice

Participants
Akio Tamura, MD, Shiwa, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

In recent years, deep learning has received a lot of attention, and multiple applications have been developed in various fields. One of the most advanced applications of deep learning is in the improvement of image quality by denoising. A new deep learning reconstruction (DLR) algorithm has recently been introduced in CT image reconstruction. This educational exhibit will present the differences between DLR and traditional reconstruction methods, their physical properties and visual evaluation, and how DLR should be used in clinical practice based on these properties.

TABLE OF CONTENTS/OUTLINE

1. The effects of object size and radiation dose on resolution characteristics are compared among DLR, model-based iterative reconstruction (MBIR), hybrid iterative reconstruction (HIR), and filtered back-projection (FBP) methods.2. Application of DLR for CT imaging with both image quality and radiation dose reduction in children.3. Innovations in CT imaging with DLR in adults. Aiming for

dose reduction, especially in patients with a high body mass index.4. Application of DLR to dual energy CT, low tube voltage imaging and ultra-high-resolution CT.

PHEE-20   How CT Happened: Getting To The First CT Image 50 Years Ago

Participants
Raymond A. Schulz, MS, Palo Alto, California (*Presenter*) Employee, Varian Medical Systems, Inc

TEACHING POINTS

Hounsfield & EMI's invention of CT benefitted from no preconceptions. Hounsfield's intuitive inventive genius overcame the lack of a college degree.

TABLE OF CONTENTS/OUTLINE

50 years ago, October 1, 1971, Hounsfield's non-invasive procedure, of a live patient's brain, was performed. Two-days later, a remarkable image appeared on the screen of a monitor - after having been processed offline on a remote mainframe computer and archived on Polaroid film. This presentation by EMI alum professionals explores new material regarding what led to CT. Interviews of former EMI employees who worked with or met Hounsfield provided a wealth of data. Unpublished archives from EMI, etc. have added new insights on the birth of CT. Keys to the success of Hounsfield & EMI included:- no preconceptions of imaging; expertise in radar electronics and managing the development of early mainframe computers. Finally, the advent of the first minicomputers allowed for onsite, in hospital computation & installation. Hounsfield showed his intuitive genius in his 16-page proposal "An Improved Form of X-Radiography". It demonstrated a clear mental model of CT including volumetric sectioning, beam filtering, image reconstruction, windowing and display. All are still in use today. He even demonstrated the basics of cone-beam CT with a drawing. Hounsfield struggled to get the project approved but benefitted from not having preconceived notions of better medical image quality requirements. Low-contrast detail was key. All of which led to a Nobel Prize a mere 8 years later

PHEE-3   Dual-source Whole-body Photon Counting CT: Physics And Images From A New Investigational System

Awards
Certificate of Merit

Participants
Elisabeth Shanblatt, PhD, Rochester, Minnesota (*Presenter*) Employee, Siemens AG

TEACHING POINTS

1 Explain the fundamentals of photon counting detectors (PCDs) and how they differ from energy integrating detectors (EIDs)2 Describe a new investigational dual-source whole-body PCD-CT scanner (NAEOTOM Alpha, Siemens Healthineers)3 Explain how these new detectors lead to improved spatial and spectral image characteristics4 Illustrate image quality in phantom and patient examples

TABLE OF CONTENTS/OUTLINE

1 What is the difference between EIDs and PCDs? EIDs require scintillation to convert x-rays to visible light readable by photodiodes. This requires reflective inter-pixel septa to decrease optical crosstalk. PCDs directly convert x-rays into electronic signal, eliminating the need for inter-pixel septa.2 Technical specifications of the novel prototype whole-body PCD-CT scanner. Description of the x-ray tubes and PCD arrays. Acquisition parameters and imaging modes are discussed.3 Spatial resolution and noise: 0.4 mm slice width in routine mode, 0.2 mm in high resolution (HR) mode. Energy thresholding allows elimination of electronic noise, resulting in improved image quality and/or reduced radiation dose4 Spectral imaging: Energy thresholding allows capabilities such as virtual monoenergetic, virtual non-contrast, and iodine map images. Uniform photon weighting improves iodine contrast. Accurate iodine quantification is shown.5 Clinical image examples demonstrating excellent image quality in an HR CTA runoff exam and a virtual monoenergetic image from a spectral coronary CTA exam with 66 ms temporal resolution.

PHEE-4   Simulation In Medical Education: Parallax In Interventional Radiology

Participants
Rachel Brader, MD, Chapel Hill, North Carolina (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Parallax is the apparent difference in the position of an object when viewed from different angles. • Parallax contributes to image artifacts, but understanding of parallax can be utilized to localize internal structures, especially in interventional radiology.• In interventional radiology standard convention to describe positioning refers to the location of the image intensifier (II) or flat panel detector (FPD) relative to the patient, ie. In Left Anterior Oblique (LAO) position the II/FPD is anterior and to the left of the patient (typically lying supine on the table). • An object further from the image detector will have apparent motion in the same direction as the image detector. For example, when evaluating the thoracic aorta and moving from Anterior to LAO position, the descending aorta will appear to move to the left (right side of the screen) relative to the ascending aorta. This is because the descending aorta is posterior to and further from the image detector than the ascending aorta in a supine patient. • Utilization of parallax can help an interventional radiologist efficiently and accurately locate structures, thereby improving the safety of the procedure.

TABLE OF CONTENTS/OUTLINE

1. Pre-content knowledge check 2. Introduction regarding parallax concepts using illustrations and phantom model 3. A series of images from IR cases demonstrating concept 4. A video of concept simulation in the IR suite 5. Post-content knowledge check 6. Summary of key teaching points

PHEE-5   What You Should Know About Plane Wave Ultrasound Imaging

Awards
Certificate of Merit

Participants
Zaiyang Long, PhD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

1. What is plane wave ultrasound imaging; 2. Why would we like to have plane wave imaging; 3. Clinical applications of plane wave imaging;

1. Background a. Conventional ultrasound imaging is typically performed by insonification of tissue line by line using narrow, focused ultrasound beams, and echo processing with a hardware beamformer. b. It suffers from limited frame rate, which depends on the field of view (FOV), line density and the number of focus, and is insufficient for many clinical tasks, such as freezing cardiac motion, 3D/4D imaging, and monitoring shear wave propagation. 2. Plane wave (PW) ultrasound imaging a. PW ultrasound imaging transmits a wide, unfocused PW and is capable of computing a wide FOV image per excitation via software beamforming. Its frame rate could reach the order of 10 kHz, but image quality is compromised. b. Coherent spatial compounding with multiple tilted PW frames was developed to improve image quality, which can be superior or comparable to conventional imaging yet with faster frame rate. 3. Clinical applications of PW imaging a. Improved B-mode imaging b. Microflow color Doppler, power Doppler, and retrospective spectral Doppler c. Shear wave elastography d. Ultrafast contrast imaging and super-resolution localization microscopy e. Functional ultrasound imaging 4. Safety consideration (Thermal Index and Mechanical Index) 5. Conclusion a. Due to major technological breakthroughs, PW imaging brings revolutionary changes and benefits to clinical ultrasound imaging.

PHEE-6 What You Should Know In Ultra High Resolution CT?

Participants
Fuyuki Washizuka, Tokyo, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

To learn about mechanism of the latest ultra-high resolution CT: UHRCT for acquiring ultra-fine structure.To learn about the use of UHRCT in applications other than ultra-fine structures.To learn the effects of partial volume suppression in UHRCT. To learn the limitation of UHRCT and the way to overwhelm them.

TABLE OF CONTENTS/OUTLINE

A. The impact of UHRCT on the depiction of ultra-fine structure.B. The usefulness of UHRCT considering exposure in pediatric CT with small structures.C. Advantage of UHRCT in peripheral abdominal vessels.D. The superiority of UHRCT in low contrast region represented by the liver. E. Consider the effect of UHRCT on the partial volume effect.

PHEE-7 Seeing More With Less: Clinical Benefit Of Photon-counting Detector CT (PCD-CT)

Awards
Cum Laude
Identified for RadioGraphics

Participants
Avinash Nehra, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

TEACHING POINTS

? To understand fundamental differences in acquisition and reconstruction between PCD-CT and conventional energy-integrating detector CT. ? To illustrate benefits of improved spatial resolution, multi-energy imaging, and decreased electronic noise across multiple clinical applications using an investigational PCD-CT system.

TABLE OF CONTENTS/OUTLINE

PCD-CT systems quantify the number and energy of incoming photons, directly converting this information into electrical signal. Absence of inter-pixel septa increases geometric dose efficiency and improves spatial resolution. Uniform weighting of photons results in higher iodine contrast and optimized spectral imaging, including reduced artifacts and lack of electronic noise. • Spatial resolution to 150 µm improves visualization of small objects, e.g., imaging findings of bronchiectasis and interstitial lung disease, small vessels at CTA, small aneurysms in the brain, and improved visualization of small bony structures. • Spectral acquisition enables multi-energy applications, such as virtual monoenergetic imaging, virtual non-calcium, metal artifact reduction, and material quantification. • The use of a tin (Sn) filter facilitates radiation dose reduction while maintaining spatial resolution and reduces metal artifacts. • The absence of electronic noise results in improved image quality perception across dose-reduced exams and large patients.

PHEE-8 Understanding Doppler Ultrasound: Technique, Artifacts And Interpretation

Participants
Cristina Gomez Varela, MD, Pontevedra, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review the basic principles of Doppler Ultrasound. Incorrect adjustment of the doppler parameters can lead to misleading imaging interpretation. To recognize the most frequent pitfalls and artifacts and highlight the nomenclature and interpretation of Doppler waveforms.

TABLE OF CONTENTS/OUTLINE

Background: Doppler physics. Doppler settings: doppler angle, sample volume, wall filters, gain, velocity scale. Doppler artifacts: aliasing, blooming, directional ambiguity, partial volume artifact, pseudoflow, flash artifact, mirror image artifact, edge artifact, twinkling artifact. Doppler waveforms interpretation.

PHEE-9 When Numbers Lie: Pearls And Pitfalls To Avoid In Hounsfield Unit Interpretation

Participants
Aaron Brumbaugh, MD, Pittsburgh, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Hounsfield units are calculated values of an attenuated photon beam, dependent on the linear attenuation coefficient. 2) The linear attenuation coefficient is proportional to the atomic number of the attenuating material, and inversely proportional to the photon energy. 3) Accurate Hounsfield unit measurement is important in varied, multisystem clinical contexts. 4) Describe the phenomenon of pseudoenhancement as a possible cause of spurious Hounsfield unit measurements, as well as potential causes of pseudoenhancement. 5) Hounsfield units serve as a semi-quantitative metric, with inter-scanner variability demonstrated across multiple generations of CT scanners. This variability cautions against quantitative applications of Hounsfield units as absolute values.

Sub-Events

INEE-1   Volume Sweep Imaging: A New Horizon In Teleradiology

Participants
Thomas Marini, MD, Rochester, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Although essential to provide high-quality care, the majority of the world population lacks access to diagnostic medical imaging. 2) Teleultrasound is a low-cost means to deliver vital diagnostic medical imaging, but its deployment is limited by availability experienced sonographers. 3) Volume sweep imaging (VSI) teleultrasound circumvents this issue by the use of standardized scan protocols based off easily recognized external body landmarks that can be performed by individuals without prior ultrasound experience. 4) Images obtained from VSI allow asynchronous teleultrasound acquisitions which can be sent over low internet bandwidths for many clinical applications including lung, obstetric, breast, thyroid, and abdominal right upper quadrant (RUQ) scanning indications.

TABLE OF CONTENTS/OUTLINE

1) Explanation of VSI teleultrasound in the context of modern telemedicine systems. This includes a discussion of asynchronous versus synchronous teleultrasound and engineering specifications of VSI teleultrasound. 2) Discussion of VSI teleultrasound training techniques and practical issues surrounding deployment. How to perform VSI examinations of the lung, pregnant abdomen, breast, thyroid, and RUQ will be shown with original posters. 3) Discussion of VSI lung, obstetric, breast, thyroid, and RUQ VSI protocols and their applications in low-resource settings. 4) Public health perspective on the use of VSI teleultrasound. 5) Medical-legal considerations of the use of teleultrasound.

INEE-10   Real World Evidence: What Do Radiologist Need To Know?

Participants
Daniel Poon, MBBS,FRCR, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

Real-world evidence (RWE) methodologies are a powerful tool for assessing the effectiveness, safety, and economic benefits of pharmaceuticals in clinical practice. Indeed, RWE is increasingly being used by the FDA (Food and Drug Administration) and EMA (European Medicines Agency) for regulatory decisions, including in the arena of medical devices and novel digital health tools.The use of RWE is likely to grow within radiology; for example, it is anticipated that the RWE approach to evidence generation will be an invaluable method to ascertain the real-world utility of AI within radiology. Furthermore, contemporary radiology provides ample potential sources of real-world data (RWD), with PACS being a primary example.We present a primer of the basic principles of RWE for the practising radiologist, to enable an understanding into the potential use cases of RWE in radiology. We also hope that a basic understanding of RWE will encourage our profession to be stalwarts of appropriate use of radiological data in all its forms.

TABLE OF CONTENTS/OUTLINE

What is RWE?Current uses of RWEWhat are the sources of real world data in radiology?What are the potential uses of RWE in radiology?What do I need to know as a radiologist?

INEE-11   Overcoming Data Shift: The Challenge To Translating AI To Clinical Practice

Awards
Identified for RadioGraphics

Participants
Youngwon Choi, Los Angeles, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) We will describe data shift and its negative impact on generalizability and clinical translation of ML models. 2) We will introduce mitigation strategies to detect and account for data shift, in particular explainability and domain knowledge.

TABLE OF CONTENTS/OUTLINE

1) Data shift description and example of its negative impact on clinical translation; 2) Mitigation strategies overview with example; 3) Importance of explainability in various AI models; 3-1) CNN for idiopathic pulmonary fibrosis (IPF) diagnosis within an interstitial lung disease (ILD) population; 3-2) CNN for prostate organ/tumor segmentation; 4) Converting domain knowledge to CNN feedable form; 4-1) ML-feature-based population maps from quantitative CT biomarkers among patients with ILD; 4-2) Radiology-based population maps of tumor occurrence in the prostate; 4-3) Pathology- and radiology-based population maps for non-visualized prostate cancer lesions; 5) Improved CNN training with domain knowledge; 5-1) Attention-gated CNNs guided with population maps;

5-2) Robust CNN for IPF diagnosis within an ILD population; 5-3) Robust CNN for prostate tumor segmentation; 6) Post-training interpretation; 6-1) Robustness of CNN for IPF diagnosis example with different image protocols; 6-2) Robustness of CNN for prostate tumor segmentation with different staging scores

INEE-12 Outsmarting AI: What Role Can The Radiologist Play In The Making And Deployment Of Artificial Intelligence Applications

Awards
Certificate of Merit

Participants
Tianyuan Fu, MD, Cleveland, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Provide radiologists an overview of the process of developing an AI based tool and deploying it in a clinical setting. This includes identifying a problem which the AI tool is designed to solve, obtaining a representative and unbiased dataset, preprocessing and labeling of data, designing and training the algorithm, and validating the AI tool in a specific clinical setting. 2) Identify points in this process in which radiologists, in particular those without a technical background, can get involved. 3) Discuss resources for radiologists to learn about the development of AI tools.

TABLE OF CONTENTS/OUTLINE

1) Overview of the steps to develop and deploy an AI based image analysis tool in the clinical setting. For each of the following steps, emphasize the role the radiologist could play. 2) Step 1: Defining the problem that we are trying to solve. 3) Step 2: Obtaining a sufficiently large, representative, and unbiased dataset. 4) Step 3: Data labeling and defining an appropriate ground truth. 5) Step 4: Design and train a deep learning algorithm. 6) Step 5: Validation and deployment of the AI tool in a clinical setting. 7) Summary of the role of radiologists in the aforementioned process. 8) Resources on the process of AI development for the curious radiologist.

INEE-13 Structured Reporting And Natural Language Processing: A Successful Marriage

Participants
Salvatore Fanni, MD, Pisa, Italy (*Presenter*) Nothing to Disclose

TEACHING POINTS

Structured reporting has showed to be an added value in radiologists work, standardising language and relevant findings specifically for different clinical scenarios. Structured reporting provides completeness, comparability and lead to analysis of a large amount of data so far underutilized. However, most radiologists still prefer free-form text reports, due to the lack of time and integration of structured reports in Radiology Information System.Natural language Processing (NLP) is an area of research that explores how to understand and analyse free-form text or speech to complete specific tasks. Artificial Intelligence has been implemented to process NLP features extracted from the text, outperforming traditional NLP methods. Convolutional or Recurrent Neural Network (CNN - RNN) are the most used models to process NLP features.Natural Language Processing and Artificial Intelligence showed us that "Reports are more than words, they are data". NLP could be a brilliant solution to achieve structured reporting in clinical daily practice, producing automatically structured reports from free-form text reports.

TABLE OF CONTENTS/OUTLINE

1. Structured reporting in radiology, relevance in clinical practice and current application 2. Basic concepts of Natural language Processing: features extraction and processing 3. Applications of NLP in Radiology, up to date overview 4. NLP and structured reporting: a successful marriage 5. Future perspectives

INEE-14 Establishing A Hospital-based Quality Control System For 3D Printed Anatomic Models

Participants
Nicole Wake, PhD, Bronx, New York (*Presenter*) Employee, General Electric Company

TEACHING POINTS

1. The workflow to create 3D printed anatomic models is complex and errors can occur at any step during the process.2. The accuracy of 3D anatomic mesh geometries may be ensured by overlaying contours of the regions of interest onto the volumetric medical images.3. Coupons/phantoms with specific geometries may be created and printed to ensure the printing process is accurate.4. Quality Assurance of 3D printed anatomic models can be performed by incorporating visual inspection, caliper measurements, surface scanning, or CT scanning after printing.5. Sterilization of anatomic models is necessary for models that come in contact with patients during operating procedures; and sterilization may affect the material properties of a final 3D printed model.

TABLE OF CONTENTS/OUTLINE

1. Summary of the typical workflow utilized to create 3D printed patient-specific anatomic models.2. Overview of verification and validation steps required to ensure the required accuracy of 3D printed medical models is achieved.3. Revision of methods used to assess geometrical and dimensional accuracy of 3D printed anatomic models.4. Synopsis of biocompatible materials and sterilization techniques commonly used in hospitals.5. Assessment of possible effects of the sterilization on the accuracy and mechanical properties of the 3D printed medical models.

INEE-15 Onboarding To The RSNA-ACR 3D Printing Registry

Participants
Nicole Wake, PhD, Bronx, New York (*Presenter*) Employee, General Electric Company

TEACHING POINTS

1. The joint RSNA-ACR 3D Printing Registry addresses the need for coordinated tracking of medical 3D printing.2. The registry collects anonymized case information on 3D printing efforts for clinical applications.3. Data entry for the registry includes information about case types, image acquisition, image segmentation, and printing.4. The registry will facilitate institutional quality

improvement efforts.5. Information collected from this registry will be used to show that there is widespread use of 3D printing in medicine and to support an application for Category I CPT Codes for 3D printed anatomic models and guides.

TABLE OF CONTENTS/OUTLINE

1. Overview of medical 3D Printing.2. Introduction to the RSNA-ACR 3D Printing Registry.3. Explanation of application process.4. Description of data dictionary and case submission.5. Benefits of registry participation.

INEE-16   Establishing A 3D Imaging Laboratory Within A Publicly-funded Academic Clinical Center In A Low-resource Country

Awards
Certificate of Merit

Participants
Silvina Zabala Travers, MD, Montevideo, Uruguay (*Presenter*) Nothing to Disclose

TEACHING POINTS

It is commonly believed that implementation of 3D technologies such as 3D biomodel navigation, virtual surgical planning and simulation with 3D printing models in the surgical planning workflow is expensive in terms of software, hardware and human resources. The purpose of this exhibit is to demonstrate step by step how we established a 3D laboratory in a publicly-funded academic clinical center in a low-resource country. Our aim is to encourage and provide tools to radiologist in a similar situation to establish their own laboratory. We review available education and leverage tools for radiologists, free software tools and possible workarounds for financial limitations. We present example 3D cases.

TABLE OF CONTENTS/OUTLINE

1)Our research survey results about considered causes for lack of 3D widespread use in Iberoamerica. 2)Review our experience setting up a 3D lab in a radiology department from a low-resource Latin-American publicly-funded academic clinical center. 3)Review available education and leverage tools for radiologists. 4)Review free open source software options for segmentation and 3D navigation. 5)Discuss possible workarounds to overcome financial limitations for hardware acquisition or hiring human resources. 6)Tips for your first steps. 7)3D biomodeling example cases from our 3D lab

INEE-18   RadLex For Semantics And Interoperability In Imaging Workflows

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Leonid Chepelev, MD,PhD, Ottawa, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

a. Radiologists benefit from the interoperability enabled by standard terminology.b. RadLex comprises standard imaging terminology and conceptual relationships between these terms, including anatomy, pathology, imaging techniques, contrast agents, imaging findings, interventions, imaging assessment categories, and many others.c. RadLex supports numerous applications, including text search, natural language processing, procedure coding, structured reporting, patient follow-up, big data integration, software interoperability, and teaching.d. RadLex provides standard terminology in image and text annotation for machine learning.e. Formalizing knowledge in an ontology facilitates the practice of Radiology

TABLE OF CONTENTS/OUTLINE

1. The role of RadLex as a key RSNA initiative.2. What is Radlex and what is an ontology?3. Benefits of representing practical clinical knowledge as an ontology a. Clinical Decision Support b. BI-RADS c. Diagnoses with actionable consequences4. How do ontologies allow us to discover deeper meaning in medical data?5. Practical Applications of RadLex a. Structured Reporting b. Report Search c. Education d. ACR Dose Index Registry e. RSNA-ACR Common Data Elements f. Cancer Care Ontario g. LOINC6. Tools in Ontology Development7. RadLex in the future of Radiology a. Personalized Medicine b. Big Data Integration c. Artificial Intelligence Integration

INEE-19   Basic Python For Advanced Radiologists

Participants
Eduardo Chiovatto, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

At the end of this presentation, you will be able to:-Learning about basics of Python and start to practice, with simple lessons and review with concepts of Python-To discuss how Python could help to create an algorithm to use for artificial intelligence models.-To develop, step by step, a Dicom viewer by Python.

TABLE OF CONTENTS/OUTLINE

-Introduction.-ObjectiveLearn basics about python.-How to start python.-Relationship with Artificial intelligence.- Development of a Dicom viewer with python.- Learn about the main difficulties and solutions.

INEE-2   Applications Of Artificial Intelligence In Cardiac MRI

Participants
Prabhakar Rajiah, MD, FRCR, Rochester, Minnesota (*Presenter*) Nothing to Disclose

TEACHING POINTS

The role of Artificial Intelligence (AI) in cardiac imaging continues to expand. It is now used in almost all aspects of cardiac MRI.1. To provide an overview of the basic principles and algorithms of AI.2. To discuss the role of AI in cardiac MRI3. To review and

illustrate the applications of AI in cardiac MRI

TABLE OF CONTENTS/OUTLINE

IntroductionDefinitions- AI, Machine learning, deep learningNetworks used in AI- Convolutional neuronal network (CNN), general adversarial network (GAN)Clinical applications of AI in cardiac MRI- Illustration with case examples.A. Image acquisition- MRI plane prescriptionB. Image reconstruction- Decreased artifacts- Decreased noise- Improved resolution- Super resolution- Decreased acquisition timeC. Segmentation of structures- Ventricular volumes, MRAD. Automated quantification- Volumes, function, scar, parametric mapping, flow, strain, aortic diameterE. Post-processing- 4D flowF. Classification (Diagnosis) of disease- Cardiomyopathy, Myocardial infarction, coronary artery disease, atherosclerosis, valvular disease, heart failureG. Prognostic factors- Risk stratificationH. RadiomicsI. Automated reportingChallenges & pitfallsFuture directionsConclusion

INEE-20   **Radiomic For Dummies : Image Texture Analysis And Much More**

Awards
Certificate of Merit

Participants
Charly Girot, DIPLENG,MS, Villejuif, France (*Presenter*) Nothing to Disclose

TEACHING POINTS

Radiomic is an image analysis process to develop quantitative imaging biomarkers. It relies, among others, on texture analysis. In the multi-step process of radiomic, 5 families of features can be identified: shape, intensity histograms, texture, filters, and fractals. Among these families, texture aims to analyze image heterogeneity patterns by analyzing pixels gray level spatial distribution in an image. Texture features are extracted from 4 matrix describing respectively recurrence of pairs of pixels (GLCM), pixel sequences (GLRLM), zones of same pixel intensity (GLZLM) and differences between a pixel and its neighbors (NGLDM). One of the main radiomic features extraction software, that we use as an example, is LIFEx (www.lifexsoft.org). Generally, recommendations for the validation of radiomic-based imaging biomarkers are now well described in the literature. It must rely on a technical validation in multi-centric studies (robustness), a clinical and biological validation (comparison to gold-standard) and a final validation in a prospective clinical study. With the fast-evolving field of deep-learning, radiomic can now make use of model-defined features instead of user pre-defined features.

TABLE OF CONTENTS/OUTLINE

After a review of what is radiomic, each family of available features will be described. LIFEx will be used as an example to illustrate the process of features extraction in a radiomic pipeline. Finally, recommendations on how to develop an imaging biomarker and associated guidelines will be reviewed.

INEE-21   **3D Printing And Augmented Reality (mixed Reality): A Combination Of Two Promises Technologies For Image-guided Neurosurgery.**

Participants
Vitor M. Sardenberg, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) 3D printing in neurosurgery has the potential to be applied to accurate replicate anatomic detail of native cranial vessels and vascular lesions, such as aneurysms, arteriovenous malformations and dissection. 2) The integration of images information into the real surgical environment, through augmented reality, can be very useful for surgeons, providing simple and easy solutions for neurosurgical procedures and supporting the transfer of preoperative plans to the surgical field. 3) Brain tumors visualization by AR can be well succeeded independently of tumor sizes and localizations. 4) Mixed reality in neurosurgical procedures can help to determine the relation between mass lesions and important brain vessels, such as the internal carotid arteries, cerebral arteries and superior sagital sinus.

TABLE OF CONTENTS/OUTLINE

- Review 3D printing techniques. - Review the most common congenital and acquired vascular anomalies of the brain, in which 3D Printing and AR could have a potential to influence the surgical planning. - Review the 3D printing applications in neurosurgery, especially in vascular lesions and in the study of the relation between brain tumors and vascular structures. - Review the potential role of AR in neurosurgical planning, and discuss the use of Apps such as M3DMIX. - Review the main advantages of mixed reality in neurosurgery.

INEE-22   **Applications Of Domain-Inspired Radiomics And Deep Learning In Neuroradiology**

Participants
Tejasvi Kainth, MD, Stony Brook, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Develop an understanding of domain-inspired radiomics pipelines and its key components.- Appreciate the role of deep learning models in providing early diagnostic and prognostic information to tailor patient-specific treatment plans.- Discuss the role of Radiomics and Deep Learning algorithms in providing predictive information about treatment outcomes in glioblastoma multiforme and medulloblastoma.- Outline current limitations and explore future directions of using Radiomics in oncology.

TABLE OF CONTENTS/OUTLINE

- Introduction to Radiomics Workflow- Introduction to Deep Learning algorithms- Role of Radiomics and Deep Learning in cancer diagnosis and staging- Role of Radiomics and Deep Learning in predicting treatment response- Limitations of Radiomics and Deep Learning- Future directions- Conclusion

INEE-23   **3d Printing In Gynecological Microanatomy And Pathology Using Microtomography**

Participants
Pedro Castro, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

1) MicroCT: non-destructive imaging tool for the production of high-resolution 3D images composed of 2D axial projections of a target specimen2) Micro-CT has grown as a technique with potential for clinical purposes in many areas of human health 3) It can provide highly accurate 3D rendering of human gynecological organs and its complex 3D anatomy

TABLE OF CONTENTS/OUTLINE

1)Review the use of microtomography in human specimens 2) Review the use of microtomography in clinical practice and medical education 4) Demonstrate the images generated by the technique in gynecological specimens 5) Demonstrate the potential of 3D printing of microscopic specimens in medical education

INEE-24 Clinical Implementation Of Deep Learning Models In A Large Multicenter Mammography Practice: A Practical Guide To Establish Robust Infrastructure For Continuous Learning

Participants
Constance Lehman, MD,PhD, Boston, Massachusetts (*Presenter*) Institutional Grant, General Electric Company;Institutional Grant, Hologic, Inc;Co-founder, Clairity, Inc.

TEACHING POINTS

With rapid expansion of artificial intelligence (AI) in the imaging sciences, deep learning (DL) models have been developed to support improved workflow, image acquisition, triage and interpretation. In this relatively early phase of AI in healthcare, emphasis has been on model training; fewer than 10% of models have undergone rigorous external validation and even fewer have been deployed in routine clinical practice.?The resources needed for clinical implementation are significantly different than those required for model development. Clinical IT support and clinical radiologists' engagement are critical for successful implementation and continuous improvement. There are limited examples of potentially transformative techniques being successfully deployed at full scale in clinical practice. This exhibit explores a real-world example of how we translated our breast imaging DL models into routine clinical practice, across multiple screening sites of a large academic medical center.

TABLE OF CONTENTS/OUTLINE

• Infrastructure to support model development to assess breast cancer risk from a screening mammogram alone • Key elements of robust infrastructure for clinical implementation of DL models to support "real time" immediate score availability to clinical radiologist • Pearls and Pitfalls of "Go Live" clinical implementation

INEE-25 Extended Reality And Arterial Intelligence For Precision Telemedicine And Spatial Education

Participants
Maki Sugimoto, MD, PhD, Tokyo, Japan (*Presenter*) Officer, Holoeyes Inc

TEACHING POINTS

) To learn the utilization of XR (virtual-augmented-mixed reality) in medical imaging. 2) To learn how to segment and export polygons of targeting organs from DICOM data from CT or MRI. 3) To learn how to select and use XR devices and applications. 4) To show illustrative examples of XR, such as in medical education, surgical planning, surgical simulation, and intraoperative navigation. 5) To learn how to use XR and A.I. to improve visual-spatial ability to mentally manipulate medical anatomy in three dimensions associated with performance on practical examinations. 6) To learn Precision Medicine by selecting radiological analysis of patient's individual medical imaging data.

TABLE OF CONTENTS/OUTLINE

1. Terminology: The representative forms such as XR (VR/AR/MR) are referring to all real-and-virtual combined environments and human-machine interactions generated by computer technology and wearables. 2. Beneficial applications of the XR devices. 3. How to integrate the spatial imaging system by interactive superimposing 3D holograms. 4. Effectiveness: Enhancing scene visualization is a feasible strategy for augmenting spatial awareness in complex anatomy education. For surgery, this reduces the length of the operation and discussion time.

INEE-26 A New Jungle Is Sprouting. It'S Not Entirely Radiologist Friendly. How AI Algorithms Mark-up Findings On Chest Radiographs?

Participants
Parisa Kaviani, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. One to 124 and counting - number of detectable findings with artificial intelligence (CXR-AI) algorithms for assessing chest radiographs is expanding. 2. Heatmaps, boxes, free-hand, arrows - many ways CXR-AI algorithms mark-up findings. 3. Not all markup options are good options - What can and can't work for CXR-AI mark-up. 4. Color, percentage, Likert scale of confidence - how CXR-AI algorithms display or not (for some algorithms) their confidence for presence of findings

TABLE OF CONTENTS/OUTLINE

1. Landscape of FDA-cleared and EU-cleared CXR-AI algorithms: Triage, detection, characterization and quantification of findings 2. What are the assessable findings with different CXR-AI algorithms? 3. Multi-vendor CXR-AI examples of how positive and negative findings are displayed and/or documented. 4. Examples of how CXR-AI algorithms quantify some findings 5. Display of AI confidence on presence of findings 6. If and how CXR-AI should communicate with radiology reports interface 7. Survey and ideas of "what radiologists want" from display format

INEE-27 Quality Management Considerations For Hospital-based Anatomical 3D Printing

Participants
Rami Shorti, PhD, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

TEACHING POINTS

Teaching Points • Understand the forces driving the need for the quality assurance program in a hospital-based 3D printing program

Teaching Points - Understand the forces driving the need for the quality assurance program in a hospital-based 3D printing program • Describe the basics of a Quality Management System (QMS) and practices implementation • Discuss the key quality control checks considerations within stem of the 3D printing process • Dive deeper into the quality control implications at each key step • Layout a simplified quality control considerations and checklist • Identify opportunities for early success in quality control implementation 3D printing at point-of-care • Identify quality control resources for continued QMS improvement

TABLE OF CONTENTS/OUTLINE

• Background: Quick history and forces driving the Quality Management System (QMS) programs for hospital-based 3D printing programs • QMS Basics • Key 3d printing QA check points: The QMS program is based on evaluating accuracy and recognizing and mitigating errors at each major step of the 3D printing process. Standard Operating Procedures (SOP) can be developed for each of these steps. These steps include: o image acquisition o image segmentation o cad processing o 3d printing o cleaning & post-processing • Implications of 3d printing QA check points • Simplified quality assurance considerations and checklist • Opportunities for early success • Quality assurance continuous improvement

INEE-28   Strengths, Weaknesses, Opportunities, And Threats (swot) Analysis Of Ai Algorithms In Abdominal Radiology

Participants
Asser Abou Elkassem, MD, Birmingham, Alabama (*Presenter*) Nothing to Disclose

TEACHING POINTS

- AI algorithms can be categorized into three main categories (black box, explainable, and transparent) based on the abdominal radiologist's ability to interpret the output - The strengths of AI include: detection of image findings, image segmentation and measurement, classification of image findings and exams, image reconstruction, and analysis of big data and radiomics- The weaknesses of AI include: difficulty in annotating data sets, difficulty in integrating AI into clinical workflows, inability to understand the mechanism of action of blackbox AI algorithms, narrowness of AI, brittleness of AI, and limited ability to detect failures for blackbox AI algorithms.- The opportunities of AI include: improvements in key domains (accuracy, efficiency and standardization), reduction in errors, and the potential for big data analysis.- The threats of AI from the abdominal radiologist's perspective include: negative perception (by trainees, clinicians and patients) and the disruption of the abdominal radiologist's job with the potential to replace certain aspects

TABLE OF CONTENTS/OUTLINE

- Introduction to artificial intelligence terminology and algorithm categorization from the abdominal radiologist's perspective - Review and categorization of current and future AI algorithms in abdominal radiology - Review the strengths, weaknesses, opportunities and threats of AI algorithms in abdominal radiology

INEE-29   3D Slicer: An Open Source Software Platform For Medical Image Analysis, 3D Visualization, And Image-Guided Therapy

Participants
Sonia M. Pujol, PhD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

3D Slicer is an open-source software platform used in clinical research worldwide. The platform provides over 300 modules and extensions for multi-modal data analysis, 3D visualization, and image-guided therapy. The goal of the exhibit is: 1. To learn how to import and export DICOM data; 2. To visualize GPU-based volume rendering; 3. To learn how to perform interactive segmentation of 2D/3D/4D data; 4. To generate ground truth training datasets for Deep Learning applications; 5. To discover Slicer AI-assisted automatic segmentation; 6. To learn Radiomics feature extraction; 7. To run Slicer in a web browser, Docker container, or Jupyter notebook kernel; 8. To use Slicer server modes for cloud-based quantification; 9. To explore interactive 3D views in virtual and augmented reality; 10. To create 3D solid objects for 3D printing; 11. To gain knowledge on real-time data fusion for surgical navigation and image-guided therapy; 12. To understand how to use 3D Slicer in clinical research applications.

TABLE OF CONTENTS/OUTLINE

Overview of the 3D Slicer platform; DICOM standard interoperability; Advanced GPU-based volume rendering; Interactive 2D/3D/4D image segmentation; 3D Markups and automated measurements; Artificial Intelligence; Radiomics; Quantitative Imaging; Cloud Computing; Virtual and Augmented reality; 3D Printing; Clinical applications in Radiology and Image-Guided Therapy; Community Resources: Slicer Forum, Slicer Documentation, and Slicer Training Compendium.

INEE-29-HC   Use Of 3D Printed Patient Specific Vascular Phantoms To Optimize The Neuro-interventionalist Mechanical Thrombectomy Approaches

Participants
Kelsey Sommer, Buffalo, New York (*Presenter*) Stockholder, QAS.AI

TEACHING POINTS

1. Learn how to use patient specific 3D neurovascular anatomical models with ex-vivo clots to simulate large vessel occlusions.2. How to use a benchtop flow study for mechanical thrombectomy simulation using 3D printed models.3. Understand the challenges related to patient anatomy, clot properties and occlusion location to optimize the interventional approach using 3D printed patient specific models. 3D-printed vascular models allow replication of complex neurovascular structures with high accuracy for neuro-interventional simulations. In this project we present a novel approach that combines 3D printing with patient specific anatomical variants for accurate simulation of acute ischemic stroke (AIS) from large vessel occlusion (LVO) treated with mechanical thrombectomy (MT).

TABLE OF CONTENTS/OUTLINE

• 3D-printing of neurovascular models for image guided neuro-interventions simulations • Large vessel occlusion simulations using clots with different mechanical properties • Middle cerebral artery (MCA) region large vessel occlusion • Neuro-intervention simulations within MCA • Understand the interventional challenges related to the patient anatomy, clot location, clot mechanical properties and geometry on the clot • Use neuro-intervention simulations to optimize the mechanical thrombectomy approach

INEE-3   Undergraduate Medical Student Radiology Teaching During Covid-19: What Has Changed And What Will Continue Post-pandemic?

Participants
Nikhil Patil, Waterloo, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Review evidence-based strategies for delivering effective and well-received virtual radiology lectures in pre-clerkship and clerkship.2. Review changes that have been made to radiology clerkship rotations and electives in the pandemic setting.3. Discuss the advantages and disadvantages of changes made to the delivery of undergraduate radiology curricula during the COVID-19 pandemic by medical educators, and suggest which strategies may persist post-pandemic.

TABLE OF CONTENTS/OUTLINE

1. Virtual delivery of core curriculuma. Remote synchronous and asynchronous lectures- Tips for designing PowerPoint slides- Audience polling- Gamificationb. Flipped classroom model- Interactive small group workshops- Incorporation of online resourcesc. Testing and invigilation strategies2. Modified radiology rotations and electivesa. Virtual electives- Virtual case-based interactive sessions and lecturesb. Pre-recorded self-directed lecture seriesc. Simulation technologies3. Benefits and drawbacks of virtual teaching in radiologya. Increased attendance at teaching sessionsb. Heightened interest in radiology as a specialtyc. Emphasis on self-directed learningd. Suitability for distance learninge. Networking and professional development4. What educational strategies will survive post-pandemic?

INEE-30-HC Move Away HIPAA And GDPR, Here Comes CrypTFlow - Secure AI Inferencing Without Data Sharing

Participants
Vidur Mahajan, MBBS, New Delhi, India (*Presenter*) Researcher, CARING;Research collaboration, General Electric Company ;Research collaboration, Koninklijke Philips NV;Research collaboration, Qure.ai;Research collaboration, Predible Health;Research collaboration, Oxipit;Research collaboration, Synapsica Healthcare Inc;Research collaboration, Quibim

TEACHING POINTS

• Currently, running Artificial Intelligence (AI) algorithms on medical images requires either the sharing of medical images with developers of the algorithms, or sharing of the algorithms with the hospitals. Both these options are sub-optimal since there is always a real risk of patient privacy breach or of intellectual property theft. • Encryption is the process of converting data into a "secret code" using a "key" making the data meaningless for anyone without the key. The challenge is that, with current technology, the key needs to be shared with the AI developer, so that the data can be converted to its meaningful form, thereby compromising the security and privacy of the data. • We propose using CrypTFlow, which uses Multi-Party Computation and encryption to run AI algorithms on medical images without sharing the encryption key described above. This means that the images remain in the hospital network, the AI algorithm remains in the AI developer's network, but the AI is still able to run on the images. • We will present the results of our experiments of running CheXpert, an AI algorithm, on Chest X-Rays.

TABLE OF CONTENTS/OUTLINE

• Current privacy and intellectual property concerns with deploying AI algorithms in clinical practice • What is encryption? • What is multi-party computation (MPC)? • What is CrypTFlow and how can it help run AI algorithms without requiring data to be shared with AI developers? • Results of running CheXpert AI algorithm using CrypTFlow - accuracy, time and computation - The Future of secure AI deployment

INEE-31   Continual Learning For Diagnostic Radiology

Participants
Camila Gonzalez, MS, Darmstadt, Germany (*Presenter*) Nothing to Disclose

TEACHING POINTS

The abstract will provide an overview of continual learning, the practice of training deep learning models with a sequence of distinct tasks, for diagnostic radiology. Continual learning is a major paradigm shift which the FDA is actively trying to regulate. In diagnostic radiology, where a variety of scanners and acquisition protocols are used, training continuously allows to leverage heterogeneous data sources while adhering to privacy constraints.We will start by describing why it is often necessary to train models continuously in the clinical practice and how continual learning differs from the static learning setup used in most deep learning evaluations. To illustrate the challenges and opportunities that continual learning poses, we will clarify the concepts of catastrophic forgetting and transferability, as well as summarize current regulatory efforts.A taxonomy of continual learning scenarios and a summary of common continual learning strategies and model architectures will also be introduced. Finally, we will outline how to carry out a thorough continual learning evaluation.

TABLE OF CONTENTS/OUTLINE

1. Motivation of continual learning in diagnostic radiology2. Continual vs. static learning3. Current regulatory guidelines for continual learning4. Understanding continual learning opportunities and challenges: catastrophic forgetting and transferability5. Continual learning scenarios6. Common continual learning strategies and model architectures7. Properly evaluating a continual learning approach

INEE-32-HC Collaborative Learning Approaches For Privacy Preserving Deep Learning Using Multi-institutional Data

Awards
Identified for RadioGraphics

Participants
Jayashree Kalpathy-Cramer, MS, PhD, Charlestown, Massachusetts (*Presenter*) Institutional Research Grant, General Electric Company;Institutional Research Grant, F. Hoffmann-La Roche Ltd

TEACHING POINTS

Deep learning methods have been shown to be brittle. In this educational exhibit, we will provide a motivation for the need of

institutional datasets to train robust and generalizable models using breast density estimation from mammograms and analysis of chest X-rays for COVID-19 as use cases.We will review multiple technical approaches for collaborative learning including the popular federated learning, cyclical weight transfer and split learning. We will discuss the advantages and limitations of these methods and recommend best practices for different scenarios.We will then discuss open-source options to ease setting up collaborative learning across institutions. We will review lessons learning from multiple large-scale national and international projects.Finally, we will discuss considerations for setting up consortia of collaborative learning sites including agreements on clinical questions, data annotation and interoperability, machine learning architecture, as well as issues around authorship and IP.

TABLE OF CONTENTS/OUTLINE

Motivation: brittleness of deep learning methods and need for multi-institutional training.Methods: discussion of the different technical approaches for collaborative learning including federated learning, distributed learning and split learning.Infrastructure and frameworks: discussion of the logistics for collaborative learning including open-source toolkits.Lessons learned: discussion of lessons learned from real-life multi-institutional federated learning projects

INEE-33-HC Image Quality And Higher Resolution Of Latest Monitor/TV Screens. Essential Toolkit For Radiologist In Image Preparation For Scientific Presentations.

Awards
Certificate of Merit

Participants
Antonio Nunziata, MD, Naples, Italy (*Presenter*) Nothing to Disclose

TEACHING POINTS

The technological evolution of screens, monitors, TVs and digital projectors has allowed an increasingly high resolution (HD, FullHD, 4K, 8K). The images prepared at 72/96 dpi for the old screens are no longer sufficient to guarantee acceptable quality. We give the radiologist an essential guide on image preparation for scientific presentations on the latest screens with higher resolution.

TABLE OF CONTENTS/OUTLINE

The screen resolution is measured in reference to the number of horizontal and vertical lines. A 4K screen with 16/9 aspect ratio has 3840 vertical lines (from which the 4K parameter, approximately 4000, mostly used in TVs) and 2160 horizontal lines (from which the parameter 2160p used mostly in computer screens). The number of lines is independent from the geometric size of the screen. A 20" and a 65" screen have the same number of lines, and therefore the same resolution. The intersections of the vertical and horizontal lines can be compared to the pixels of digital images. So a digital image, to be faithfully represented on a 4K screen, must have at least 3840 x 2160 = 8.3 Mpx. The various resolutions and aspect ratio of the screens, the various digital images, the various color modes, the effects of compression on the image quality and a final toolkit for the optimal preparation of the images are illustrated in uploaded pdf.

INEE-34-CS Chest Cinematic Rendering: An Interactive Universal Application Approach To Anatomy Education

Participants
Sara Raminpour, BS, Baltimore, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

After reviewing this exhibit, users will:1. Understand how photorealistic 3-D CT images created by CRT (cinematic rendering technique) can be used in novel ways in medical trainees' education.2. Improve their knowledge of chest normal anatomy using 360 interactive tutorial displays of anatomic structure.3. Enhance their learning experience with a self-assessment section.

TABLE OF CONTENTS/OUTLINE

1. Home: presents a brief overview of CRT (cinematic rendering technique) and the entire app.2. Normal Anatomy Tutorial: demonstrates a pattern-based approach to chest anatomy, using an organ system-based approach; each section provides illustrations, an interactive 360 visualization, and a discussion. A. Muscle - lower neck, chest wallB. Bone - vertebrae, ribs, sternumC. Lungs- airways, lung parenchymaD. Vascular - arterial, venousE. Cardiac - pericardium, valves, chambers, coronary arteries3. Quiz: provides a self-assessment of 41 various questions in 5 main organ systems of the chest. Users will be able to get their scores by submitting their answer to each question.

INEE-36-CS Using The Open Health Imaging Foundation (OHIF) Framework To Build Web-based Imaging Applications

Participants
Erik Ziegler, MSc,PhD, Boston, Massachusetts (*Presenter*) Consultant, Radical Imaging LLC;Consultant, Novometrics LLC

TEACHING POINTS

The purpose of this exhibit is to:1. Explain how radiologists can build their own imaging tools and applications using the open source Open Health Imaging Foundation (OHIF) framework to address their custom use cases.2. Discuss the components of a full fledged zero-footprint web-based imaging application and how they interact using various APIs (e.g. DICOMweb).3. Explain how advanced functionality, such as 3D visualization, image fusion, and segmentation, can be incorporated in these applications.4. Demonstrate how to organize specific function sets into custom workflow modes for optimizing efficiency5. Demonstrate how this type of system can be deployed both securely and cost effectively.

TABLE OF CONTENTS/OUTLINE

- Open source resources for radiology and AI applications- Relationships between components in web imaging applications- Building custom measurement toolsIncorporating advanced visualization and segmentation tools- Building custom workflow modes for the OHIF Viewer (e.g. configuring the application to provide functionality for use cases like ProstateCancer.ai, NCI Imaging Data Commons, XNAT)- Deploying scalable secure web imaging applications locally or using cloud resources- Future directions

INEE-37-CS NCI Imaging Data Commons: Status Update

Participants

Andriy Fedorov, PhD, Arlington, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

The National Cancer Institute's (NCI) Cancer Research Data Commons (CRDC) aims to establish a cloud-based data science infrastructure. The Imaging Data Commons (IDC) is a component of CRDC to enable access and exploration of de-identified imaging data, and to support integrated analyses with non-imaging data available in other components of CRDC, such as genomics and proteomics repositories. IDC uses a combination of commercially available Google Cloud Platform and open source components. IDC relies on the DICOM standard to harmonize both imaging and image-derived data. As CDRC grows, imaging datasets will be cross-linked to genomic, proteomic, and clinical data about the subjects. The IDC portal is available at https://imaging.datacommons.cancer.gov, and integrates a customized web viewer for visualization of images and image annotations. Production release of IDC is planned for Fall 2021, and will include all of the public TCIA collections. In this exhibit the attendees will learn about the scope and status of IDC, its role within CRDC, and the plans for future development, including support of digital pathology, annotations and derived data.

TABLE OF CONTENTS/OUTLINE

Overview of CRDC and IDC; Data curation and the role of The Cancer Imaging Archive; Portal; Viewer; Organization of data; Data versioning; Integration of tools; Use case development; Documentation and user support resources; IDC cloud credit program; Status update and plans for future development.

INEE-38-CS Training Visuospatial And Visuomotor Skills For Ultrasound Imaging With A Game

Participants
Lukas Mayer, MSc, Flensburg, Germany (*Presenter*) Nothing to Disclose

TEACHING POINTS

This hands-on exhibit will allow attendees toa) experience a simulation-based ultrasound training tool that focuses on simple non-anatomical objects that can be examined with a virtual ultrasound probeb) improve their visuospatial understanding of cross-sectional ultrasound image creationc) improve their visuomotor skills with regard to ultrasound probe handlingd) assess the benefits of using gamification elements in a training toole) learn how educational games can be developed for medical imaging with a game engine

TABLE OF CONTENTS/OUTLINE

A simulation based learning game for ultrasound imaging will be presented with the following content:1. Introduction: Using a virtual ultrasound probe to examine non-anatomical objects2. Minigames to train visuospatial and visuomotor skills (e.g., "Identify Object", "Recreate Slice")3. Game design elements (e.g., scoring system, campaign mode)4. Implementation of the game with the help a game engine

INEE-39-CS : The Federated Tumor Segmentation Initiative: The First Real-world Large-scale Federation Focusing On Neurooncology

Participants
Spyridon Bakas, PhD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

There is a growing body of literature offering evidence of the potential impact that artificial intelligence (AI) methods can have towards healthcare. To ensure robustness and generalizability of AI methods, ample and diverse multi-site patient datasets are desired. However, there are various factors that hinder access to such data in the current paradigm of multi-site collaborations, which include the tedious bureaucratic processes, data ownership concerns, and legal considerations reflected in patient privacy regulations. To tackle these issues, we introduce the Federated Tumor Segmentation (FeTS) Initiative, which includes an open-source software toolkit for data-private collaborative learning of AI methods across multiple international institutions using federated learning (FL). The goals of the exhibit are to: (i) broaden the understanding of the general community regarding FL, (ii) showcase how a user can leverage FL to train a model across various sites, (iii) present results of the first real-world federation across 50 collaborating sites, focusing on brain tumors, (iv) discuss privacy and data protection concerns and how FeTS hopes to solve it.

TABLE OF CONTENTS/OUTLINE

This exhibit will present a toolkit to define a FL-based model training problem and deploy it across multiple partnering sites, ensuring a data-private AI training paradigm. Specific principles to protect data privacy will be described, along with common pitfalls to avoid when performing an FL-based study.

INEE-4 Radiomics Analysis Using The Image Biomarker Standardization Initiative (IBSI): Benchmarks And Guidelines

Awards
Cum Laude

Participants
Martin Vallieres, PHD, Sherbrooke, Quebec (*Presenter*) Nothing to Disclose

TEACHING POINTS

Radiomic studies still suffer from severe reproducibility problems that prevent the routine use of these methods in clinical practice. For example, it was previously shown that differences in feature definitions and implementation workflows (e.g., interpolation) can lead to coefficients of variation as high as 150% for some texture features. To overcome these challenges, about 75 researchers from 25 institutions in 8 countries have now participated in the Image Biomarker Standardization Initiative (IBSI). For better reproducibility of high-throughput medical image analysis, the IBSI seeks to provide a standardized computation workflow for radiomics, as well as benchmark datasets and values. To achieve compliance with the IBSI standards, research teams have the possibility to calibrate their computation pipeline by performing benchmark tests designed by the IBSI team and described in comprehensive reference manuals. This presentation aims to facilitate this calibration process by explaining in detail the radiomics

computation workflow of the IBSI.

TABLE OF CONTENTS/OUTLINE

(1) IBSI tools: documentation, datasets and website; (2) Radiomics computation workflow of the IBSI; (3) IBSI benchmark tests explained; (3a) IBSI 1 - Phase 1: computing radiomics features without image processing; (3b) IBSI 1 - Phase 2: computing radiomics features with image processing; (3c) IBSI 2 - Phase 1: computing imaging filters; (3d) IBSI 2 - Phase 2: computing radiomics features from filtered response maps.

INEE-40-CS MIDRC: Medical Imaging and Data Resource Center

Participants
Maryellen Giger, PhD, Chicago, Illinois (*Presenter*) Advisor, Emalex Biosciences, Inc;Stockholder, Hologic, Inc;Royalties, Hologic, Inc;Shareholder, Quantitative Insights, Inc;Co-founder, Quantitative Insights, Inc;Shareholder, QView Medical, Inc;Royalties, General Electric Company;Royalties, MEDIAN Technologies;Royalties, Riverain Technologies, LLC;Royalties, Canon Medical Systems Corporation

TEACHING POINTS

Medical imagesplay an essential clinical role in the diagnosis, treatment and monitoring ofCOVID-19, because they provide quantitative information about the lungs andother organs that are targets of the virus. In response to the need for collection, artificial intelligence analysis, anddissemination of imaging and associated data, the American College ofRadiology (ACR), the Radiological Society of North America (RSNA), and theAmerican Association of Physicists in Medicine (AAPM) have jointly developedthe Medical Imaging and Data Resource Center, hosted at theUniversity of Chicago.

TABLE OF CONTENTS/OUTLINE

This multi-institutional initiative represents a model partnership spearheaded by the medical imaging community aimed at accelerating the transfer of knowledge and innovation, including clinical problem identification, discovery, development, evaluation, translation, implementation, and dissemination. This education exhibit explains the MIDRC model for data collection, organization and dissemination in support of AI-focused research on the imaging of Covid-19.

INEE-5 Users' Feedback Vs. Apple Analytics Statistics: A Challenge Ahead For Medical And Educational Ios Developers

Participants
Sara Raminpour, BS, Baltimore, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. An overview of App Store Connect and review of each data item that App Analytics and Sales and Trends provide for a single app.2. To present the frustration that developers encounter after publishing an app in terms of user feedback and analyzing statistics from different analytics.3. To compare App Analytics to Google Firebase Analytics in keeping track of user engagement with our app.4. To discuss statistical comparisons of free and paid apps and challenges ahead for each free app developer.

TABLE OF CONTENTS/OUTLINE

1. A brief overview of App Store Connect:A. Overview of App Analytics and its metrics.B. Overview of Sales & Trends and its metrics.2. Description of different ways the developers are able to get users' feedback and challenges they encounter to achieve reasonable data:A. Apple Rating and Review.B. Social Media Poll.3. A brief review of Google Firebase Analytics and how we can retrieve more helpful statistics from it in comparison to App Analytics regarding user engagements with an app.4. The challenges that free iOS app developers may encounter in getting a reasonable number of downloads.

INEE-6 Voice-triggered Macros - A Radiologist-friendly Method Of Increasing Productivity And Reducing Burnout

Awards
Certificate of Merit

Participants
Shawn Lyo, MD, Brooklyn, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

Macros are saved sequences of commands which are triggered by user defined inputs. Macros can reduce the biomechanical and attentional demands associated with performing multi-step tasks, and may potentially reduce repetitive stress injury and burnout . Tools such as AutoHotkey mostly utilize mechanical input for triggering macros; however, macros can also be triggered using speech recognition and user defined phrases. Voice-triggered macros are easy to remember and intuitive for radiologists who are more accustomed to dictation. We review the benefits and drawbacks of voice-triggered macros using the free software VoiceMacro, through demonstrations of multiple scenarios ranging from simple commands to advanced usage including integration with AutoHotkey.

TABLE OF CONTENTS/OUTLINE

I. What are macros and how can they make radiologists' lives easier a. Comparison of mechanical and voice triggered macros II. Macro demonstrations: a. Simple inputs i. EMR orders ii. PACS commands 1. Examples: Axial MIP iii. EMR Navigation 1. Examples: Switch directly to protocoling menu, surgical pathology b. Intermediate i. Communication 1. Telephone calls 2. Beeper paging 3. E-mail 4. Directory look up ii. Frequent reference lookup 1. Examples: TI-RADS calculator, Head and Neck anatomy atlas, etc. iii. Education 1. Study resources tied to dictation macros c. Advanced i. Advanced text manipulation 1. Calculate lesion volume from reported dimensions ii. Integration with AutoHotKey II. Potential for future integration with AI III. Conclusion

INEE-7 Deep Learning Reconstructions: Diagnostic Impact

Participants
Serageldin Kamel, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) DLR markedly reduces image noise and preserves image texture 2) Early evidence suggests significant capacity for rad dose reduction of 46-61% compared to hybrid IR, including for low contrast liver lesion detection task (albeit with lower reader confidence) 3) No free lunch; next gen DLR algorithms will need to address mild loss of high spatial frequency information in clinical images

TABLE OF CONTENTS/OUTLINE

1) Reconstruction Background - how did we get here? a) Reconstruction history b) Iterative recon (IR) limitations c) Unique QA issues for IR d) Case examples 2) What is DLR? 3) Phantom Evidence 4) Clinical Evidence 5) DLR Implementation a) Assessing your practice baseline b) Determining intended clinical tasks 6) DLR pitfalls 7) Conclusion

INEE-8   How Should Radiologists Use AI To Fight COVID-19 Pneumonia?

Awards
Cum Laude

Participants
Rintaro Ito, MD,PhD, Nagoya, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation

TEACHING POINTS

Pneumonia reported for the first time at the end of 2019 was caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). This is one of the diseases that radiologists are currently most interested in as COVID-19 pneumonia. The development of artificial intelligence (AI) in medical imaging is accelerating, and it is now applied to clinical practice. AI studies for COVID-19 pneumonia are being actively conducted. It would be the first time in history that AI research has been conducted worldwide for a single disease. In those studies, there are similarities, differences, good performance, and some problems. The next generation of radiologists will need to use AI properly. Knowing about the current AI research trends, development speed, and problems will help them become more familiar with AI.

TABLE OF CONTENTS/OUTLINE

There are three sections in the educational exhibit. The first section presents an overall analysis of AI studies of medical imaging performed on COVID-19 pneumonia. This section analyzes the study objectives, number of study data, number of COVID-19 cases, sensitivity, specificity, and Area under the curve (AUC). In the second section, we present an extract of AI studies with popular objectives and analyze each AI study. In the third section, we discuss the problems with AI studies on medical images with COVID-19 pneumonia.

INEE-9   Validation System For Mammography Using Deep Learning: Guarantee Of Appropriate Technique

Participants
Haruyuki Watanabe, PhD, Maebashi, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Breast cancer is the commonest cause of cancer death in women worldwide. Mammography (MMG) plays an important role in the early detection and assessment of patients. Guaranteeing the image quality of the MMG is necessary to maintain the accuracy of the diagnosis. However, diagnosis depends on the imaging techniques of operators, it shows the variability of diagnostic accuracy. Thus, we propose a deep convolutional neural network (DCNN) classification regarding the validation of mammogram imaging techniques. It can guarantee the quality of mammograms and give useful information for retaking MMG. Furthermore, the proposed method makes it possible to present MMG image quality improvements to the operator. The major teaching points of this exhibit are to: 1. automatically classify the quality in MMG. 2. understand how to classify schemes in the computer-aided detection system using DCNN. 3. be useful for the diagnosis in MMG.

TABLE OF CONTENTS/OUTLINE

To provide DCNN classification regarding validation of mammograms and to discuss clinical usefulness toward an accurate diagnosis in MMG.

BREE

Breast Education Exhibits

Sub-Events

BREE-1   Contrast Enhanced Mammography. Advantages And Controversies.

Awards
Cum Laude

Participants
Rosa M. Lorente-Ramos, MD, PhD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

-To review contrast enhanced mammography (CEM) technique. -To understand usefulness and limitations of CEM in detection, diagnosis, local staging and follow-up of breast cancer. - To analyze controversial points in CEM: Indications, protocols, limitations and pitfalls. - To become familiar with normal and abnormal imaging findings providing correlation with imaging (mammogram, US, MR) and pathology, emphasizing pitfalls, diagnostic difficulties and differential diagnosis.

TABLE OF CONTENTS/OUTLINE

We review the basics and state-of-the-art of CEM highlighting subjects which may cause conflicts while the technique is implemented in a Breast Imaging Department. 1. Basics of CEM. 2. Technique: Before the exam. Image acquisition. After acquisition. 3. Controversies. - Use. Indications (symptomatic breast, screening, staging, neoadjuvant treatment); Adjunct tool to traditional methods; CEM vs MR; - Protocols. Optimization: pros and cons for different protocols. - Limitations. 4. Imaging. - we present a series of normal and abnormal cases, including frequent and uncommon lesions with mammography, US, MR and pathology correlation - Artifacts and potential pitfalls are analyzed.

BREE-10   Dedicated Breast CT: State Of The Art

Participants
Yueqiang Zhu, Tianjin, China (*Presenter*) Nothing to Disclose

TEACHING POINTS

¦ Dedicated breast CT (BCT) is an emerging modality with enormous potential in the future of breast imaging by addressing numerous clinical needs from diagnosis to treatment. ¦ Current BCT systems differ in acquisition modes (cone-beam, fan-beam, parallel-beam), imaging techniques (absorption-contrast, phase-contrast), and detector types (flat-panel energy-integrating, photon-counting). ¦ Advantages of BCT include lack of breast compression, no tissue overlap, improved patient comfort compared with DM and DBT, and rapid acquisition, concurrent assessment of microcalcifications and contrast enhancement compared with MRI. ¦ BCT shows either noninferiority or superiority with DM and numerical comparability to MRI after contrast administration in diagnostic statistics, demonstrates excellent performance in lesion characterization, density assessment, implant evaluation, and intervention, and exhibits potential in future screening. ¦ There are still details to be decided regarding BCT techniques. Contrast media dosage and optimal delay time have to be determined. Mean glandular dose of CE-BCT is high due to multi-phase acquisition. Table design has limitation in imaging axilla. Discomfort remains in some patients during scanning. Several artifacts occur in scanning and post-processing. ¦ New imaging modalities such as phase-contrast BCT, spectral BCT, and hybrid imaging are in the progress of R & D.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. History 3. Technique 4. Clinical application 5. Future perspectives 6. Summary

BREE-11   Breast Cancer In Women Under Age 30: An Overview

Participants
Arielle Sasson, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

(1) Breast cancer is rare in adolescents and young women, but more aggressive with a worse prognosis compared to older women. (2) High risk women due to family history, certain germline mutations (i.e., TP53) or who have received mantle radiotherapy should undergo high risk screening.(3) Imaging protocols for palpable breast lesions in those under 30 years old will be reviewed.(4) Breast cancer treatment can result in fertility impairment and premature menopause and should be addressed.

TABLE OF CONTENTS/OUTLINE

(1) Background- Incidence of breast cancer in young women- Behavior, prognosis, imaging features, molecular subtype and risk of recurrence in those under 30- Risk Factors: a. Diseases/past medical history, b. Deleterious gene mutations, c. Familial risk(2) Surveillance and Risk Assessment- Who should undergo screening less than 30 and why(3) Young Women with Breast Cancer: Unique Challenges- Long-term complications, e.g., fertility loss and cardiotoxicity- Fertility preservation- Increased risk of

psychological issues(4) Imaging Evaluation- Standard protocols to evaluate palpable masses in women under 30 years old, i.e., ACR Appropriateness Criteria(5) Case Series- Present pathology and multi-modality imaging findings from patients with breast cancer under age 30 years(6) References

BREE-12   Revitalizing Breast Imaging Rotations: Suggestions To Increase Resident Interest

Participants
Darrell Morris, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

(1) Hands-on experience is essential to the apprenticeship-based education model, a structured framework to the breast imaging rotation will increase resident interest.(2) The foundations of breast imaging should be introduced in a plain, understandable manner, with readily available resources.(3) Early exposure to Breast ultrasound and MRI should be encouraged along with involvement in breast consults and patient-facing tasks.(4) Strategies to make the rotation more interactive such as question bank assignments, journal club presentations and participation in multidisciplinary conferences should be encouraged.

TABLE OF CONTENTS/OUTLINE

(1) Getting Started: The First Breast Rotation and Early Introduction to:- Breast imaging- Mammography- How to read a Mammogram- Breast imaging interpretation Lexicon/ BI-RADS- Positioning and Clockface localization of lesions- Observing technologist during mammograms and US- Views for diagnostic mammography(2) Beyond the Basics- Early exposure to procedures including MRI biopsy- Early exposure to patient-facing tasks and breast consults(3) Reading & Reinforcing information- Suggested reading- Question bank- Educational presentations(4) Breast Imaging Aunt Minnie's- Academic lecture Jeopardy

BREE-13   Peer Review Vs. Peer Learning: The How And Why Of The Paradigm Shift In Breast Imaging

Participants
Darrell Morris, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

(1) Outcome Assessment of breast imaging interpretations is necessary for improving quality assurance.(2) Peer-learning fosters a culture that encourages a nonpunitive process that encourages focused learning and reduces diagnostic errors.(3) Transitioning from a numerical score-based model to a qualifying assessment model, helps facilitate identification and discussion of learning and quality improvement opportunities.(4) An anonymous review process decreases the risk of reviewer bias and increases participation of radiologists who may be weary of privacy concerns.(5) Consensus Oriented Group Peer Review (COGR) peer learning, prioritizes group discussion of cases to improve outcomes, solidify and optimize group standards of practice and fosters peer feedback.(6) COGR strategies help to answer whether the report directly answers the clinical question, whether report wording was clear and whether the appropriate recommendation was justified.

TABLE OF CONTENTS/OUTLINE

(1) Quality Assurance in Radiology- Quality assurance in breast imaging- MQSA(2) History of Peer Review in Radiology- RADPEER- Limitations of peer review model(3) What is Peer Learning- Advantages- Limitations- Peer Feedback- Peer coaching(4) What is Consensus-Oriented Group Peer Review (COGR)- Advantages- Limitations(5) Implementing case based COGR strategies in breast imaging- Involvement of entire section by rotating presenters- Case Examples

BREE-14   Moving Beyond Gynecomastia- Pictorial Review Of Less Common Benign And Malignant Findings In The Male Breast

Participants
Haley Letter, MD, Jacksonville, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

Diagnostic mammography is the first-line imaging tool for the evaluation of the symptomatic adult male breast. The majority of male breast lumps are due to gynecomastia or benign lipomas, which can occur at any age and demonstrate classic findings on mammography. The purpose of this pictorial review is to describe key mammographic findings that suggest diagnoses other than gynecomastia, including characteristically benign lesions and suspicious lesions requiring additional diagnostic work-up and/or biopsy, in order to increase radiologists' confidence and accuracy in making these diagnosis.

TABLE OF CONTENTS/OUTLINE

Utilizing an interactive pictorial case based approach drawn from our case experience, we will review imaging findings of common and uncommon male breast pathology, highlighting at least one important distinguishing factor that makes its particular appearance inconsistent with gynecomastia. Cases included:1) Lipoma 2) Pseudogynecomastia 3) Simple cyst 4) Ductal carcinoma in situ presenting as calcifications 5) Invasive ductal carcinoma 6) Primary breast lymphoma 6) Benign spindle cell tumor 7) Metastasis to the breast 8) Kaposi sarcoma in a male to female transgender patient with HIV 9) Abscess. Many of the cases presented will also demonstrate concomitant gynecomastia, which will serve to highlight the important mammographic distinctions.

BREE-15   Imaging Atlas Of Axillary Lymphadenopathy After COVID-19 Vaccination

Participants
Beatriu Reig, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Vaccines administered in the deltoid muscle may cause ipsilateral axillary lymphadenopathy (LAD). Any vaccine type can cause axillary LAD, but this is more common with mRNA vaccines due to their immunogenicity. • Vaccine-related LAD is often in the apical portion of the axilla, near the axillary vein and artery, and may involve axillary levels I, II, III, as well as supraclavicular and cervical lymph nodes. • Duration of vaccine-related LAD is unknown and may be variable, with studies showing up to 10 weeks in some patients.

TABLE OF CONTENTS/OUTLINE

1) Brief introduction: LAD as a complication of all vaccines, including COVID-19 vaccines 2) Anatomy: a) Lymphatic drainage of the

1) Brief Introduction: LAD as a complication of all vaccines, including COVID-19 vaccines 2) Anatomy: a) Lymphatic drainage of the breast and upper extremity b) Lymph node (LN) stations: axillary levels I, II, III; supraclavicular 3) Morphology of normal and abnormal LNs on mammogram, ultrasound, MRI, PET a) smooth or focal cortical thickening, rounded morphology, loss of fatty hilum, non-hilar vascular flow, rim or heterogeneous enhancement on MRI b) No single size criterion defines an abnormal lymph node 4) Imaging atlas of vaccine LAD on mammography, ultrasound, MRI, and PET-CT a) Multimodality correlation b) Evolution of LAD over time 5) Management of LAD in setting of COVID-19 vaccination a) In asymptomatic patients b) In patients with recently diagnosed breast malignancy 6) Pitfalls/controversies a) Differential diagnosis: metastatic breast cancer, lymphoma b) Resolution over time of vaccine-related LAD has not been defined c) Endpoint of follow-up has not been defined

BREE-16   Pediatric Breast Masses

Participants
Kason Ashe, DO, Morgantown, West Virginia (*Presenter*) Nothing to Disclose

TEACHING POINTS

The majority of breast conditions occurring in pediatric patients are benign, including normal developmental changes and benign neoplastic lesions. Breast malignancy has an exceedingly low incidence.Ultrasound is the first-line imaging modality in pediatric patients. Mammography has a limited role, secondary to risks associated with exposure to ionizing radiation as well as the reduced sensitivity of mammography in extremely dense breast tissue encountered in adolescent patients.Clinical history and exam findings are important in guiding imaging and management decisions. Given the extremely low incidence of malignancy in pediatric patients in addition to the risk of damaging breast bud development with interventions such as core needle biopsy, a conservative approach of sonographic and clinical follow-up is generally warranted.

TABLE OF CONTENTS/OUTLINE

Review the most common symptoms prompting breast imaging in pediatric patients.Discuss the most appropriate imaging evaluation for pediatric patients with breast symptoms.Review the most frequently encountered pathologies, imaging characteristics, and discuss management.This content will be delivered by providing the clinical history and physical exam findings, imaging, pathology, treatment, and patient outcomes for cases including juvenile fibroadenoma, phyllodes tumor, gynecomastia, abscess/mastitis, breast bud formation, epidermal inclusion cyst, intramammary lymph node, reactive lymphadenopathy, infantile hemangioma and mammary duct ectasia.

BREE-17   Certifications, Audits, And National Benchmarks: Breaking Down The Basics For The New Mammography Attending

Participants
Ellen Clark, MD, Clinton, Connecticut (*Presenter*) Nothing to Disclose

TEACHING POINTS

This poster prepares the upcoming graduate or new mammography attending to understand the MQSA requirements for certification and maintenance of certification, and introduces the yearly audit. We will delve into the details of the raw and derived data included in an audit, using a real example. By applying PPV1, PPV2, and PPV3 to real examples, we will provide the reader a more intuitive understanding of these challenging statistics. Finally we will discuss the significance of the Breast Cancer Surveillance Consortium and national benchmarks and guidelines that can be used for comparing one's own audit.

TABLE OF CONTENTS/OUTLINE

1. MQSA Initial Certification; 2. MQSA Continuing Certification; 3. The Yearly Audit; 4. Definitions of PPV1, PPV2, and PPV3; 5. Example Audit; 6. National Benchmarks from the Breast Cancer Surveillance Consortium (BCSC).

BREE-18   Lymphoma Of The Breast - A Multimodality Review Of Imaging Findings

Participants
Adam Brown, MBChB, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

After reading this educational exhibit, delegates will be able to:1) Recognise the imaging findings of lymphoma of the breast across multiple imaging modalities including mammography, ultrasound, MRI and FDG-PET/CT with histopathological correlation.2) Describe the key radiological findings that allow it to be distinguished from other malignant and non-malignant breast pathologies.

TABLE OF CONTENTS/OUTLINE

Introduction: Breast lymphoma is a rare hematological malignancy. Primary breast lymphoma originates in the lymphoid tissue of the breast in the absence of extramammary disease. Secondary breast lymphoma is the most common cause of metastasis to the breast. Breast lymphoma poses a diagnostic challenge to radiologists due to non-specific imaging findings.Imaging findings: Features of breast lymphoma on imaging, such as a mass, skin changes and lymphadenopathy, will be discussed and illustrated with case examples on mammography, ultrasound, MRI and PET/CT. Features which distinguish more common breast cancers from breast lymphoma, such as spiculation, distortion and calcification will also be discussed. Breast implant associated anaplastic large cell lymphoma, an important consideration in women with history of implants, will also be illustrated.Conclusion: Breast lymphoma can be indistinguishable from other breast malignancies on imaging alone. However, clinical history and certain imaging features can provide clues. Tissue sampling provides definitive diagnosis.

BREE-19   Breast Malignancies After Mastectomy With Autologous Or Implant Reconstruction

Participants
Amy Maduram, MD, San Diego, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

(1) After mastectomy, patients face a plethora of options such as immediate vs delayed reconstruction and autologous flap vs implant placement. Since no standardized screening guidelines currently exist for imaging the reconstructed breast, it is vital for radiologists to be aware of the different presentations of malignancies after mastectomy. (2) Most recurrences present as palpable subcutaneous masses at the flap margin or edge of the implant and may be mammographically occult or incidentally identified on

surveillance imaging. Implant-associated lymphoma and new primary malignances in residual breast tissue are also possible after mastectomy. (3) Surgical and oncological treatment varies: local sites of malignancy can be treated with wide excision and chemoradiation. Multiple sites of recurrence or involvement of the flap pedicle may necessitate removal of the reconstruction.

TABLE OF CONTENTS/OUTLINE

(1) Overview of post-mastectomy reconstruction: (1a) Patient choice to reconstruct or not (1b) Current techniques and types of autologous and implant reconstruction (1c) Surgical complications after mastectomy such as residual breast tissue. (2) Challenges to screening and imaging the reconstructed breast. (3) Cases of recurrence after implant. (4) Cases of recurrence after autologous reconstruction. (5) Cases of additional malignancies in the post-mastectomy breast. (6) Self-assessment quiz.

BREE-2   Benign Mammography Findings: Tips And Tricks. Proceed? No Need!

Awards
Certificate of Merit

Participants
Marcela Lauar, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To demonstrate benign findings in mammography that do not require further investigation, and can be diagnosed in the mammography itself, sparing patients from unnecessary exams, procedures and psychological impairment. To didactically illustrate the most common benign features in mammography, and how to differ them from similar suspicious findings.

TABLE OF CONTENTS/OUTLINE

Evaluation of benign mammography findings from our service's personal archive, including calcifications, lesions containing fat, skin lesions, silicone-related findings, muscular anomalies, among others. Complementary ultrasound and magnetic resonance image are also included in this presentation on the purpose of correlating the image methods, although not necessary to diagnosis.Take home messages.References.

BREE-20   Breast Imaging Controversies In The Elderly: To Screen Or Not To Screen

Awards
Identified for RadioGraphics

Participants
Cindy Lee, MD, Woodbury, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

Controversies of breast cancer screening in elderly: • Inconsistent recommendations: Women over age 74 excluded from all randomized control trials; best evidence from observational and modeling studies. • Overdiagnosis: Low with benefits outweighing risks until age 90. • False-positives: Screening mammography is more effective in older women with higher cancer detection rates and fewer false-positives. • Overtreatment: Cancers in older women have more favorable tumor biomarkers and histology subtypes, offering many treatment options. Many older women want to be treated and are more likely undertreated. • New technology: Digital breast tomosynthesis further improves screening accuracy in all ages. • Upper age limit for screening: Annual screening yields the greatest mortality reduction with most cancer deaths saved and life-years gained in women > age 70 years

TABLE OF CONTENTS/OUTLINE

1. Intro: Compare existing breast cancer screening guidelines for elderly from U.S. and international organizations; Consider trends in life expectancy. 2. Review outcomes of screening from clinical trials, observational studies and modeling predictions. 3. Analyze controversies of breast cancer screening in elderly. 4. Understand screening underutilization and breast cancer undertreatment in the elderly. 5. Decide when to stop screening in the elderly based on age, individual preferences, overall health and comorbidities

BREE-21   Health Disparity And Breast Cancer Outcomes In Asian Women: A Case-based Analysis

Awards
Identified for RadioGraphics
Magna Cum Laude

Participants
Yiming Gao, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

Breast cancer disparity in Asian women is not well understood due to a relative paucity of data and a perception of lower cancer incidence and higher survival as compared to other racial ethnic groups. However, Asian women are prone to early onset breast cancer and have a propensity for HER2 enriched tumors. According to CDC data published in 2021, among Asian/Pacific Islander women, 35% of all new cancers are breast cancers, and breast cancer incidence is rising. The Asian diasporas represent the fastest growing demographic in the United States, albeit heterogenous across a wide cultural and socioeconomic spectrum. Thus, race alone does not sufficiently account for the complex disparities that exist. We will discuss challenges and nuances in breast cancer diagnosis, management, and prevention in these patients via a case-based review.

TABLE OF CONTENTS/OUTLINE

1. Background a. Rising incidence b. Asian diversity 2. Immigrants vs US-born Asians a. Longer stay in US --> rising breast cancer risk b. Prior data: lower risk in immigrant than US-born c. New data: higher risk in immigrants than US-born 3. Breast density in Asians a. Higher density overall b. Risk distinct from whites c. Density vs BMI vs Risk d. Effectiveness of conventional screening 4. Tumor biology a. Early onset (<age 40) b. HER2+ prevalent 5. Poor screening attendance a. Regardless of status, wealth, access b. Cultural perceptions 6. Clinical implications

Demystifying The Diagnostic Display

Participants
Sherwin Chiu, MD,MPH, Augusta, Georgia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Understand specifications used to describe mammography monitors.2) Recognize the impact of monitor specifications on image interpretation.3) Identify differences between 5-megapixel and 12-megapixel monitors.4) Learn to use calibration patterns for equipment auditing

TABLE OF CONTENTS/OUTLINE

1) Introduction to important monitor specifications.a) Resolution - the number of pixels the monitor can use to display images.b) Pixel pitch - distance between the center of two adjacent pixels which is the same as pixel width.c) Bit depth - the number of different shades of grey a single pixel can display.d) Viewing Angle - degree to which images can still be viewed with acceptable quality.2) Detector vs monitor resolution.a) 70 - 140 microns vs 165 - 168.6 microns.b) Binning is required due to larger pixel size on both 5MP and 12 MP monitors, but causes information loss.3) Comparing 5 MP and 12 MP monitors.a) Size - significant difference.b) Resolution - similar in dual vs single setup.c) Bit depth - functionally similar.d) Pixel width - similar.e) Color depth - major advantage for multi-modality use.f) Summary of differences found in study comparing 8 MP vs 5 MP monitors.4) Evaluation of monitor function and quality assurance.a) Understanding quality control patterns.b) Use of patterns to evaluate both spatial resolution and contrast.

BREE-24 **Calling The Shots: What Radiologists Need To Know About Axillary Lymphadenopathy In The COVID Era**

Awards
Cum Laude
Identified for RadioGraphics

Participants
Meng Zhang, MD, Dallas, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Axillary lymphadenopathy is a known side effect of mRNA-based COVID-19 vaccines, which may present a diagnostic dilemma on imaging for high risk and oncologic patients.2. Breast radiologists should be familiar with evolving data regarding vaccine-induced lymphadenopathy to minimize the confounding effect on breast cancer patients in different stages of treatment and surveillance.3. Careful review of patients' clinical and vaccination history, as well as ancillary imaging findings, help inform management of axillary lymphadenopathy with goals to reduce unnecessary biopsy in the general screening and breast cancer survivor populations, while avoiding potential delays in diagnosis of metastatic disease in oncologic patients.

TABLE OF CONTENTS/OUTLINE

• Summarize the incidence and onset timing of axillary lymphadenopathy in the Pfizer-BioNTech SARS-CoV-2 and Moderna SARS-CoV-2 vaccine trials with a literature review of emerging publications.• Illustrate the imaging and histologic features of reactive lymphadenopathy and axillary nodal metastasis, with an emphasis on patterns and locations of abnormal findings.• Discuss outcomes of axillary lymphadenopathy observed on imaging studies during initial work up, response to treatment, and survivor surveillance exams in the recently vaccinated patient.• Review important clinical considerations and ancillary radiologic findings to inform management decision of short-term surveillance versus further work-up including biopsy during the different stages of oncologic care.

BREE-25 **Axillary Lymphadenopathy In COVID-19 Vaccine Recipients: What To Do?**

Participants
Consuelo Gatica, MD, Santiago, Chile (*Presenter*) Nothing to Disclose

TEACHING POINTS

1.- Recognize the typical findings of a pathological lymphadenopathy on ultrasound. 2.-Identify in which cases we should consider vaccination adenopathy. 3.- Learn the recommendations for the mannagement of axillary adenopathy in patients with recent Covid-19 vaccination

TABLE OF CONTENTS/OUTLINE

1.-Definition and classification of axillary lymphadenopathy. 2.-Ultrasound Features: Parenchymal cortical thickness, loss of fatty hilum, irregular outer margins, abnormal vascularization in color Doppler mode. 3.-Usual management of patients with axillary lymphadenopathy. 4.-Previous studies of axillary lymphadenopathy as vaccination side effects: Pfizer BioNTech, Moderna, Coronavac, Aztrazeneca. 5.-Important previous history: Timing and side (right v.s left arm) of vaccination , which type of vaccine, personal history of previous cancer, family history of breast cancer. 6.-Management algorithm and BIRADS for patients with axillary lymphadenopathy in context of recent Covid-19 vaccination. 7.-Local cases and our management

BREE-26 **Preoperative MRI Evaluation Of Lymphedema: The Role Of The Breast Radiologist**

Participants
Haydee Ojeda-Fournier, MD, San Diego, California (*Presenter*) Research Consultant, View Point Medical;Stockholder, CureMetrix, Inc

TEACHING POINTS

SYNOPSIS: Upper extremity lymphedema is a debilitating progressive swelling often caused by breast surgery and lymph node dissection. Physical therapy and manual lymphatic drainage can temporize the progression of symptoms. Evolving microsurgical techniques, including lympho-venous anastomosis and lymph node transplant, can improve clinical symptoms. The plastic surgeon requires a presurgical assessment to plan the type and location of the surgery. MR Lymphography has been shown to identify lymphatic channels and their depth and allows the surgeon to plan for the type of surgery and location of the incision. TEACHING POINTS: By the end of this educational exhibit, the learner will:1. Review the clinical significance of lymphedema.2. Know the

protocols for MR Lymphography.3. Appreciate the need for clinical and nuclear medicine correlation.4. Describe the role of breast radiologist in the workup and preoperative assessment of lymphedema.

TABLE OF CONTENTS/OUTLINE

Introduction; Nuclear medicine lymphoscintigraphy; MR protocols; Number of lymph nodes; Dermal thickening; Honeycomb; Epifacial fluid collection; Evaluation of muscular compartment; Fluid infiltration; Lymphatic channels; Additional findings; Grading of lymphedema; Surgical options: lymphatic-venous anastomosis (LVA) v. lymph node transfer; Clinical management; Conclusion.

BREE-28   Idiopathic Granulomatous Mastitis Of The Breast. Tips And Tricks For Diagnosis.

Participants
Rosa M. Lorente-Ramos, MD, PhD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

-To review idiopathic granulomatous mastitis of the breast, highlighting clinical presentation, pathological and imaging findings as well as differences from inflammatory breast cancer -To illustrate common and uncommon imaging findings (mammogram, US, MR) of cases from our series with pathological correlation. -To analyze and discuss the specific management of those lesions, including diagnostic difficulties and imaging work-up. -To emphasize pitfalls and clues to differential diagnosis.

TABLE OF CONTENTS/OUTLINE

Idiopathic Granulomatous Mastitis is a rare benign inflammatory condition of the breast which may mimic advanced inflammatory breast cancer and infections both clinically and on imaging. At pathology it is characterized by non-caseating granulomas around the lobules and ducts in the breast without specific infectious agents, trauma, or foreign bodies. Keys for differential diagnosis should be recognized. We present: 1. Definition. Pathology. 2. Clinical presentation of idiopathic Granulomatous Mastitis. 3. Imaging findings. Mammograms, US, MR, interventional procedures. 4. Differential diagnosis: Infections: acute Mastitis (puerperal and non-puerperal), Granulomatous infections: Tuberculous mastitis; Sarcoidosis and autoimmune diseases (Granulomatosis with Polyangiitis and giant cell arteritis); Inflammatory breast cancer. 5. Management and outcome.

BREE-29   What's On The Menu: A Smorgasbord Of Cases From A Safety Net Hospital

Participants
Kevin Dao, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Safety net hospitals provide care to a diverse and vulnerable population. Hence, radiologists who serve this community encounter a wide variety of pathologies, often presenting at advanced stages. This exhibit will utilize a case-based approach to explore breast diseases that present to the largest safety net hospital in New England. Each case will help educate radiologists not only about the disease and its management but also about the social determinants that may have contributed to the condition.

TABLE OF CONTENTS/OUTLINE

1.Overview of a typical patient population that presents to safety net hospitals with focus on demographics, socioeconomic status, language barrier, and other contributory social determinants of health. 2.Case based presentations of advanced diagnoses of breast disease frequently encountered in patients presenting to a safety net hospital. These diseases may include but not limited to locally advanced breast cancer, inflammatory breast cancer, granulomatous mastitis, papillomatosis, and implant associated complications. Rarer diagnoses will include less common infectious processes (filariasis, sparganosis, tuberculosis), rare inflammatory conditions (lupus mastitis, IgG4 disease) and neoplasms (fibromatosis, metaplastic carcinoma). 3.For each case, discussion focused on imaging presentation and management with teaching points focused on strategies to streamline care, systems-based adaptations, and community outreach, with the ultimate goal of improving outcomes now and in the future.

BREE-3   The Riches In The Niches Of Breast Cancer Tumor Board: A Radiologist's Guide To Post Mastectomy Radiation Therapy

Awards
Identified for RadioGraphics

Participants
Laura Machado, MD, Darby, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

Teaching points: Well-established indications for post-mastectomy radiation therapy (PMRT) are few, and examples include inflammatory breast cancer and > 3 metastatic lymph nodes found at axillary lymph node dissection.Broader indications for the use of PMRT such as metastatic nodes found at sentinel node biopsy are still evolving and require a multidisciplinary discussion of management at breast tumor board.Although the exact timing of reconstruction with respect to radiotherapy is still uncertain, delayed autologous reconstruction is preferable in most patients. There are critical decision-points in the use of PMRT at which the radiologist and key imaging findings play a pivotal role.

TABLE OF CONTENTS/OUTLINE

Table of Contents/Outline Review established and controversial indications for post-mastectomy radiation therapy. Present cases for which a discussion of PMRT may arise at multidisciplinary breast tumor board and apply guidelines to the clinical dialogue. Discuss types and timing of breast reconstruction when PMRT will be performed. Discuss common complications of PMRT and provide examples. Identify critical decision-points in tumor board at which the radiologist plays a pivotal role.

BREE-30   Navigating Implantable Devices Seen On Breast Imaging

Participants
Robert Pugh, MD, Cincinnati, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

· Identify the array of implantable devices encountered on breast imaging studies · Review breast imaging techniques and special

Identify the array of implantable devices encountered on breast imaging studies.· Review breast imaging techniques and special considerations for patients with implantable devices.· Discuss methods of differentiating similar appearing devices.· Summarize artifacts associated with these implanted devices and methods of remediation.· Recognize potential complications seen with implanted devices in the breast.

TABLE OF CONTENTS/OUTLINE

· Imaging techniques/considerations/physics:-- Mammogram-- Ultrasound-- MRI· Positioning/additional views· Artifacts related to devices:-- Causes-- Corrections· Complications seen with devices:-- Lead, electrode, or catheter breakage-- Device malfunction-- Migration-- Infection· Case Examples with Imaging Findings:-- VP shunt-- Loop recorder-- Sleep apnea device-- Vagal nerve stimulator-- Dual and single chamber implantable cardioverter defibrillator (ICD)-- Pacemaker-- Bioabsorbable marker-- Suture-- Retained object-- Tissue expander-- Nipple piercing-- Localization devices: magnetic seed, RFID, I-125 seed, SaviscoutConclusions:· Various implantable devices can be seen on routine breast imaging studies.· Appropriate identification and characterization of these devices are key for optimizing imaging technique and reducing associated artifacts.· Complications with implantable devices can be detected on breast imaging studies and should be properly managed.

BREE-31   Breast Manifestation Of Hematologic Malignant Diseases

Participants
Priscila Zanin Nano Tjong, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Breast manifestations of hematological diseases are rare, and may mimic other breast malignancies. Since these pathologies have different treatment management, it is important for the radiologist to known this entities, in order to suspect the diagnosis. Our intent is to review how hematologic diseases manifest in the breast, by demonstrating a series of cases of multiple myeloma (MM), myeloid sarcoma and lymphomas in a multimodality imaging approach. MM is a primary malignancy of bone marrow characterized by clonal proliferation of plasma cells and production of monoclonal immunoglobulin. Only few cases of multiple myeloma are reported in the literature. Myeloid sarcoma is a neoplasm composed of immature granulocytes or monocytes that usually occurs in patient with history of acute myeloid leukemia. The presentation as a breast mass is uncommon, with only 67 cases reported in the literature.The most common histological subtype of breast lymphoma is a diffuse large B cell. It can manifest as a single or multiple masses or as an inflammatory-like appearance. PET-CT/FDG is highly sensitive and specific in the evaluation of treatment response, tumor staging and/or restaging.

TABLE OF CONTENTS/OUTLINE

Evaluation of a series breast manifestations of hematologic diseases by demonstrating imaging features in multimodality methods, such as ultrasound, magnetic resonance image (MRI) and positron emission tomography (PET-CT), based on our service's personal archive.

BREE-32   Not Every Finding In The Axilla Is Malignant. What Should Residents Know?

Participants
Karina Pesce, MD, Capital Federal, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate imaging features of normal and benign etiologies with correlates of cases from our database To discuss the diagnostic challenges and differential diagnosis

TABLE OF CONTENTS/OUTLINE

1-Introduction 2-Anatomy of the axilla. 3- Review benign etiologies such as inflammatory causes, infectious diseases, collagen vascular diseases, and miscellaneous. 4-Pictorial imaging of normal findings and benign pathology A-Accessory breast tissue B-Lymph node lesions: Reactive lymphadenitis, Intranodal silicone, Tattoo Pigment C- Vascular lesions: Mondor's Disease D-Neurogenic lesions: neuroma E-Skin and subcutaneous lesions: Epidermal cysts, lipoma F-Post-surgical complications: Seroma, Hematoma, silicone G-Muscular pathology: Poland Syndrome, Aggressive fibromatosis 5-Conclusions

BREE-33   Liquid Biopsy In Breast Cancer . What Should Radiologists Know?

Participants
Karina Pesce, MD, Capital Federal, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review liquid biopsy in oncology with emphasis in breast cancer. To discuss the potential role of liquid biopsy compared with needle core biopsy in the diagnosis of breast cancer. To analyze the role of the liquid biopsy in the management of breast cancer.

TABLE OF CONTENTS/OUTLINE

A liquid biopsy consists of anybody fluid that contains tumor material suitable for molecular characterization. Therefore, this term includes blood, the most used human liquid sample, but also other fluids such as urine, ascitic fluid, pleural effusion, cerebrospinal fluid, and saliva. Both primary tumors and metastases can release tumor material into these body fluids, mainly consisting of circulating tumor cells (CTCs), nucleic acids (cNAs), and extracellular vesicles (cEVs). Although Thomas Ashworth described the presence of tumor cells in the blood of breast cancer patients for the first time in 1869, it was not until recent years that the scientific community focused their attention on the study of blood CTCs. 1-Introduction 2-History of liquid biopsy in breast cancer 3-Histological biopsies versus liquid biopsy 4-Advantages and disadvantages 5-Ongoing trials of liquid biopsy in breast cancer 6-Challenges and practical considerations

BREE-35   Safe Use Of Contrast Media In Breast Imaging; A Practical Guide

Participants
Faezeh Sodagari, MD, New Haven, Connecticut (*Presenter*) Nothing to Disclose

TEACHING POINTS

Vascular-based breast imaging is becoming more popular due to its high sensitivity. Contrast-enhanced breast MR, the most widely

used vascular-based breast imaging technique, relies on Gadolinium-based MRI contrast agents. Other emerging imaging techniques include contrast-enhanced mammography. Molecular-based imaging and contrast-enhanced ultrasound. Optimal use of these agents requires familiarity with safety guidelines, indications, patient selection, and prevention and management of short-term or long-term adverse events. This exhibit aims to review different types of contrast agents used in breast imaging, indications, patient selection, management of potential adverse events, safe use during pregnancy and breastfeeding, as well as controversies surrounding long-term or repeated exposures to contrast media.

TABLE OF CONTENTS/OUTLINE

1) Contrast-enhanced breast imaging modalities: i) Contrast-enhanced MRI ii) Contrast-enhanced mammography (CEM) iii) Molecular breast imaging iv) Contrast-enhanced ultrasound (CEUS) 2) Practical aspects of contrast administration i) IV access ii) Injection methods iii) Contrast extravasation 3) Patient selection i) Contrast reactions (a) Definition and types (b) Risk factors (c) Classification (d) Premedication (e) Treatment ii) Impaired renal function (a) Screening (b) Minimizing risk (c) Treatment iii) Pregnancy and breast-feeding 4) Controversies: i) Gadolinium deposition ii) Steroid premedication cost-effectiveness] iii) Off label, non-FDA contrast agents

BREE-36   Delays In Diagnosis Of Breast Cancer: An Emerging Phenomenon That Can Have Long-term Consequences.

Participants
Flavia Sarquis, MD, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

Mammography screening was paused during COVID 19 pandemic. Women risk having breast cancer diagnosed at a more advanced stage, contributing to higher rates of breast cancer-related deaths that could potentially have been avoided with regular screening.We are still catching up.Experts predict thousands of undiagnosed cancers.After reading this education exhibit the radiologist will know:COVID-19 had an acute impact on breast imaging facilities.Declines in screening can lead to delays in diagnosis.The disruption in breast cancer screening services for months due to the pandemic may add thousands of deaths from breast cancer this decade.

TABLE OF CONTENTS/OUTLINE

Challenges of providing medical care during a global pandemic.Experience of a breast imaging facility in screening, diagnostic , follow-up and interventional procedures.Future best practices for delivering breast imaging care amid the ongoing and geographically shifting COVID-19 pandemic.Illustrative based cases showing delayed breast cancer diagnosis. Conclusions

BREE-37   How We Do It: Intralesional Therapy For Granulomatous Mastitis.

Participants
Haydee Ojeda-Fournier, MD, San Diego, California (*Presenter*) Research Consultant, View Point Medical;Stockholder, CureMetrix, Inc

TEACHING POINTS

SYNOPSIS: Granulomatous mastitis is idiopathic inflammation of the breast. Recurrent aseptic abscesses, fistulous drainage, and pain lead to decreased quality of life. The etiology and management of this unusual process are controversial. Management ranges from observation to mastectomy. Core biopsy for exclusion of breast cancer is essential. A sample of aspirated fluid or a core biopsy sample should be submitted to Microbiology for culture, including AFB and fungal on initial evaluation to exclude an infectious etiology. A high dose of oral steroid therapy can be used for medical management. However, this can lead to significant side effects, including glucose imbalances and severe insomnia. Recent attempts at an intralesional injection of steroids in conjunction with the breast surgeon and rheumatology consultation have been reported in the literature. This educational exhibit demonstrates how we set up a program for intralesional therapy of granulomatous mastitis. TEACHING POINTS: By the end of this educational exhibit, the learner will: Review the clinical presentation of granulomatous mastitis. Understand current medical and surgical therapies. Learn the protocol for intralesional therapy for granulomatous mastitis.

TABLE OF CONTENTS/OUTLINE

Introduction; Clinical presentation and appearance; Imaging features by Mammogram, Ultrasound, and MRI; Medical Therapy; Surgical options; Hydrocortisone intralesional injections; Differential considerations; Clinical management; Conclusion.

BREE-38   Important Imaging Characteristics Following Ultrasound Guided Cryoablation Of Breast Cancer: 5 Year Follow Up From The ICE3 Trial

Participants
Kenneth Tomkovich, MD, Freehold, New Jersey (*Presenter*) Speakers Bureau, IceCure Medical, Inc

TEACHING POINTS

The purpose of this exhibit is: 1. To demonstrate the optimal technique to perform successful ultrasound guided cryoablation of primary breast invasive ductal carcinoma. 2. To review inclusion criteria, methods, and interim results of the ICE3 trial for the primary treatment of low-grade breast cancers using ultrasound guided cryoablation without surgical excision. 3. To illustrate important "new normal" imaging findings seen post treatment following breast cancer cryoablation including 5 year follow up mammography from the ICE3 trial. 4. Illustrate cases of post cryoablation biopsies with benign pathology to recognize commonly expected imaging findings to potentially avoid these biopsies in future patients.

TABLE OF CONTENTS/OUTLINE

Techniques of ultrasound guided breast cancer ablation. Cryoablation as a primary treatment for low-risk invasive ductal carcinoma of the breast. Review of the ICE3 trial and associated imaging findings post breast cancer cryoablation: Mammography-Ultrasound-MRI-Image guided biopsy. Future implications.

BREE-39   Early Lessons Regarding Management Of COVID-19 Vaccine Related Adenopathy On Breast MRI

Participants
Samantha Zuckerman, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. COVID-19 vaccination-related adenopathy may include any of the following imaging features: a. Level I, II, III involvement b. Surrounding soft tissue inflammation and edema c. Diffuse nodal enlargement with cortical thickening and loss of fatty hila d. May spare adjacent lymph nodes2. Follow-up to resolution should be tailored to individual cancer risk, allowing adequate time for resolution without impacting or delaying diagnosesa. Women with prior or current history of malignancy should have shorter follow-up times than those undergoing high risk or supplemental screening3. Other vaccines, such as Shingles and Pneumovax, may also cause adenopathy. Follow-up may be based on COVID-19 vaccination-related adenopathy guidelines.

TABLE OF CONTENTS/OUTLINE

1. Overview of evolving literature on COVID-19 vaccination-related adenopathy and controversy regarding delays in breast cancer screening 2. Discussion of how management decisions should differ in high-risk MRI screening populations versus average risk screening population 3. Examples of MRI-detected COVID-19 vaccination-related adenopathy and follow-up outcomes 4. Reporting of early outcomes data - length of follow-up and biopsy outcomes

BREE-4   Piercing The Pectoralis: Procedure Cases And Considerations

Awards
Certificate of Merit

Participants
Nancy Emelife, MD, Stanford, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

Upon completion of this educational exhibit, participants will be able to: 1) List differential diagnoses for pectoralis major muscle-associated lesions. 2) Demonstrate optimal patient positioning and procedure techniques when sampling masses within/adherent to the pectoralis major muscle or aspirating fluid collections deep to the pectoralis major muscle. 3) Describe sampling techniques to prevent pneumothorax. 4) Recognize surgical considerations for masses suspected to be non-mammary malignancies before biopsy. 5) Identify situations that may indicate CT-guided biopsy as an alternative to US-guided biopsy.

TABLE OF CONTENTS/OUTLINE

Background: 1) Pectoralis major muscle-associated primary/recurrent breast malignancies versus non-mammary origin masses. 2) Technical challenges and considerations for safe use of ultrasound or CT guided biopsy (i.e. patient positioning, needle orientation, biopsy trajectory, and sampling technique). 3) Indications for pre-biopsy planning with surgeon. Cases: Pictorial review of 5 US-guided and 1 CT-guided biopsy procedures of lesions associated with the pectoralis major muscle: 3 recurrent breast cancers within the pectoralis major muscle, 1 invasive breast cancer densely adherent to the pectoralis major muscle, 1 postoperative fluid collection deep to the pectoralis major muscle requiring aspiration for possible infection, and 1 mass within the pectoralis major muscle for which differential included sarcoma. Emphasis will be on technical/biopsy considerations and outcomes.

BREE-42   Catch Me If You Can- Paget's Disease Of The Breast

Participants
Alisha Rathi, MD, Manhasset, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. More common in 5th or 6th decades, Males > Females, and usually unilateral 2. Presents as an ulcerated, crusted, or scaling lesion on the nipple that can involve the areola 3. Diagnosis may be delayed given overlap of clinical findings with more common diseases (i.e, eczema, allergic contact dermatitis, and psoriasis). Punch biopsy is performed to diagnose PD 4. Dedicated mammogram and ultrasound is critical as 95-98% of patients will have concomitant malignancy in the breast 5. Prevalence of multifocality is 40% and multicentricity is 34% 6. In patients with symptoms suggesting PD, consider magnification mammographic views of the anterior breast to assess the nipple areolar complex for suspicious microcalcifications 7. Radiologists should be familiar with the normal appearance of the nipple on breast MR to differentiate it from PD or other pathologies including inflammatory breast cancer and nipple involvement by retroareolar breast malignancy.

TABLE OF CONTENTS/OUTLINE

1. Epidemiology of Paget's Disease (PD) ?2. Clinical and Pathologic features ?3. Imaging Findings ? a. Multimodality imaging findings ? b. Differentiating normal nipple from PD on breast MR ? c. Recognizing PD from involvement of the nipple by breast parenchymal disease. ?4. Benign and malignant mimics ?5. Diagnosis, treatment, staging/prognosis

BREE-43   Breast Cancer Recurrence: How To Predict The Predictable?

Participants
Priscila Zanin Nano Tjong, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

After treated, breast cancer may reappear even after some time in the absence of disease, usually in the first 5 years. The risk of recurrence depends on many factors, and special attention should be focused on patients considered high risk for breast recurrence. This presentation shows some examples of how predicting tools for recurrence of breast cancer were helpful in diagnosing the condition in early stages, during follow-up image exams, sparing the patient from treating a more evolved disease in the future. Our intent is to didactically show how recurrence breast cancer predictors, like PREDICT Score, can be an important tool for radiologists, and how to use this resource in our medical practice.

TABLE OF CONTENTS/OUTLINE

To illustrate cases in which breast cancer recurrence was spotted in image follow up exams, based on our service's personal achieve, including MMG, US, MRI, PET-CT, of the cases presented, as well as the correlation with their risk factors for recurrence, including average survival rate and risk category provide by predict tools.

BREE-45   Mammographic Appearance Of Iatrogenic And Non-iatrogenic Foreign Bodies In The Breast

Participants
Shama Jaswal, MBBS, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Review common foreign bodies found at breast imaging and their mammographic appearance.2. Demonstrate mammographic findings of iatrogenic foreign bodies: Surgical and biopsy clips and lines/ tubes/ medical devices. 3. Demonstrate mammographic findings of non-iatrogenic and traumatic foreign bodies: Gunshot shrapnel and jewelry / adornments / tattoo ink. 4. Describe the strengths and weaknesses of mammography, ultrasound, and MRI in the evaluation of foreign material identified at breast imaging.

TABLE OF CONTENTS/OUTLINE

1. Common foreign bodies found at breast imaging and their mammographic appearance a. Iatrogenic foreign bodies i. Description of the unique appearance of a variety of iatrogenic foreign bodies ii. Example cases include surgical and biopsy clips, lines, tubes, and medical devices b. Non-iatrogenic foreign bodiesi. Description of the unique appearance of a variety of non-iatrogenic foreign bodies ii. Example cases of traumatic non-iatrogenic foreign bodies: gunshot shrapnel iii. Example cases of non-traumatic non-iatrogenic foreign bodies: tattoo ink2. Describe the strengths and weaknesses of mammography, ultrasound, and MRI in the evaluation of foreign material identified in breast imaginga. Mammography: i. Highly sensitive ii. Safe to detect metallic material and medical devicesb. Ultrasound: i. Cost-effective and safe; may detect an abscess ii. Limited deep tissue resolutionc. MRI: i. May help to detect complications ii. Unsafe for ferromagnetic foreign material

BREE-46   Clinical Application Of Contrast Enhanced Spectral Mammography In Predicting Response To Neo Adjuvant Chemotherapy

Participants
Juan Qiu, Guilin, China (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To understand the technical concept of contrast enhanced spectral mammography(CESM) and its implementation. 2. To understand which type of lesion can be evaluated under CESM. 3. To know why CESM could provide an accurate assessment of tumor response after neo-adjuvant chemotherapy(NAC), comparable to that provided by MR. 4. To introduce quantitative objective evaluation in predicting response to neo-adjuvant chemotherapy with RECIST 1.1 and combined evaluation methods.5. To recognize the limitations and benefits of CESM in treatment monitoring.

TABLE OF CONTENTS/OUTLINE

1.Background and physics of Contrast Enhanced Spectral Mammography. 2. Clinical application of CESM in acting as a promising modality of follow-up of cases after NAC. 3. Variables influence tumor shrinkage and its evaluation during NAC, including primary tumor size, edema or necrosis.4. Qualitative and quantitative evaluation of CESM in Predicting Response to NAC. 5. Benefits and limitation of CESM.

BREE-47   Implementation Of A Breast Biopsy Clinic: Engaging Medical Students

Participants
Eric Swy, MD, Cincinnati, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

Key considerations when implementing a breast biopsy clinic for maximum engagement of learnersDefine radiologist role in patient breast careCreation of realistic breast biopsy models and targetsHow to implement hands-on experience with ultrasound (US), multiple biopsy devices, and US/stereotactic biopsy techniquesUnique layout considerations for US and stereotactic/tomosynthesis clinicsHow to create an effective and safe environment for procedural skill developmentHow to provide constructive feedback while building confidence and procedural competenceConsiderations for longevity and sustained success of the breast biopsy clinic

TABLE OF CONTENTS/OUTLINE

Introduction to the breast biopsy clinic at our institutionPotential breast biopsy modelsChicken BreastKnox Gelatin with Metamucil RecipeBolognaFuture: 3D printed breastPotential biopsy targetsOlives Blueberries Eggshells - calcifications Fluid-filled glove/balloon - cystsRoles, Mentoring, Graduated ResponsibilitiesSpecial considerationsContact vendor for expired devicesBlock set time when US/mammography unit is not in useLayout of US ClinicIntroduction to the US unitNumbing techniquesNeedles and biopsy devicesTechniques: Open-chamber vs closed-chamber Clip placementLayout of Stereotactic/Tomosynthesis ClinicIntroduction to Mammography UnitApproachPositioningTargetingSampling techniqueCheckoutSkill demonstrationWeekly clinicsProgression of skillsChallenging biopsy targetsFuture ImprovementsConclusion

BREE-48   Easy-Peasy! Simplifying Breast Cancer 8th American Joint Committee On Cancer (AJCC) Staging System

Participants
Ayla Yamamoto Mota, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Describe and illustrate the preoperative staging of breast cancer with the 8th American Joint Committee on Cancer's (AJCC) staging system.- Emphasize radiologist's role in recognizing and reporting breast cancer imaging findings that can change staging and clinical / surgical management.- Discuss the major changes in the 8th AJCC's staging system.

TABLE OF CONTENTS/OUTLINE

- Introduction: description of the major changes in the 8th AJCC's staging system.- Anatomic staging system: discuss the categories of the anatomic staging and emphasize the key information that the radiologist must search and report.- Prognostic staging system: focus on important concepts for the radiologist.- Ultrasound, mammography and magnetic resonance images: illustrate and facilitate the understanding of the categories of the staging system.- Conclusion

BREE-49   Mammographic Asymmetries BI-RADS V5 Edition: Pearls And Pitfalls, Discussion N Multi-modality Imaging And Correlation With Pathology

Participants
Shima Roknsharifi, MD, Bronx, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

An asymmetry is defined as a unilateral mammographic density with concave margins, not meeting criteria for a mass. Depending on the type, asymmetries are present on 0.3-0.9% of screening mammograms and correlate with malignancy up to 15% of the time. Therefore, it is important to further evaluate and manage asymmetries based on the BI-RADS standardized approach. This presentation aims to discuss asymmetry classification based on the fifth edition of the BI-RADS lexicon, to define management protocols including appropriate BI-RADS category assignment, and to consider the differential diagnosis and pathologic correlation for asymmetries.

TABLE OF CONTENTS/OUTLINE

Classification asymmetry, focal asymmetry, developing asymmetry, global asymmetry. Algorithmic approach to the finding. Assigning appropriate BI-RADS category and management plan. Differential diagnosis: Broad with main consideration of *benign lesions: Normal variation, post-traumatic/surgery including post reduction and fat necrosis, pseudoangiomatous stromal hyperplasia (PASH), diabetic mastopathy, infection/inflammation. *Malignancies: invasive ductal carcinoma (including different variants), invasive lobular carcinoma. Pathology related to each differential diagnosis.

BREE-5   Metastasis To The Breast.What Radiologist Should Know?

Participants
Karina Pesce, MD, Capital Federal, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

To discuss the major clinical, imaging and histological features that will be helpful in order to achieve a proper diagnosis and management. To illustrate imaging features and pathological correlates of cases from our database. To discuss the diagnostic difficulties and differential diagnosis of these cases.

TABLE OF CONTENTS/OUTLINE

Metastasis is a term used to describe the spread of tumor cells from primary sites to surrounding structures and distant sites. It is considered a significant cause of morbidity and mortality. Distant metastasis is an indicative marker of the aggressive nature of the primary tumor. The clinically observed rate of breast metastases from extrammary malignancies is rare, ranging from 0,2 to 1,3%.Cancers that most frequently metastasize to breast parenchymal include Lymphoma, Melanoma and less frequently: Lung, Ovarian, Carcinoid tumors, Hypernephromas, Carcinomas of the liver, Tonsil, Pleura, Pancreas, Cervix, Perineum, Endometrium and Bladder. The recognition of metastases to the breast from extramammary tumor is clinically important. Most patients are treated with systemic therapy or palliative care, so accurate preoperative diagnosis guides appropriate management including the avoidance of unnecessary surgery.

BREE-50   Scoring A Triple Whammy: Understanding The Clinical, Pathologic, And Imaging Features Of Triple Negative Breast Cancer

Participants
Iris Chen, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

Triple-negative breast cancer (TNBC) is a subgroup of breast cancer without estrogen, progesterone, or human epidermal growth factor receptors. TNBC represents 15-20% of all breast cancers and is associated with BRCA. Key imaging features of TNBC on mammography include irregular shape, ill-defined, and spiculated margins. On ultrasound, TNBC tends to appear as a hypoechoic or complex mass with an irregular shape and non-circumscribed margins. Magnetic resonance imaging (MRI) is the most accurate imaging modality to evaluate TNBC and demonstrates intra-tumoral T2 hyperintense signal and rim enhancement on post-contrast images. TNBC has a poor prognosis given its aggressive course, high rates of recurrence, and limited therapeutic options given its lack of target receptor expression. Prompt recognition and diagnosis by imaging is essential. Treatment often involves chemotherapy, and MRI can be used to predict chemotherapy efficacy and pathologic complete response.

TABLE OF CONTENTS/OUTLINE

This exhibit will review the epidemiology, imaging features, pathology correlation, treatment/management, and prognosis of TNBC. We will discuss the key imaging findings of TNBC on multi-modality imaging and discuss the sensitivity and specificity of each feature. We will review how to distinguish TNBC from similar-appearing benign and malignant breast masses to avoid pitfalls in misdiagnosis. Lastly, these concepts will be reinforced through illustrative cases and interactive quiz questions.

BREE-51   Imaging Of The Pediatric Breast: Review Of Normal Development And Spectrum Of Pathology

Awards
Identified for RadioGraphics

Participants
Sonia Phadke, MD, Atlanta, Georgia (*Presenter*) Nothing to Disclose

TEACHING POINTS

Pediatricians may refer patients for breast imaging, typically ultrasound, for a number of reasons. Unlike the adult population, primary breast cancer is extremely rare in the pediatric population, which may signal that pediatric breast imaging is overutilized. Recognition of normal adolescent breast development and its variants is integral when interpreting pediatric breast imaging.? Most commonly, pediatric breast masses are benign entities including fibroadenoma, cyst, fibrocystic changes. Rarely do pediatric breast masses display malignant potential. Management of pediatric breast masses is more conservative than that of adult breast masses with history and clinical exam playing a crucial role in diagnosis and management.

BREE-52 Hiding In Plain Sight: Non-mass Lesions At Breast US

Participants
Julia Colombo, MD, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

• A non-mass finding is a focal area of alteration in the echo-structure different from that of the surrounding glandular tissue and from that at the same place in the contralateral breast. It is a subtle finding that does NOT conform to a mass shape. • It can be categorized by echogenicity (hypoechoic, hyperechoic, mixed) and distribution (isolated focus, multiple foci, speckled pattern, tubular-ductal, regional, lineal-segmentary). • Associated features such as posterior attenuation, calcifications, an echogenic halo and architectural distortion help to distinguish them. • Color Doppler is not always determinant. • Correlation of non-mass findings at US with mammogram and MRI findings is essential for a correct interpretation and categorization. • While at present it is not included as a BIRADS descriptor, its appearance is sometimes suspicious and biopsy is necessary. • The vast majority of this findings are benign, but when malignant, DCIS and ILC are the most frequent pathologies.

BREE-53 Hindsight Is 2020: Understanding The Impact Of The COVID-19 Pandemic On A Provincial Population-based Organized Breast Screening Program

Participants
Helena Bentley, MD, Vancouver, British Columbia (*Presenter*) Nothing to Disclose

TEACHING POINTS

The COVID-19 pandemic has widely disrupted modern healthcare systems. Access to timely, high-quality organized breast screening programs (OBSPs) remains essential to improved patient outcomes.Using data generated from our provincial cancer organization, which exclusively serves a provincial population of over 5 million residents, upon review of this educational exhibit the reader will be better able to: (1) recall the initial response of our provincial population-based OBSP to the COVID-19 pandemic; (2) describe the decrease in screening volumes in this program as a result of the COVID-19 pandemic and the disproportionate effects observed on certain segments of the population; (3) recognize the impacts of the subsequent decrease in downstream referrals of patients to provincial cancer centers for further evaluation; (4) estimate the decrease in early detection and diagnosis of breast cancer attributed to the aforementioned decrease in screening volumes; and (5) discuss recovery strategies employed.

BREE-54 Fast And Furious Breast Lesions: Not All Bad!

Participants
Chloe M. Chhor, MD, Brooklyn, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this educational exhibit is to:Review kinetic assessment in differentiating between benign and malignant breast lesions.Describe differences in kinetic assessment between abbreviated/ultrafast and standard dynamic contrast enhanced MRI.Illustrate with example cases of benign breast masses with early phase enhancement.Discuss the role of T2-weighted and T1 precontrast non-fat sat sequences in categorizing early enhancing breast lesions as benign or suspicious.

BREE-55 COVID-19 and Breast Cancer: To Screen or Not To Screen?

Participants
Julia Colombo, MD, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

• In a pre-COVID-19 era it was said that 1 in 8 women would have breast cancer before the age of 80. • Breast cancer screening in women is extremely important because it allows us to detect subclinical lesions that treated properly and in a timely fashion give our patients a better chance of survival. • During the COVID-19 pandemic thousands of women chose to postpone their breast cancer screening studies. • On the early stages of the pandemic scientific societies recommended to postpone breast cancer screening in women with previously normal studies (BIRADS 1 and BIRADS 2 categories). Afterwards scientific societies encouraged

women to return to routinely breast cancer screening, nonetheless lots of women where fearful of returning to health care facilities.
• While the COVID-19 pandemic should be taken very seriously and we should do our best to avoid non-essential clinical practices, breast cancer screening, given its high prevalence, is of the utmost importance and should be performed complying with all the current protocols available for the safekeeping of our patients.

TABLE OF CONTENTS/OUTLINE

• Short overview of breast cancer screening recommendations during COVID-19 • Main objective of breast cancer screening, its benefits. • Cases of our clinical practice • Conclusion

BREE-56   Fat Necrosis: A Consultant's Conundrum

Awards
Certificate of Merit

Participants
JINITA MAJITHIA, MUMBAI, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

Teaching Points:1. To familiarize the radiologist to a wide range of imaging appearances of fat necrosis: Ranging from benign to malignant appearing.2. Optimize the use of different imaging modalities, like Mammography, Sonography, Contrast Enhanced Mammography and MRI, in diagnosing fat necrosis so as to avoid unnecessary procedures / biopsies.3. To advocate the importance of follow up: At times fat necrosis can have sinister appearances on initial imaging which on follow up reveal benignity.

TABLE OF CONTENTS/OUTLINE

This exhibit will be contain different etiologies of fat necrosis ranging from post-traumatic, post-operative to post radiation, and their multi-modality imaging approach.Post-operative imaging appearances of fat necrosis following different procedures like breast conservative surgery and reconstructive surgery will be demonstrated.Post radiation fat necrosis following EBRT (External Beam Radiotherapy), APBI (Accelerated Partial Breast Irradiation) will be discussed. It will be a pictoral walk-through, through different appearances on various imaging modalities.

BREE-57   Insiders' Tips For Breast Imaging Proceduralists From Pathologists, Surgeons And Oncologists

Participants
Jameson Cumsky, MD, Phoenix, Arizona (*Presenter*) Nothing to Disclose

TEACHING POINTS

Radiologists performing breast imaging interventions play a critical role in supporting downstream care provided by their multidisciplinary colleagues, including pathologists, surgeons and oncologists. Through informed collaboration with multidisciplinary stakeholders, radiologists can implement strategies to modify their techniques for breast interventions to support high quality longitudinal patient care. Participants will learn: New pathological/oncological stains and biomarkers used by multidisciplinary team to enable high quality personalized care How to evaluate appropriateness of quality/quantity of biopsy specimens in real time and selection criteria for appropriate biopsy devices. Multidisciplinary suggestions regarding image guided biopsies, optimization of pathological investigation and processing of specimens, and strategies to avoid unnecessary surgeries and/or biopsies.

TABLE OF CONTENTS/OUTLINE

Background: Opportunity to share lessons learned from on-going multidisciplinary discussions regarding breast interventions at our tertiary care referral center. Overview of changing landscape for breast cancer specimen testing, new biopsy devices, and biopsy capabilities of new advanced imaging modalities. Strategies for breast interventions to optimize patient outcomes: Instrument selection Tissue sampling Information exchange and accurate lesion management Pathological and oncological evaluation and therapy Surgical outcomes following image guided localization

BREE-58   Beyond Breast Cancer: Chest Wall Masses On Breast Imaging

Awards
Certificate of Merit
Identified for RadioGraphics

Participants
Heba Albasha, MD, Cincinnati, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

Review normal breast chest wall anatomy and lymph node stations.Understand imaging findings which suggest lesion origin and chest wall invasion.Discuss the background and multimodality breast imaging features of various benign and malignant chest wall masses, recognizing that not all breast masses found on breast imaging are breast cancer.

TABLE OF CONTENTS/OUTLINE

Breast/chest wall anatomyMuscles/Soft tissuesBonesLymph node stationsOverview of imaging workup MammographyUltrasoundMRIPositioning techniques/Field-of-view limitationsBenign and malignant chest wall mass cases:Inflammatory/Infectious massesCutaneous tumorsAdipocytic tumorsMuscular tumorsFibrous tumorsPlasma cell tumorVascular tumorsPeripheral nerve sheath tumorsOsseous and skeletal tumorsMetastasis from distant cancerLocally invasive breast cancerMetastatic breast cancer

BREE-59   Implementation Of Targeted Automated Breast Ultrasound In A Diagnostic Breast Imaging Clinic: How We Do It

Participants
Gary Wang, MD,PhD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Use of targeted automated breast ultrasound (ABUS) for diagnostic indications can promote care equity by increasing access to high quality diagnostic breast ultrasound (US) in settings with limited handheld breast US expertise. Successful integration of ABUS into the diagnostic breast imaging (BI) setting requires optimization of clinical workflow, image acquisition, and communication protocols. Familiarity with pearls and pitfalls of ABUS image acquisition and interpretation is essential to support confident imaging interpretation in the diagnostic setting. ABUS technologists and interpreting radiologists should be comfortable with problem-solving techniques related to image artifacts, patient groups, and exam indications.

TABLE OF CONTENTS/OUTLINE

We review:1. Rationale for employing ABUS as a diagnostic breast US modality2. Considerations when planning to implement ABUS in the diagnostic setting3. ABUS-integrated clinical workflow used in our diagnostic BI clinic4. Diagnostic ABUS image acquisition protocol5. Diagnostic ABUS interpretation and reporting6. Pearls and pitfalls of ABUS in the diagnostic setting: (a) Artifacts, (b) Problem-solving techniques, and (c) Incidental findings7. Case examples of diagnostic ABUS exams illustrating pearls and pitfalls

BREE-6   Update On Lobular Neoplasia

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Samantha L. Heller, MD, PhD, New York, New York (*Presenter*) Research support, Koios Medical

TEACHING POINTS

Management of lobular neoplasia (LN) is often controversial with known variability in approaches to this high-risk lesion. Historical shifts in understanding of the disease have contributed to confusion regarding excision versus surveillance. However, evolving recognition of both distinct histopathologic variants of LN and the importance of stringent radiologic-pathologic correlation offer potential for more consistent management strategies. In this case-based review, we will examine the distinct pathologic variants of LN and discuss the current literature with respect to evidence-based management.

TABLE OF CONTENTS/OUTLINE

1) Intro/wide variability in management of LN2) Historical shifts in understanding a) 1941 (Foote and Stewart)-DCIS precursor; b) 1970's (Haagenson/Rosen)-risk marker; c) 1992 (Eusebi)-pleomorphic LCIS and variants 3) Non-obligate precursor 4) Risk marker 5) Upgrade rates a) Rad-path correlation b) Rad-path concordance i) Sampling (Cores/Needle gauge/modality) ii) Lesion size iii) Incidental vs. targeted c) Histopathologic variants appropriately classified? 6) Short-term management - Case based review with rad-path correlation: a) Atypical Lobular Hyperplasia b) Lobular carcinoma in situ (LCIS) classic type c) Pleomorphic LCIS d) Florid LCIS 7) Long-term management: a) Chemoprevention and MRI screening 8) Summary

BREE-60   Phantoms For Ultrasound Breast Interventionism: A Low-cost Experience.

Participants
Giannina Secco, MD, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review different types of phantoms. To illustrate a step by step way to build one. To discuss the benefits of using them.

TABLE OF CONTENTS/OUTLINE

Phantoms are widely used for practicing interventional techniques, and in this poster we highlight the benefits of the home-made ones, specially for skill developing in ultrasound guided procedures of the breast. US is an economic, mobile, widely available, minimal risk and efficient technique, that allows a controlled advance of the needle in real time. These advantages combined with low cost phantoms, can lead to well prepared and confident residents/fellows before experiencing with real patients.

BREE-61   Multimodality Imaging Review Of HER2-Positive Breast Cancers And Response To Neoadjuvant Chemotherapy.

Awards
Cum Laude
Identified for RadioGraphics

Participants
Leah Portnow, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. HER2+ breast cancer patients have improved outcomes with newer targeted chemotherapies including first-line agents trastuzumab and pertuzumab.2. Calcifications are more commonly associated with HER2+ cancers, and calcifications remaining on mammography after neoadjuvant chemotherapy may or may not correlate with malignancy and pathologic tumor size.3. Breast MRI has the highest sensitivity and specificity in assessing residual disease burden when compared to the pathologic gold standard.4. The standard of care for detecting residual disease and thus overall prognosis is based on pathologic confirmation.

TABLE OF CONTENTS/OUTLINE

1. Overview of HER2+ breast cancer pathology and patient demographics2. Current Perspectives on Surgical and Oncologic Treatment of HER2+ breast cancers3. Review of Multimodality Imaging Findings of HER2+ breast cancers: A pictorial display of pre- and post-neoadjuvant chemotherapy casesa. Pathologic concordantb. Pathologic discordant4. Future directions of HER2 positive breast cancer - Imaging, Surgical Treatment, and Clinical Trials

BREE-62   Cutaneous Lesions Encountered In Breast Imaging

Participants
Brianna Vey, MD, Atlanta, Georgia (*Presenter*) Nothing to Disclose

Nonmalignant and malignant breast dermatologic conditions can be encountered in breast imaging setting and be challenging to differentiate.Recognizing clinical features, multimodality imaging findings, and histologic diagnosis when needed is important to establish the diagnosis of breast cutaneous disorders.Understanding of specific imaging work up is crucial in management of breast cutaneous disorders.

TABLE OF CONTENTS/OUTLINE

IntroductionExhibit ObjectivesDescribe normal skin anatomy and imaging.Review common benign and malignant breast dermatologic conditions.Differentiate non-malignant breast cutaneous disorders and malignant breast conditions by reviewing associated clinical presentations, imaging findings with pathologic correlations.Discuss management of lesions including imaging work up of benign and malignant cutaneous breast conditionsCutaneous Breast ConditionsInflammatory (Benign) Skin lesionsi. Epidermal Inclusion Cystii. Benign Skin Calcificationsiii. Radiation Dermatitis iv. Hidradenitis Supportiva v. Skin abscessMalignant skin lesions i. Inflammatory Breast Cancer ii. Advanced Breast Cancer with Skin Involvement iii. Radiation Induced Angiosarcoma iv. Paget's Disease v. Metastatic Melanoma vi. Mycosis Fungoides vii. Kaposi Sarcoma

BREE-63   Common And Uncommon Masses Of The Nipple-areolar Complex

Participants
Jose Lopez, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

1.Present a pictorial review of commonly known and uncommon nipple-areolar complex lesions.2.Build a differential for nipple-areolar complex lesions using history and mammographic/sonographic/MRI findings.

TABLE OF CONTENTS/OUTLINE

1. Review radiologic and clinical presentations of commonly known benign and malignant lesions.2. Review radiologic and clinical presentations of uncommon benign and malignant lesions.

BREE-64   Breast Imaging In Children And Adolescents: From Science To Practice - A Pictorial Essay.

Participants
Vanessa Merjane, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is: 1. To review the basic concepts of embryology, anatomy and physiology of normal breast development.2. To discuss multimodality imaging features of common developmental abnormalities, benign and malignant breast diseases in children and adolescents through a case-based review. 3. To suggest a management algorithm based on clinical and imaging findings to avoid unnecessary procedures as well as delays in the diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Embryology 2. Anatomy 3. Physiology / Normal breast development 4. Review of imaging modalities 5. Developmental abnormalities 6. Benign cystic masses 7. Benign solid masses 8. Malignant masses 9. Management algorithm

BREE-65   Fibrous Capsule Lesions: Far Beyond Lymphoma

Participants
Natalia Lima, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:1. To emphasize imaging aspects of the normal fibrous capsule;2. To present different lesions originating from fibrous capsule other than lymphoma;3. To discuss the most frequent changes and lesions related to fibrous capsule and the imaging aspects in different methods (mammography, ultrasound and magnetic resonance imaging).

TABLE OF CONTENTS/OUTLINE

1. Illustrate with cases from our database the usual aspects of the fibrous capsule;2. Correlation of imaging findings with clinical aspects and histopathological results;3. Present and analyze the various presentations imaging findings of the most common lesions of the fibrous capsule and correlate with histopathological results, such as- Contracture;- Calcifications;- Masses;- Lymphoma.

BREE-66   Invasive Lobular Carcinoma: Imaging Aspects In Different Methods (mammography, Tomosynthesis, Ultrasound And Magnetic Resonance Imaging) And Correlation With Tumor Molecular Profile

Participants
Natalia Lima, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:1. To present, based on confirmed cases by percutaneous biopsy and/or surgery from January 2015 to March 2021, the main characteristics of invasive lobular carcinoma (ILC) in different methods of breast imaging (mammography, tomosynthesis, ultrasound and magnetic resonance imaging);2. To correlate the imaging findings with the tumor molecular profile (immunohistochemistry analysis);3. To demonstrate the main characteristics, including clinical aspects and forms of presentation of invasive lobular carcinoma according to each histological and molecular subtype.

TABLE OF CONTENTS/OUTLINE

1. Illustrate the ILC aspects with percutaneous biopsy/surgical proven cases from our Breast Imaging Center, using the four different imaging methods:- Mammography;- Tomosynthesis;- Ultrasound;- Magnetic resonance imaging.2. Teaching cases showing the challenging aspects based on imaging findings and correlate with clinical and pathological findings in different scenarios, such as:- ILC - Late enhancement;- ILC - Synchronous invasive breast cancer;- ILC - Multifocal with microcalcifications;- ILC - MMG ocult;- ILC related to hormonal replacement therapy.3. Correlate the imaging findings with the immunohistochemistry profile of ILC

in the different histological subtypes:- Classic;- Solid;- Alveolar;- Mixed;- Tubulo-lobular;- Pleomorphic.4. Exemplify the imaging aspects of the ILC and its different molecular profiles:- Luminal A;- Luminal B;- HER2+;- Triple negative.

BREE-67   Breast Cancer In Pregnant And Lactating Women. What Do Residents Need To Know?

Participants
Giannina Secco, MD, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

To discuss the key clinical, and imaging features helpful to properdiagnosis and management. To illustrate imaging features and pathological correlates of cases from ourdatabase. To discuss the diagnostic difficulties and differential diagnosis

TABLE OF CONTENTS/OUTLINE

Breast cancer is the second most common cause of oncological death around the world, only surpassed by lung cancer. In addition, breast cancer is one of the most commonly diagnosed malignancies during pregnancy, followed by blood and skin cancers.In the presence of a palpable or symptomatic mass in a pregnant or lactating patient, it is warranted to investigate the aetiology of the abnormality. The management of pregnant and lactating patients is safe and must be done in a multidisciplinary way.

BREE-68   What Lurks Beneath The Shadows: The Diagnostic Challenges Of Nipple And Retroareolar Breast Masses

Participants
Jason Chan, Ottawa, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

Approximately 8% of breast cancers are situated in the retroareolar region (within 2 cm of the nipple), and cancers in this area are considered more challenging to diagnose and biopsy than cancers elsewhere in the breast. The overall rate of missed breast cancers has been reported as high as 35%, and this may be higher in the retroareolar breast. Since missed cancers may have devastating consequences, it is imperative for radiologists to be aware of the challenges and commonly missed areas, or "blind spots", such as the retroareolar region. The purpose of this educational exhibit is to raise awareness of the diagnostic challenges in detecting retroareolar cancers and to provide tips on how radiologists can improve their detection of retroareolar cancers through a pictorial review of missed and interesting cases.

TABLE OF CONTENTS/OUTLINE

The challenges of retroareolar masses and tips to avoid missed lesions: how to optimize visualization and assessment of the retroareolar "blind-spot", the increasing role of using MRI for problem solving and evaluation of nipple discharge, and the importance of correlating imaging findings with a physical exam.Tips on how to biopsy retroareolar and intraductal masses and review the common and more rare pathologies.

BREE-69   Breast Cancer Screening In Childhood Cancer Survivors: An Update In Evidence-based Risk Management

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Yiming Gao, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

Breast cancer risk among childhood cancer survivors remains substantial despite advances in radiation therapy to curtail exposure. Cumulative risk among survivors of Hodgkin's lymphoma is up to 25% by age 45 vs. 1% in the general population and rises with time, and breast cancer survival is worse among these patients. Current screening guidelines focus on prior exposure to chest radiation, but the spectrum of at-risk survivors is wider. Compared to BRCA mutation carriers who have similar breast cancer risk, childhood cancer survivors have significantly poorer adherence to screening despite its mortality benefits. We will discuss new evidence in risk-based screening in the context of modern therapy, and consider challenges and mitigating strategies.

TABLE OF CONTENTS/OUTLINE

1. Childhood Cancer Survivors a. Exposure to developing breast tissue b. Average age breast cancer ~ 40 2. Breast cancer in young survivors a. High risk if XRT < age 30, dose = 10 Gy b. Prone to Triple Negative cancers 3. Risk considerations a. Low dose/large field --> ? risk b. High dose/small field --> ? risk c. XRT + Chemo (synergistic) --> ?? risk d. Chemo without XRT --> ? risk 4. Radiation therapy advancement a. Smaller field, Lower dose, Conformal techniques b. Mantle XRT dose (~40 Gy) >> Modern therapy 5. Screening guidelines a. Annual screening age = 25 or 8 years after XRT, whichever later b. Mammogram + MRI --> highest sensitivity/specificity 6. Poor screening adherence (12.6-57.1%) a. Transition from pediatric to adult care challenging 7. Case-based review

BREE-7   Breast Masses In Children And Adolescents

Awards
Identified for RadioGraphics

Participants
Laura Harper, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Review breast embryology, early and pubescent breast development and recognize the spectrum of variations of normal development.-Compare various imaging modalities and best practice guidelines for evaluating breast masses in children and adolescents and understand why the diagnostic approach to the developing breast is different from that of the adult breast.-Learn a wide range of common and uncommon benign, borderline and malignant lesions of the pediatric breast and their diagnostic

management.

TABLE OF CONTENTS/OUTLINE

This will be a multimodality case-based review of the spectrum of breast masses in children and adolescents. The appropriateness of various imaging modalities, diagnostic imaging approach and next steps in management will be emphasized. Clinical images and pathologic slides will be included when available.Development: Breast embryology, pre-pubertal breast buds, five tanner stages of pubertal breast development.Normal variations of normal breast development: Asymmetric breast buds, accessory breast tissue, gynecomastia.Infection: Abscess/mastitis.Lymphatic/Vascular: Infantile hemangioma, lymphangioma.Benign masses: Cyst, fibroadenoma and juvenile fibroadenoma, intraductal papilloma and juvenile papillomatosis, pseudoangiomatous stromal hyperplasia.Borderline breast masses: fibroepithelial lesions, phyllodes tumor, neuroblastoma-like schwannoma.Malignant breast masses: invasive ductal carcinoma, lymphoma, rhabdomyosarcoma.

BREE-70   Tomosynthesis Guided Breast Procedures: Pearls And Pitfalls

Participants
Tali Amir, MD, Montvale, New Jersey (*Presenter*) Nothing to Disclose

TEACHING POINTS

Digital breast tomosynthesis (DBT) guided breast procedures have expanded to include both breast biopsy and preoperative localization. DBT procedures offer advantages of increased conspicuity of low contrast lesions, as well as time and dose reduction. Recognizing advantages, pitfalls and problem-solving techniques for DBT guided procedure can help ensure success.

TABLE OF CONTENTS/OUTLINE

Through a case based series, we will discuss: 1. DBT guided biopsy a) Appropriate clinical setting b) Advantages over traditional DM stereotactic biopsy c) Potential pitfalls d) Problem solving techniques 2. DBT guided preoperative I-125 seed localization a) Appropriate clinical setting b) Advantages over traditional two-view preoperative localization c) Potential pitfalls d) Problem solving techniques

BREE-71   When A 5 Is Benign: Pictorial Review Of Breast Malignancy Mimics

Awards
Certificate of Merit

Participants
Bill Zhou, Los Angeles, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

There are a multitude of benign, high-risk, inflammatory, post-surgical, and artifactual breast entities which can mimic features of malignancy. Frequently, these entities prompt tissue biopsy and not infrequently, they cause additional workup due to radiologic-pathologic discordance, causing both emotional stress and financial burden for patients. Based on our institution's own experience, the most over-called discordant findings resulting in additional excisional biopsy are stromal fibrosis, fat necrosis, and radial scar on final pathology. The objectives of this exhibit are to 1) recognize common and uncommon mimics of breast malignancy and 2) appreciate their mammographic, ultrasound, and MRI imaging characteristics with the hopes of reducing unnecessary surgical interventions.

TABLE OF CONTENTS/OUTLINE

Benign Entities: 1. Fat necrosis 2. Stromal fibrosis 3. Sclerosing adenosis 4. Fibroadenoma 5. Hemangioma 6. Pseudoangiomatous stromal hyperplasia 7. Intrammmary lymph node. 8. Granular cell tumor.High-risk Entities: 1. Atypical lobular hyperplasia 2. Atypical ductal hyperplasia 3. Usual ductal hyperplasia 4. Lobular carcinoma in situ 5. Papilloma 6. Radial scar/complex sclerosing lesion 7. Phyllodes tumor.Inflammatory Entities: 1. Mastitis 2. Diabetic mastopathy 3. Mondor disease.Post-surgical: 1. Post-surgical changes 2. Scar tissue 3. FloSeal 4. Bovie artifact.Artifacts: 1. Dead pixels 2. Dust on detector 3. Motion artifact.

BREE-72   Artificial Intelligence In Breast Imaging: What's Going On In Real World?

Participants
Fernamda Amorim, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Breast imaging has become the most clinical of radiology's specialties. A complex workflow including multimodality diagnostic evaluations, high patient volume, outcome audits is part of routine for breast imagers. Newer artificial intelligence (AI) methods, particularly deep learning (DL), are showing great promise improving diagnosis, clinical decision making, patient outcomes, and workflow areas in breast imaging. The advances in the computer power and mathematical algorithms has enabled the use of complex multilayered deep neural networks, resulting in improvement in performance of machine interpretation of highly standardized imaging tasks.

TABLE OF CONTENTS/OUTLINE

Discuss AI current applications on Mammography, Digital breast tomosynthesis (DBT), handheld ultrasound (US), Automated breast US and magnetic ressonance imaging (MRI). Future directions on this imaging modalities and limitations. Potential uses of AI in breast imaging: diagnosis (detection and classification of lesions), clinical decision making (assesing breast cancer risk based on algorithms that mix patient data and image characteristics, such as breast density / mamographic parenchymal pattern), Outcomes analyses (breast cancer detection rates, recall rates and positive predictive values) and Workflow (improving reading time in diagnostic breast imaging, with no decrease in accuracy). Review the evidence supporting AI in practical and the challenges remaining.

BREE-73   On Target: A Step-by-step Guide For Residents To Learn Stereotactic Biopsy

Participants
Ayla Yamamoto Mota, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

- To familiarize resident physicians with the stereotaxis technique for diagnosing suspicious breast lesions seen on mammography;- Considerations about the equipment and needles used in the procedure;- Illustrate the stereotactic biopsy step by step, from planning to managing possible complications, with images documented in our radiology department.

TABLE OF CONTENTS/OUTLINE

-Learning the indications, contraindications, planning and technique os stereotactic breast biopsy; -Describe the post-biopsy care that should be directed to the patient; -Identify the main complications and learn how to manage them; -Image appearance in the step by step of stereotactic breast biopsy, facilitating the understanding of the resident who has not yet performed it.

BREE-74   Hey You, We Have Our Own Lesions! A Case;#8211;Based Quiz For An Update Of Breast Lesions In Children And Adolescents, Diagnostic Approach And Management

Awards
Certificate of Merit

Participants
Mariana de Oliveira Leite, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To explain in an illustrative, clear and interactive way, in the form of a quiz, normal breast development and its anomalies.To demonstrate the role of each imaging modality in the evaluation of pediatric breast findings.To emphasize the differential diagnosis and investigation algorithm in pediatric age group and practices to avoid.To clarify the management of imaging findings in children and adolescents, since most are benign and inappropriate invasive procedures can damage breast development.To clarify which cases require biopsy.

TABLE OF CONTENTS/OUTLINE

To simplify understanding of normal breast development and the spectrum of pediatric breast lesions, that differ from those in adults and in the vast majority are benign. Ultrasound is the first imaging modality. Management is usually conservative.To show clinical cases that illustrate image manifestation of breast lesions in children and adolescents.To provide an educational basis for radiologists to reassure patients, families and healthcare professionals that the risk of malignancy of pediatric breast lesions is low.To reaffirm that physical examination and history are key to appropriate management in this population.To standardize an approach for management of pediatric breast masses, calling attention to the indications and particularities of each method.To elucidate alarming clinical history or radiographic findings of pediatric breast lesions that should lead to histopathological analysis and clarify those that can be followed-up with safety.

BREE-75   Breast Cancer Under The Age Of 30-An MRI Approach

Participants
Niels Vinicius Padua Carvalho, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The aim of this exhibition is to: Review the recommendations for screening in this age group. Understand how to access and interpret a breast MRI. Discuss the current concepts about breast cancer MRI findings in young women. Show the breast cancer data and rates from our institution in this age group. Highlight the importance of this method to guide the proper management of these patients.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION: Epidemiological profile of breast lesions in this population. Recommendations for screening, control and surveillance in young women, and when to use MRI. IMAGING INTERPRETATION: Imaging techniques acquisition and protocols. ACR BI-RADS method for interpretation and reporting system of the findings. STATISTICAL DATA: Breast MRI and breast cancer in women under the age of 30 from our institution between 2016 and 2021.INTERACTIVE CASE-BASED DIDATICS: Sample cases to illustrate and solidify the concepts about the main findings of breast cancer in young women's MRI. CONCLUSION: Breast cancer under the age of 30 are rare but it is associated with poor survival. Early detection and proper management have the potential to improve survival, less invasive treatments and a better quality of life. Therefore, we need to know how to manage these patients, their screening and complaints.

BREE-76   Axillary Lymph Node Imaging In Breast Cancer

Awards
Certificate of Merit

Participants
Aishwarya Gulati, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

At the end of this presentation, the reader will be able to: 1. Understand the normal appearance of axillary lymph nodes and suspicious features on ultrasound. 2. Understand the technique of scanning the axilla as well as the available diagnostic modalities. 3. Understand the various options available to sample these lymph nodes, the indications to sample as well as the technique. 4. Understand the implication of preoperative diagnosis on clinical management.

TABLE OF CONTENTS/OUTLINE

1. Normal Anatomy a. Morphology and distribution 2. Importance of Lymph Nodes in Breast Cancer a. Staging, sentinel node biopsy, axillary dissection 3. Role of Imaging a. Ultrasound, MRI, PET scan 4. US Technique a. Patient positioning, ultrasound protocol 5. Normal and Abnormal Lymph Nodes on Ultrasound a. Comparison of imaging features and corresponding sensitivity/specificity for malignant involvement b. Collection of lymphadenopathy secondary to COVID vaccination 6. Image-guided Sampling a. Indications and technique b. Comparison of sensitivity and specify among sampling techniques 7. Impact on Management 8. Future Developments

BREE-77   Breast Incidental Findings: You Better Not Ignore Them!

Awards
Certificate of Merit

Participants
Rodrigo Carneiro, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To list the main benign and malignant breast incidental findings identified on different imaging modalities, including CT, PET-CT and MRI; 2. To demonstrate how to more accurately describe breast incidental lesions found in different imaging modalities; 3. To demonstrate the importance of a systematic exam analysis by the radiologist, avoiding missing the diagnosis of relevant incidental findings. 4. To warn clinicians and patients about the high rate of malignancy in breast incidental findings and assist in the management of these injuries. 5. Instructions for radiologists about the importance to communication and monitoring in relevant incidental findings.

TABLE OF CONTENTS/OUTLINE

1. Main benign and malignant incidental breast lesions; 2. Normal and abnormal breast appearance on CT; 3. Illustrated teaching cases from our department of breast incidental findings in different imaging modalities and their outcomes, including: CT angiography, Coronary CT angiography, CT of the ribs, Chest CT, Mediastinal MRI and PET-CT scan. 4. Systematic imaging analysis: tips from specialists to avoid missing lesions; 5. Show our department's strategy to report and follow up these findings, providing assistance to the patient to be able to proceed with further investigation when necessary.

BREE-78   Ultrasound Of Pediatric Breast Lesions - A Summary

Participants
Hiral Banker, MD, Memphis, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Breast masses in children are uncommon and mostly benign. Differential diagnostic considerations of a breast mass in children are different from adults. Ultrasound is the primary modality in pediatric breast mass evaluation and biopsy is rarely performed due to the potential of damage to the developing breast. Thorough knowledge of ultrasound appearance of different breast conditions is necessary, especially for the pediatric radiologists to differentiate lesions which may warrant extensive management from those in which aggressive/surgical diagnostic procedures and treatment is not necessary. This exhibit will review the common and uncommon conditions of the pediatric breast with image illustrations.

TABLE OF CONTENTS/OUTLINE

• Overview of ultrasound the appearance of the prepubertal and pubertal pediatric breast and normal variants. • Describe clinical presentation and imaging appearance of various breast lesions with case illustration. • Explain key radiological differentiating features of pediatric breast masses including congenital conditions, infection, neoplasm, trauma, and vascular lesions. • Review uncommon pediatric breast lesions with case illustration, e.g., breast metastasis from rhabdomyosarcoma, pediatric breast fibrous histiocytoma.

BREE-79   Application Of Deep Learning To Establish Diagnostic Model Of Breast Lesions Usingdynamic Videograyscaleultrasound Imaging

Participants
Nan Zhang, Beijing, China (*Presenter*) Nothing to Disclose

TEACHING POINTS

This study aimed to establish artificial intelligence (AI) diagnostic models of breast lesions using dynamic video US imaging, , which will help radiologists detect lesions and classify lesions between benign and malignant.

TABLE OF CONTENTS/OUTLINE

Methods:Using pathology and follow-up results as a reference, the dynamic video US images of 2,091 breast lesions were evaluated and used to establish an AI model. The diagnostic performance of the AI diagnostic model and the radiologist was calculated and compared. Results: The accuracy of the AI model for the detection of lesions in the test set was 98.4%. The sensitivity, specificity, PPV, NPV and accuracy of radiologists were higher than those of the AI model, but the difference was not statistically significant, respectively (P&gt0.05). The AUC of radiologists was 0.930, and of the AI model was 0.894, the difference was not statistically significant (P&gt0.05). The AUC of the AI model that predicted the probability of malignancy was 0.945. And when the cut-off value was 0.0298, the Youden's index was the highest, which was 0.809. Conclusions: The diagnostic performance of the AI diagnostic model of dynamic video US images is comparable to that of radiologists. And with the development of AI technology, AI diagnostic model for real-time detection of lesions and classification of benign and malignant breast lesions will gradually achieve.KEY WORDS: Artificial intelligence, Breast ultrasound, Deep learning, Dynamic video

BREE-8   T2 Bright Lesions On Breast MRI: Benign And Malignant Causes

Participants
Averi Gibson, MD, Worcester, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Discuss the differential for T2 bright lesions seen on breast MRI. 2. Present examples of both benign and malignant T2 bright lesions. 3. Analyze the differences between the appearance of T2 bright benign and malignant etiologies. 4. Recognize that a complete understanding of the imaging features of T2 bright lesions will help to reduce false positives while still identifying the more rare T2 bright malignant lesions.

TABLE OF CONTENTS/OUTLINE

1. Introduction including MRI's role in breast cancer screening/workup and interpretation of T2 breast MRI sequences. 2. Case

presentations of specific T2 bright pathologies, including a discussion of the clinical history, imaging, diagnosis and management for each lesion. The following pathologies will be discussed: cyst, fibroadenoma, fat necrosis, apocrine metaplasia, tubular adenoma, benign lymph nodes, metastatic lymph nodes, mucinous breast cancer, and necrotic breast cancer. 3. Compare and contrast imaging features of benign and malignant etiologies. 4. Summary/Conclusion

BREE-80 What To Expect When You'Re Expecting: Unique Features Of Breast Lesions In Pregnant Women

Participants
Carolina Kiebert, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review the epidemiology and clinical presentation of breast tumors in pregnant and lactating women.To review the best imaging methods for diagnostic investigation.To show the radiological and anatomopathological characteristics of the main breast cancer in pregnant and lactating women.To point out the clinical management and treatment of breast cancers in these patients.

TABLE OF CONTENTS/OUTLINE

To review breast imaging workup for pregnant and lactating patients.Briefly review benign entities that can simulate breast cancer in pregnant women.Focus on clinical and imaging forms of pregnancy-associated breast carcinoma in association with anatomopathological aspects.Highlight some of the recommendations for the treatment of these tumors by illustrating this exhibit with cases from our radiology department.

BREE-81 Keeping Up With Controversies: Everything You Need To Know About Breast Health In Elderly Patients

Awards
Certificate of Merit

Participants
Denny Lara Nunez, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Discuss key concepts about screening in elderly patients including benefits and risks 2. Review different guidelines, recommendations and evidence on screening mammography in older women 3. Assess normal aging imaging findings in mammography 4. Describe different benign and malignant breast pathologies frequently found in elderly patients 5. Discuss controversies regarding screening in elderly patients

TABLE OF CONTENTS/OUTLINE

1. Comparison between different screening guidelines including a discussion of controversies. 2. Review of general aspects and imaging findings of benign breast pathology in elderly women including the following: mastalgia, benign calcifications, fibroadenomas, ductal ectasia, cysts. 3. Description of each of the following categories for breast cancer in elderly women: A.Epidemiology B.Clinical presentation C.Imaging findings D.Treatment and management 4.Discussion of tumor biology and changes through age 5.Review of normal aging changes in breast imaging studies 6.Discussion of ethical aspects and assessment of older patients

BREE-82 Breast Imaging Controversies In The Elderly Population

Participants
Manisha Bahl, MD,MPH, Boston, Massachusetts (*Presenter*) Consultant, Lunit Inc;Advisory Board, Accolade Inc

TEACHING POINTS

Breast cancer is the second most common cause of death from cancer among women in the United States, with increasing incidence and mortality rates with age. The incidence of breast cancer peaks in women aged 70-79 years, and it is estimated that nearly half of breast cancer-related deaths occur in women aged 70 and older. Controversies exist with regard to screening guidelines for the elderly. For example, the American Cancer Society recommends that older women continue biennial screening mammography until their life expectancy is less than 10 years, while the United States Preventive Services Task Force recommends biennial screening mammography until the age of 74 years. Concerns also exist with regard to overdiagnosis and overtreatment of breast cancer in the elderly. However, older women are not as likely as younger women to undergo standard treatments for breast cancer, which may diminish the adverse effects of overtreatment, since older women are more likely to have competing comorbidities and/or favorable tumor biological profiles.

TABLE OF CONTENTS/OUTLINE

This educational exhibit will review: (1) breast cancer statistics in the elderly population (e.g., incidence, screening utilization), (2) the biological profile of breast cancers in the elderly, (3) the controversial guidelines for screening mammography, and (4) breast imaging and treatment considerations including concerns with regard to overtreatment.

BREE-83 AI For Breast Imagers: Past, Present, And Future

Participants
Alyssa Watanabe, MD, Manhattan Beach, California (*Presenter*) Officer, CureMetrix, Inc;Stockholder, CureMetrix, Inc

TEACHING POINTS

To provide an overview of nomenclature and used in artificial intelligence and new forms of CAD such as CADx and CADt. The challenges of AI including non-binary nature of breast disease, the lack of gold standard for breast tissue density, and promise of data driven reports will be discussed.

TABLE OF CONTENTS/OUTLINE

The history of artificial intelligence (AI) and evolution toward use of deep learning and convolutional neural networks (CNN) will be covered. The basics of artificial neural networks and generational adversarial networks (GAN) will be explained along with how these techniques relate to new algorithms for breast imaging including lesion and case scoring, triage, tissue density classification, image

enhancement, and breast risk stratification. The current status and future of deep learning models in breast imaging will be presented as well as how AI may impact imaging workflow, physician performance, and patient management. The impact of AI in structured reports and interactive reporting and the potential of federated learning will be covered. The challenges of AI in breast imaging, such as shades of gray of breast pathology, how to train machines in subjective analysis such as tissue density, regulatory issues, QA, and generalizing to different equipment vendors and demographics are discussed. A brief review of how to analyze algorithms will also be covered.

BREE-84   Better Late Than Never - The State Of Locally Advanced Breast Cancer In 2021

Awards
Certificate of Merit

Participants
Victoria Wells, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Breast cancer is the most common cancer among women with the 2nd highest death rate after lung cancer and is the most common cancer globally as of 2021. Screening mammography helps to detect cancer early with improved outcome. In this exhibit we review the typical presentation of locally advanced breast cancer (LABC) and discuss the factors that may contribute to late presentations including health disparities, education, socioeconomic factors, and non-compliance with screening. We will review the imaging presentation and work-up and discuss the multidisciplinary approach which includes staging, neoadjuvant chemotherapy, decision points for surgery/XRT, and long-term outcomes. Lastly, we will present strategies to decrease the percentage of cases that present in the future including educational outreach regarding screening mammography and risk assessment in the breast imaging suite.

TABLE OF CONTENTS/OUTLINE

Review of LABC and clinical symptoms leading to patient presentations. Review factors that contribute to late presentation including social determinants of health, noncompliance with screening, and delays in care. Using cases, discuss diagnosis and staging including imaging (mammogram, US, PET/CT, bone scan, MRI), biopsy, and pathological evaluation. Discuss treatment options and outcomes for patients with LABC. Present strategies to decrease the incidence of late presentation in a breast imaging practice.

BREE-85   Through The Looking Glass: Demystifying Breast Pathological Markers

Awards
Identified for RadioGraphics

Participants
Victoria Wells, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Breast imagers regularly perform image-guided biopsies of breast lesions and provide management recommendations based on the radiologic-pathologic concordance. As diagnostic partners, pathologists perform immunohistochemical stains utilizing biomarkers to characterize the biopsied tissue and determine pathologic diagnoses including breast malignancy, lymphoma, and benign breast diseases. Utilizing a case-based approach, this exhibit will review biomarkers commonly used by pathologists to classify breast core tissue specimens into benign or malignant entities. Furthermore, we will discuss the role of immunophenotypes in breast cancer and their therapeutic implications.

TABLE OF CONTENTS/OUTLINE

Review role of biopsy indications in evaluation of patients presenting for diagnostic imaging evaluation Provide overview of pathological approach to classifying breast core biopsies including H&E staining, immunohistochemical markers, and FISH Present cases of benign and malignant biopsies with focus on how biomarkers, H&E and immunohistochemical markers are used to determine specific diagnoses including malignancy, lymphoma, and variety of benign diseases including fibroadenoma, phyllodes, complex sclerosing lesion, fibromatosis, granulomatous mastitis, and papilloma.

BREE-86   Extra-Mammary Vascular Findings Detectable On Breast Magnetic Resonance Imaging (MRI): A Pictorial Review.

Participants
Sonya Khan, MD, Fullerton, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Familiarity with the imaging characteristics and basic management of extra-mammary vascular findings detectable on contrast-enhanced breast magnetic resonance imaging (breast MRI) is crucial for the interpreting physician. Such findings may require additional imaging evaluation, treatment, or even urgent intervention, with missed/misinterpreted findings posing a dangerous risk to the patient.2. Establishing a knowledge base via review of key MRI sequence-specific imaging characteristics to aid accurate detection/differentiation of common and uncommon extra-mammary vascular pathologies.3. Review of multimodality imaging correlates for each pathology.4. Targeted discussion of key evidence-based clinically appropriate management pearls for each vascular finding, aimed at prompting recommendations that optimize patient care following accurate interpretation.

TABLE OF CONTENTS/OUTLINE

1. Multimodality (MRI, ultrasound, computed tomography [CT], angiography) imaging review of common, uncommon, incidental and critical extra-mammary vascular findings detected on breast MRI examinations performed at our institution, including:a. axillary hematoma versus pseudoaneurysm;b. pulmonary arteriovenous malformation;c. extra-mammary hemangioma;d. cardiac pathology;e. great arch vascular anomalies.2. Summary of key evidence-based clinically appropriate management guidelines for each reviewed pathology.

BREE-87 Is It Time To Consider Active Surveillance For Atypical Ductal Hyperplasia?

Participants
Cecilia L. Mercado, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

TEACHING POINTS• Atypical ductal hyperplasia is a nonobligate precursor to breast carcinoma and carries an associated elevated risk for the development of breast cancer.• Current management guidelines for atypical ductal hyperplasia dictate surgical excision for most cases.• Challenges with overtreatment of atypical ductal hyperplasia remain while clinical trials explore active surveillance for low grade DCIS.• Various patient and lesion criteria can be used to minimize overtreatment of ADH and allow for consideration for active surveillance

TABLE OF CONTENTS/OUTLINE

TABLE OF CONTENTS/OUTLINE1. Introduction2. Background• Definition of atypical ductal hyperplasia, nonobligate precursor and associated elevated risk• Imaging appearance (calcifications, mass, and nonmass enhancement in cases on MRI)• Pathology diagnosis and contrast with borderline ADH-DCIS lesions and DCIS3. The American Society of Breast Surgeons Consensus Guidelines for management of atypical ductal hyperplasia• Surgical excision for most cases• Active surveillanceo small-volume ADH and ADH completely excisedo imaging and pathology concordanceo consider breast cancer risk factors4. Overtreatment of ADH5. Additional patient and lesion criteria that can be used to support active surveillance of ADH• Criteria includeo Additional high-risk lesiono Mode of biopsyo Lesion typeo Lesion sizeo Genetics of atypical ductal hyperplasiao Use of DCE-MRI to triage patients to surgery vs. active surveillance

BREE-88 Male Breast MRI: Think Outside The Box And Put Them Inside The Tube

Participants
Tatiana Tucunduva, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To familiarize general radiologists, surgeons and clinicians with breast magnetic resonance imaging (MRI) in male patients. - To present clinical and imaging of some benign and malignant pathologies male breast in MR, and correlate it with other imaging modalities. - To demonstrate situations which MR had an important role in evaluating male breast imaging.

TABLE OF CONTENTS/OUTLINE

- Introduction: There are no clear indications or guidelines for performing MRI in male patients, even in the setting of a diagnosis of breast cancer. But there are few instances where MRI may help clinicians and surgeons. In this review of cases that were performed in our institution, we aimed to provide better understanding of when it may be helpful to perform breast MRI in male patients.- Mammography, ultrasound, chest computed tomography and MR images: clinical cases which breast MR had an important role.- Conclusion.

BREE-89 Mitigating The Impact Of Coronavirus Disease (COVID-19) Vaccinations On Patients Undergoing Breast Imaging Examinations: A Multimodality Case Based Breast Imaging Review

Awards
Certificate of Merit

Participants
Leslie Lamb, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Reports of patients with axillary lymphadenopathy identified on breast imaging after COVID-19 vaccination were described soon after vaccines were administered in December 2020. As these reports became more numerous in vaccinated patients, our division implemented a pragmatic management approach in consultation with our referring clinicians and breast specialists (medical oncology, surgery, and radiation oncology), based on clinical presentation (screening, diagnostic, pre/peri cancer treatment) and imaging findings. Our recommendations align with the ACR BI-RADS Atlas (5th Edition) and aim to: 1) reduce patient anxiety, provider burden and cost of unnecessary evaluation of enlarged nodes in the setting of recent vaccination and 2) avoid delays in vaccinations and breast cancer screening during the pandemic.

TABLE OF CONTENTS/OUTLINE

1. History of vaccine related adenopathy 2. CDC guidelines and recommendations for currently approved COVID-19 vaccines 3. Breast imaging COVID-19 vaccine position statements 4. Ipsilateral axillary lymphadenopathy in setting of COVID-19 vaccine: i. Multimodality case-based review in (a) screening, (b) diagnostic, and (c) pre/peri- cancer treatment settings ii. Incidence, outcomes and cost-savings analysis of diverse management protocols

BREE-9 Imaging Findings Of Acellular Dermal Matrix Used In Breast Reconstructive Surgery: What Do Radiologists Need To Know?

Participants
Manuela Durando, Turin, Italy (*Presenter*) Nothing to Disclose

TEACHING POINTS

The major teaching points of this exhibit are:1. To review the current role of Acellular Dermal Matrix (ADM) in implant-based breast reconstruction2. To describe the normal ed abnormal imaging findings (including mammography, ultrasound and MRI features) related to the presence of ADM in Implant-Based Breast Reconstruction3. To gain awareness of the possible imaging changes, during time, of ADM

TABLE OF CONTENTS/OUTLINE

1)Different surgical techniques used in breast reconstruction; 2)Use of ADM in Implant-Based Breast Reconstruction: 2a) Indications, contraindications, disadvantages, and advantages; 2b) Human ADM versus animal ADM; 3) Mammography, ultrasound

and MRI findings of ADM (human and animal): 3a) Common appearance; 3b) Changing over time; 3d) Differential diagnosis from recurrence, postoperative seroma/hematoma, fat necrosis or extracapsular implant rupture; 3e) Sample cases; 3f) Tips & tricks; 4) Clinical implications and summary

BREE-90   Li-fraumeni Syndrome And Breast Cancer: What, Why, How And Who.

Participants
Yana C. Silva Neves, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

-To assess and give an update in detail the concepts of Li-Fraumeni Syndrome (LFS) with a focus on breast cancer. -To understanding the epidemiologic, genetic and pathophysiologic features associated with Li-Fraumeni Syndrome. -To empower and educate the radiologist to appropriately contribute to patient management, ensure accurate and timely diagnosis and make LFS-specific imaging recommendations.

TABLE OF CONTENTS/OUTLINE

-Define what Li-Fraumeni Syndrome is, its current clinical diagnostic criteria and the importance of knowledge of it for radiologists.-Describe how the TP53 gene mutation contributes to oncogenesis in patients with LFS and show the factors associated with the highest prevalence of this syndrome in America. -Draw the profile of patients with LFS and despair the attention for this diagnosis in patients with early-onset BC (under 36 years) or very early-onset BC (under 31 years), as well as detailing the screening in this population.-Describe the main imaging findings and their histopathological correlation and review other types of breast cancer associated with this syndrome, such as breast implant-associated anaplastic large cell lymphoma and postoperative radiation-induced malignancies.

BREE-91   Bia-alcl: A Review Of The Recent National/ International Guidance And Best Practise Guide

Participants
Aia Mehdi, MBBS, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Breast Implant Associated Anaplastic Large Cell Lymphoma is an emerging Non-Hodgkin Lymphoma associated with exposure to breast implants.- It presents as two clinical entities - 'effusion-only' and 'mass-forming' and has uniquely congruent radiologic-pathologic features and highly nuanced imaging findings- prompt diagnosis and subsequent treatment initiation can be achieved by utilization of appropriate imaging, and results in an excellent prognosis-Imaging diagnosis in BIA-ALCL has recently undergone review, with publication of international guidance: MHRA PRASEAG guidance (Feb 2020) and NCCN Guidance (October 2021).-In our tertiary specialist centre for BIA-ALCL, cases presented at the multidisciplinary team meeting frequently have had a) inappropriate imaging tests b)inappropriate results interpretation. Imaging features in the context of suspect BIA-ALCL can be particularly challenging and prone to misinterpretation.

TABLE OF CONTENTS/OUTLINE

In this exhibit we will provide:- An introduction to evidence-based imaging features of BIA-ALCL- An outline of how the latest guidance have optimized the imaging pathway- A novel imaging pathway which simplifies and stratifies diagnosis based on: the disease subtype, management step, and disease stage- Demonstrative challenging clinical cases with learning points- Tips and tricks for reporting radiology residents and attendings on common imaging 'false-positives' and 'false-negatives'

BREE-92   Breast Infection With Corynebacterium Species, An Important Mimicker Of Breast Cancer Benefiting From A Directed Diagnostic And Therapeutic Approach

Participants
Fabio Accorsi, MD, London, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

Inflammatory breast disease is a known clinical and imaging mimicker of breast cancer. There is growing evidence for the pathologic role of corynebacteria in acute mastitis, granulomatous mastitis, and breast abscess, but these organisms present unique microbiological and histological challenges which contribute to their under-recognition as potential pathogens in breast infection. Corynebacteria are infrequently detected on gram stain and when seen are commonly dismissed as non-pathogenic contaminants. Additionally, culturing of some subspecies is difficult, requiring modified culture media and extended incubation. Lastly, corynebacteria have a broad and varied antibiotic resistance profile with special pharmacokinetic considerations. The astute radiologist may play a critical role by eliciting the possibility of corynebacterium infection when submitting fluid or tissue samples for gram-stain, culture, and sensitivity, facilitating rapid and accurate diagnosis, susceptibility testing and appropriate subspecialty care. They may also be the first to suggest repeat sampling in indeterminate cases falsely presumed to be contaminated with corynebacteria.

TABLE OF CONTENTS/OUTLINE

a) 1. Case 1: Corynebacterium infection mimicking inflammatory breast cancer - Imaging at Presentation. b) 2. Case 1: Diagnosis and Treatment c) 3. Case 1: Long-term Follow-up and Teaching Points d) 4. Case 2: Corynebacterium infection mimicking focal breast cancer 5. Case 3: Corynebacterium infection mimicking multifocal breast cancer

BREE-93   Sonography Findings Not Included In The Birads Lexicon: We Have To Weigh Non-mass Lesions

Participants
Helena de Souza, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:1- To review the available definitions and the main image features of non-mass lesions on ultrasound;2- To illustrate the differential diagnosis of non-mass lesions;3- To demonstrate the importance of recognizing non-mass lesions and how correlation with mammography and breast MRI can improve detection and accuracy of benign and malignant lesions.

-Illustrative teaching cases from our department of the categorization system focused on echogenicity and distribution of non-mass lesions;-Review of the most common breast lesions that may present as non-mass lesions;-Illustrative teaching cases from our department demonstrating lesions categorized as non-mass lesions on ultrasound, their correlation in different imaging modalities and with the respective pathologic examination.

BREE-94   A Guide To Preoperative Seed Bracketing Of Breast Lesions

Participants
Joao Horvat, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To discuss the impact of preoperative localization in breast cancer treatment. - To describe the advantages and disadvantages of preoperative seed localization in comparison with other approaches. - To demonstrate the imaging aspects of lesions that necessitate preoperative bracketing and what to discuss with the breast surgeon. - To show how to perform the procedure of seed bracketing through a step-by-step practical guide. - To teach the clinical difficulties of the procedure through challenging cases and how to overcome them.

TABLE OF CONTENTS/OUTLINE

- Introduction to preoperative localization of breast lesions. - Description of the use of radioactive seeds in clinical practice. - Comparison between preoperative seed localization and other modalities for the management of breast lesions. - The importance of seed bracketing in breast conservation surgery. - Systematic approach to identifying lesions that may require seed bracketing. - What to discuss with the breast surgeon - Practical guide on how to perform seed bracketing. - Template reporting system - Literature review focusing on bracketing of breast lesions. - Example cases with mammographic and pathologic correlation. - Clinical difficulties of seed bracketing and how to overcome them. - Teaching point summary and conclusion.

BREE-95   A Pictorial Review Of The Phylloides Tumor In The Breast Though Not That Innocent

Participants
Jenny Quevedo Parada, MD, ciudad de mexico, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

To Identify the morphological characteristics by mammography and ultrasound of the phylloides tumor. To correlate the imaging findings according to the histopathological grade of the phylloides tumor. To recognize the differences between benign, borderline, and malignant phyllodes tumors.

TABLE OF CONTENTS/OUTLINE

Introduction Definition Classification Imaging characteristics by mammography and ultrasound Cases Teaching points Summary

BREE-96   Contrast Enhanced Mammography What Residents Need To Know

Awards
Certificate of Merit

Participants
Maria Lopez Mena, MEd, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

To recognize differences between conventional mammography and contrast enhanced mammography To review the image acquisition of contrast enhanced mammography To review the clinical applications and contraindications of contrast enhanced mammography To describe typical artifacts of contrast enhanced mammography

TABLE OF CONTENTS/OUTLINE

Introduction Image protocol and acquisition Clinical applications and contraindications Typical artifacts Cases Teaching points Summary

BREE-97   The Money Behind Mammo: A Dive Into The Finances Of Breast Imaging

Participants
Sean Raj, MD, Dallas, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Digital breast tomosynthesis (DBT) is an emerging and adjunctive modality in the breast imager's repertoire, improving cancer detection rates and decreasing recall rates 2. DBT can be integrated effectively and economically into any breast imaging practice 3. Reimbursement for DBT and DBT-based procedures is substantially different from traditional 2D mammography and has a significant impact on the bottom line of a professional practice 4. Breast imaging has historically been considered 'money losers' to Radiology practices; however, in the age of DBT and with increasing state mandates for DBT coverage, breast imaging can potentially be the most financially rewarding section in a practice. 5. Understanding the interplay between RVUs, CPT codes, reimbursements (professional and technical), and practice expenses is critical to comprehending compensation

TABLE OF CONTENTS/OUTLINE

1. Summarize current literature on DBT including its impact on cancer detection rate (sensitivity) and positive predictive value (specificity) 2. Review breast density legislation and impact on screening with DBT 3. Discuss current indications in screening and diagnostic settings and procedures 4. Discuss financial models and reimbursement; HCPCS/CPT codes and CMS Physician Fee Schedule; geographic modifiers 5. Review RVUs per exam/procedure; AAARad data and implications 6. Upstream and downstream financial impact of DBT machine acquisition and utilization, including RVUs generated per day and Radiologist staffing considerations

BREE-98   Radiomics In Breast Imaging For Noob

Participants

Nazimah Ab Mumin, MBChB, Sg Buloh, Malaysia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1.Radiomics is a method for the mathematically quantify medical images. 2.Radiomics analyses in breast imaging require a methodical step-by-step approach 3.Various factors influence radiomics features in the radiomics workflow 4.Guidelines and quality checklists should be used to improve radiomics studies' quality. 5.Using a freely available software may be helpful for AI noob

TABLE OF CONTENTS/OUTLINE

1.Background: what is radiomics (artificial intelligence vs machine learning vs deep learning) ? 2.Radiomics: step by step guide for a newbie 3.What are the limitations of radiomics? 4.What are the available software for machine learning in breast imaging? 5.The future of radiomics: the rise of the machines.

Printed on: 06/28/22

Abstract Archives of the RSNA, 2021

Sub-Events

NREE-1   Endoscopic Skull Base Surgery: Surgical Anatomy For The Radiologist

Participants
Rachel Stein, DO, Jacksonville, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Describe the relevant anatomy of the nasal sinuses and ventral skull base essential for understanding the endoscopic skull base surgical approach from both the otolaryngology and neurosurgical perspectives - Outline the imaging considerations for evaluation on pre-operative imaging of skull based lesions - Describe the classification system of the clivus for pre-operative approach planning and highlight the relevant anatomy in each section of the clivus - Define the postoperative appearance and complications on immediate post-operative and follow-up imaging

TABLE OF CONTENTS/OUTLINE

- Historical Overview of Endoscopic Skull Base Surgery - Anatomical Review of the Pertinent Surgical Anatomy - Imaging Consideration of the Sinus - Imaging Considerations of the Skull Base - Postoperative Appearance and Complications

NREE-10   MRI And PET Imaging Features Of Retired Athletes With Repetitive Mild Traumatic Brain Injury

Participants
Mari Miyata, MD, Chiba, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

After following this exhibit, the reader will be able to: (1) understand the clinical manifestations of repetitive mild traumatic brain injury (rmTBI) and the common pathological hallmarks of chronic traumatic encephalopathy (CTE) in retired athletes; (2) review the unique findings of conventional magnetic resonance imaging (MRI) in retired athletes with rmTBI related to gross neuropathological features of advanced CTE; (3) review the uptake patterns of [18F]-PM-PBB3 (tau-positron emission tomography [PET]) images in retired athletes with rmTBI similar to postmortem neuropathological studies of CTE; (4) find it helpful to differentiate rmTBI from other forms of young-onset dementia.

TABLE OF CONTENTS/OUTLINE

1. Indication to rmTBI and CTE in retired athletes / 2. MRI finding in retired athletes with rmTBI 2.1 Cavum septum pellucidum 2.2 Enlarged perivascular spaces 2.3 Atrophy of the thalamus 2.4 Shrinkage of the mammillary bodies 2.5 Thinning of the corpus callosum 2.6 Enlargement of the lateral and third ventricles 2.7 Atrophy of the brainstem 2.8 Depigmentation of the substantia nigra (absence of "Swallow Tail Appearance" on susceptibility-weighted images) 2.9 Negative findings / 3. PET imaging finding of retired athletes with rmTBI 3.1 Tau-PET ([18F]-PMPBB3) images 3.2 Amyloid-PET ([11C]-PiB) images

NREE-100   What Is The Problem? Isn't It Just A Cyst? A Practical Diagnostic Approach To Cystic Or Cyst-like Lesions Of The Posterior Fossa

Participants
Larissa Martins, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is: -To review the patterns and differential diagnoses of cystic or cyst-like lesions of the posterior fossa.-To discuss the spectrum of common and uncommon posterior cysts lesions in case-based approach. -To emphasize the key imaging to propose a specific diagnoses.

TABLE OF CONTENTS/OUTLINE

-Introduction -Anatomy and embryology of the posterior fossa-Diagnostic algorithm for cystic or cyst-like lesion of the posterior fossa Discussion of the main differential diagnoses in the context of relevant clinical and epidemiological scenarios-Review of patterns of image findings-Conclusion.

NREE-101   Function And Fibers - Functional MRI And DTI Fiber Tractography Application In Brain Tumor Resection

Participants
Matthew White, MD, Omaha, Nebraska (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is: 1. To review the pre-operative appearance of fMRI activations and white matter tracts with

correlation to the neurological outcomes. 2. To explain the utility of fMRI and DTI fiber tractography in brain tumor resection.

TABLE OF CONTENTS/OUTLINE

Analysis of extraaxial, intraaxial, benign and malignant brain tumors included oligodendrogliomas, astrocytomas, ependymomas, meningiomas, AVMS and metastatic tumors. The pre-operative functional status was compared to the post-operative status. Neurological functions and the associated WM tracts evaluated included the vision, language, motor, and sensory systems. mBAND task based FMRI paradigms are discussed and compared to conventional fMRI sequences accelerated with parallel imaging techniques. Resting State FMRI applications are demonstrated and compared to conventional task based fMRI sequences. The effect on white matter tracts by tumors are analyzed by DTI fiber tractography and utilizing color fractional anisotropy maps. Also reviewed are the differential effects of myelination on T2 FLAIR images that demonstrate white matter tract involvement by tumor. The technical difficulties and limitations of fMRI and DTI analysis are demonstrated. The limitations of DTI tractography due to effects of mass effect, edema and infiltrating tumor are outlined.

NREE-102   **Don'T Forget The Big Twelve! A Pictorial Review Of Cranial Nerve Anatomy And Pathology.**

Participants
Karol Cardenas, MD, Quito, Ecuador (*Presenter*) Nothing to Disclose

TEACHING POINTS

There is a wide range of possible pathologies related to cranial nerves, which is why imaging plays a major role in detecting lesions at this level. However, imaging assessment of cranial nerves is often undermined. To overcome missing important pathologic findings, radiologists must become familiar with the anatomy, imaging techniques and pathology. The purposes of this exhibit are: (1) to present a simple illustrative and dynamic review of the anatomy of the cranial nerves, (2) to identify the visible course of each cranial nerve in imaging techniques, both MRI and CT, (3) to provide a systematic review of common and uncommon pathology of the cranial nerves based on case studies.

TABLE OF CONTENTS/OUTLINE

Introduction; imaging techniques for evaluation of cranial nerves; illustrative and radiologic anatomy of the real and apparent origin and course of the cranial nerves; overview and systematic approach for the differential diagnosis of cranial nerve pathology; examples of some of the most common and interesting pathological cases (e.g. viral neuritis, cranial nerve hypoplasia, neural sheath and meningeal tumors, leptomeningeal spread of tumor, among others); summary.

NREE-103   **Role Of Diffusion Weighted Imaging In Optic Pathway Pathologies**

Participants
Vikrant Khare, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

DWI can aid in differentiating the location and laterality of optic nerve involvement when other modalities are equivocal. By utilizing additional information gained from DWI and ADC maps, radiologists can aid in determining the underlying etiology of multiple disease processes and help in looking at overall prognosis.After viewing this exhibit, the reader will become familiar with the anatomy of the optic pathway, utilize DWI as an additional parameter to aid in diagnosis of pathologies ranging from inflammatory, infectious, vascular, and neoplastic in origin, and help predict likely clinical outcome based on qualitative and quantitative DWI & ADC data. Furthermore, the reader will be able to differentiate various causes of optic neuritis and optic neuropathies; gain a sensitive marker for papilledema & increased intracranial pressure; assess clinical outcomes in traumatic optic neuropathy; and use DWI and ADC values in differentiating benign from malignant tumors.

TABLE OF CONTENTS/OUTLINE

1. Outlining the anatomy of the optic pathway and associated visual field defects; 2. Brief overview of DWI and ADC;3. Case sets, broken down by region of the optic pathway which is affected, discussing:a. Differentiating benign from malignant tumor types; b. Differentiating between various inflammatory and infectious processes; c. Use of DWI in trauma and clinical outcome; d. Use of DWI in global brain processes, such as ischemia.

NREE-104   **Terrible Tremors: Imaging Review Of Focal Epilepsy Causing Lesions In Adults.**

Participants
Karla Jonguitud, MD, Nuevo Laredo, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is: Review the most common manifestations in the imaging of epilepsy in adults.To know the purpose of radiological imaging of epilepsy in adults.Explain the most common manifestations encountered with neuroimaging and assess their role in the initial diagnosis and monitoring of epilepsy in adults. Discuss the imaging findings of differential diagnosis of focal epilepsy causing lesions in adults.

TABLE OF CONTENTS/OUTLINE

General features of epilepsy in adults. Clinical correlates of seizure foci. Diagnostic procedures in evaluating the patient with seizures. Purpose of radiological imaging in focal epilepsy in adults. Imaging protocols for the evaluation of focal epilepsy in adults. Imaging findings of the major causes of focal epilepsy in adults. Mesial temporal sclerosis. Abnormalities of neuronal proliferation, migration, organization: Focal cortical dysplasia. Periventricular nodular heterotopia. Polymicrogyria. Schizencephaly. Neurocutaneous syndromes: Tuberous sclerosis. Sturge Weber syndrome. Neoplasm or mass: Ganglioglioma. Dysembryoplastic neuroepithelial tumor. Pleomorphic xanthoastrocytoma. Oligodendroglioma. Astrocytoma. Hypothalamic hamartoma. Multinodular and Vacuolating Neuronal Tumor. Encephaloceles. Vascular lesions: Infarct. Cavernous malformation. Arteriovenous malformation. Trauma. Infection. Controversial: Incomplete hippocampal inversion. Diagnostic considerations and pearls in focal epilepsy in adults. Conclusions.

NREE-105   Multi-mechanisms Of Viral Induced Neurological Manifestations: Lessons Learned From Emerging And Re-emerging Infections

Awards
Certificate of Merit

Participants
Carolina Rimkus, MD,PhD, Sao Paulo, Brazil (*Presenter*) Speaker, F. Hoffmann-La Roche Ltd

TEACHING POINTS

To review the pathogenesis of viral-induced neurological manifestations, focusing on emerging and re-emerging agents: John Cunningham virus, human immunodeficiency virus, measles, zika virus, and SARS-CoV-2To discuss, through a case-based approach, clinical and imaging tips that help identify the etiological agent and the possible pathological mechanism involved

TABLE OF CONTENTS/OUTLINE

IntroductionViral infection can trigger neurological syndromes through different mechanisms: (1) Direct infection; (2) Immune-mediated mechanism; (3) Systemic inflammation / cytokine storm. Confirming the role of an infectious agent in a neurological syndrome is challenging because: (1) diseases depend on complex interactions between environmental, host and microbial characteristics; (2) microorganisms might act in a hit-and-run manner, and be undetectable by symptoms onset; (3) MRI presentation is often non-specific. A systematic analysis of epidemiological factors, clinical, laboratorial and imaging signs might help to identify the etiological agent and the probable pathological mechanismClinical and Imaging features1. Epidemiology: JC-virus and high-efficacy immunomodulatory drugs; HIV in pre and post-HAART era; Measles and decreases in vaccination rates; Zyka virus and Aedes sp; Sars-CoV-2 pandemic2. Signs and symptoms- Paraclinical exams; Cerebral spinal fluid (direct viral infection vs immune-mediated response); EEG; Laboratory markers of systemic infection / cytokine storm3. MRI presentationTake-home messages

NREE-106   Post-operative Imaging Of Craniosynostosis: A Simplified Approach.

Participants
Maria Clara Lorca, MD, Pittsford, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. In this exhibit, we will review the role of low dose CT and 3D volumetric reformations in depicting imaging appearances of various types of craniosynostosis surgery2. Describe the expected post-operative findings and complications seen after craniosynostosis surgery. 3. Describe with clinical pictures and 3D reformations the long-term appearance/correction of the calvarium, orbits and facial bones after surgery.

TABLE OF CONTENTS/OUTLINE

Describe the role of low dose CT and 3D volumetric reformations in the preoperative evaluation of craniosynostosis including alerting surgeons about findings that could lead to potential complications during surgery. Depict the imaging appearances of various types of craniosynostosis surgery. Review with clinical pictures, case examples and illustrations the expected post-operative findings, including comparison of pre and post-operative imaging to track long-term appearance/correction of the calvarium.

NREE-107   Neurosarcoidosis Association With The Glymphatic-lymphatic Fluid Transport System

Awards
Certificate of Merit

Participants
Shotaro Naganawa, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Gain a deeper understanding of the Glymphatic-Lymphatic fluid transport system with recently updated concepts.2. Briefly review the imaging findings of pulmonary sarcoidosis for comparison with Neurosarcoidosis3. Review several neurosarcoidosis cases and explore their association with the Glymphatic-Lymphatic Fluid Transport System

TABLE OF CONTENTS/OUTLINE

Glymphatic-Lymphatic Fluid Transport System-Glymphatic system-meningeal lymphatic vessels-CSF influx and efflux Imaging of pulmonary sarcoidosis-perilymphatic distribution-well-defined nodules-hilar and mediastinal lymphadenopathy Imaging of neurosarcoidosis-pachymeningeal involvement-leptomeningeal involvement-pituitary and hypothalamic involvement-cranial nerve involvement-parenchymal involvement-optic nerve lesion-spinal cord involvement Other diseases involving Glymphatic-Lymphatic system-carcinomatous meningitis-lymphoma

NREE-108   Craniosynostosis: A Didactic Approach

Awards
Certificate of Merit

Participants
Danielly Santos SR, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Review the normal anatomy of the pediatric skull. To discuss imaging features of various types of craniosynostosis, score the CT findings that impact the choice of surgical repair, and describe expected postoperative appearance after such repairs.

TABLE OF CONTENTS/OUTLINE

Craniosynostosis is the premature fusion of cranial sutures, resulting in characteristic deformities of the skull, in addition to facial asymmetries accompanied by functional consequences, such as increased intracranial pressure, visual impairment, deafness, and

cognitive deficits. The incidence is about 1: 2,500 live births. Sagittal suture is the most involved (39 -57%). It is classified as simple (single suture) versus complex (multiple sutures) and isolated (75%) versus syndromic. Imaging exams are essential for an accurate diagnosis, identification of anomalies and coexisting complications, surgical planning, and post-treatment evaluation. The surgical options for the treatment of craniosynostosis are diverse and the radiologist needs to know the main surgical techniques and the tomographic findings that influence the choice of technique.

NREE-11 Imaging Of The Ventricular Shunt Systems : How Can We Help The Neurosurgeons

Awards
Certificate of Merit

Participants
Amit K. Agarwal, MD, MBBS, Jacksonville, Florida (*Presenter*) Consultant, Authentic4D;Stockholder, Gilead Sciences, Inc

TEACHING POINTS

1. To illustrate imaging appearances of the ventricular shunt system2. Identification of common shunt complications and causes of shunt malfunction3. Update on the latest/new programmable shunt catheters

TABLE OF CONTENTS/OUTLINE

1. Types and Components of CSF Shunts-Programmable Ventricular Shunt System-Non-Programmable (fixed-pressure) Ventricular shunt system2. Imaging Evaluation of CSF Shunts 3. Complications of CSF Shunt and Shunt Malfunction -CSF Shunt Placement -CSF Shunt Obstruction -CSF Collections -Infection -Overdrainage4. Summary

NREE-110 Neurolisteriosis, Thinking Beyond Rhombencephalitis

Participants
Aimpavee Keeratiratwattana, MD, Bangkok, Thailand (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Imaging findings of listeria monocytogenes brain infection. 2. Imaging appearance of characteristic brain abscess with worm-like appearance** in neurolisteriosis. 3. Differential diagnosis of brain infection with worm-like appearance**Worm-like appearance was defined as a linear/curvilinear tubular shape lesion in the brain parenchyma. This appearance is typically described on post contrast T1-weighted image, but can also be seen on other sequences. This worm-like appearance portrays transaxonal cell-to-cell spread of listeria infection. This worm-like appearance can occur in isolation or as part of a brain abscess.

TABLE OF CONTENTS/OUTLINE

1. Describe imaging findings of Listeria monocytogenes brain infection2. Example cases of neurolisteriosis with characteristic brain abscess with worm-like appearance3. Show example cases of neuromelioidosis and cerebral sparganosis which are important differential diagnosis of brain infection with worm-like appearance.

NREE-111 Don't Forget To Look At The Base Of The Skull: Benign And Malignant Diseases Of The Clivus

Participants
Pablo Penalver Calero, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

-To review the embryology, anatomy and anatomical relationships of the clivus and its typical appearance on CT and MRI scans depending on age. -To highlight the importance of studying this anatomical region in every brain imaging test due to the variety of lesions that can settle on it. -To describe the different benign and non-tumor lesions that affect this bone and their radiological features. -To present the different malignant lesions that affect the clivus, their radiological appearance and the important complications derived from the infiltration of significant neighboring anatomical structures.

TABLE OF CONTENTS/OUTLINE

-Introduction: clivus anatomy, embriology and changes in appearance with age -Benign clival tumors: meningioma and macroadenoma -Malignant clival tumors: metastasis, lymphoma, chordoma, plasmocytoma and nasopharyngeal carcinoma -Non-tumor clival lesions: fibrous dysplasia, arrested pneumatization of the skull base, ecchordosis physaliphora and fossa navicularis magna -Conclusions

NREE-112 Pocket Survival Guide To Whole Spine Radiography: What The Surgeon Needs Us To Report

Participants
Tomas Bernstein, MD, Santiago, Chile (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Understand the unique characteristics of whole spine X-ray. 2. Learn to quantify classic radiographic alignment measures 3. Apprehend pelvic parameters uncommonly reported but essential for the surgeon. 4. Develop a systematic approach to whole spine radiography

TABLE OF CONTENTS/OUTLINE

1. Anatomy and biomechanics of spinal alignment 2. Special characteristics and different projections of whole spine X-ray 3. Causes of spinal deformities 4. Classic spinal alignment measures 5. Other essential angles that needs the surgeon 6. Post-surgical assessment

NREE-114 Exploring The Cerebral Cortical Veins And Bridging Veins Of The Skull Base In Preoperative Evaluation Of Craniotomies: Beyond Conventional Imaging

Participants
Sayani Mahal, MBBS, Jodhpur, India (*Presenter*) Nothing to Disclose

Cerebral cortical veins and bridging veins of skull base as insignificant in size as they may seem, have the potential to wreak havoc if injured during surgeries. To add to this, is the abundance of variant anatomy that makes it mandatory to competently trace the course of such veins. Preoperative assessment aids in localizing the exact site of corticectomy by identifying the corridor in between the cortical veins and prevents their inadvertent injuries. Computed tomographic (CT) venography and MR venography (TOF and phase-contrast) can depict the convexity veins that drain the surface of the brain. But traditional preoperative imaging in 2D planes is not capable of adequately displaying the inconspicuous anatomy of the bridging veins and veins at the skull-base which show a curved course. Curved multiplanar maximal intensity projection reformats on 3D post contrast T1 gradient images are better suited for demonstration of this cerebral venous anatomy and their variants.

TABLE OF CONTENTS/OUTLINE

1. Overview of the standard craniotomy approaches and the venous structures at risk of injury in each type. 2. Anatomy of the cortical veins and bridging veins of the skull-base and demonstration of precise anatomic planes for reformatting skull-base veins. 3. Anatomic variations in their course and drainage patterns.

NREE-115   Potholes On The Pathway! Imaging Spectrum Of Middle Cerebellar Peduncle Lesions

Participants
Surbhi Singh, MD, Bangalore, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To describe the imaging anatomy of middle cerebellar peduncle with emphasis on cortico-cerebellar pathways. - To discuss various pathologies that have predilection to middle cerebellar peduncle with clinical implications and management. - To highlight clinical and imaging clues that would enable radiologists to narrow their differentials.

TABLE OF CONTENTS/OUTLINE

Retrospective review of 3000 MRI brain studies at our institute from June 2018 to March 2021 yielded 126 cases with lesions that involved middle cerebellar peduncles. Cases are broadly classified into: 1. Cerebrovascular: Ischemic Infarcts, pontine hemorrhages 2. Infective: Tuberculomas, bacterial abscess 3. Neoplastic: Gliomas, Lymphoma, medulloblastoma, neurofibromatosis 4. Neurodegenerative: MSA, Spinocerebellar ataxia, Wallerian degeneration 5. Vascular Malformations: Cavernomas, AVM 6. Demyelinating: Neuromyelitis Optica, Multiple Sclerosis 7. Metabolic: Wilson's disease, Osmotic demyelination 8. Iatrogenic: Radiation necrosis, Post-surgical gliosis This spectrum would be presented in a case-based approach with clinical/imaging pearls and pitfalls.

NREE-116   The Last, But Not Least Diagnostic Hypotheses: CNS Dural Arteriovenous Fistulas Non-invasive Imaging.

Participants
Daniela Vasconcellos, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:- To discuss and ilustrate many types of imaging presentation of dural arteriovenous fistulas (dAVF) focusing on early diagnosis by non-invasive methods.- To purpose a classification of clinical manifestations based on gravity of the symptoms, between benign and aggressive, and to exemplify the most relevant imaging features of each one.- To highlight imaging features and red flags that support confident diagnosis of dAVF.

TABLE OF CONTENTS/OUTLINE

- Anatomy, epidemiology and physiopathology- dAVF classification- Low flow versus High Flow- Angiographic classification- Clinical manifestations:- Topographic division- Clinical-radiological correlation- Classifications based on their gravity and their imaging features- Contribution of non-invasive imaging methods to dAVF diagnosis.- Computed tomography- Magnetic resonance imaging- 3D Time-of-flight MR angiography- Arterial spin label- Dynamic-susceptibility contrast MRI perfusion:- Highlight imaging features and red flags that support confident diagnosis of dAVF.- Venous thrombosis- Parenchymal abnormalities: edema, hemorrhage.- Dilated cortical veins without a nidus.- Dilated pial vessels at subarachnoid space.- Flow voids- Evaluation of retrograde arterialized cortical / sinus venous drainage using SWI sequence- Therapeutic options and post-treatment evolution.

NREE-117   Autoimmune Demyelinating Diseases Beyond Classic Multiple Sclerosis.

Participants
María José Risco Fernandez, Toledo, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To review the multiple sclerosis (MS) variants, and other autoimmune demyelinating disorders such as neuromyelitis optica spectrum disorders (NMOSD), acute disseminated encephalomyelitis (ADEM) and anti-myelin oligodendrocyte glycoprotein (anti-MOG) syndromes, their characteristics and distribution.- To illustrate these diseases using images from our database to highlight the imaging findings of each disease in magnetic resonance imaging (MRI).- To analyse key features in order to distinguish these entities from MS and from other etiologies.

TABLE OF CONTENTS/OUTLINE

In the last few decades, MS variants and other types of autoimmune demyelinating disorders including NMOSD, ADEM and anti-MOG disease are recognized as entities of their own. They are frequently misidentified as MS due to the similarities of their clinical manifestations and imaging findings.Knowledge of clinical course, lesion characteristics and distribution could aid in diagnosis of them. MRI is the standard imaging technique of diagnosis of these autoimmune demyelinating diseases. Early and accurate diagnosis of all these conditions is highly important due to different therapeutic approaches depending on the entity.This review is intended to give an overview of the diverse spectrum of autoimmune demyelinating disorders, focused on MS variants, NMOSD, ADEM and anti-MOG, other secondary etiologies and the most common differential diagnosis.

NREE-118   Leptomeningeal Enhancement On Postcontrast 3D-flair Imaging In Multiple Sclerosis: A Retrospective Study In A General Hospital.

Participants
Elton Barud, BMedSc, Uberaba, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:1. Briefly describe the pathophysiology of leptomeningeal enhancement on postcontrast 3D-FLAIR imaging in multiple sclerosis.2. Pictorial review of leptomeningeal enhancement on postcontrast 3D-FLAIR imaging in multiple sclerosis from our archives (from January 2017 to April 2021 and a review of the literature.3. Evaluate the difference in sensitivity between 1,5T and 3T MRI scanners, as well as time-to-acquisition after gadolinium injection for leptomeningeal enhancement detection.

TABLE OF CONTENTS/OUTLINE

A- Pathophysiology of leptomeningeal enhancement on postcontrast 3D-FLAIR imaging in Multiple Sclerosis.B- Pictorial case review from our collection and a review of the literature. C- Imaging appearance.D- Patterns and localization of leptomeningeal enhancement.E- Atypical imaging appearance: red flags and pitfalls.

NREE-119   **Tertiary Center Experience In Fast Neuroradiology Protocol Development And Implementation**

Awards
Identified for RadioGraphics

Participants
Laura Eisenmenger, MD, Middleton, Wisconsin (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Review techniques employed in the development and execution of Fast Abbreviated Survey Technique (FAST) protocols• Outline the FAST Neuroradiology protocols currently employed at tertiary academic center• Understand the role of FAST protocols in Neuroradiology

TABLE OF CONTENTS/OUTLINE

Introduction Definition of a "FAST" protocol General acquisition and reconstruction techniques Clinical applications in neuroradiologyFAST Neuroimaging MR Stroke Protocols (with MRA) FAST Stroke without contrast Indications Sequences, parameters, acquisition times Limitations Case examples FAST Stroke with contrast Indications Sequences, parameters, acquisition times Limitations Case examplesFAST Neuroimaging MR Brain Protocols (without MRA) FAST Brain without contrast Indications Sequences, parameters, acquisition times Limitations Case examples

NREE-12   **The Dangerous Waters Of Western Australia**

Participants
James Waldron, MBBS, Perth, Australia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) To present an overview of spinal injury imaging findings in patients with water-related accidents (surfing, diving, body boarding, and miscellaneous other activities) in Western Australia. 2) To identify common mechanisms of injury from different water-related traumatic spine injuries. 3) To recognize types and radiological hallmarks of bony, soft tissue and spinal cord injuries on imaging, incurred from water-related accidents.

TABLE OF CONTENTS/OUTLINE

1) Introduction 2) Surfing injuries: Mechanism, Pathology (extension teardrop fracture, spinal cord compression and traumatic disc herniation) - Imaging correlates identified on CT and MRI.3) Diving injuries: Mechanism, Pathology (vertebral fractures and soft tissue injuries) - Imaging correlates identified on CT and MRI4) Wave-related injuries: Mechanism, Pathology (spinal cord haemorrhage and vertebral artery injury) - Imaging correlates identified on CT and MRI5) Miscellaneous injuries: Morel-Lavallée Lesion

NREE-121   **Neurological Disorders In Pregnancy: What The Radiologist Needs To Know**

Participants
Angelo Duarte, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:- Discuss the reasons that make diagnosing neurological disorders in pregnancies, childbirth, and puerperium so challenging- Review the physiology of pregnancy and its relationship with the occurrence of new neurological disorders and exacerbation of pre-existing diseases- Describe the main neurological diseases of pregnancy, emphasizing their radiological findings and clinical presentation to stimulate clinical reasoning- Review the main pre-existing diseases that may exacerbate during the gestation period*?aß?e ?? ???te?ts/??t???e • Introductiono Factors that contribute to the variety of neurological symptoms in pregnancyo Review of physiological changes in pregnancy and their role in the occurrence of neurological disorders• Neurological disorders related to pregnancy and childbirtho Cerebrovascular diseaseso Pituitary disordero Metabolic disordero Related to medical procedures• Exacerbation of pre-existing neurological condition o Demyelinating diseaseso Tumors

NREE-122   **Different Strokes: A Comprehensive Review Of Radiological Stroke Mimics**

Awards
Cum Laude

Participants
Cillian McNamara, BMBCh,MSc, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

Radiological stroke mimics are non-vascular disorders that have imaging appearances in common with an infarct, such as diffusion or

perfusion abnormalities.Accurate identification of mimics depends on the neuroradiological expertise of the reporting center.Common stroke mimics are seizures, metabolic disturbances, tumors, infection and migraine.Rarer stroke mimics include mitochondrial disorders, radiotherapy complications, and autoimmune disorders.Retrospective imaging review often reveals clues that could have helped identify a stroke mimic from the outset.Often, the only way to definitively diagnose a stroke mimic is to interpret the imaging in light of in-depth clinical information and laboratory results.With the use of clinical, lab data and MR, the inappropriate admission rate for stroke mimics falls to <1%.

TABLE OF CONTENTS/OUTLINE

Frequency of stroke mimics and a review of the relevant terminology.Review of the clinical consequences of inappropriate thrombolysis.A comprehensive case-based review of common and rarer radiologic stroke mimics.A review of the subtle nuances in differentiating very challenging stroke mimics such as transient peri-ictal MRI abnormalities, reversible cerebral vasoconstriction syndrome and migraine.A review of the diagnostic clues on initial imaging studies that could have aided earlier correct diagnosis.A case-based quiz to apply newly learned imaging tips.

NREE-123   Lymph-fomo: Fear Of Missing Out On Central Nervous System Lymphoma In The Immunocompromised Patient

Participants
Olivia Goldberg, BMBS, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Update on the aetiology and pathophysiology of immunodeficiency-associated CNS lymphomas using illustrative cases of key WHO 2016 subtypes 2. The imaging findings of CNS lymphoma with a focus on the key differences between immunocompetent and immunocompromised individuals 3. Approach to differentiate lymphoma from other complications of immunosuppression, including opportunistic infection and other malignancies 4. Awareness of advanced imaging techniques to aid diagnosis and inform treatment choices

TABLE OF CONTENTS/OUTLINE

Primary CNS lymphoma (PCNSL) has myriad appearances on imaging which are highly dependent on patients' immune status. In the immunocompromised, the classical radiological signs of PCNSL may be absent and there is a risk of misdiagnosis for other pathology such as opportunistic infection. Imaging has a pre-eminent role in the immunosuppressed as biopsy may be precluded by the risk of post-surgical infection. This challenge is compounded by an ever-growing and increasingly complex cohort of immunocompromised patients, secondary to a greater range and usage of immunotherapies, more transplantation (solid organ and haematopoietic cell) and HIV. To meet this challenge, we will provide a diagnostic framework to immunosuppressed patients with possible PCNSL with illustrative cases of many subtypes. The presentation will finish with a glimpse of the future with a spotlight on emerging techniques and novel post processing tools.

NREE-125   Cerebral Amyloid Related Disorders

Awards
Cum Laude

Participants
Lucas Ghisleri, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Cerebral ßA related disorders are Alzheimer's disease (AD), classic and inflammatory cerebral amyloid angiopathy (CAA) and cerebral amyloidoma.- AD dementia is the end point of events that leads to cognitive impairment, with the accumulation of ß amyloid (ßA) plaques as the first detectable change, succeeded by functional and metabolic markers. Structural changes occur later, in a temporal pattern that reflects the histological findings.- Classic CAA can present with a variety of hemorrhagic lesions, including lobar hemorrhages, microbleeds, superficial siderosis and subarachnoid hemorrhage, in addition to ischemic lesions, including cortical microinfarctions and ischemic changes of the supratentorial white matter (WM).- Inflammatory CAA is characterized by an inflammatory infiltrate next to amyloid deposits which manifests as asymmetrical WM edematous lesions in association to classic findings of CAA.- Amyloidoma is a rare pseudotumoral deposit of ßA on the supratentorial WM with marked low T2 signal and avid contrast enhancement

TABLE OF CONTENTS/OUTLINE

- IntroductionCerebral amyloid genetics and physiology- Alzheimer DiseaseEpidemiology and physiopathologyStructural imaging: A mirror of dementia pathologyThe role of imaging biomarkers: Amyloid-PET and FDG-PETLaboratorial detection of Aß: future perspectives- CAAEpidemiologyPhysiopathology of classic and inflammatory CAAImage patterns and differential diagnosis of classic and inflammatory CAA- AmyloidomaImage pattern and differential diagnosis

NREE-126   A Radiologist`s Guide To Interpret Arterial Spin Labeling (ASL) MR Perfusion: A Simplified Review Of The Technique, Clinical Indications And Interpretation Of Findings

Awards
Identified for RadioGraphics

Participants
Tatiana Iutaka, BDS, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Present a practical guide to interpret Arterial Spin Labeling (ASL) MR perfusion;Review the techniques and the methods of the ASL sequence, including technical difficulties;Discuss the main clinical applications and their usefulness in the daily routine of the radiologist; Suggest a simplified approach including a step-by-step of interpreting image findings.

TABLE OF CONTENTS/OUTLINE

Introduction and initial considerations;Techniques and the methods of the ASL sequence;Main clinical applications of ASL sequence and the typical imaging findings;Interpretation approach with a step-by-step;Final remarks.

NREE-127   Imaging Findings Of Intracranial Injuries Post Radiotherapy

Participants
Neomir Fabris, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Radiation treatment injuries may appear similar to tumor progression and can develop during treatment, months to years later. Radiation injury can be divided into acute, early-delayed and late-delayed on the basis of which time they manifest after radiation therapy, including leukoencephalopathy, pseudoprogression, radionecrosis and secondary neoplasms. Our objectives are: 1. To illustrate most common post radiation injuries to brain. 2. To review the imaging findings in acute, early delayed and late delayed radiation-induced brain injuries. 3. Emphasizing the role of Advanced MRI techniques and its implications in management. 4. To correlate different cases with the local treatment types, such as whole-brain radiotherapy and stereotactic radiosurgery.

TABLE OF CONTENTS/OUTLINE

We will show the best cases of our archive that consists of more than two thousand cases of post-radiotherapy injury from which we will select more cases to illustrate and enrich the presentation. 1) The radiation therapy a) Treatment planning b) Whole Brain Radiotherapy c) Specialized steriotatic machines d) Brachytherapy e) Lesions Commonly Treated with SRS. 2) Treatment Effects a) Radiation Necrosis b) Pseudoprogression and Pseudoresponse c) Pseudoresponse and Antiangiogenic Therapy d) Radiation Vasculopathy e) Radiation-induced Leukoencephalopathy f) SMART Syndrome g)Secondary Malignancies h) Radiation-induced Brain Tumors and Tumor-like Lesions.

NREE-128   The Unusual Suspects: When Brain Tumors Don't Follow The Rules

Participants
Cillian McNamara, BMBCh,MSc, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Atypical imaging presentations of CNS tumors can cause diagnostic confusion and delay.- Glioblastoma multiforme (GBM) accounts for 60% of all primary brain tumors and are usually recognized when presenting in its typical form as a solitary, supratentorial mass. These can evade diagnosis by presenting in unusual locations or as highly vascular variants which may be mistaken for vascular malformations.- Meningiomas comprise 30% of all primary brain tumors with many radiological variants which have distinctive imaging features. Extracranial meningioma metastases occur rarely and are underrecognized.- Rare tumors can cause confusion by presenting in unexpected locations.

TABLE OF CONTENTS/OUTLINE

- Brief introduction to the epidemiology of various primary brain tumors and present an imaging review of several histologically confirmed 'atypical' cases to contrast with more typical presentations.Two subgroups:1) CNS tumors presenting in an unusual location. - GBMs presenting in the posterior fossa, as pituitary masses, and as leptomeningeal disease- Meningiomas presenting in the orbital wall or as metastases- Chordomas presenting in unusual extra-axial and intradural locations- Spinal tumors such as an extra-axial ependymoma and an extradural nerve sheath tumors 2) CNS tumors presenting with unusual imaging features. - Highly vascular GBMs initially diagnosed as vascular malformation- Pediatric tumors which caused diagnostic uncertainty due to atypical imaging features including an embryonal tumor and a pilocytic astrocytoma

NREE-129   Beyond Degeneration: Challenges In Intervertebral Disc Pathology

Participants
Valerio D'Agostino, MD, Naples, Italy (*Presenter*) Nothing to Disclose

TEACHING POINTS

The objectives of this case-based educational exhibit are:1. To briefly review the radiological features of discopathy.2. To summarize the possible evolutions of degenerative discopathy, with emphasis on the less frequently encountered. 3. To describe and illustrate the imaging findings in the most unusual cases.

TABLE OF CONTENTS/OUTLINE

This educational exhibit will follow this outline:1. Introduction to the pathophysiological mechanisms of degeneration of the intervertebral discs.2. Brief summary of usual clinical and radiological features.3. Review of the possible evolutions of degenerative discopathy, focused on the most unusual ones and the ones that may pose diagnostic challenges.4. Case-based illustration of uncommon progressions of disc degeneration and protrusion / herniation.

NREE-13   Sellar, Suprasellar, And Parasellar Masses: Comprehensive Imaging Review And Surgical Approaches

Participants
Zachary Jenner, MD, Sacramento, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

Sellar, suprasellar, and parasellar spectrum of pathologies include neoplastic, congenital, vascular, and inflammatory/infectious etiologies. Symptoms include headache, visual changes, and cranial neuropathy. CT identifies bone involvement, internal calcification, and vascular components. MRI signal characteristics are vital in differentiating similar lesions. While most lesions require histopathologic evaluation, expert knowledge of skull base anatomy and awareness of key imaging features are useful in limiting the differential diagnosis and identifying surgical approaches.

TABLE OF CONTENTS/OUTLINE

1. Sellar Space. Neoplasm: pituitary adenoma, pituitary apoplexy/hemorrhage, meningioma, craniopharyngioma, metastasis. Congenital: Rathke cleft cyst. Vascular: aneurysm. Infectious/Inflammatory: abscess, Wegener's. 2. Suprasellar Space. Neoplasm: optic pathway glioma, germinoma. Developmental: dermoid, lipoma, hypothalamic hamartoma, ectopic pituitary, epidermoid & arachnoid cysts. Inflammatory/Granulomatous: Langerhan's cell histiocytosis (LCH), lymphocytic hypophysitis, sarcoidosis. 3. Central Skull Base. Neoplasm: chordoma, chondrosarcoma, plasmacytoma. Other: encephalocele, epidermoid. 4. Cavernous Sinus. Neoplasm: meningioma, metastasis, lymphoma, perineural tumor, schwannoma, LCH. Vascular: aneurysm, cavernous-carotid fistula,

thrombosis, hemangioma. Infectious/Inflammatory: Tolosa-Hunt, invasive fungal sinusitis, sarcoidosis 5. Surgical approach/techniques

NREE-130   Genetic Disorders Associated With Stroke: What Radiologists Need To Know.

Awards
Cum Laude

Participants
LAÍSE NERI, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To describe the mechanisms of genetic ischemic and hemorrhagic strokes.To recognize the classification of genetic disorders associated with stroke.To illustrate imaging findings related to genetic stroke.

TABLE OF CONTENTS/OUTLINE

IntroductionMechanisms of genetic ischemic and hemorrhagic strokes.Classification of genetic disorders associated with stroke: arteriopathies; metabolic diseases, connective tissue disorders.Illustrative cases : Fabry Disease, Sickle Cell Disease, Cerebral Autosomal Dominant, Arteriopathy With Subcortical Infarcts and Leukoencephalopathy, Cerebral Autosomal Recessive Arteriopathy With Subcortical Infarcts and Leukoencephalopathy, Retinal Vasculopathy With Cerebral Leukodystrophy, Mitochondrial Encephalopathy, Lactic Acidosis, and Strokelike Episodes, Moyamoya Disease, Susac's Syndrome, Arterial Tortuosity Syndrome, ACTA2 mutation, William's syndrome), Conclusion, Take-home messagesReferences

NREE-131   All That Glitters Is Not Gold: Idiopathic Intracranial Hypertension (IIH) And Its Mimics

Awards
Certificate of Merit

Participants
Olivia Goldberg, BMBS, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Update on the consensus guidelines for the investigation of papilloedema 2. Review of the clinical presentation, neuroimaging findings and proposed aetiology of IIH 3. Approach to distinguishing IIH from its mimics and when those should be considered 4. Current management options in IIH

TABLE OF CONTENTS/OUTLINE

Idiopathic intracranial hypertension (IIH) is an important clinical entity, particularly given the association with obesity which is increasing in incidence. IIH patients often have a distinct clinical phenotype and frequently present with headaches, papilledema and visual changes. Imaging is essential in the workup, particularly in excluding secondary causes. Classical imaging features, such as expansion of the optic nerve sheath complexes, empty sella turcica and cerebellar sagging have variable reliability and are commonly found incidentally in asymptomatic patients. These features are the consequence of longstanding raised intracranial pressure rather than specifically those of IIH. Importantly, other pathologies can masquerade as IIH on imaging, particularly vascular shunts. Ultimately, patients require a thorough workup with IIH being a diagnosis of exclusion. Here we present series of cases that had classical symptoms and signs of IIH in whom the diagnosis was confirmed or an alternative diagnosis was reached, for example dural arteriovenous fistula or a compressive calvarial lesion. We will highlight features where alternative pathology should be suspected, and the crucial role of the radiologist.

NREE-132   Malformation Maladies - Magnetic Resonance Imaging In Congenital Malformations Of Brain

Participants
Suman Prabhakar, MBBS,MD, Bangalore, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review the basic embryological development of the brain. 2. To illustrate various congenital malformations of the brain with respect to the stages of development. 3. To review the spectrum of congenital malformation of the brain in a quiz format.

TABLE OF CONTENTS/OUTLINE

We discuss the basic embryology of the brain. Being rare and complex, congenital anomalies of the brain needs to be diagnosed on MRI at the earliest for appropriate management, prognostication, and counseling of neurological outcomes. Background: We review the spectrum of congenital malformations of the brain in a quiz format. • Each case has a brief clinical history at the top of the slide followed by representative images and questions. • The following malformations are discussed based on stages of development: Chiari malformations, cephaloceles, corpus callosum agenesis/dysgenesis, polymicrogyria, holoprosencephaly, Joubert's syndrome, agyria--pachygyria complex, Lhermitte - Duclos disease, nodular and lobar heterotopia, septo optic dysplasia, coronal cleft in the pons, cerebellar dysplasia, complete commissural agenesis, megalencephaly, schizencephaly (open and close), lissencephaly, and Dandy-Walker complex. This educational exhibit is presented in a quiz based format targeted to residents and emphasizing on the correlation between the stage of development and resultant malformation.

NREE-133   Radiomic Of Glioma: Multiparametric MRI Correlates Of Genotyping And Molecular Markers.

Participants
Samika Kanekar, Providence, Rhode Island (*Presenter*) Nothing to Disclose

TEACHING POINTS

To discuss the gliomagenesis and associated molecular markers with various gliomas. To correlate the imaging findings with the various Genotyping and molecular markers in low grade and diffuse glioma.

TABLE OF CONTENTS/OUTLINE

We retrospectively reviewed the imaging studies from our PACS system of 55 patients with glioma (low, diffuse gliomas and

glioblastoma), which forms the basis of this exhibit. All patients had undergone basic MRI along plus advanced imaging techniques such as MR spectroscopy, MR perfusion (dynamic susceptibility contrast magnetic resonance (MR) perfusion, DTI, fMRI, and ADC value calculation. 46 of these tumors had a histopathology correlation with the imaging findings. Imaging parameters: site, size, margins, enhancing pattern, nonenhancing component, T2-FLAIR mismatch, necrosis area, percentage of necrosis area inside the enhancing lesion, ADC values, rCBV, multivoxel chemical shift MR spectroscopy, and FA and MD value calculations from DTI. Various imaging markers were correlated with the phenol and genotyping markers. For easy understanding of this exhibit, we have categorized this exhibit under following heading: isocitrate dehydrogenase (IDH) status, O6-Methylguanine-DNA methyltransferase (MGMT), molecular genetics of glioblastoma and gliomagenesis, Alpha-thalassemia/mental retardation syndrome X-linked (ATRX) and TP53 mutations, 1p/19q codeletion as a marker for oligodendroglial tumors, Diffuse midline glioma and H3 K27M-mutant and TERT promoter mutations.

NREE-134 Venous Drainage Of The CNS: Review From Anatomy To Congenital And Acquired Abnormalities And Everything Between

Participants
Fernanda Assuncao, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:To review venous drainage brain embryology and anatomy;To improve knowledge regarding MRI techniques used for assessing the brain venous system;Pictorial review of the main abnormalities involving CNS venous system, including congenital abnormalities, vascular malformation, neoplastic lesions and everything between and potential pitfalls. To emphasize the key imaging points to arrive at a diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Introduction1.1 Embryology1.2 Anatomy1.3 MRI techniques2. Describe the imagine features and patterns of involvement3. Conclusion

NREE-135 Hemangioblastoma Imaging Aspects: Typical And Atypical Lesions And Mimicking Diseases

Participants
Vitória Taumaturgo da Costa, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is: 1- To review the epidemiology of hemangioblastomas and its sporadic or disease-associated presentations (Von Hippel Lindau). 2- To show the hemangioblastomas typical imaging aspects, such as high vascularization, cerebellar and solid-cystic tumor, and vivdly enhancement of the mural solid nodule component as well as the atypical presentations. 3- To exemplify differential diagnosis and situations that mimic hemangioblastomas, such as ependymomas, pilocytic astrocutoma and metastasis.

TABLE OF CONTENTS/OUTLINE

1 - Illustrated cases of hemangioblastomas (HBM) from our neurorradiologic group since 2006 to 2021. 2 - Clinical association of HBM presentations: sporadically HBM, von Hippel Lindau associated HBM, HBM mimmicking other conditions, atypical presentation of HBM. 3- Correlation between imaging findings and hystological aspects such as absence of high grade morphological features, presence of capillary vessels and the specific marker (inhibin A).

NREE-136 Atypical Spinal Cord Tumors: When Expect The Unexpected

Participants
Fernanda Assuncao, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:- Review the epidemiology, clinical scenarios and the typical imaging features of the most common spinal cord tumors;- Illustrated review of a series of cases of atypical spinal cord tumors;- To emphasize the key imaging features to narrow the differential diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Introduction1.1 Epidemiology1.2 Clinical scenarios1.3 Typical imaging features2. Series of cases of atypical spinal cord tumors;3. Conclusion

NREE-138 Spondylotic Myelopathy: An Expanding Spectrum Of Imaging Findings

Participants
Fernanda Assuncao, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:- Review the anatomy, physiopathology and epidemiology of spondylotic myelopathy;- Pictorial review of typical and atypical cases;- Highlight the key imaging features to prompt precise diagnosis and guide proper treatment.

TABLE OF CONTENTS/OUTLINE

1. Introduction1.1 Epidemiology1.2 Typical imaging features2. Series of cases with typical and atypical imaging findings3. Differential diagnosis4. Conclusion

NREE-139 What Could Go Wrong? A Case Collection Of Cerebellopontine Angle Lesions

Participants
Akm Rahman, DO, Pittsford, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

Familiarize radiologists with the radiologic presentation of CPA lesions.Recognize characteristic and differentiating factors between lesion types. Understand the post-treatment appearance and recurrence presentation.

TABLE OF CONTENTS/OUTLINE

Anatomy: The exhibit will begin with an overview of the Cerebellopontine angle anatomy. Structure: The different structures will be highlighted with an emphasis on function and relation to other parts of the brain, spinal cord, and body. Lesions: Each lesion will be explained with: Pathology, Key Factors, Case, Imaging. Schwannoma: Benign tumors originating from Schwann cells. Meningioma: Most common meningeal tumor originating from meningocytes. Lipomatous meningioma: Rare benign metaplastic meningioma. Epidermoid liposarcoma: Dedifferentiated liposarcoma containing notable epithelial features. Aneurysm: Confined bulbous blood vessel dilation typically of arterial origin. CPA Arteriovenous Malformation: Vascular malformation characterized by vessels spread through normal brain parenchyma. Trigeminal Schwannoma: Encapsulated tumors originating from trigeminal Schwann cells. Cyst: Fluid filled cavity lined with epithelium. CPA Cavernous Hemangioma: Benign tumor originating from blood vessels.CPA Lipoma: Benign tumors originating from mature adipocytes. Differentiating Factors:The exhibit will conclude with comparisons and contrasts between the lesions to aid in distinguishing between them.

NREE-14   Longitudinal Extensive Transverse Myelitis: Thinking Beyond Neuromyelitis Optica Spectrum Disorders

Participants
Barbara Trapp SR, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Teaching Points:The purpose of this exhibit is:To sediment the imaging findings that define longitudinal extensive transverse myelitis (LETM).To demonstrate the main imaging characteristics of LETM in the scenario of Neuromyelitis Optica Spectrum Disorders (NMOSD).To demonstrate the main differential diagnoses of LETM.To help expand the differential diagnoses through the distinct imaging patterns of LETM through a pictorial essay of the various associated conditions.

TABLE OF CONTENTS/OUTLINE

Table of contents/outline: Powerpoint LayoutDefinition of LETMLETM in NMOSDNMOAnti-MogADEMDifferential diagnosisThe following topics will include a brief clinical and pathological overview and a detailed discussion of the main imaging findings that give clues for the correct etiological diagnosis.Inflammatory disordersSystemic Lupus ErythematosusSjögren syndromeSarcoidosisBehçetMultiple sclerosisInfectious disordersLyme diseaseVaricella-zosterCytomegalovirusHTLVPoliovirusToxoplasmosisTuberculosisNocardiaSyphilis EsquistossomoseNeoplastic disordersAstrocytomaEpendymomaLymphomaMetastasisParaneoplastic disordersVascular disordersSpinal cord infarctionFibrocartilaginous embolism syndromeSpinal cord arteriovenous shuntsTraumatic conditionsMetabolic disordersSubacute combined degenerationDegenerativeSpondylotic myelopathyPost radiotherapyOthersSpinal form of cerebrotendinous xanthomatosisMitochondriopathies

NREE-140   Neurologic Complications Of Immunotherapy

Awards
Cum Laude

Participants
Amit Desai, MD, Jacksonville, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Understand mechanisms of action of a wide variety of immunotherapies. 2. Learn immunotherapy-mediated neurologic complications including clinical presentation and imaging appearance. 3. Review prognosis and management of immunotherapy-mediated neurologic complications.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Review of immunotherapies including clinical indications and mechanisms of action. Therapies will include but are not limited to:a. Ipilimumbab b. Nivolumab c. Pembrolizumab d. Natalizumab e. Cabozantinib f. Rituximab g. Bevacizumab h. Bapineuzumab i. CAR T cells j. Vaccines 3. Clinical Cases: Review clinical and imaging presentations of immunotherapy-mediated neurologic complications followed by prognosis and management. Complications will include but are not limited to:a. Hypophysitis b. Aseptic Meningoecephalitis c. Acute or Chronic Encephalopathy d. Seizures e. PRES f. Pseudoprogression & Tissue Necrosis g. PML-IRIS ADEM Myelopathy h. Demyelinating Polyneuropathy4. Conclusion.

NREE-141   Outcome Prediction For Head And Neck Cancer Patients: How Can We Improve Further?

Awards
Certificate of Merit

Participants
Maryam Vejdani-Jahromi, MD,PhD, Cambridge, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Outcome prediction is crucial for head and neck cancer (HNC) patient care to individualize the treatment for a better outcome. TNM calcification has been used for years, primarily based on the size, location, and extent of the primary lesion. However, not only size or extent but also the histological type or degree of differentiation is important to predict the outcome. More recently, we learned the viral status such as HPV and EBV, and immunohistochemistry feature is also crucial to determine the outcome. With the advancement of imaging technology and clinical knowledge, numerous clinical and imaging data are currently available for each patient. Therefore, the development of reliable artificial intelligence, specifically machine learning (ML) and deep learning (DL) applications, has been anticipated to utilize such data for more accurate diagnosis and outcome prediction. The purposes of this exhibit are: 1) to review the historical and current practice for HNC outcome prediction and treatment planning, 2) to review currently available clinical and imaging biomarkers for HNC, 3) to review ML and DL approaches for predicting outcome, and 4) to discuss the future directions and radiologists' roles in predicting outcome and treatment individualization for HNC patients.

TABLE OF CONTENTS/OUTLINE

1. Review of the AJCC TNM classification. 2. Review of clinical biomarkers. 3. Review of imaging biomarkers. 4. Review of ML/DL

1. Review of the AJCC TNM classification. 2. Review of clinical biomarkers. 3. Review of imaging biomarkers. 4. Review of ML/DL approaches for HNC outcome prediction. 5. Discussion on the future direction and radiologists' roles.

NREE-142   When Should I Think About Parasitic Brain Infections? Tips And Traps

Participants
Fernanda Assuncao, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:- Review the epidemiology and pathophysiology of different parasitic infections that affect the central nervous system (CNS); - Pictorial review of the main neuroparasitosis;- Highlight the key imaging features to narrow the differential diagnosis and guide proper treatment.

TABLE OF CONTENTS/OUTLINE

1. Introduction1.1 Epidemiology1.2 Clinical scenarios2. Describe the imaging features and patterns of involvement of the main neuroparasitosis; 3. Differential Diagnosis 4. Conclusion

NREE-143   Tuberous Sclerosis: Not Merely A Collection Of Findings. A Global Neuronal Migration Disorder Point Of View.

Participants
Lee Van Diniz, MD, Botucatu, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Tuberous sclerosis is a neurocutaneous disorder characterized by the development of multiple benign tumors of the embryonic ectoderm. The condition arises from mutation in tumor suppressor genes involved in the mTOR pathway. We are going to examine the spectrum of brain abnormalities encountered in TSC and presents them as not merely a collection of lesions but more cohesively in the context of a global neuronal migration disorder. Our purpose is to review the pathophysiology of tuberous sclerosis complex (TSC) and mTOR pathway and learn about the different presentations and imaging findings in TSC.

TABLE OF CONTENTS/OUTLINE

Tuberous sclerosis has a number of multiorgan manifestations. We are going to review a step-by-step approach to the central nervous system manifestations of TSC discussing about: 1) Brain embriology and the mTOR pathways abnormalities in neuronal migration. 2) The classical findings in patients with TEC: Cortical/subcortical tubers , white matter abnormalities, subependymal hamartomas and Subependymal Giant Cell Astrocytoma. 3) The findings of TSC in fetal MRI. 4) The role of Perfusion Weighted Imaging, Spectroscopy and Diffusion Tensor Imaging in the spectrum in the diagnosis of TSC lesions. 5) Review the non-parenchymal findings in brain studies: Shagreen patches, retinal hamartomas, osseous manifestations, and other abnormalities in TSC. 5) Review the findings of other diseases related to the mTOR pathway and neuronal migration disorders. 6) Focus on the differential diagnosis of TSC in brain MRI.

NREE-145   Neurogenetics And Imaging Of Ataxia.

Participants
Sangam G. Kanekar, MD, Hershey, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To discuss the etiology, pathogenesis and neurogenetics of ataxia and illustrate the neuroimaging patterns in different types of ataxia. 2. To discuss the clinical, genetic and imaging approach of inherited ataxia.

TABLE OF CONTENTS/OUTLINE

Ataxia is defined as "an inability to coordinate voluntary muscular movements." Clinically, identifying the etiology of ataxia can be a complex task. In this exhibit we focus on highlighting the salient points in distinguishing the various types and causes of ataxia and discuss the neurogenetics of the respective ataxic disorder. Differentiating acquired from inherited forms of ataxia can help determine the expected disease course. Inherited etiologies involve a genetic or biochemical defect which leads to the formation of ataxia. For better understanding we classify ataxia into autosomal dominant, autosomal recessive and X-linked ataxia.

NREE-148   Traumatic Spinal Cord Injury - Mechanism, Clinical Presentation And Imaging Features.

Participants
Savith Kumar, MBBS, MD, Bangalore, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

Spinal cord damage may be due to primary or secondary injury. Primary injury is caused by the initial mechanical force which bruise or tear into the spinal cord tissue and secondary injury leads to progressive damage. MRI findings in TSCI ranges from concussion which is normal on imaging to cytotoxic edema, edema, hemorrhagic contusion, hematoma and cord transection. Intramedullary damage in TSCI can be quantified based on the distinct pattern of signal intensity on T2 weighted image which has prognostic implication..

TABLE OF CONTENTS/OUTLINE

Traumatic spinal cord injury(TSCI) is a debilitating neurological condition. Spinal cord damage after trauma is due to primary insult at the site of injury and secondary cascade of changes occurring at and remote from the site of injury. The type and extent of cord injury determines the severity of the initial neurological impairment and improvement over time. The main mechanisms of injury are impact with compression, distraction and transection. MRI is the imaging modality of choice and imaging features range from cytotoxic edema, edema, hemorrhagic contusion, hematoma and cord transection. MRI based imaging metrics or scoring system are also available for prediction of neurological and functional recovery. Contents Illustration of mechanism of spinal cord injury. Description and Illustration of Clinical features and clinical classification. Case illustration of various imaging features in spinal cord trauma. Illustration of MRI based imaging metrics or scoring system.

NREE-149   Multiple Sclerosis Lesions In The Spinal Cord: Mimics

Participants
Akm Rahman, DO, Pittsford, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review the general pathophysiology and clinical presentation of multiple sclerosis.To understand the radiologic findings associated with multiple sclerosis as it presents in the spinal cord through a case-based presentation.To systematically classify and identify etiologies for spinal cord lesions in the form of a comprehensive differential diagnosis.To explore the radiologic features of each lesion etiology in terms of their distinguishing characteristics, incorporating correlations to their clinical pathophysiologies when relevant

NREE-15   Brain MRI Findings And Clinical Features Of Triplet Repeat Diseases

Awards
Certificate of Merit

Participants
Ryo Kurokawa, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Understand the concept of triplet repeat disease (TRD) 2. Demonstrate the brain MRI findings of TRD 3. Show how clinical features can contribute to the diagnosis of TRD

TABLE OF CONTENTS/OUTLINE

I. What is TRD?: The concept of TRD; Pathomechanisms of TRD (loss-of-function, polyglutamine disease,toxic gain-of-function [RNA], polyalanine disease, unknown mechanisms) II. Loss-of-function: Fragile X syndrome (FXS), Fragile XE syndrome (FRAXE), Friedreich's ataxia (FRDA) III. Polyglutamine disease: Huntington disease (HT), Dentatorubral-pallidoluysian atrophy (DRPLA),Spinocerebellar ataxia 1 (SCA1), SCA2, SCA3, SCA6, SCA7, SCA17,Spinal and bulbar muscular atrophy (SBMA) IV. Toxic gain-of-function (RNA): Fragile X-associated tremor ataxia (FXTAS), Myotonic dystrophy type 1 (DM1) V. Polyalanine disease: Cleidocranial dysplasia (CCD), Holoprosencephaly 5 (HPE5),Oculopharyngeal muscular dystrophy (OPMD) VI. Unknown mechanism: Neuronal intranuclear inclusion disease (NIID), Oculopharyngeal myopathy with leukoencephalopathy (OPML), Oculopharyngodistal myopathy (OPDM), SCA8, SCA12, Huntington disease-like 2 (HDL2)Summary 1. TRDs have different pathomechanisms, including loss-of-function, polyglutamine disease,toxic gain-of-function (RNA), polyalanine disease, and unknown mechanisms. Summary 2. Some TRDs have pathognomonic radiological features that can help in differentiation. Summary 3. Clinical features can help diagnose TRDs, especially when radiological findings are similar to others.

NREE-150   Imaging Of Gliomas In 2021. What Is New In The 5ThEdition Of The Who Classification?

Awards
Certificate of Merit

Participants
Octavio Arevalo, MD, Shreveport, Louisiana (*Presenter*) Nothing to Disclose

TEACHING POINTS

- The new WHO classification of the CNS tumors simplifies the glial tumors to three main categories: Astrocytoma IDH-wildtype, Astrocytoma IDH-mutant, Oligodendroglioma IDH-mutant and 1p/19q co-deleted.- The pediatric and adult gliomas are now believed to be two different group of diseases. - There are imaging signs with a high specificity and PPV for a preoperative prediction of tumor molecular status such as the T2/FLAIR mismatch, the heterogeneous texture, and the pattern of calcification among others.- Certain molecular drivers are promising targets for guided therapies.

TABLE OF CONTENTS/OUTLINE

- Background- 4th edition of the WHO classification for CNS tumors- cIMPACT-NOW updates- 5th edition of the WHO classification for the CNS tumors. What changed?- Imaging biomarkers for specific tumor genotypes- The role of advanced imaging in the molecular diagnosis era- Illustrative cases- Summary

NREE-151   The Need For Speed: Sequence Innovations For Accelerated Neuro MRI Protocols

Awards
Magna Cum Laude

Participants
Michael Hoch, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Reducing patient scan time with accelerated acquisition techniques can decrease waiting lists, motion artifacts and incomplete exams. 2) Familiarize yourself with recently introduced accelerated MRI techniques and gain a conceptual understanding of image reconstructions. 3) Learn clinical scenarios where accelerated MRI techniques are useful such as screening exams, head and neck imaging, and for neurosurgical planning.

TABLE OF CONTENTS/OUTLINE

Aggressive Parallel Imaging - Ultrahigh coil element density providing excellent SNR and rapid acquisition. Take advantage of aliasing with reconstructions based on coil sensitivity due to location. Increase patient throughput.Simultaneous Multislice - Concurrently acquire multiple diffusion slices during each acquisition with controlled aliasing and partially parallel reconstructions. Once reserved for only research subjects, can now be used in clinical patients and for tractography applications.Radial VIBE - k-space sampling along rotated spokes. Accelerate acquisition by reducing the number of spokes with maintained diagnostic image quality. Benefits head & neck imaging by reducing artifacts.Compressed Sensing - Uses incoherent under-sampling of k-space and iterative reconstruction to accelerate acquisitions. Advantageous for screening such as IAC and metastasis protocols.Deep-Learning Denoising - MP-PCA isolates and removes thermal noise. Allows shorter scan times to achieve similar image quality. May prove useful for functional neurosurgery planning.

NREE-152   Tips And Tricks For Application Development Using Pretrained Medical AI Models.

Participants
Hiroto Yamashiro, RT,MS, Toyoake, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Deep learning has begun to be used as essential tool in radiology. However, preparation of expensive hardware and difficulty in collecting images data by ethical and time constraints makes barrier in development of deep learning using medical images. Therefore, we can solve these challenges by using pretrained deep learning model provided from cloud resources. The purpose of this exhibition is to show what kind of deep learning model will be useful for the study. And we introduce our study applicating Clara that is framework provided by NVIDIA as an example.Major teaching points of this exhibit are:1.Deep learning research using medical images have some challenges.2.Pretrained models using natural images show some solutions.3.NVIDIA Clara project and application example using the segmentation model.

TABLE OF CONTENTS/OUTLINE

1.Research of deep learning using medical images-Barriers to use medical images -Solution using pretrained models2.What is the NVIDIA Clara project?3.Fully automated grading system of glioma using Clara segmentation model

NREE-153   A New Insight Into Imaging Of Gliomas: PET-MRI. Here Is How We Do It.

Participants
Yukiyoshi Kimura, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

-To recognize the typical and atypical imaging features of high and low-grade gliomas.- To explain and illustrate the importance of the distinction between recurrence and pseudoprogression.- To describe the main distinctive imaging and molecular characteristics between recurrent gliomas and pseudoprogression. - To understand how to evaluate the response of surgical and chemoradiation therapy through different imaging modalities and its advantages and limitations. - To review the recent advancements in hybrid imaging (PET-MRI) in the assessment of recurrent gliomas vs. treatment-related changes.

TABLE OF CONTENTS/OUTLINE

-Introduction-Indications-PET MRI Protocol (patient preparation, PET radiotracer selection, radiotracer's advantages and limitations, MR sequences, and acquisition times).-Advanced MRI sequences (DWI, DSC and DCE, and spectroscopy) in the evaluation of recurrence vs. pseudo-progression. -PET-MRI fusion evaluation with different radiotracers. -Pictorial review of recurrent disease and pseudo-progression with illustrative cases. -Take-home points-References

NREE-154   Multi-delay ASL And SWI: An Effective Combination In Clinical Routine

Awards
Certificate of Merit

Participants
Jerome Hodel, Paris, France (*Presenter*) Nothing to Disclose

TEACHING POINTS

To understand the value of Arterial Spin labeling (ASL) and Susceptibility-weighted Imaging (SWI) combined in the daily routine practice.To learn how to distinguish between acute stroke, migraine and seizure using ASL/SWI.To understand the specific value of ASL/SWI for the detection of small arteriovenous shunt and for the characterization of brain tumors.To understand the potential role of ASL/SWI in avoiding GBCA use.

TABLE OF CONTENTS/OUTLINE

Table of Contents1/ Technical aspects (including FSE read-out, multidelay ASL, TOF effect), post-processing.2/ Dedicated MRI protocol according to the clinical context.3/ Pictorial review: combined used of ASL and SWI in a wide range of pathologies, comparison with conventional MR imaging including post-contrast imaging.4/ Diagnostic algorithm with corresponding imaging findings.5/ Pitfalls and mimics.6/ Take home messages.OutlineThe combined use of SWI and ASL improves the diagnostic accuracy of MRI.ASL is sensitive to the arterial transit time explaining the specific value of multidelay ASL.Routine evaluation of ASL/SWI helps: (i) to distinguish stroke mimics from acute stroke, (ii) to detect small arteriovenous shunt, (iii) to characterize brain tumors. ASL artifacts are useful markers of pathology.ASL/SWI may be potentially promising to avoid GBCA in selected cases.

NREE-155   First Seizure In Adults: How To Image?

Participants
Jerome Hodel, Paris, France (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To learn how to optimize imaging protocol in patients with first seizure- To understand the specific value of specific MR sequences such as DWI, SWI, ASL and high resolution MPRAGE in such patients- To learn how to distinguish between seizure, acute stroke and migraine using MRI

NREE-156   Brain Under Attack: Identifying Penumbra Areas In The Normal-appearing White Matter

Participants
Jonadab Dos Santos Silva, MS, Niteroi, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Multiple sclerosis has a broad spectrum of hidden white matter lesions that may not always be visually identifiable. Nevertheless, subtle changes in normal-appearing white matter signal may still correlate with disease progression, proving a more objective parameter in the analysis of MS images.Identifying white matter regions with a higher likelihood of becoming lesions may be a step for monitoring patient treatment and subclinical disease activity.By combining multiple MR sequences, we can optimize detection of penumbral lesions, which may represent a spectrum of regions of altered signal that may have a higher potential of evolving into active lesions.

NREE-158   MRI Evaluation Of Thrombectomy Candidates In Acute Ischemic Stroke (AIS): Is It Time For A Change?

Participants
Emmanuel Alejandro Gamarra Aviles, MD, Castelli, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

Describe the role of MR imaging in the evaluation of thrombectomy candidates in acute ischemic stroke. Understand the relevance of DWI-ASPECTS and DWI-FLAIR MISMATCH and know the cutoff values for predicting unfavorable outcomes in a case-based approach.Explain the contribution of SWI to provide information on thrombus localization and composition.Identify stroke mimics and offer differential consideration for emergency "code stroke" cases.Review recent evidence-based guidelines for triage in AIS and how to interpret them.Recognize periprocedural complications in endovascular stroke treatment.Notice the utility of AI concerning workflow and image interpretation in patients with acute stroke.

NREE-159   An Anatomic Approach To Sellar Lesions

Participants
Tabassum A. Kennedy, MD, Madison, Wisconsin (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. The differential diagnosis for sellar masses includes neoplastic and non-neoplastic conditions.2. Generating a differential diagnosis for sellar lesions is best organized from utilizing an anatomic approach.3. Understanding the clinical considerations are important for surgical management of sellar lesions.

NREE-16   The Brain Circuits And Tracts

Awards
Certificate of Merit

Participants
Ryo Kurokawa, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The aim of this review is to 1. Understand the anatomy of the brain circuits and tracts 2. Demonstrate the pathological conditions that involve the brain circuits and tracts 3. Know the clinical symptoms caused by the diseases

Anatomy; cortico-pontocerebellar tract (afferent); Dentaro-rubro-thalamic tract (efferent); Diseases: crossed cerebellar diaschisis; brain contusion and diffuse axonal injury; Listeria brainstem encephalitis 4. Guillain-Mollaret triangle Anatomy; Diseases: germinoma; cavernous malformation; pontine infarction 5. Cortico-basal ganglia-thalamo-cortical (CBGTC) loop Anatomy; Parkinson's disease 6. Pyramidal tract Anatomy; Diseases: horizontal gaze palsy with progressive scoliosis (HGPPS); adrenoleukodystrophy; Krabbe disease; amyotrophic lateral sclerosis 7. Optic pathway Anatomy; Diseases: Leber hereditary optic neuropathy; lymphoma; glioblastoma; postoperative degeneration 8. Auditory pathway Anatomy; Diseases: adrenoleukodystrophy; glioblastoma

NREE-160-HC Clinical Experience Using Novel Multidimensional Diffusion Magnetic Resonance Imaging For Characterization Of Tissue Microstructure In Various Brain Pathologies

Participants
Vasanth Venugopal, MD, New Delhi, India (*Presenter*) Chief Medical Officer, CARPL.ai

TEACHING POINTS

Multidimensional diffusion (MDD) MRI is a novel imaging technique that provides information enabling better discrimination of the average rate, microscopic anisotropy, and orientation of diffusion within microscopic tissue environments. We share our experience in the evaluation of MDD's clinical feasibility in various brain pathologies, where we employed Diffusion Tensor Distribution (DTD) imaging to retrieve nonparametric intravoxel DTDs. DTD allows separation of tissue-specific diffusion profiles of the main brain components, e.g., white matter, grey matter, cerebrospinal fluid and pathological tissue environments such as edema through so-called 'bins', namely the 'thin', 'thick', 'big', and the new fourth bin, 'sparse'. Microscopic anisotropy is not confounded by cell alignment over the voxel scale, unlike conventional fractional anisotropy. Long processing times (a few hours) are needed to generate DTD maps. Current MDD sequences, albeit optimized, feature longer TE compared to conventional diffusion sequences. This imposes a lower image resolution (3x3 mm2) in order to maintain reasonable signal-to-noise ratio. Distortion artefacts could be corrected upon acquisition of a reverse phase-encoding b0 image (for 'topup' processing).

TABLE OF CONTENTS/OUTLINE

1. Basic physics underlying MDD MRI 2. Pros and cons of the sequence 3. Highlight key differential diagnostic points in different brain indications: infections - tuberculomas and cysticercosis, sudden onset of loss of balance, fits, radiation damage and seizures

NREE-161-CS Imaging Diagnosis Of Dural Arteriovenous Fistula: Findings, Pitfalls, And Virtual 3D Tour Of Anatomy

Awards
Magna Cum Laude

Participants
Leanne Lin, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Diagnosing dural arteriovenous fistula (dAVF) is difficult on cross sectional imaging • Dilated leptomeningeal vessels and visualization of early venous drainage can suggest presence of dAVF, however this is highly dependent on contrast bolus timing • Often multiple modalities are required to make the diagnosis of dAVF • Cerebral angiogram is still gold standard to fully characterize the fistula, particularly to visualize venous reflux

TABLE OF CONTENTS/OUTLINE

• Background o Clinical manifestations of dAVF o Classification schemes § Borden § Cognard o Likelihood of hemorrhage • Interactive 3D tour of anatomy • Non-invasive imaging findings o Basic vascular anatomy o Imaging modalities for diagnosis o Imaging pitfalls, mimics and differential diagnosis • Case based review and 3D reconstructions o Cognard type I dAVF from posterior division of left ascending pharyngeal artery to left internal jugular vein o Cognard type IIa dAVF from left STA and occipital branches to sigmoid sinus. o Cognard type IIb dAVF from right occipital to sigmoid/jugular junction o Cognard type III right parietal MMA to cortical vein AVF o Cognard type IV cerebellar AVF with multiple meningeal and external carotid branch feeding arteries • Treatment options • Summary

NREE-162-CS Preoperative Surgical Planning Using Augmented And Virtual Reality

Participants
Noam Peled, PhD, Somerville, Massachusetts (*Presenter*) Co-founder, FIND Surgical Sciences Inc

TEACHING POINTS

Multimodal imaging and neurophysiology are critical for neurosurgical planning and crucial for neuroscience research in the diseased and healthy brain. 3D and 4D visualization of the data affect the decision-making process, the extent of invasive investigations, and the number of steps taken in epilepsy surgery. For both clinical practice and research, developing composite measures becomes possible once quantitative datasets from different modalities such as PET, MEG, fMRI, EEG, and invasive EEG are co-registered. This data fusion improves the detection of epileptogenic lesions and decreases the need for invasive monitoring. We implemented a multimodal analysis and visualization platform (mmvt.org). This platform enables clinicians to interpret multi-modality neuroimaging datasets for better surgery readiness and surgery outcomes. To simulate as closely as possible the actual brain surgery, we are developing an Augmented Reality (AR) where the clinicians can see a hologram of the subject's head and brain, which is constructed from a pre-operative MRI. The surgeons can directly visualize the neural activity on the 3D brain. Our AR application enables free hands while performing surgery-like operations. Neurosurgeons can seamlessly use "realistic operation planning tools" in a way that mimics the interaction they are about to perform, which can increase surgery readiness dramatically.

TABLE OF CONTENTS/OUTLINE

1. Multimodal integration2. Multimodal analysis3. Multimodal visualization4. AR/VR in surgical planning

NREE-17 Role Of Multi Delay Arterial Spin Labelling Using Arterial Cerebral Blood Volume As A Novel Imaging Biomarker For Magnetic Resonance Imaging Grading Of Glial Neoplasms As Compared To T2 Dynamic Contrast Susceptibility Perfusion Technique

Participants
Krishna Pratap Senger JR, MD, MBBS, Trivandrum, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. ASL derived aCBV as a non invasive novel imaging biomarker for grading brain gliomas.2. Early recognition of glial neoplasm dedifferentiation to higher grades on follow up.

TABLE OF CONTENTS/OUTLINE

SYNOPSIS: Gliomas are primary brain neoplasms requiring perfusion imaging for grading. This study is evaluating a novel parameter aCBV (arterial cerebral blood volume) derived from multidelay arterial spin labelling(ASL) for grading primary glial neoplasm. BODY: Purpose Histo-genetic makeup defines a glioma. Perfusion parameter derived from multidelay ASL - (aCBV) can serve as a novel non invasive imaging biomarker. This study, the first of its kind, is undertaken to find the diagnostic utility of multi delay ASL derived aCBV as compared to DSC (rCBV) parameters. Materials and Methods: This is a pilot study involving 15 patients of brain gliomas. aCBV maps were generated and normalised values compared with rCBV. Results In our study of 15 patients (06 cases- low grade glioma and 09 cases- high grade gliomas). In the statistical analysis (using R software version 4.0.3) the AUC for normalised aCBV of multidelay ASL perfusion is 1.00 with sensitivity and specificity of 100 % each for a cut off of 1.1 and for normalised rCBV of DSC perfusion is 1.0 with sensitivity and specificity of 100% each for a cut off of 1.0 between low and high grade lesions. Pearson correlation coefficient was , 0.94 p<0.001Conclusion Using multidelay ASL derived aCBV we can differentiate between high and low grade gliomas with good statistical correlation with DSC derived rCVB.

NREE-18   Not Just Scoliosis: An Imaging Overview Of Juvenile Spinal Disorders

Participants
Aparna Madhavan, MBChB, Bury, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

The learning objectives for this educational exhibit are:-To discuss the spectrum of aetiologies affecting the juvenile spine-To provide an approach in the image interpretation of the juvenile spine-To illustrate the radiological features of the various spinal diseases in the juvenile spine

TABLE OF CONTENTS/OUTLINE

The content of the exhibit will include:• Imaging protocols in the assessment of the juvenile spine• Radiological features of the spectrum of aetiologies affecting the juvenile including those that are unique to the juvenile spine. Example cases include:- Juvenile Idiopathic Arthritis and post treatment complications- Hirayama's disease- Scheuermann's disease- Spondylolysis and pars defects-Posterior ring apophyseal fracture (PRAF)

NREE-19   Gadolinium Retention On Brain MRI: Pearls And Pitfalls

Participants
Nathan Hyson, MD, Detroit, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Review the risk factors and suspected etiology of gadolinium retention.2. Gadolinium contrast retention within the subdural space, subarachnoid space, ventricles, internal auditory canals, and globes can be an important mimic of pathology on brain MRI examinations.3. Discordance between globe signal and ventricle signal on FLAIR imaging can be an important clue gadolinium retention may be present.4. This is an important entity for radiologists to be aware of so as to ensure appropriate follow-up and avoid misdiagnosing more sinister pathologies.

TABLE OF CONTENTS/OUTLINE

1. Review the risk factors for gadolinium retention, most importantly decreased renal function.2. Utilizing a system-based and pathophysiologic-based outline, illustrate examples of the potential pitfalls of gadolinium retention.3. Examples will include mimics of hemorrhagic conversion of an infarct, labrynthitis, meningitis, perilesional hemorrhage, ventriculitis, and hypophysitis.4. Illustrate the importance of follow-up in distinguishing mimics of pathology from true pathology.

NREE-2   Voxel-based Brain Tumor Segmentation: 10 Steps Towards Volumetric Accuracy

Participants
Jonadab Dos Santos Silva, MS, Niteroi, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Voxel-based morphometry (VBM) is a fast and reproducible image processing technique and can be performed through a semiautomated analytical pipeline;2. This proposed protocol optimizes tumor-to-parenchyma contrast ratio, facilitating tumor tissue delimitation;3. Accuracy is proportional to voxel size, thus 3D isotropic MRI volumes are preferred for spatial resolution purposes;4. VBM allows for detection of the actual tumor architecture, providing a more accurate tumor volume estimation

TABLE OF CONTENTS/OUTLINE

Steps from the raw image to tumor volume estimation:1. DICOM to NIfTI conversion;2. T1 intensity normalization;3. T1 skull stripping;4. Linear registration of T1+C to T1 space;5. T1+C brain extraction using the T1 brain mask as a template;6. Intensifying contrast-enhancing regions;7. Signal thresholding to isolate highly contrast-enhanced regions;8. Filling the holes within the tumor;9. Cleaning voxel clusters other than the tumor;10. Tumor volumetric measurement.

NREE-20   Primary Lymphomas Of The Central Nervous System: Subtypes Of A Great Imitator And Their Radiopathologic Correlations.

Participants
Nadia Lorite Diaz, MD, Sabadell, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

Primary lymphomas of the central nervous system (CNS) have a wide spectrum of manifestations on imaging studies. MRI is the imaging modality of choice. Although there is classic pattern of MRI findings, radiologists need to be familiar with atypical findings

that can be mistaken for manifestations of other conditions, including those that do not present with masses (e.g., vasculitis, infections, granulomatous diseases, etc.). This presentation describes the diverse manifestations of the different subtypes of primary CNS lymphomas on imaging studies, correlating these findings with the pathology findings according to the latest WHO classification of CNS tumors.

TABLE OF CONTENTS/OUTLINE

I - Introduction to primary CNS lymphomas. II - New WHO classification (2016) of primary CNS lymphomas (8 subgroups). III - Typical imaging findings and patterns of dissemination. IV - Case series illustrating the different subtypes of primary CNS lymphomas and the particularities of each on neuroimaging and pathology studies, with special emphasis on atypical findings that can lead to confusion with other conditions and on the differential diagnoses with these conditions. V - Conclusions.

NREE-21   **MRI Findings Of Tumors Of CNS Along With cIMPACT-NOW Looking Ahead To The Who Classification 2021**

Awards
Identified for RadioGraphics

Participants
Ryo Kurokawa, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this presentation is to summarize the practical recommendations on CNS tumor classification proposed in the Consortium to Inform Molecular and Practical Approaches to CNS Tumor Taxonomy-Not Official WHO (cIMPACT-NOW), and to contrast the MRI images with histological and molecular information while looking ahead to the WHO classification 2021.

TABLE OF CONTENTS/OUTLINE

Content organization What is cIMPACT-NOW? Update 1: Not otherwise specified (NOS) and not elsewhere classified (NEC). Update 2: Clarification of diffuse midline glioma, H3 K27M-mutant, and diffuse astrocytoma/anaplastic astrocytoma, IDH-mutant. Update 3: Recognizing histologically lower-grade astrocytic gliomas, IDH-wild type as glioblastoma, WHO grade IV. Update 4: Pediatric-type diffuse glioma with mutations in the MAPK and mTOR pathways. Update 5: Grading of IDH-mutant astrocytomas based on homozygous CDKN2A/B deletion status. Update 6: Various new entities and suggested name modifications. Update 7: Classification of ependymal tumors based on molecular status.

NREE-22   **Infectious Diseases And Mimickers Presenting As Dural Based Masses: The Role Of Magnetic Resonance Imaging**

Participants
Thiago B. Matias, MD, Campinas, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:• Review and illustrate the imaging findings of infectious diseases presenting as dural based masses and mimicking entities.• Describe the main imaging patterns of these entities, including tuberculosis, paracoccidioidomycosis, subdural empyema and differential diagnosis, highlighting key points to the differential diagnosis.

TABLE OF CONTENTS/OUTLINE

• Imaging patterns of infectious diseases presenting as dural based lesions and mimickers:o Tuberculosis.o Paracoccidioidomycosis.o Subdural empyema.• Differential diagnosis based on a pictorial review using representative cases from a tertiary hospital database.• Final remarks.

NREE-23   **Hypophysitis: Radiologic-Pathologic Correlation**

TEACHING POINTS

1. Provide an overview of normal pituitary gland development, anatomy, and histology.2. Review the pathophysiology of hypophysitis.3. Discuss differential diagnoses of primary versus secondary hypophysitis.4. Identify common imaging findings of hypophysitis and associated changes with disease progression.5. Describe correlating histopathological features of varying etiologies of hypophysitis.6. Review indications for medical versus neurosurgical management of hypophysitis.

TABLE OF CONTENTS/OUTLINE

I. IntroductionA. Definition and epidemiologyB. Clinical manifestationsII. Development, anatomy, and histology of the normal pituitary glandII. Pathophysiology of hypophysitisA. Natural history and role of imaging in monitoring disease progressionIV. Case-guided review of imaging findings and correlating histopathology including, but not limited to, the following differential diagnosesA. Primary hypophysitis (Lymphocytic, Granulomatous, Xanthomatous, IgG4-related, Necrotizing)B. Secondary hypophysitis (Medication-induced, adjacent sella/parasella pathology [pituitary adenoma, pituitary hyperplasia, infection, Rathke's cleft cyst, craniopharyngioma, metastases, etc], systemic disease [sarcoidosis, granulomatosis with polyangiitis, Langerhans cell histocytosis, etc])V. Factors influencing medical management versus neurosurgical intervention

NREE-24   **Cystic Malformations Of Posterior Fossa Made Easy**

Participants
Abdullah Ameen, MBBS, Karachi, Pakistan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) To discuss the brief anatomy of the posterior fossa 2) To describe different types of cystic posterior fossa malformation, their pathophysiology, and outcome 3) To describe the role of MR imaging in diagnosing and differentiating different types of posterior fossa cystic malformations 4) To enable the attendees and participants of diagnosing the posterior fossa cystic malformations quickly and easily by using a predefined approach.

TABLE OF CONTENTS/OUTLINE

Cystic malformations within the posterior fossa are rather common findings in pediatric neuroimaging. Differentiation between the various posterior fossa cystic malformations is important in terms of diagnosis, management, prognosis, and counseling of the affected families. A spectrum of disorder is included in posterior fossa cystic malformations including Dandy-Walker malformation, vermian hypoplasia, mega cisterna magna, Blake's pouch cyst, and arachnoid cyst. We will discuss how to differentiate these different types of malformation quickly and easily by looking at the mid-sagittal MR section and evaluating the images for the following parameters - Posterior fossa (Enlarged or normal) - Vermis (Normal or atrophied) - 4th ventricle (Enlarged or normal) - Tegmento-vermian angle (Normal or increased) (Normal is close to zero degrees however less than 18 degrees is widely considered normal) - Hydrocephalus (Present or absent)

NREE-25   A New Tool: 18-FCH PET/CT In Baseline Staging And Response Assessment Of Primary CNS Lymphoma

Participants
George Bitar, MBBS, MSc, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Central nervous system (CNS) lymphomas are uncommon but devastating diseases.The primary form is restricted to the CNS at diagnosis, constituting 2-4% of all primary brain malignancies. Secondary CNS involvement occurs early following the diagnosis of aggressive non-Hodgkin lymphomas, with a median interval of 5-12 months from diagnosis to detection. Both sub-types have a poor prognosis. 2. Contrast-enhanced magnetic resonance imaging (CE-MRI) is the current standard for baseline staging and response assessment of CNS lymphoma. However, differentiating viable disease from other causes of enhancement can be challenging. 3. Non-neoplastic causes of abnormal brain enhancement can limit accurate staging and overall prognostic efficacy of CE-MRI. 4. Abnormal choline metabolism is a hallmark of oncogenesis and cancer progression. We describe the novel use of 18F-fluoromethylcholine as a tracer within the context of baseline staging, interim and 'end-of- treatment' response assessment of CNS lymphoma.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Goals and challenges in imaging of CNS lymphoma 2(a) Non-neoplastic causes of abnormal brain enhancement on CE-MRI. 2(b) Absence of a validated prognostication tool for CNS lymphoma treatment 3. 18F-fluoromethylcholine positron emission tomography/computed tomography: The principles 4. Clinical relevance and applications 4 (a) Baseline assessment 4 (b) Interim response 4 (c) End of treatment assessment 5. Pitfalls 6. Future Directions

NREE-26   The Many Faces Of Bevacizumab: A Case-based Review Approach

Awards
Certificate of Merit

Participants
Camila Amancio, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:- Review the timeline of glioblastoma treatment with focus on antiangiogenic therapy with Bevacizumab (BEV), also giving practical information for radiologists about administration and mechanisms of action.- Review and application of the Response Assessment in Neuro-Oncology (RANO) criteria.- Review the literature in a case-based approach focusing on high grade gliomas, giving teaching points for each demonstrative case that will allow the reader to recognize patterns of imaging after or during BEV therapy and possible interpretations.

TABLE OF CONTENTS/OUTLINE

- Review of BEV therapy: what/ where/ how/ and when to use this medication in the context of glioma. The mechanisms of action will be shown through schematic drawing.- Timeline with the evolution of glioblastoma treatment and focus on the RANO criteria. Application of RANO criteria on MRI.- Review of the literature with teaching points in a case-based approach of high grade glioma:*Effects of BEV;*Restricted diffusion induced by BEV: viable tumor vs coagulative necrosis;*Possible imaging biomarkers of BEV therapy response: cerebral blood volume (CBV), Ktrans , ADC values;*Radiological progression patterns after BEV failure (classification);*Patterns of perfusion imaging;- Limitations and future perspectives in MRI Assessment of BEV therapy - An original case of application of chemical exchange saturation transfer (CEST) MRI and our interpretation in a patient in BEV therapy.

NREE-27   ABC Of Non-compressive Myelopathy: Tips And Tricks For General Radiologists

Participants
Mohamed Elsakka, MBBCh,MRCS, Watford, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Windowing the MR sequences can help depict the abnormal cord signal clearer.- Using a systematic approach through combing the symptom onset and the signal characterisation, such as the one proposed in our article, can help the radiologist narrow down the differentials and can direct the clinical history/examination.- Acute onset myelopathy is likely to represent as vascular, demyelinating or infective causes. Consider adding Diffusion weighted imaging (DWI) sequence for infarction and brain/contrast imaging for demyelinating/infective causes in acute onset myelopathy.- Subacute onset myelopathy is likely to represent as neoplastic, neuro-degenerative or metabolic causes. Consider cord expansion for neoplastic causes and brain imaging for degenerative causes.- Not all neoplasm cause cord expansion, such as intra-vascular lymphoma.- Infective causes can present as either acute or subacute onset myelopathy.- A normal cord signal does not rule out myelopathy if the clinical picture fits.

TABLE OF CONTENTS/OUTLINE

- Algorithmic approach for non-compressive myelopathy (more extensive).- Acute onset myelopathy.- Subacute onset myelopathy.- Application of algorithmic approach on cases from our institute.- Normal cord signal myelopathy.- Take home message.

NREE-28   CSF, You Should Not Be Here! How To Recognize CSF Leak In CT-cisternography And CT-myelography Images

Participants
Mika Shibuya, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

CSF leak results from direct communication of the CSF to extra-cranial / extra-spinal space, and may have different etiologies, clinical manifestation and image depending on their location. CSF leaks from the skull base are related to symptoms such as rhinorrhea / otorrhea; and when located in the spine, they are commonly related to orthostatic headache due to hypovolemia. High-resolution CT with or without intrathecal contrast administration (CT-cisternography) shows bone defects and extravasation of the contrast material in the extracranial compartmeeds, especially in the anterior cranial fossa. CT-Myelography / Digital Subtraction Myelography (DSM) shows findings such as extravasation of the contrast material in the epidural compartments and along the axilla of the nerve root or, more rarely, extravasation into a paraspinal vein (CSF venous fistulas), mainly in the thoracic spine and thoracolumbar junction. It's extremely important for radiologists to recognize the main locations and imaging findings of CSF leaks, which are often subtle, especially in cases of CSF venous fistulas, since the diagnosis and therapeutic success of these patients depend, at least in part, on their correct location.

TABLE OF CONTENTS/OUTLINE

Introduction. How to investigate - The role of imaging. Where to look? Why should we recognize this entity?

NREE-29   Diffuse Midline Glioma: Basic And Advanced Neuroimaging

Participants
Ryo Kurokawa, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:1. To review the characteristics of diffuse midline glioma (DMG) 2. To show conventional neuroimaging findings in DMG 3. To demonstrate how advanced neuroimaging modalities help in the diagnosis of DMG

TABLE OF CONTENTS/OUTLINE

1. What is DMG? - Epidemiology; - H3 K27M-mutant and H3 G34R-mutant; - Genetic associations, molecular updates, and future molecular targeted therapies 2. Conventional neuroimaging findings in DMG- Conventional CT and MRI imaging findings in DMG in the brain and spinal cord 3. Advanced neuroimaging findings in DMG - Dynamic susceptibility contrast (DSC); -MRI perfusion images; - Amide proton transfer-weighted (APTw) images; - Magnetic resonance spectroscopy (MRS); - Texture analysis

NREE-3   Susceptibility-weighted Imaging (SWI) Sequence, Principles And Clinical Applications: A Primer For Residents

Participants
Michaela Cellina, Milan, Italy (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To report the principles of SWI. 2. To show the importance and the role of SWI in neurological disorders. 3. to provide an overview of clinical cases showing SWI usefulness.

TABLE OF CONTENTS/OUTLINE

SWI is a relatively new magnetic resonance imaging (MRI) technique that is being used to help the differential diagnosis of many brain diseases. It is based on differences in magnetic susceptibility of various components, such as deoxygenated blood, blood products, iron, copper, calcium, allowing for a new source of contrast in MRI. SWI is a fully flow compensated, three-dimensional, high spatial resolution, gradient-echo sequence using magnitude and phase images either separately or in combination with each other.SWI can be applied in different neurological scenarios: to assess small injuries, subtle subarachnoid hemorrhages, and diffuse axonal injury in the traumatic context, to provide information adjunctive to those of DWI in ischemic stroke, and to highlight its hemorrhagic transformation, to identify brain microbleeds, characteristics of different pathological conditions (e.g. amyloid angiopathy, hypertensive encephalopathy), to help the detection of vascular malformations, to visualize the iron deposition in neurodegenerative disorders and in multiple sclerosis plaques. Moreover, the use of SWI can help the grading of cerebral malignancy thanks to the identification of intralesional hemorrhagic and calcified foci.

NREE-30   DISH - The Forgotten And Neglected Spondyloarthropathy

Participants
Jawad Hussain, MD, Mineola, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1 - Radiologists and trainees should have a working knowledge of Diffuse Idiopathic Skeletal Hyperostosis (DISH) and its associated extra-thoracic bony and non-bony findings. 2 - Radiologists must understand prevalence of DISH along the spine; cervical, thoracic, and lumbar. 3- Radiologists should be alert for co-morbidies of DISH via compression of adjacent structures and its associations with metabolic syndrome.

TABLE OF CONTENTS/OUTLINE

After reviewing this exhibit, learners should be able to identify the imaging characteristics of DISH and its associated complications. A. Describe the Resnick and other criteria for diagnosing DISH and, treatment, if needed. B. Review the extra-thoracic bony and non-bony involvement of DISH and its prevalence along the spine; cervical, thoracic, and lumbar. C. Understand the associating complications from compression of adjacent structures and correlation with Metabolic Syndrome. D. Utilizing imaging and clinical data in deciphering DISH from ankylosing spondylitis. E. Review the relevant radiology literature on this topic.

NREE-31   Multiple Sclerosis Imaging: Today And Tomorrow

Participants
Jonadab Dos Santos Silva, MS, Niteroi, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. In multiple sclerosis imaging, we have done:- 3D FLAIR: Cortical and periventricular demyelinating lesions. - 3D T1: Black holes.- T2: Infratentorial lesions.- Post-contrast T1: Acute inflammatory lesions.2. We are starting to do:- 3D T1 volumetric analysis: Quantitative volumetric assessment.- Post-contrast SWI: Central vein sign.- DIR and PSIR: Juxtacortical lesions.3. What we can implement in our analyses:- SWI: Smoldering lesions.- PET: Microglial activation.- DTI: Lesions in normal-appearing white matter.- rs-fMRI: Disruptions in the default-mode network.4. What imaging can tell us about multiple sclerosis:- Demyelination and lesion load- Dissemination in space and time- Distinction between chronic and acute lesions- Global and focal changes in cerebral structure

TABLE OF CONTENTS/OUTLINE

1. Today: What we have done - 3D FLAIR - 3D T1 - T1 - Post-contrast T12. Today: What we are starting to do - 3D T1 volumetric analysis - Post-contrast SWI - DIR/PSIR3. Tomorrow: What we can do - SWI/PET - DTI - rs-fMRI4. What imaging can tell us about MS - Demyelination and lesion load - Dissemination in space and time - Distinction between chronic and acute lesions - Global and focal changes in cerebral structure

NREE-32   Diagnostic Approach To Intraventricular Neoplasms

Participants
Irene Cifuentes Garcia, BMBS, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To illustrate the basic anatomy of the cerebral ventricles. 2. To list and illustrate the most important imaging features of common cerebral intraventricular tumors. 3. To analyze differential diagnosis of these lesions.

TABLE OF CONTENTS/OUTLINE

There is a wide variety of intraventricular tumors and in many cases they can be asymptomatic and can be discovered as casual findings, or they can present with different symptoms depending on the location and size (including intracranial hypertension, headaches, ataxia, paresis or focal neurological deficits).It is important to know the anatomy and function of the ventricles to understand the different entities that can occur in the cerebral ventricles and understand the symptoms that cause these neoplasms.The imaging findings of different intraventricular neoplasms types, can be similar. Therefore, it is important to know not only the main CT or MRI imaging findings, but also, location of these neoplasms and patient's age and gender, in order to narrow the differential diagnosis.We review the basic anatomy of the ventricles and provide the main imaging features of the most common intraventricular tumors.

NREE-33   Paget Disease Of The Temporal Bone And Skull: A Pictorial Review.

Participants
Sofía Ventura- Diaz, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review the basic anatomic architecture of the temporal bone and the petrous apex. 2. To recognize the radiologic spectrum through different imaging modalities of cranial and temporal Paget disease. 3. To know the differential diagnosis of temporal Paget disease. 4. To revise the possible complications of cranial Paget disease.

TABLE OF CONTENTS/OUTLINE

Introduction: definition, epidemiology, physiopathology and diagnosis. Normal anatomy of the temporal bone. Radiographic features and stages: multimodality imaging review. Differential diagnosis of petrous apex: case-based imaging review. Complications of cranial Paget disease. Basic epidemiology and brief retrospective analysis of the Paget disease cases recorded in our institution the last 12 years, analyzing the relationship to hearing loss and polyostotic affection. Conclusions.

NREE-34   Subcortical U-fiber: A Diagnostic Key To White Matter Disease

Awards
Certificate of Merit

Participants
Shu Suzuki, MD, Tokyo, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

White matter diseases comprise a very broad differential diagnosis. Subcortical U-fibers are known as short association fibers and have unique features. We aim to familiarize radiologists with identifying the presence or absence of subcortical U-fiber involvement.

TABLE OF CONTENTS/OUTLINE

•Anatomical and pathological features of subcortical U-fibers•Radiologic pattern of white matter disease•Cases in which subcortical U-fibers are generally spared-Chronic small-vessel ischemic disease-Delayed post-hypoxic leukoencephalopathy-Post-radiation therapy•Cases in which subcortical U-fibers are preferentially affected1. Autoimmune/demyelinating-Progressive multifocal leukoencephalopathy (PML) -Multiple sclerosis (MS)-Acute disseminated encephalomyelitis (ADEM) 2. Metabolic-Wilson disease-Kearns-Sayre syndrome/chronic progressive external ophthalmoplegia -L-2 hydroxyglutaric aciduria 3. Vascular-Posterior reversible encephalopathy syndrome (PRES)-ECMO-related multiple microbleeds (COVID-19 case) 4. Neurodegenerative-Neuronal intranuclear inclusion disease (NIID)

NREE-35   What Is The Extracellular Ph Of Brain Tumors And How Can We Detect Brain Tumors Using Gadolinium-based-contrast Agents?

Participants
Yuki Matsumoto, MS, Tokushima, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. The relaxivity of contrast agents depends on the pH value.2. pHe mapping of brain tumors might help to evaluate the malignancy of a tumor.

TABLE OF CONTENTS/OUTLINE

[Purpose] The purpose of this study was to investigate the relaxivity in relation to the pH value of each contrast agent. Moreover, pHe mapping was conducted to assess brain tumors. [Materials and Methods] A phantom experiment was performed using gadobutrol and gadoteridol. We prepared different pH-solution samples with known acidity (pH 6.0 to 7.8) that were used with different concentrations (0.1, 0.2, and 0.4 mmol) of contrast agents. Imaging was performed using a 3T MRI system (FUJIFILM Healthcare Corporation) to measure the T1 value. A single coronal-slice scan was performed using a fast spin-echo-based inversion recovery (FSE-IR) protocol, and the relaxivity values were calculated individually for each pH. The pH can then be calculated using leasts-squares fitting of the Hill-modified Henderson-Hasselbalch equation (relaxivity-pH curve). Finally, the pH map of the brain tumor was calculated using the nonlinear function obtained from the phantom experiments. [Results] The phantom experiments indicated that the relaxivity-pH curve was different from that of the contrast agent. The mean pHe value showed the trend that tumor malignancy gives lower pHe value, primary brain tumor was significantly lower than other brain diseases (P<0.001).

NREE-36   Brave New World: Current Concepts In Cortical Development Malformations

Participants
Barbara Trapp SR, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Teaching points:The purpose of this exhibit isTo simplify the understanding of the embryological processes and the main genetic pathways that can lead to malformation of the cortical development.To explore the most recent definition and classification of malformations of cortical development.To show a pictorial essay of the main magnetic resonance imaging findings of cortical development malformations divided into subgroups, and its etiological correlation when applicable.

TABLE OF CONTENTS/OUTLINE

Table of contents/outline:Powerpoint layoutIntroduction: Normal embryology overview, characterizing the three major stages of cortical development: cell proliferation and apoptosis, cell migration, post-migrational development. Considerations about normal cortex imaging and conspicuity of malformation of the cortical development according to age-related image changes (myelination and maturation). Proposed magnetic resonance imaging protocol.Definition and imaging features of malformation of the cortical development: Microcephaly. Macrocephaly. Focal cortical dysplasia - Types I to III. Grey matter heterotopia: Periventricular nodular, Subcortical (transmantle, ribbon-like, "brain in brain" malformation, aventriculy). Lissencephaly- Agyria, Pachygyria, Subcortical band heterotopia. Cobblestone malformation. Polymicrogyria. Schizencephaly - open lip, closed-lip. Disgyria.

NREE-37   A New Global Tool For CNS Lymphoma Imaging: Treatment Response Assessment Maps

Participants
George Bitar, MBBS, MSc, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Central nervous system (CNS) lymphomas are uncommon but devastating diseases. The primary form is restricted to the CNS at diagnosis, constituting 2-4% of all primary brain malignancies. Secondary CNS involvement occurs early following the diagnosis of aggressive non-Hodgkin's lymphomas, with a median interval of 5-12 months from diagnosis to detection. Both subtypes have a poor prognosis.2. Contrast-enhancement magnetic resonance imaging (CE-MRI) is the current standard for baseline staging and response assessment of CNS lymphoma. However, differentiating viable disease from other causes of enhancement can be challenging.3. Non-neoplastic causes of abnormal brain enhancement can limit accurate staging and overall prognostic efficacy of CE-MRI.4. We describe the role of a novel tool, Treatment Response Assessment Maps (TRAMs) in characterisation the nature of any abnormal enhancement on CE-MRI and in determining whether there is viable tumor.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Challenges in imaging of CNS lymphoma including the limitations of contrast-enhanced MRI. 3. The principles of Treatment Response Assessment Maps 4. Clinical relevance and applications 4 (a) Baseline assessment 4 (b) Interim response 4 (c) End of treatment assessment 5. Pitfalls 6. Future Directions

NREE-38   From The Fragile X Premutation To The Hot Cross Bun: An MRI Unique Guide For Assessment Of Posterior Fossa Adult Diseases

Participants
Elissandra Lima, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To discuss the spectrum of posterior fossa adult diseases through MRI, emphasizing degenerative, autoimmune, genetic, drug-related, and infectious diseases. To illustrate some diseases' typical imaging presentations, like the hot cross bun sign in multiple system atrophy-C (MSA-C) and the middle peduncle abnormalities on fragile X - tremor associated/ ataxia syndrome (FXTAS). To demonstrate the imaging pearls, etiology, physiopathology, and clinical highlights of posterior fossa adult diseases.

TABLE OF CONTENTS/OUTLINE

1. Background. 2. Imaging protocol. 3. Clinical perspective and importance of analysis of posterior fossa diseases through MRI. 4. The genetical cascade of events implicated in the FXTAS premutation. 5. Imaging pearls, including the middle cerebellar peduncles abnormalities on FXTAS and the hot cross bun sign in MSA-C. 6. Other diagnoses including alcoholic cerebellar degeneration, drug-induced cerebellar degeneration, autoimmune, cerebellar PRES, and infectious cerebellitis. 7. Flowchart for assessment of posterior fossa abnormalities presenting in adults. 8. Take-Home messages.

NREE-39   The Brain Is Love, Anger, Hatred, And Passion: Unraveling The Functional Anatomy And Disorders Of The Limbic System In Minutiae

Participants

Elissandra Lima, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To exhibit the macroscopic anatomy of the limbic system through 3T MRI and illustrations. To explain the limbic components' functionality, including the de amygdala, the hippocampus, cingulate gyrus, parahippocampal gyrus, dentate gyrus, and the hypothalamus. To demonstrate the correlation between anatomy, functionality, and human behavior. To exemplify the importance of MRI limbic assessment in demonstrating disorders of the limbic system.

TABLE OF CONTENTS/OUTLINE

1. Background. 2. Phylogenetic evolution of the limbic system. 3. Functional and imaging anatomy, including the cingulate gyrus, parahippocampal gyrus, hippocampus, amygdala, and mammillary bodies. 4. Clinical perspective: limbic relationship with appetite, sleeping disorders, emotional disorders, olfaction, sexual behavior, memory, addiction, motivation, and cognition. 5. Imaging assessment of the limbic diseases, including dementia, encephalitis, global transitory amnesia, tumors, and epilepsy. 6. Take-Home messages.

NREE-4 **NOWinBRAIN - A Systematic, Comprehensive, Extensive And Spatially Correlated Image Repository Of Surface And Planar Anatomy Of The Brain, Head And Neck**

Participants
Wieslaw Nowinski, DSc,PhD, Warsaw, Poland (*Presenter*) Nothing to Disclose

TEACHING POINTS

The exhibit: 1) Demonstrates correlated planar and joint surface-planar anatomy of the brain, head and neck; planar (2D) anatomy represented as MR (axial, coronal and/or sagittal) triplanar is labeled and surface (3D) anatomy represented as polygonal virtual models is parcellated by color and labeled; 2) Provides novel image display as sequences of spatially correlated 2D-3D image pairs located in a stereotactic coordinate system, facilitating understanding 3D relationships and structure localization; 3) Presents a wide spectrum of images, in total over 5,700 images systematically organized, named and grouped into almost 500 albums (folders); 4) Is suitable for medical students and residents, and educators to prepare presentations.

TABLE OF CONTENTS/OUTLINE

The repository contains 6 anatomic galleries derived from 3D brain atlases constructed from multiple 3/7 T MR and CT scans of a living brain. Galleries G1-G5 created earlier contain surface anatomy fully parcellated by color and labeled, and organized into image (appearance and context) sequences. For RSNA 2021 this repository is extended, enhanced, and a radiologic gallery (G6) added with correlated surface and planar anatomy of the brain, head and neck placed in a stereotactic coordinate system. G1 contains primary tissue classes from which the other classes are constructed. G2, G3, G4 comprise double-tissue, triple-tissue and quadruple (or more)-tissue classes, respectively. G5 contains context tissue classes. The repository is publically available at www.nowinbrain.org

NREE-40 **The Good , The Bad And The Ugly - Multifaceted Imaging Of Radiation Necrosis In High Grade Gliomas**

Participants
Jitin Goyal, MBBS, New Delhi, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. High-grade gliomas have a meager 5-year survival rate of just 10% . Initial treatment with surgical exploration involves removing the enhancing component of the tumor with further adjuvant treatment by radiation with a combination of chemotherapy. During this period of follow-up, radiation necrosis (RN) may occur in neuroparenchyma with a reported incidence of 3%-24%. 2. Perfusion and diffusion-weighted MR imaging have been advocated in the follow-up of these tumors, where differentiation of RN and tumor are pivotal from a management viewpoint. 3. Central restriction with high ADC values, lesion quotient less than 0.3 [defined as the ratio of the area of T2WI hypointensity and area of tumor enhancement] and lower rCVB values on perfusion images are imaging features favoring RN. 4. Radiation-induced changes may be classified as either pseudoprogression, those occurring within the first 6 months with a self-limiting clinical course and late radiation necrosis, occurring 12-18 months post radiation therapy with progressive enhancing lesions. Both are clinically distinct entities but bound by similar histological resemblances and imaging appearances. 5. Progressive enhancement and involvement of corpus callosum have been ascribed to tumor recurrence, but there exists an overlap in imaging features between RN and tumor recurrence.

TABLE OF CONTENTS/OUTLINE

Clinical cases depicting easy (good), bad (tricky) and ugly (difficult) cases of RN with conventional, diffusion and perfusion imaging in post treated cases of high-grade gliomas.

NREE-41 **Don't Lose Your Sleep Over This: A Review Of The Pineal Region Anatomy And Conditions**

Awards
Certificate of Merit

Participants
Flavia Sprenger, MD, Curitiba, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

• There is a broad spectrum of pineal region lesions and imaging findings may overlap• Locating the lesion epicenter is fundamental to establish differential diagnosis• Neuraxis evaluation is indispensable on some neoplasms• Communication with the surgery plays a major role and the reports must include necessary information to surgical planning

TABLE OF CONTENTS/OUTLINE

TABLE OF CONTENTSAnatomyThe pineal is a small endocrine organ located inside the posterior aspect of the third ventricle, between the superior colliculi and connects to the diencephalon by the gland's stalk.A myriad of lesions can arise from the pineal regions. Conditions can be separated in congenital and benign lesions, primary malignancies and related structures tumors. We

present 16 emblematic cases, with surgical and pathological correlation and differential diagnosis.Congenital and benign lesions• Pineal cyst• Dermoid cyst• Epidermoid cyst• LipomaNeoplasms• Pineocytoma• Pineoblastoma• Atypical theratoid rabdoid tumor• Papillary tumor of the pineal region• Pineal parenchymal tumor of intermediate differentiation• Germinoma• Medulloblastoma• Glioblastoma• Trilateral retinoblastomaRelated structures conditions• Meningioma• Thalamic glioma with pineal invasion

NREE-42   The Biggest Challenge Of Neuroradiology: Reviewing Encephalic Congenital Abnormalities And Their Genetic Correlation

Participants
Heber Colares Costa, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate the spectrum of encephalic congenital abnormalities along with their genetic relationship. To explain the cascade of the genetic mechanisms involved in encephalic's congenital structural disorders. To demonstrate the mechanisms of proliferation, migration, and organization of neuronal precursor cells and the respective morphologic abnormalities counterparts. To depict the differential diagnoses and a flowchart for assessment of congenital encephalic disorders.

TABLE OF CONTENTS/OUTLINE

1. Background. 2. Imaging protocol. 3. Clinical perspective and importance of analysis of congenital abnormalities. 4. The genetical cascade of events implicated in encephalic development. 4. Imaging assessment and their correlation with the genetic abnormalities. 5. Imaging pearls correlated with proliferation, migration, and organization of the precursor cells. 6. Differential diagnoses including congenital infections. 7. Flowchart for assessment of congenital encephalic disorders. 8. Take-Home messages.

NREE-43   Fast-stroke-MRI In A Time-counted Stroke-unity: The Protocol, The Advantages, The Imaging Pearls, And The Therapeutic Applicability

Participants
Elissandra Lima, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To depict the Fast-MRI protocol to the assessment of acute ischemic stroke in the emergency room. To explain the indications of the protocol, including wake-up stroke, the prolonged onset of symptoms, and differential diagnosis evaluation. To explain the advantages and disadvantages of utilizing MRI for acute stroke evaluation. To demonstrate that fast stroke MRI protocol can be complementary to CT for indication of endovascular therapy in stroke patients with prolonged evolution time, establishing ischemic penumbra, and supporting the therapeutic.

TABLE OF CONTENTS/OUTLINE

1. Background. 2. Fast-MRI protocol. 3. Clinical perspective and importance of establishing the correct diagnosis of stroke, considering stroke-mimics. 4. Fast MRI indications. 5. Advantages and disadvantages. 6. The search for mismatch FLAIR-DWI in patients with unknown onset of symptoms and wake-up stroke. 7. The therapeutic implications of the mismatch perfusion-diffusion in patients with prolonged onset of symptoms. 8. Imaging pearls and their correlation with therapeutic management. 9. Differential diagnoses of stroke and the MRI importance. 10. Flowchart for assessment of acute ischemic stroke with emphasis on MRI assessment. 11. Take-Home messages.

NREE-44   Vasculopathy From An Evolving Evil: Neuroimaging Assessment Of The COVID-19 Vascular Complications And Beyond

Participants
Elissandra Lima, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate the imaging spectrum of encephalic vascular complications related to SARS-CoV-2 infection. To explain the vascular complications that could be related to the COVID-19 spectrum, including large vessel stroke, intracranial hemorrhage, microhemorrhage, hypoxic-ischemic lesions, and venous thrombosis. To explain the cascade of thrombophilic conditions involved in the physiopathology of the vascular complications. To demonstrate the hemorrhagic complications related to the SARS-CoV-2, including those related to the treatment against the pro-thrombotic state. To depict the post-COVID-19 symptoms that could be related to the vascular spectrum of the disease.

TABLE OF CONTENTS/OUTLINE

1. Background. 2. Imaging protocol. 3. Clinical perspective and importance of analysis of the CoVID-19 vascular spectrum. 4. The cascade of thrombophilic conditions involved in physiopathology. 5. Imaging assessment and their correlation with thrombophilic conditions. 6. Imaging pearls correlated with large vessel stroke, intracranial hemorrhage, microhemorrhage, hypoxic-ischemic lesions, and venous thrombosis. 7. Post-COVID-19 symptoms that could be related to the vascular spectrum of the disease. 8. Flowchart for assessment of neovascular-COVID-19 disease. 9. Take-home messages.

NREE-45   The Virus And The Nerve: Imaging Post-COVID-19 Neuropathies In Children

Participants
Elissandra Lima, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate the MRI spectrum of post-COVID-19 neuropathies in children. To depict the physiopathology involved and the clinical aspects of post-COVID-19 neuropathies. To explain the many subtypes of COVID-19 related neuropathies, including Guillain-Barré syndrome, multiple cranial neuropathies, neuritis optica, and olfactory nerves involvement.

TABLE OF CONTENTS/OUTLINE

1. Background. 2. Best Imaging protocol related to the kind of involvement. 3. Clinical perspective and importance of analysis of post-COVID-19 involvement in children. 4. The physiopathological mechanisms implicated in COVID-19-induced neuropathies,

including the immune-mediated and direct invasion by the virus. 5. Imaging post-COVID-19 Guillain-Barré Syndrome, multiple cranial neuropathies, neuritis optica, and olfactory nerve involvement. 6. Differential diagnoses including another virus, bacteria, systemic conditions, demyelinating diseases, and tumoral involvement. 7. Flowchart for assessment of post-COVID-19 neuropathies. 8. Take-Home messages.

NREE-46   The White Plaque In The Black Blood: A New Perspective In The Assessment Of Atheromatous Plaques Through Encephalic Vessel Wall Imaging

Participants
Elissandra Lima, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate the spectrum of intracranial atheromatous disease through vessel wall imaging: stenosis and occlusion evaluation, plaque´s morphologic and extension, hemorrhagic, and inflammatory /angiogenic components. To explain the clinical and therapeutic relevance of the vessel wall imaging evaluation of intracranial atheromatous disease together with its parenchymatous and functional encephalic effects. To demonstrate that the vessel wall imaging assessment of atheromatous plaques is superior to traditional MRI angiography in demonstrating the patent lumen and plaque morphology. To identify potential imaging pitfalls, differential diagnoses, and post-therapeutic assessment.

TABLE OF CONTENTS/OUTLINE

1. Imaging techniques, protocol, and pitfalls. 2. Clinical standpoint and importance of analysis of intracranial atheromatous plaques through vessel wall imaging and conventional MRI angiography. 3. Comparison between vessel wall imaging and conventional MRI angiography. 4. Vessel wall imaging point of view. 5.Atheromatous disease´s parenchymatous consequences and functional abnormalities. 6.Post-therapeutic evaluation through MRI vessel wall imaging. 7. Differential diagnoses, including vasculitis. 8.Take-Home messages.

NREE-47   A Primer On Medium Vessel Occlusion Stroke

Awards
Cum Laude

Participants
Johanna Ospel, MD, Basel, Switzerland (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Definition of medium vessel occlusion (MeVO) stroke- Reporting MeVO stroke imaging (what the clinician wants to know)1) Location of MeVO stroke: anterior, middle, posterior cerebral artery 2) Primary & secondary MeVOs 3) Tissue viability

TABLE OF CONTENTS/OUTLINE

What are MeVOs? - Vessel occlusion of medium-sized intracranial arterial vessels (M2/3, A2/3, P2/3 segments) - Disabling deficit (depending on MeVO location: eg. hemianopsia > PCA, leg palsy > ACA) - Poor outcomes of MeVO stroke with medical treatment > mechanical thrombectomy as an emerging therapyWhat are typical imaging findings of MeVOs? - Small vessels and relatively distal location > subtle imaging findings > MeVO detection is challenging - Advanced imaging techniques can help:--multiphase CT angiography (mCTA) --color-coded mCTA maps --mCTA tissue level perfusion maps --CT perfusionHow to differentiate primary vs. secondary MeVOs?- Primary ("de novo") MeVOs- Secondary MeVOs (large vessel occlusion > MeVO): --Spontaneous thrombus migration --Iatrogenic after IV thrombolysis--Iatrogenic procedure-related (during thrombectomy)- Imaging findings in secondary MeVOs:--Ischemic changes outside the MeVO territory ("discrepant infarct pattern")--Multiple MeVOsHow to assess tissue viability MeVO stroke? - ASPECTS generally high in MeVO stroke due to the distal occlusion location & cannot be used to assess ischemic changes for anterior ACA and PCA MeVOs - Alternatives: mCTA collateral status & mCTA perfusion/CTP maps

NREE-48   The Immunity Against The Humanity: MRI Assessment Of Auto-immune Diseases From The Neocortex To The Spine

Participants
Elissandra Lima, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate the spectrum of MRI features of autoimmune diseases manifesting in the central nervous system. To explain the cascade of the immuno-mediated mechanisms involved in each autoimmune disorder. To demonstrate the imaging pears and highlights of some disorders, and the etiology, physiopathology, clinical issues, and differential diagnoses.

TABLE OF CONTENTS/OUTLINE

1. Background. 2. Imaging protocol. 3. Clinical perspective and importance of analysis of autoimmune diseases. 4. Graphics for the immune-mediated cascade of physiopathology events implicated in autoimmune diseases. 5. Imaging assessment of the autoimmune diseases, including autoimmune encephalitis, lupus, antiphospholipid syndrome, catastrophic antiphospholipid syndrome (CAPS), Bechet disease, and neuromyelitis optica spectrum disorders. 6. Differential diagnosis. 7. Flowchart for imaging assessment of autoimmune -diseases. 8. Take-Home messages.

NREE-49   The Future That Awaits Us: A Brief Treatise Of The Most Recent Genetic Complexity Of CNS Neoplasms

Participants
Heber Colares Costa, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate the most recent genetic alterations described in the CNS tumors and correlate with the pathology, imaging, and prognosis.To identify the most recent updates based on cIMPACT-NOW updates and the last available edition of the WHO classification. To demonstrate the news families of tumors and the importance of comprehensive molecular classification of tumor types.

NREE-5 Demyelinating And Dysmyelinating Disorders Of The Central Nervous System: A Case-based Review

Participants
Philip Lee, BA, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

The demyelinating and dysmyelinating disorders of the CNS are a heterogenous group of pathologies with significant clinical and neuroradiological overlap. While most imaging findings are non-specific, there are certain key findings that are highly suggestive for certain disorders. We highlight these best diagnostic clues and review the spectrum of demyelinating and dysmyelinating CNS diseases in a case-based quiz format.

TABLE OF CONTENTS/OUTLINE

- Demyelinating and dysmyelinating disorders o Broad overview normal myelination - Autoimmune demyelinating o Multiple sclerosis (MS) o Neuromyelitis Optica Spectrum (NMO) o Tumefactive demyelinating lesion (TDL) - Infectious demyelinating o Acute disseminated encephalomyelitis (ADEM) o Progressive multifocal leukoencephalopathy (PML) o Differentiation from HIV Encephalitis/Toxoplasmosis - Inflammatory o Sarcoidosis o Lupus o Susac syndrome o Autoimmune limbic encephalitis o Cytotoxic lesions of the corpus callosum - Dysmyelinating disorders o Metachromatic Leukodystrophy o X-Linked Adrenoleukodystrophy o Leigh Syndrome o Canavan Disease

NREE-50 CT Angiography Findings In Symptomatic Carotid Disease- It's Not All About Stenosis!

Participants
Johanna Ospel, MD, Basel, Switzerland (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Role of carotid CT angiography (CTA) in acute stroke imaging- Systematic assessment of extracranial carotid disease - High risk imaging features on CTA- Definition of Symptomatic Non-Stenotic Carotid disease (SyNC): 2 mandatory components: 1) high risk carotid plaque features 2) ischemic changes in the ipsilateral internal carotid artery (ICA) territory

TABLE OF CONTENTS/OUTLINE

Role of CTA in acute stroke- Carotid CTA recommended for all patients with suspected acute stroke- Traditionally, degree of stenosis has been considered the most important feature for determining stroke risk- BUT: increasing evidence that features other than stenosis are also associated with high stroke risk (SyNC)- Radiologists can be the first to suggest SyNC and thereby guide further patient management High risk imaging features on carotid CTA- Degree of stenosis: measured with NASCET criteria: <50% vs. 50-70% vs. >70%- Plaque thickness: measured perpendicular to the vessel centerline- Calcifications: extensive calcifications > lesser stroke risk vs. extensive soft-plaque component > greater stroke risk - Surface irregularity & ulceration- Plaque density: low density (lipid-rich) vs. intermediate density (intra-plaque hemorrhage), quantitative measurements (Hounsfield Units)- Carotid web: shelf-like projection into the carotid lumen, not a truly atherosclerotic lesion but increases stroke risk- Changes in plaque morphology over time: suggests plaque instability, requires prior imaging for comparison

NREE-51 (Mis)match Point For MRI Assessment In Neoplastic Lesions: Changing The Game

Participants
Heber Colares Costa, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review the importance of evaluating the signal intensity in T2 and FLAIR to suggest a diagnosis of astrocytoma or oligodendroglioma. To illustrate that a hyperintense lesion in T2 and a hypointense lesion in FLAIR (mismatch FLAIR-T2) suggest the absence of the 1p-19q codeletion (astrocytoma) and could be found in DNETs. To explain that the absence of the mismatch is non-specific. To correlate the Imaging finding with the patient prognosis: oligodendrogliomas have a slightly better outcome than astrocytomas, and DNETs have a favorable prognosis.

TABLE OF CONTENTS/OUTLINE

1. Histopathological and genetic considerations of oligodendrogliomas and astrocytomas (grade 2), based on the last genetic updates (cIMPACT-NOW) and WHO classification. 2. Histopathological and genetic considerations of DNETs (grade 1), based on the last genetic updates (cIMPACT-NOW) and WHO classification. 3. Flowchart of T2-FLAIR signal evaluation. 4. Mapping the imaging pearls contemplating T2 and FLAIR signal on astrocytomas and oligodendrogliomas. 5. Imaging pearls contemplating T2 and FLAIR signal on DNETs. 6. Take-home messages.

NREE-52 Imaging Pearls For Assessment Of Granulomatous Lesions: The Easy, The Problematic, And The Rare

Participants
Heber Colares Costa, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate the typical and atypical imaging features and etiologies of the granulomatous lesions. To differentiate granulomatous diseases from neoplasms such as lymphoma. To distinguish granulomatous lesions from other inflammatory and infectious conditions.

TABLE OF CONTENTS/OUTLINE

1. Background. 2. Typical imaging features of granulomatous lesions, including tuberculosis, neurotoxoplasmosis, fungi, and syphilis.

3. The atypical and rare presentations, including parenchymatous syphilis lesion. 4. Differential diagnoses including lymphoma and other lymphoproliferative diseases. 5. T2 vs. diffusion mismatch in the diagnosis of granulomatous diseases versus lymphoma. 6. The imaging features distinguishing between granulomatous lesions and other inflammatory lesions, such as a pyogenic abscess. 7. Flowchart of assessment of granulomatous lesions. 8. Take-home messages.

NREE-53 Know What Is Hiding At The Crossroads: A Radiologist's Guide To Corpus Callosum Abnormalities

Awards
Certificate of Merit

Participants
Loai Aker, MD, Doha, Qatar (*Presenter*) Nothing to Disclose

TEACHING POINTS

1- Review the radiological anatomy of the corpus callosum. 2- Categorize various pathologies of the corpus callosum. 3- Clinically correlate the imaging features to aid narrow the differential diagnoses. 4- Analyze the imaging features of different corpus callosum pathologies in a case-based approach. 5- Correlate radiological features of corpus callosum mass lesions with their histopathological counterpart whenever applicable.

TABLE OF CONTENTS/OUTLINE

1- Radiological anatomy of the corpus callosum (CC). 2- Categories of corpus callosum pathologies. 3- Signs and symptoms of corpus callosum affection. 4- Case scenarios demonstrating imaging features of different corpus callosum pathologies such as: * Dysgenesis of CC. * Infarction of CC. * Demyelinating lesions of CC (MS, Suzac syndrome, etc.). * Cytotoxic Lesions of CC. * Lymphoma involving CC. * High grade glioma involving CC. * Lipoma of CC. * Diffuse Axonal Injury. * Cerebral fat embolism. * Critical illness associated micro-bleeds involving CC.

NREE-54 Angiographic Neurovascular Anatomy (part 1): Internal Carotid Artery, Important Branches And Variants

Participants
Dylan Wolman, MD, Palo Alto, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

A detailed understanding of neurovascular anatomy is critical to safe and effective diagnostic and interventional neuroangiography, including a knowledge of fine arterial branches typically below the resolution of CT or MR angiography. However, comprehensive summary pictorial references are limited. This five-part educational series aims to incorporate extensive annotated digital subtraction angiography (DSA) images to review the anatomy of the anterior and posterior circulation most critical to the neurointerventionalist. This first portion of the series aims to:• Review the segmental anatomy of the internal carotid artery.• Review the branches of the internal carotid artery and their important anastomoses and supply.• Review common aneurysms and congenital anomalies of the internal carotid artery.

TABLE OF CONTENTS/OUTLINE

These educational exhibits will be presented as computer exhibits with illustrative digital subtraction angiography case examples throughout. The topics to be covered in this section include:• Embryologic development of the internal carotid artery.• Internal carotid artery segmental nomenclature.• Internal carotid artery branch nomenclature, supply, and important anastomoses.• Relationship of the segments of the internal carotid artery to the dural rings.• Aneurysms of the internal carotid artery.• Congenital anomalies, including persistent caroticobasilar anastomoses, aplasia of the of the internal carotid artery, and aberrant internal carotid artery.

NREE-55 Angiographic Neurovascular Anatomy (part 2): Middle Cerebral Artery, Important Branches And Variants

Participants
Dylan Wolman, MD, Palo Alto, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

A detailed understanding of neurovascular anatomy is critical to safe and effective diagnostic and interventional neuroangiography, including a knowledge of fine arterial branches typically below the resolution of CT or MR angiography. However, comprehensive summary pictorial references are limited. This five-part educational series aims to incorporate extensive annotated digital subtraction angiography (DSA) images to review the anatomy of the anterior and posterior circulation most critical to the neurointerventionalist. This second portion of the series aims to:• Review the segmental anatomy of the middle cerebral artery.• Review bifurcation and trifurcation patterns of the middle cerebral artery.• Review territorial supply patterns of the middle cerebral artery.• Review distal branch nomenclature and supply.• Review anatomic variants of the middle cerebral artery.

TABLE OF CONTENTS/OUTLINE

These educational exhibits will be presented as computer exhibits with illustrative digital subtraction angiography case examples throughout. The topics to be covered in this section include:• Middle cerebral artery segmental nomenclature.• Bifurcation and trifurcation patterns of the middle cerebral artery.• Perfusion patterns of the middle cerebral artery as a predictor of sites of occlusion in ischemic stroke, and relevant branch anatomy for endovascular thrombectomy.• Middle cerebral artery distal branch nomenclature and supply.• Anatomic variants, including Manelfe variants and fenestrations.

NREE-56 Angiographic Neurovascular Anatomy (part 3): Anterior Cerebral Artery, Important Branches And Variants

Participants
Dylan Wolman, MD, Palo Alto, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

A detailed understanding of neurovascular anatomy is critical to safe and effective diagnostic and interventional neuroangiography,

including a knowledge of fine arterial branches typically below the resolution of CT or MR angiography. However, comprehensive summary pictorial references are limited. This five-part educational series aims to incorporate extensive annotated digital subtraction angiography (DSA) images to review the anatomy of the anterior and posterior circulation most critical to the neurointerventionalist. This third portion of the series aims to:• Review the segmental anatomy of the anterior cerebral artery.• Review the cortical branches of the anterior cerebral artery and their supply.• Review anatomic variants of the anterior cerebral artery.

TABLE OF CONTENTS/OUTLINE

These educational exhibits will be presented as computer exhibits with illustrative digital subtraction angiography case examples throughout. The topics to be covered in this section include:• Anterior cerebral artery segmental nomenclature.• Anterior cerebral artery branch nomenclature and supply.• Anatomy of the anterior communicating artery complex and its common variants.• Anatomy and supply of the recurrent artery of Heubner and medial lenticulostriate perforators.• Anatomic variants of the anterior cerebral artery, including the azygous anterior cerebral artery, infraoptic origin of the anterior cerebral artery, persistent primitive olfactory artery, and bihemispheric anterior cerebral arteries.

NREE-57   Angiographic Neurovascular Anatomy (part 4): Posterior Cerebral Artery And Important Branches

Participants
Dylan Wolman, MD, Palo Alto, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

A detailed understanding of neurovascular anatomy is critical to safe and effective diagnostic and interventional neuroangiography, including a knowledge of fine arterial branches typically below the resolution of CT or MR angiography. However, comprehensive summary pictorial references are limited. This five-part educational series aims to incorporate extensive annotated digital subtraction angiography (DSA) images to review the anatomy of the anterior and posterior circulation most critical to the neurointerventionalist. This fourth portion of the series aims to:• Review the segmental anatomy of the posterior cerebral arteries.• Review the distal branch anatomy of the posterior cerebral arteries, including important variants.• Review the arterial supply and infarct patterns of the thalamus.

TABLE OF CONTENTS/OUTLINE

These educational exhibits will be presented as computer exhibits with illustrative digital subtraction angiography case examples throughout. The topics to be covered in this section include:• Embryologic development of the posterior cerebral arteries.• Posterior cerebral artery segmental nomenclature.• Distal branch nomenclature and supply.• Thalamic arterial supply.• Important anatomic variants, including hemodynamic balance between anterior choroidal and posterior cerebral arteries, the Artery of Percheron, and the Artery of Davidoff and Schechter.

NREE-58   Angiographic Neurovascular Anatomy (part 5): External Carotid Artery And Important Anastomoses

Participants
Dylan Wolman, MD, Palo Alto, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

A detailed understanding of neurovascular anatomy is critical to safe and effective diagnostic and interventional neuroangiography, including a knowledge of fine arterial branches typically below the resolution of CT or MR angiography. However, comprehensive summary pictorial references are limited. This five-part educational series aims to incorporate extensive annotated digital subtraction angiography (DSA) images to review the anatomy of the anterior and posterior circulation most critical to the neurointerventionalist. This fifth portion of the series aims to:• Review the anatomy of the major branches of the external carotid artery.• Review important external to internal carotid or vertebrobasilar anastomoses. • Review detailed anatomy of each major external carotid artery branch, with particular attention to the ascending pharyngeal, middle meningeal, and distal internal maxillary arteries.

TABLE OF CONTENTS/OUTLINE

These educational exhibits will be presented as computer exhibits with illustrative digital subtraction angiography case examples throughout. The topics to be covered in this section include:• Major branches of the external carotid artery.• Detailed angiographic anatomy of each major branch, including the: Superior thyroid, lingual, facial, ascending pharyngeal, occipital, superficial temporal, middle meningeal, and distal internal maxillary arteries• Clinically relevant external carotid to internal carotid or vertebrobasilar anastomoses. • External carotid branch cranial nerve supply.

NREE-59   Imaging Features Of Molecularly-defined Ependymal Tumors: Essential Classification Updates

Participants
Samantha Pisani Petrucci, MD, PhD, San Francisco, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Genomic profiling data informing the upcoming WHO CNS tumor classification update has demonstrated that ependymal tumors are genetically- and molecularly-distinct entities according to the anatomic compartments at which they arise. Supratentorial, posterior fossa, and spinal cord ependymomas are further divided into subtypes based on gene fusions, methylation profiles, and gene amplification, respectively.2. Numerous studies demonstrate characteristic clinical and pathological features of each new molecularly-defined ependymoma subtype; despite the essential clinical role of medical imaging, descriptions of representative MRI features are scarce.3. Interpreting radiologic findings in the context of molecular-genetic tumor characteristics can directly impact patient care by improving diagnostic precision, prognostication, and disease monitoring.

TABLE OF CONTENTS/OUTLINE

I. Overview of the molecularly-based restructuring of the ependymal tumor group as to be included in the upcoming 5th edition of the WHO Classification of CNS tumors, including key clinicopathologic features.II. Characteristic imaging features of each ependymoma subtypea. Supratentorial ependymomai. C11orf95-RELA fusion-positiveii. YAP1 fusion-positiveb. Posterior fossa ependymomai. Group PFAii. Group PFBc. Spinal ependymomai. MYCN-amplifiedii. Myxopapillary ependymomaIII. Summary and Quiza. Summary of key imaging features of each subtypeb. Quiz: apply this new knowledge to a few example cases to improve diagnostic

precision

Participants
Ana Paula Fonseca, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are: Review the anatomy of the thalamus and basal ganglia, including its anatomical limits, vascularization characteristics and normal CT and MR imaging findings and related clinical syndromes. Discuss and illustrate the imaging patterns of the main lesions in the thalamus and basal ganglia, including vascular, metabolic, traumatic, tumoral, inflammatory, infectious, among others. Describe through illustrative cases the scenarios for diagnosis, focusing on typical imaging patterns, unexpected findings and red flags that aid the diagnosis.

TABLE OF CONTENTS/OUTLINE

Anatomy of the thalamus and basal ganglia. Main pathologies involving the thalamus and basal ganglia.Metabolic disorders - Hyperammonemia; Non-ketotic hyperglycemia; Hypoglycemia; Leigh's disease; Wilson's disease; Osmotic myelinolysis; Wernicke's encephalopathyVascular disorders - Cerebral venous thrombosis; Arterial occlusion (artery of Percheron territory infarct); Hypoxic-ischemic encephalopathy.Degeneratives disorders - Neurodegeneration with brain iron accumulation; Creutzfeldt-Jakob disease; Fahr diseaseInflammatory and infectious - Behçet's disease MS, NMOSD, MOG; ADEM; Viral encephalitis; COVID-19; Toxoplasmosis; Tuberculosis; Primary CNS vasculitisNeoplasms - Glioma; CNS lymphoma; Neurofibromatosis type 1; GerminomaTraumatic - Traumatic axonal injuryToxic poisoning - Carbon monoxide; Methanol; Vigabatrin poisoning; CarbamateRed flags and diagnostic approach.

Participants
Barbara Trapp SR, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:To discuss basic MR technical requirements and protocol suggestions for a good quality vessel wall imaging. To show main applications in clinical practice of this recently available MR sequence. To show, through a pictorial review, imaging characteristics of several intracranial and cervical vascular diseases.

TABLE OF CONTENTS/OUTLINE

Powerpoint Layout:Technical considerations and protocol recommendations. VWI MR applications: Atherosclerotic disease; Arterial dissection; Post-thrombectomy changes; CNS vasculitis - infectious (including neurosyphilis, neurotuberculosis, bacterial, viral...) and non infectious; Reversible cerebral vasoconstriction syndrome; Intracranial aneurysm - rupture risk; ruptured aneurysms and instability signs; Moyamoya disease; Amyloid angiopathy; Arteriovenous malformations; Carotid web; CADASIL; Brain metastasis (versus T1 CE SPGR); Perineural spread (versus T1 CE SPGR); Tumoral venous sinus invasion.

Participants
Joshua Breeden, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The anatomy of the skull base can be a challenging topic for radiologists of all levels and subspecialty training. Non-contrast enhanced head CT (NECT head) is one of the most frequently ordered studies in the emergent setting to rule-out and rule-in numerous pathologies. The field-of-view for NECT head typically begins at the level of the foramen magnum and ends at the vertex of the skull. Radiologists, therefore commonly encounter the skull base and a familiarity with anatomy and pathology of the skull base is requisite to interpreting NECT head. Additionally, radiologists often utilize complex imaging studies, such as MRI, to further characterize and identify pathology of the skull base. We will identify and describe the basic anatomy that defines the skull base, dividing the skull base into anterior, central and posterior. We will go onto describe the detailed anatomy of the skull base, highlighting important structures that are often involved in pathology. Utilizing this foundational anatomy, we will highlight an approach to pathology of the skull base by providing a plethora of cases with broad pathology. This image-rich review will highlight teaching points that will aid radiologists in narrowing their differential diagnosis for pathologic entities in the skull base.

TABLE OF CONTENTS/OUTLINE

Introduction; Basic skull base anatomy; Detailed skull base anatomy; Quiz Yourself; Image-rich case review: Pathology to Highlight Anatomy

Participants
Tatiana Iutaka, BDS, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:Review the neurovascular involvement related to COVID-19. Discuss the physiopathology of neurovascular injury related to COVID-19.Describe and demonstrate through clinical cases, the main clinical and imaging scenarios of common and uncommon findings of COVID-19-related neurovascular injury, including ischemic stroke, hemorrhages, hypoxic-ischemic injury, cerebral venous thrombosis, spinal cord ischemia and posterior reversible encephalopathy syndrome.

TABLE OF CONTENTS/OUTLINE

Pathophysiology of neurovascular injury related to COVID-19.Common and uncommon findings of neurovovascular involvement by COVID-19.Ischemic stroke. Large artery ischemic stroke. Lacunar ischemic stroke. Hemorrhages. Intracerebral hemorrhage. Small focal hemorrhage, diffuse microhemorrhages. Subarachnoid hemorrhage. Intraventricular hemorrhage. Acute hemorrhagic necrotizing

encephalopathy.Hypoxic-ischemic injury.Cerebral venous thrombosis.Spinal cord ischemia.Posterior reversible encephalopathy syndrome.Final remarks

NREE-63   3-dimensional High-Resolution Magnetic Resonance Vessel Wall Imaging For The Evaluation Of Rare Cerebrovascular Pathologies

Participants
Zelan Ma, Guangzhou, China (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. High-resolution magnetic resonance vessel wall imaging (HRMR-VWI) provides added diagnostic capacity relative to conventional luminal imaging techniques.2. HRMR-VWI may boost diagnostic confidence of rare cerebrovascular pathologies and reducing diagnostic delay.3. Typical HRMR-VWI features of various kinds of rare cerebrovascular diseases.

TABLE OF CONTENTS/OUTLINE

1. HRMR-VWI is a modern imaging technique in the characterization of cerebrovascular vessel wall pathology.2. MR sequences and protocols for HRMR-VWI of cerebrovascular pathologies.3. Case based review of typical imaging features of rare vessel wall pathologies such as vasculitis, dissection and carotid web, etc.4. Summary

NREE-64   Diffusion Weighted Imaging Of The Brain: When The Tale In Black And White Adds More Color To The Plot

Awards
Certificate of Merit

Participants
Loai Aker, MD, Doha, Qatar (*Presenter*) Nothing to Disclose

TEACHING POINTS

1- To review the basic physical and technical principles of diffusion weighted imaging (DWI). 2- To simplify the approach to practical interpretation of DWI sequence. 3- To demonstrate the various clinical applications of DWI sequence. 4- To emphasize the importance of DWI sequence as a part of functional multi-parametric imaging. 5- To present case-based scenarios to illustrate DWI features associated with different pathologies. 6- To review the potential limitations of DWI that the neuroradiologist should consider in daily practice.

TABLE OF CONTENTS/OUTLINE

1- The basic technical principles. 2- Practical approach to the interpretation of DWI sequence. 3- Limitations. 4- Clinical applications: - Ischemia. - Neoplastic conditions. - Infections. - Inflammatory conditions. - Post operative and therapeutic follow up. - Developmental and congenital pathologies.

NREE-65   Infectious Myelitis And Mimickers: How MRI Can Help?

Participants
Fabiano Reis, Campinas, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:• Review the main imaging findings of infectious myelopathies disorders and main mimicking entities.• Describe the main imaging patterns of these diseases, including paracoccidioidomycosis, schistosomiasis, cysticercosis, histoplasmosis, tuberculosis, HIV, pyogenic spondylodiscitis and differential diagnosis, highlighting the role of MRI differentiating these entities.• Suggest a MRI-based algorithm to approach these cases, emphasizing the spinal cord imaging red flags and how they can help the radiologist reach the correct diagnosis.

TABLE OF CONTENTS/OUTLINE

• Imaging patterns on MR of spinal cord infections and mimickers:Paracoccidioidomycosis;Schistosomiasis;Cysticercosis;Histoplasmosis;Tuberculosis;HIV;Pyogenic spondylodiscitis;Vascular disorders, such as arterial and venous infarction;Demyelinating diseases, such as multiple sclerosis, neuromyelitis optica spectrum disorders and acute disseminated encephalomyelitis (ADEM);Spinal cord neoplasms, such as ependymoma, hemangioblastomas, meningioma and metastasis;Hypertrophic pachymeningitis;Transverse myelitis.• Assessments of possible differential diagnosis based on real cases from the archive of a Tertiary University Hospital.• Diagnostic algorithm.• Final remarks.

NREE-66   The Mechanism Of The Aneurysms: Saccular, Blood Blister, Fusiform, And Pseudoaneurysms To Blow The Mind!

Awards
Certificate of Merit

Participants
Elissandra Lima, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate the assessment of intracranial aneurysms by CT angiography, MRI angiography, and digital subtraction angiography. To describe the terminology, etiology, physiopathology, most frequent locations, disease associations, and treatment options for intracranial aneurisms. To explain the genetic abnormalities that are involved in physiopathology.

TABLE OF CONTENTS/OUTLINE

1. Background. 2. MRI and CT angiography imaging protocol. 3. Genetic abnormalities involved in physiopathology and related disorders. 4. Imaging assessment of intracranial aneurysms emphasizing saccular, blood-blister, fusiform, mycotic, and pseudoaneurysms. 5. Digital subtraction angiography assessment with emphasis on therapeutics. 6. Flowchart for assessment of

intracranial aneurisms. 7. Take-Home messages.

NREE-67 The Odorless Scent Of The COVID-19 Pandemic: A Look At The Anosmia Through MRI Evaluation Of The Olfactory Bulbs

Participants
Elissandra Lima, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To demonstrate that anosmia is a common symptom during COVID-19 and can remain persistent for long periods even after the disease's cure. To discuss the physiopathology implicated in the post-COVID-19 olfactory bulbs' involvement.To explain the best MRI protocol for assessment of the olfactory bulbs. To illustrate the involvement of olfactory bulbs in patients with COVID-19-related anosmia through MRI, including the volume, morphology, signal, and nerve filia.

TABLE OF CONTENTS/OUTLINE

1. Revision of epidemiology and clinical presentation of COVID-19 related anosmia. 2. Physiopathology implicated in the olfactory bulb's involvement. 3. Imaging protocol for the best assessment of the olfactory bulbs. 3. Imaging pearls of the involvement of olfactory bulbs, including the volume, morphology, signal, and nerve filia. 4. Flowchart of MRI evaluation. 5. Treatment options in patients with persistent anosmia after the cure of COVID-19. 6. Take-home messages.

NREE-68 Where's Wally? The Benefits Of 3D-FLAIR Reconstruction Post-processing Technique To Assess Focal Cortical Dysplasia

Participants
Thyago Queiroz, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Focal cortical dysplasia (FCD) is part of a large and heterogeneous group of malformations of cortical development. It is characterized by disordered cortical lamination with or without abnormal cell types. Magnetic resonance images (MRI) are essential for diagnostic and surgical planning, however, it is well known that FCD may affect small areas of the cortex and be difficult to detect even by an experienced neuroradiologist. The purpose of this exhibit is to present through illustrative cases, the benefits of the 3D-FLAIR reconstruction to increase the accuracy of detection and preoperative evaluation of FCD.

TABLE OF CONTENTS/OUTLINE

Case-base review: - Introduction - Physiopathology, clinical aspects, and classification of FCD - A range of 3T brain MRI of FCD will be provided, always including the perspective of 3D-FLAIR reconstruction, supporting its benefits in the assessment of this cortical malformation - Conclusion - References

NREE-7 Brainstem Stroke Quiz: An Illustrative Insight Into The Classic Syndromes

Participants
Martin Saenz, MBBS, Bilbao, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

Due to its complex internal anatomy, brainstem strokes produce location-dependent symptomatology.Classic brainstem stroke syndromes result from predominantly ischemic lesions in specific locations.High-resolution MR images that provide good anatomic detail, as well as a precise understanding of the functional anatomy of the brainstem, are essential tools that will enable radiologists to make a correct interpretation of the sometimes subtle imaging findings in this anatomic area.

TABLE OF CONTENTS/OUTLINE

Objective The aim of this presentation is to illustrate and help the reader understand the complex location-related symptomatology of the brainstem infarcts, therefore facilitating their MRI-based detection.Background Brain stroke is a leading cause of morbidity and mortality worldwide, and approximately %10-15 of them occur in the brainstem.Anatomy The brainstem contains several cranial nerve nuclei and it is crossed by multiple tracts connecting the brain and the spinal cord. Cross-sectional labeled illustrations are included.Symptomatology Big clinical differences are noted depending on the exact location of the stroke within the brainstem. Numerous classic syndromes result from ischemic lesions in specific locations.Imaging findings: Unlike CT, which has poor sensitivity in the posterior fossa, high-resolution MR images allow much better detection and spatial location of the ischemic lesions.Illustrated quiz-mode cases will be presented with an educational purpose.Conclusions: See the teaching points.

NREE-70 Imaging Findings Of Neurologic Complications In Oncologic Patients

Awards
Cum Laude

Participants
Gabriela Bandeira, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

-To describe the neurological complications of cancer found in oncologic patients and their mechanisms.- To describe the neurological complications of various modalities of current cancer treatment (chemotherapy, radiotherapy and immunotherapy) found in oncologic patients and their mechanisms.- To illustrate imaging findings of neurologic complications in oncologic patients.

TABLE OF CONTENTS/OUTLINE

- Introduction- Neurological complications of cancer found in oncologic patients : hemorrhagic stroke, ischemic stroke, (including Trousseau syndrome), autoimmune encephalitis, wernick encephalopathy, infectious complications.- Neurological complications of various modalities of current cancer treatment : SMART syndrome, mineralizing angiopathy, leukoencephalopathy, RCVS (reversible cerebral vasoconstriction syndrome) , radionecrosis, pseudoprogression, hypophysitis.- Illustrative cases with the imaging findings of neurologic complications in oncologic patients.- Conclusion

Autoimmune Diseases Of The Central Nervous System

Awards
Certificate of Merit

Participants
Graham Tooker, MD, East Thetford, Vermont (*Presenter*) Nothing to Disclose

TEACHING POINTS

Discuss pathophysiology of autoimmune diseases within the central nervous system.Review imaging findings for common and rare autoimmune disordersUnderstand the overlap between different autoimmune disordersRecognize autoimmune syndromes that may be amenable to treatment

TABLE OF CONTENTS/OUTLINE

This exhibit will present a case based study of the pathophysiology and imaging findings of common and rare autoimmune disorders of the central nervous system including:Systemic Lupus Erythematosus, Antiphospholipid Antibody Syndrome, Neuromyelitis Optica, Multiple Sclerosis including Balo's Concentric Sclerosis and Marburg subtypes, Neurosarcoid, IgG4 related disease, Behcets Disease, Susac Syndrome, Chronic Lymphocytic Inflammation with Pontine Perivascular Enhancement Responsive to Steroids (CLIPPERS), Giant Cell Arteritis, Takayasu Arteritis, Primary Central Nervous System Vasculitis, Granulomatous Polyangiitis

NREE-72 **Am I Seeing Dots?! The Imaging Patterns And Significance Of Cerebral Microhaemorrhages**

Participants
Namir Asmar, MBBCHIR, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Overview of the MR techniques and technical considerations in imaging cerebral microhaemorrhages (CMH)2. Review the wide spectrum of diseases associated with CMHs and their associated imaging patterns3. Recognise the role of the characteristic distribution of CMHs in elucidating the underlying pathology4. Insight into the clinical significance and management of patients with CMH

TABLE OF CONTENTS/OUTLINE

Cerebral microhaemorrhages (CMH) are defined as small foci of blood (up to 5-10 mm) within the brain parenchyma, which are increasingly identified on magnetic resonance (MR) imaging due to increased use of higher field strengths and dedicated sequences such as susceptibility weighted imaging.The presentation illustrates, with examples, the wide spectrum of diseases associated with CMH, including their presence in critical illness most recently in association with COVID-19 infection. Particular attention is given to the characteristic morphology and distribution of CMHs on MR as this can often help guide or arrive at the diagnosis. There remains controversy surrounding the clinical significance of CMHs, however, as they also have a strong association with normal aging. Nonetheless they play an important role not only in diagnosis but also in prognostication; for example, their presence being an increasingly recognised marker of worse outcome in stroke patients. The presentation concludes by exploring the role the of CMHs in guiding management decisions, such as in the adjustment of anticoagulation therapy in these patients.

NREE-73 **Imaging Spectrum Of Congenital Spine And Spinal Cord Anomalies**

Participants
Zoya M. Patni, MBBS, Mumbai, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate different MRI imaging features of spinal dysraphism. MRI is an excellent modality for classifying and evaluating the different congenital spine and spinal cord abnormalities.To understand other anomalies associated with spinal dysraphism.

TABLE OF CONTENTS/OUTLINE

MRI has proven to be superior in evaluation of Spinal dysraphism's due to its superior soft tissue contrast and multiplanar capabilities. We present a pictorial review of 87 patients with spine and spinal cord abnormalities whom were imaged on a 1.5-T MR system. Imaging features were evaluated and it was found that a total of 29 patients had Spinal dysraphism, 66 had spondylodysplasia and 8 had anomalies associated with spinal dysraphism. The most common type were Closed dysraphism (82.75%).The most common open dysraphism were myelomeningocele. The commonest associated anomaly with open & closed dysraphism was tethered cord with dural ectasia (24 %). Lipoma was the commonest closed dysraphism without any associated anomaly. In total 66 patients had spondylodysplasia with segmentation anomalies being the commonest. Partial block vertebra was the most common segmentation anomalies, seen in 36 % of patients followed by complete block vertebra in 28.8%.

NREE-74 **Multimodality Imaging Of Vertebral Artery Dissections: What Radiologists Need To Know**

Participants
Arijit Chakraborty, DO, Miami, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Vertebral artery dissections of several etiologies are an important cause of strokes, particularly in younger patients.2. The anatomical differences between the extracranial and intracranial components of the vertebral arteries must be understood to assess the potential consequences of dissections.3. The various morphologic appearances of dissections have characteristic imaging findings on CTA, MRI/MRA and DSA imaging.4. Vessel wall MR imaging is an emerging tool used to further characterize and increase sensitivity in the detection of arterial dissections.5. Each modality is susceptible to particular limitations in the postoperative setting.

TABLE OF CONTENTS/OUTLINE

1. General overview of the pathophysiology of a dissection2. Discussion of the typical, atypical and variant imaging findings regarding extra- and intracranial vertebral artery dissections3. General overview of vessel wall MR imaging4. Review CTA, MRI, and DSA correlative findings in addition to vessel wall MR imaging through case examples5. Review postoperative appearance and

evaluation of vertebral artery stenting

NREE-76   Amide Proton Transfer, Perfusion And Diffusion Weighted Imaging Of Pediatric Brain Tumors With Pathological Correlation

Participants
Sevcan Turk, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Amide proton transfer weighted imaging (APTw) shows exchangeable amide protons of mobile protein in the tissue which provides additional molecular information to assess the lesion-APTw demonstrates high signals not only in hypercellular components of tumor but also affected by extracellular tumor matrix.-APTw is useful in the detection of recurrent or residual tumor.-APTw can show perilesional tumor invasion and white matter tumor infiltration.-APTw signal is higher in tumor progression than pseudoprogression.-APTw is with less distortion and susceptibility artifact than DSC perfusion.-Pros and cons of different modalities including APTw, DWI, and PWI and discuss the pitfalls.

TABLE OF CONTENTS/OUTLINE

- Overview of imaging characteristics of supratentorial and infratentorial pediatric brain tumors including pilocytic/pilomyxoid astrocytoma, low and high grade infiltrating astrocytoma, diffuse midline glioma, ependymoma, medulloblastoma, and other embryonal tumors with emphasis on perfusion (DSC, DCE, ASL), diffusion and APTw imaging maps-Discuss pearls and pitfalls in interpreting APTw in comparison with DWI and PWI in pediatric brain tumors.-Grading and genetic mutation correlation with diffusion and APT parameters.-APTw imaging potential for treatment response assessment.- Blood products, necrosis, calcifications, and extracellular matrix affect the signals on APTw imaging.

NREE-77   Mechanical Thrombectomy For Transcatheter Aortic Valve Implantation (TAVI) Peri-procedural Stroke

Participants
Jose Pablo Martinez, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

Embolic large brain vessel occlusions must be investigated in patients with acute neurologic deficits early after TAVI.Understanding the origin and composition of the embolus we aim to retrieve during mechanical thrombectomy will help us choose the most appropriate recanalization strategy, for what CT and DSA findings are crucial.Direct aspiration through a wedge-positioned catheter is an adequate first-choice technique for TAVI-related brain emboli removal.Dual-stentriever techniques should be considered after failed attempts to retrieve solid emboli straddling brain large artery bifurcations.

TABLE OF CONTENTS/OUTLINE

Background: TAVI is the first-line treatment for patients with symptomatic severe aortic valve stenosis and high surgical risk. Stroke is a common complication that significantly increases mortality. Causes: Peri-TAVI stroke is usually related to embolism during the procedure. New-onset atrial fibrillation and brain hypoperfusion during the intervention are less frequent. Diagnosis Exhaustive neurological examination must always be performed immediately after TAVI. Patients with neurologic deficits will benefit from CT and angio-CT.Treatment: Mechanical thrombectomy is the first-line treatment for hyperacute brain large vessel occlusions. We present four cases of mechanical thrombectomy for the treatment of TAVI-related stroke performed at our institution: emboli of different origins, including fragments of native and prosthetic valves, were retrieved using classic and novel techniques.

NREE-78   Amide Proton Transfer, Diffusion And Perfusion Weighted Imaging Of Adult Gliomas

Participants
Sevcan Turk, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Amide proton transfer weighted imaging (APTw) shows exchangeable amide protons of mobile protein in the tissue which provides additional molecular information to assess the lesion-APTw correlates well with WHO grade of gliomas and predicts IDH mutation status.-APTw is useful to show perilesional invasion and white matter tumor infiltration.-APTw signal is higher in tumor progression than pseudoprogression, accuracy is more than 85% in the literature.-APTw is with less distortion and susceptibility artifact than DSC perfusion which is limited due to signals from normal vascular structures such as choroid plexus.-Pros and cons of different modalities including APTw, DWI, PWI, and their pitfalls will be discussed.

TABLE OF CONTENTS/OUTLINE

-Overview of imaging characteristics of adult low and high-grade gliomas with emphasis on APTw, PWI (DSC, DCE, ASL), and DWI-Grading and genetic mutation correlation with APTw, perfusion, and diffusion parameters.- Emphasis on the observations that APTw demonstrates non-enhancing component of tumor, tumor infiltration in the white matter with or without vasogenic edema.-Differentiation of treatment affects including postsurgical changes, pseudoprogression, and radiation necrosis from true tumor progression, using APTw, PWI, DWI.- Effect of blood products, necrosis, calcifications, and extracellular matrix on APTw imaging.

NREE-79   Dentate Nucleus Involvement In Various Diseases - A Pictorial Assay

Participants
Isha Pasari JR, MBBS,MD, Mumbai, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Knowing the anatomy of the deep cerebellar nuclei is important. 2. Many pathologies affect the dentate nuclei of the cerebellum. 3. The presence and pattern of dentate nucleus involvement in the presence of other associated imaging findings can even provide a clue to the diagnosis in certain cases.

TABLE OF CONTENTS/OUTLINE

1. Discuss the normal anatomy and appearance of dentate nucleus. 2. Enlist multiple conditions involving dentate nucleus. 3.

Describe various diseases affecting dentate nucleus with associated other imaging findings. 4. Focus on clinical history correlation for reaching a diagnosis. 5. Discuss few specific pattern of dentate nucleus involvement in certain diseases.

NREE-8   Imaging Review Of Neurological Emergencies In Oncology

Participants
Sannidhi Dewan, Mumbai, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Most common neurological emergencies in a known case of cancer are due to mass effects of the primary and/or metastatic neuro-parenchymal lesions and associated severe vasogenic edema. 2. High suspicion for adverse neuro-effects of various chemotherapeutic agents should be considered when a patient's imaging shows bilateral symmetrical acute lesions which cannot be explained by the primary disease. 3. Post contrast CT/MR venography is an excellent tool to evaluate Dural venous sinuses and radiologist plays an important role in detection and management of sinus thrombosis. 4. Cancer patients are vulnerable to severe CNS infections and detailed knowledge of these pathologies is essential for an on-call radiologist and helps differentiating mass forming infective lesions from primary/metastatic disease.

TABLE OF CONTENTS/OUTLINE

1. Review the classification, pathophysiology and clinical features of neurological emergencies in adult oncology. 2. Describe cross-sectional imaging features of neurological emergencies using typical and atypical cases as examples. 3. Describe role of radiologist in timely diagnosis and management of these conditions.

NREE-80   Let's Go With The Flow! The Use Of 3D T2-CUBE And SPACE Flow Void Artifact To Evaluate CSF Dynamics In Different Clinical And Surgical Conditions

Participants
Ferdinand Cabrera Filho, MD, Niteroi, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

There are different clinical settings in which evaluating the presence (or absence) of CSF flow in the ventricular system or between the ventricular system and adjacent structures may help to the determine the diagnosis or best management strategy. In addition to detailed anatomical information, three-dimensional isotropic Turbo Spin Echo sequences, such as the SPACE (Siemens) and CUBE (GE), can provide functional data on the CSF dynamics through the artifact produced by the flow. The radiologist's familiarity with these sequences can be a valuable tool for the interpretation of several pathologies that involve CSF dynamics, such as obstructive hydrocephalus, congenital malformations and evaluation of postsurgical complications. The objective of our work is to discuss and present several clinical and surgical cases using the SPACE and CUBE techniques, where the presence or absence of the CSF flow void was an important element for diagnostic conclusion and patient treatment.

TABLE OF CONTENTS/OUTLINE

- The physics of SPACE (Siemens) and CUBE (GE) sequences and their CSF flow void artifact. Potential clinical applications of MRI T2 flow void artifact and imaging findings: - Obstructive hydrocephalus. - Postsurgical pseudomeningoceles. - Congenital malformations. - Assessment of patency and integrity of third ventricle floor in third-ventriculostomy (surgical and spontaneous). - Assessment of patency in surgically fenestrated arachnoid cysts.

NREE-81   "Let'S Filter It": A Neuroradiological Review Of The Main Renal Diseases"

Participants
Raissa Leite, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Renal failure affects the nervous system with high frequency. Uremia, a direct metabolic consequence of kidney failure, can affect the central and peripheral nervous system. Kidney transplantation and immunosuppressive drugs with high frequency cause neurological problems in the postoperative period, such as: infections, post-transplantation lymphoproliferative disorders and movement disorders secondary to the use of cyclosporine. Dialysis is associated with a variety of complications. Important aspects of pathophysiology, clinical manifestations, together with image changes are essential and highlighted in this study for investigation and appropriate treatment.

TABLE OF CONTENTS/OUTLINE

Kidney diseases manifest themselves in different ways under the central nervous system and with a high frequency, whether peripheral or central. They can be of several causes, standing out toxic-metabolic and endocrine, that culminate in renal failure and exhibit peculiar alterations of image in the neuroimaging, being associated to a variety of complications. The objective of this work was to update the main neuroradiological manifestations of kidney diseases, so that the radiologist can identify them early, aiming at the diagnosis and appropriate treatments.

NREE-82   Clinical And Neuroimaging Patterns Of Thrombotic Microangiopathies

Participants
Heber Colares Costa, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate the spectrum of thrombotic microangiopathies, including disseminated intravascular coagulation (DIC), thrombotic thrombocytopenic purpura (TTP), hemolytic uremic syndrome (HUS), and antiphospholipid antibody syndrome (AAS). To demonstrate the common MRI pattern of thrombotic microangiopathies, which includes multiple foci of hemorrhagic material, ischemic lesions, and a posterior reversible encephalopathy pattern. To associate the clinical profile of the patient with the corresponding type of thrombotic microangiopathy for a specific diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Imaging protocol: emphasis on SWI and Phase Map for bleeding identification, as well as diffusion for recent ischemic lesions.

2.Thrombotic microangiopathies: clinical and etiological concepts. 3. Main MRI patterns: hemorrhagic, mixed, and PRES-like. 4. MRI features and correlation with the clinical context: DIC, TTP, HUS, AAS. 5. Conclusion: Differential diagnosis based on clinical and imaging highlights.

NREE-83   Neuroimaging Spectrum In Patients With Altered Sensorium In A Critical Care Setting: A Comprehensive Pictorial Review

Participants
Sayani Mahal, MBBS, Jodhpur, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

Serial neurological examination and use of neuroimaging forms the core of neurocritical care practice in intensive care unit. Computed tomography of head with added angiographic and perfusion imaging is the workhorse in critical care scenario providing a massive advantage of fast imaging and competence. It can detect the most common causes of intensive care admissions like acute trauma, ischemic stroke, intracranial hemorrhage and its outcome like brain herniation. Magnetic resonance imaging of brain, given the better resolution, is the problem-solving investigation in CT negative patients. Although most of the diagnoses in critical care patients are characteristic as far as imaging is concerned, there exist a conundrum of conditions which are exceedingly rare to come across in critical practice. This pictorial is aimed at demonstrating spectrum that ranges from the cases with classical neuroimaging features to those rare extra-ordinary findings.

TABLE OF CONTENTS/OUTLINE

1. Neuro-Intensive Care Section recommendation for critically ill patients. 2. Imaging algorithm for patients with altered sensorium in intensive care unit. 3. Step-wise approach and diagnosis of an array of conditions causing altered sensorium.

NREE-84   Neuroradiological Findings In Psychiatric Organic Diseases: A Pictorial Review

Participants
Hudson Silva, MD, Recife, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibition is to: -Describe the main organic pathologies commonly presented with psychiatric manifestations, subdivided into endocrine/metabolic, internal medicine, and neurological diseases. -Illustrate in a didactic approach the main neuroradiological findings, highlighting the key features that allow the differential diagnosis.

TABLE OF CONTENTS/OUTLINE

Introduction Main neuroimaging findings in psychiatric organic diseases according to three subgroups -Endocrine and metabolic diseases: osmotic demyelination, hypoglycemia, and Wernicke encephalopathy. -Internal medicine diseases: High-altitude cerebral edema (HACE), Neuroacanthocytosis, Whipple's disease, hepatic and uremic encephalopathies, HIV angiopathy, Progressive multifocal leukoencephalopathy (PML), malaria, neurosyphilis, Bechet's disease, limbic encephalitis, meningeal lymphoma and carcinomatosis. -Neurological diseases: posttraumatic brain injury, cerebral neoplasia, anti-NMDA encephalitis, neurodegenerative diseases, normal pressure hydrocephalus. Propose a systematic approach to the differential diagnosis. Conclusions References

NREE-86   The S Rule For Hemorrhagic Stroke: A Pictorial Update On CT Spontaneous Intracerebral Hemorrhage Expansion Markers

Participants
Carlos Suevos, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To summarize the basic Computed Tomography (CT) features of Intracerebral Hemorrhage (ICH) which determine its management in current clinical practice.2. To explore brand-new ICH Expansion Biomarkers which help predict its evolution in order to develop a deeper understanding of its prognosis. 3. To propose an useful guidance for analyzing ICH according to the S rule as a quality assurance (QA) to reach an homogenous report amongst different radiologist profiles.

TABLE OF CONTENTS/OUTLINE

1. Introduction.2. Classical ICH CT features.3. New developing ICH CT Expansion Markers.4. ICH Structured Reporting in Clinical Practice.5. Conclusion

NREE-87   Intracranial Arteriovenous Malformation In Infants: A Pattern Through Images.

Participants
João Victor Rodrigues SR, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are: • Describe the physiopathology of arteriovenous malformations in infants. • Within each arteriovenous malformation, discuss and illustrates the key clinical and radiological features. • Review illustrative cases in different imaging modalities.

TABLE OF CONTENTS/OUTLINE

• Pediatric brain arteriovenous shunts usually have a higher incidence of multifocal and high-flow lesions, induced remote arteriovenous shunts, venous thrombosis/ectasias, rapid cerebral atrophy, and systemic manifestations. • Although most classification of vascular malformation is based on angioarchitectural and histomorphological features, certain vascular malformations do not fit into any categories, point toward a spectrum of overlapping disease entities. • Classifying those shunt types according to anatomical space with recognition of the venous drainage enables to identify and predict potential consequences through its venous function on a developing brain. • Therefore we propose a sample recognition of the high flow arteriovenous shunts according to the specific pattern through image cases by a retrospective and descriptive study of brain MRI and angiography in our institution.

NREE-88   Contrast-enhanced 3D T2-FLAIR Imaging Of The Brain: What Should Radiologists Know?

Awards
Certificate of Merit

Participants
Minako Azuma, Miyazaki, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Three-dimensional T2 fluid-attenuated inversion-recovery (3D T2-FLAIR) MR imaging is sensitive to low concentrations of gadolinium (Gd) and slow flow compared with T1-weighted imaging. 2. Contrast-enhanced (CE) 3D T2-FLAIR imaging is thought to show only signals of Gd in the interstitial space and in contact with fluid because the signal from inside the blood vessel is suppressed. 3. Knowing the characteristics of CE-3D T2-FLAIR imaging will help in the accurate diagnosis of brain lesions.

TABLE OF CONTENTS/OUTLINE

1. Basics of 3D T2-FLAIR sequence (1) The relationship between the Gd concentration and the signal intensity of CE-3D T2-FLAIR (2) The relationship between the velocity of flow and the signal intensity of CE-3D T2-FLAIR 2. Clinical application of CE-3D T2-FLAIR imaging (1) Normal appearance of the brain: Circumventricular organs (posterior lobes of the pituitary gland, pineal gland, area postrema, vascular organ of the lamina terminalis, subfornical organ, subcommissural organ, choroid plexus) (2) Pericortical enhancement in normal aging, mild cognitive impairment, and Alzheimer disease (3) Leptomeningeal enhancement: Infectious leptomeningitis, leptomeningeal carcinomatosis, sarcoidosis, Wernicke encephalopathy (4) Wall enhancement of cystic pituitary lesions: discrimination of craniopharyngioma from Rathke's cleft cyst, "Donut-like enhancement" of cystic pituitary adenoma 3. Take home points 4. References

NREE-9   Neuro-Behçet Disease: Spectrum Of Imaging Findings

Awards
Magna Cum Laude

Participants
Eugenio Gil, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

1 - Understand basic pathophysiology and clinical presentation.2 - Recognize typical imaging findings.3 - Recognize atypical and uncommon presentations that should not be missed or misinterpreted.4 - Realize important imaging or clinical clues that should help with differential diagnosis.

TABLE OF CONTENTS/OUTLINE

1 - Basic pathophysiology and clinical presentation.2 - Typical imaging findings: a) Parenchymal: Brainstem, basal ganglia, lobar involvement.b) Non-parenchymal: Venous thrombosis, Intracranial hypertension, aseptic meningitis.3 - Uncommon presentationsa) Longitudinally extensive myelitis.b) Pseudotumoral presentation.c) Carotid pseudoaneurysm.c) Progressive cerebellar and brainstem atrophy.4 - Differential diagnosis: a) Inflammatory demyelination: neuromyelitis optica, multiple sclerosis.b) Other inflammatory diseases: Neuro-Sweet syndrome.c) Infection: listeria rhombencephalitis, neurosyphilis.d) Vascular: brainstem AV-fistula

NREE-90   Prematurity, Periventricular Leukomalacia, And Hemorrhage Of The Germinal Matrix: A Mind Map To Pathophysiology, Imaging, And Prognosis

Awards
Certificate of Merit

Participants
Elissandra Lima, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review the imaging patterns of hypoxic-ischemic injuries in the preterm infant. To demonstrate the physiopathological mechanisms and differences between mild and severe hypoxic-ischemic events in preterm infants and the prognosis. To illustrate the MRI features of germinal matrix hemorrhage and its graduation. To present the differences between preterm and full-term hypoxic-ischemic imaging patterns.

TABLE OF CONTENTS/OUTLINE

1. Background/Introduction. 2. Imaging modalities, including MRI and ultrasonography. 3. MRI protocols and basics of interpretation. 4. Physiopathological mechanisms of hypoxic-ischemic injuries in the preterm infant. 5. Normal magnetic resonance imaging of the preterm and myelination patterns. 6. Imaging the mild-to-moderate hypoxic-ischemic injury. 7. White matter injury of prematurity or periventricular leukomalacia. 8. Germinal matrix-intraventricular hemorrhage. 9. The severe hypoxic-ischemic lesion in the preterm. 10. Disparities between preterm and full-term infants hypoxic-ischemic imaging patterns. 11. Flowchart of evaluation. 12. Take-home messages.

NREE-91   Neuroimaging Of Progressive Multifocal Leukoencephalopathy In Diverse Clinical Scenarios

Participants
Yoshiaki Ota, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:1. To review pathogenesis of progressive multifocal leukoencephalopathy (PML) 2. To demonstrate imaging features based on different clinical backgrounds3. To illustrate imaging mimics and pitfalls.

TABLE OF CONTENTS/OUTLINE

1. Pathogenesis- Non-inflammatory demyelination2. Background- HIV infection- Multiple sclerosis under natalizumab treatment-

Hematologic and oncologic conditions under immunosuppressant treatment- Rheumatologic diseases under immunosuppressant treatment- Organ transplantation3. Imaging features of PML- Conventional MRI: typically T1 hypointense and T2 hyperintense lesions in the subcortical U-fiber rather than in periventricular white matter- Enhancement: typically not associated with enhancement, but commonly seen in the setting of natalizumab-associated PML, which may depend on patient's immunological status- DWI: DWI hyperintensity at the lesion margin.- SWI: hypointensity along cortical-subcortical junction adjacent to PML demyelinating lesions - MR spectroscopy: increase of Choline peak, decrease of NAA peak- DSC perfusion MRI: usually decreased rCBV and rCBF seen in the lesion- PET-CT: different FDG uptakes varying based on immunological status- Diffusion tensor image: early detection of demyelination4. Mimics and pitfalls- Posterior reversible encephalopathy syndrome (PRES)- PML-IRIS- CNS lymphoma

NREE-92   Don't Break The Flow! - Review Of Cerebrospinal Fluid Circuit And Intraventricular Lesions.

Participants
Julia Brunelli, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Through this pictorial essay will be made a review based on cases and original drawings about the cerebrospinal fluid (CSF) circuit, and intraventricular lesions that can interrupt this flow. Intraventricular pathologies will be addressed by typical imaging patterns (such as diffusion restriction, cysts, solids with or without enhancement) and an algorithm to narrow differential diagnoses. The purpose of this exhibition is to:- Review the anatomy of the Ventricular System;- Describe how is the cerebrospinal fluid circulation according to the classic and the new theories;- Recognize the main etiologies of intraventricular lesions, according to their main MR imaging findings;- Organize the radiologic reasoning with an algorithm.

TABLE OF CONTENTS/OUTLINE

ANATOMICAL CONCEPTS - Ventricular system and MRI anatomyCEREBROSPINAL FLUID DYNAMICS- Classical CSF Flow- The new CDF DynamicsINTRAVENTRICULAR LESIONS - Didactic algorithm of imaging differential diagnosis- Imaging aspects of intraventricular pathologiesINTERACTIVE CASE-BASED DIDACTICS - Sample cases to illustrate and solidify the concepts

NREE-93   Pediatric Craniofacial Vascular Lesions In The Age Of Genomics And Proteomics

Participants
Abdullah Khan, MD, Sacramento, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Describe current concepts of genomics and proteomics in syndromic pediatric craniofacial vascular lesions. 2) Describe the role of the radiologist in defining imaging-based approaches. 3) Understand the difference between syndromic, sporadic and related lesions

TABLE OF CONTENTS/OUTLINE

There is increasing evidence that abnormal expression of certain genes underlies CNS vascular lesions. Upregulation or downregulation of genes influences embryogenesis, vasculogenesis and angiogenesis signaling pathways, generally through protein assembly. Genomics have been clearly linked to various syndromic lesions in craniofacial vascular malformations, i.e. HHT, PHACE syndrome, RASA1 mutation, CLOVES, Macrocephaly capillary malformation syndrome, CLAPO, NF1, Klippel-Trenaunay and Sturge Weber syndrome, syndromic AVMs (CM-AVM, CAMS), and some forms of Moyamoya. Radiologists are uniquely positioned to design imaging-focused approaches for improved definitions of such syndromes. Genome wide association studies have also suggested abnormal gene expression in sporadic vascular lesions, i.e. low-flow vascular anomalies, including venous/lymphatic/capillary/mixed malformations, AV-fistulas and AVMs. Lastly, somecerebrovascular vascular lesions are more clearly understood to result from underlying conditions, such as sickle cell disease, cardiac conditions or coagulopathies.

NREE-94   Ocular And Visual Disturbances - Inside The Brain, What Remain?

Awards
Certificate of Merit

Participants
Guilherme Chaves, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Neuro-ophthalmic disorders have a broad spectrum of differential diagnosis and many diseases with ophthalmic manifestations may have a normal orbital evaluation. The objective of this pictorial essay is to review optic tract anatomy, focusing on the encephalic regions related to vision and to discuss the main brain disorders with ophthalmic manifestations. The retrochiasmatic visual pathway is composed by optic tracts, lateral geniculate bodies, optic radiations and visual cortices, while the brainstem and cerebellum are involved in efferent visual function. Many pathological processes can manifest as visual disturbances, such as hypoxic/ischemic injuries, hemorrhage, demyelination, neurodegenerative diseases, genetic disorders, tumors, infections/inflammatory diseases, vascular malformations and post radiotherapy disorders. Localizing the cause of visual disturbances sometimes requires looking beyond the eyes. Clinical findings may help to determine the lesion location and neuroradiologists should understand these clinical manifestations to know where to search.

TABLE OF CONTENTS/OUTLINE

1. Review optic tract anatomy; 2. Describe the afferent and efferent visual pathways; 3. Anatomical view of primary and secondary cortices; 4. Differential diagnosis of ocular and visual disturbances based on anatomic correlation: cortex, white matter, brainstem, cavernous sinus and optic chiasm.

NREE-95   Common And Unusual Intradural Extramedullary Masses. Are You Sure You Have Seen It All?

Awards
Certificate of Merit

Participants
Sofia Velasco, MD, MPH, Ottawa, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review the intradural extramedullary space lesions, emphasizing key imaging findings that lead to a diagnosis.To illustrate the use of imaging landmarks to precisely localize a lesion in the intradural extramedullary space in challenging scenarios.Lesions associated with syndromes will be highlighted along with recommendations for further imaging workup.

TABLE OF CONTENTS/OUTLINE

Approach - Location- Each pathology will include clinical features with cases illustrating key imaging findings - Pearls.- Schwannoma- Schwannomatosis- Meningioma Key signs including Arachnoid isolation sign and Gingko leaf sign- Calcified meningioma and surgical implications- Neurofibromas Neurofibromatosis type 1 and Neurofibromatosis type 2- Multiple Inherited Schwannomas, Meningiomas, Ependymomas- Myxopapillary ependymoma encapsulated vs. non-encapsulated- Paraganglioma- Leptomeningeal metastases - 4 different patterns including rare case of metastatic GBM.- Lymphoma- Benign Lesions of the Conus Medullaris-Summary

NREE-96   Stroke-like Migraine Attacks After Radiation Therapy (smart) Syndrome: What We Know And What Remains Unknown

Participants
Yoshiaki Ota, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:1. To review the postulated pathophysiology of SMART syndrome2. To present typical and atypical MRI findings of SMART syndrome3. To demonstrate other delayed complications of radiation therapy

TABLE OF CONTENTS/OUTLINE

1. Pathophysiology of SMART syndrome- Late ionizing radiation effects upon mitochondrial DNA- Vessel narrowing or occlusion due to delayed radiation effects 2. Neuroimaging of typical and atypical SMART syndrome- Typical MRI findings: gyriform enhancement and correlative abnormal T2 and fluid-attenuated inversion recovery (FLAIR) signal - Atypical MRI findings: locally restricted diffusion, brainstem lesion 3. Advanced imaging assessment- DCE-MRI: locally increased permeability- DSC-MRI: local increased cerebral blood volume- Arterial spin labeling (ASL): local increased perfusion- MR spectroscopy: reduced N-acetyl-aspartate (NAA) signal without increased choline and large lipid peak - FDG PET-CT: low FDG uptake 4. Other delayed complication of radiation therapy- Microhemorrhage/cavernoma/meningioma/siderosis/basal ganglia calcification

NREE-97   Differential Diagnosis Of Inflammatory And Auto-immune Diseases Of The Spinal Cord

Participants
Marina De Freitas, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

* Review and discuss inflammatory and auto-immune disorders that affect the spinal cord, focusing on image patterns and key points to differentiation between demyelinating and non-demyelinating causes. * Exemplify mimicking disorders in order to scrutinize a practical approach for the differential diagnosis. * Review the main diagnostic modalities that are used evaluate.

TABLE OF CONTENTS/OUTLINE

* Introduction on the theme and epidemiology. * Didactic illustration and presentation of the main inflammatory and auto-immune disorders that affecting the spinal cord. * Discuss and review selected cases of the different diseases of transverse myelitis, including: -- Demyelinating diseases, such as multiple sclerosis, neuromyelitis optica spectrum disorder (NMOSD), myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD), acute disseminated encephalomyelitis (ADEM) -- Non-demyelinating diseases, such as rheumatoid diseases (systemic lupus erythematosus - SLE, dermatomyositis, Sjogren syndrome, Behçet disease), sarcoidosis, autoimmune glial fibrillary acidic protein astrocytopathy (GFAP), Guillain-Barré syndrome and Miller Fisher variant, paraneoplastic syndromes, IgG4 related disease, radiation-induced myelopathy. * Review the clinical and radiologic features of each inflammatory and auto-immune spinal cord diseases, identifying their typical findings and patterns. * Conclusion.

NREE-98   Dissecting The Intracranial Corticospinal Tract: A Review Of MRI Techniques To Understand The Anatomy, Pathophysiology And Clinical Correlations Of CST Disorders

Participants
Tatiana Iutaka, BDS, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Review the anatomy, embryology and pathophysiology of corticospinal tract (CST);Describe the clinical findings and the topographic diagnosis of CST disorders;Discuss and illustrate through clinical cases, the clinical and imaging features of CST disorders, organizing them according to the etiology;Discuss the importance and application of the different MRI sequences in CST disorders;Suggest a practical approach according to the topography of CST disorders

TABLE OF CONTENTS/OUTLINE

Anatomy, embryology and pathophysiology of CST.CST DisordersDevelopmental CST hypoplasia or aplasiaHoloprosencephaly;Schizencephaly;Corpus callosum dysgenesiaAbnormal CST Guidance at the MidlineCongenital Mirror Movements;Klippel-Feil Syndrome;Molar Tooth Midbrain-Hindbrain MalformationDegenerative Amyotrophic Lateral Sclerosis;Primary lateral sclerosis;Multiple System Atrophy;Hereditary Spastic ParaplegiaToxic and Metabolic Krabbe Disease (Adult variant);X-Linked Adrenoleukodystrophy (Adult variant);Cerebrotendinous Xanthomatosis;Adult-Onset Leukoencephalopathy with Axonal Spheroids and Pigmented Glia;Wernicke Encephalopathy;Chronic Hepatic Encephalopathy;Osmotic Demyelination Syndrome;Vitamin B12 Deficiency;OthersInflammatory and Infectious Neuromyelitis Optica Spectrum Disorder;Neuro-Behçet;HTLV-1 Infection;OthersVascular Hypoxic Ischemic Brain Injury;OthersNeoplastic Tumor DisseminationMiscellaneousWallerian DegenerationPractical diagnostic approach

NREE-99   Beyond Anatomy: Looking To The Pixels - Radiomics And Radiogenomics In Neuro-oncology

Participants

Guilherme Chaves, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

In modern radiology, studies of radiomics and radiogenomics have grown exponentially because they analyze the image beyond its phenotypic aspects through the data that the image produces. In neuro-oncology, a broad and heterogeneous field in neuroradiology, such studies increase the accuracy of diagnosis and follow-up, besides being essential to radiologists in understanding this new field of study and its proven applications. Radiomics is defined as the conversion of images to higher dimensional data and the subsequent mining of these data for improved decision support, involving combining radiomic data with other patient characteristics. The radiomic data correlated with genomic patterns is known as radiogenomics. The combination of this subset of radiomic features with genomic data may increase diagnostic, prognostic, and predictive imaging power. In neuro-oncology, due to various tumor characteristics, researches involving radiomics and tumor molecular identification and mutations, prognostic assessment and to differentiate pseudo-progression from tumor progression are increasing and there are many recent publications in this field.

TABLE OF CONTENTS/OUTLINE

1. Radiomics and radiogenomics: definition, imaging acquisition, processing and analysis. 2. Review the new classification of the World Health Organization concerning Central Nervous System Tumors. 3. Application of radiomics and radiogenomics in neuro-oncology showing in a didactic way the consolidated aspects already published.

GUEE-1   Pathology Of The Scrotum: US Assessment and Pictorial Review

Participants
Pérez Perez Arroyuelos, Galdakao-Usansolo, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

Sonography is the imaging modality of choice for examination of the scrotum. Objectives of this study: Review the normal US anatomy of testes and scrotum. Illustrate a wide variety of pathologic conditions afecting the scrotum. More in-depth assessment of the most representative diseases.

TABLE OF CONTENTS/OUTLINE

We reviewed all the scrotal sonographies made in our institution during a period of 10 years. Representative cases are illustrated in this exhibit (with other imaging techniques and radio-pathologic correlation when possible) grouped according the following headings:1 Infectious conditions: orchitis, epididimitis, pyocele, abscesses, chronic epididimitis. 2 Mechanical causes: testicular torsion, torsion of testicular appendages, segmental testicular infarction, scrotal trauma and hematoma. 3 Tumors. Testicular tumors: A) Germinal cell tumors (seminomatous and nonseminomatous) B) Sex cord-stromal tumors C) Others (lymphoma, epidermoid cyst). Extratesticular tumors: adenomatoid tumors, leiomyosarcoma, malignant fibrous histiocytoma. 4 Tumor-like lesions: nodose vasitis, adrenal rests, splenogonadal fusion, focal fibrosis. 5 Miscellaneous conditions: inguinoscrotal hernia, intratesticular and extratesticular varicocele, sperm granuloma, postvasectomy changes, spermatocele and epididymal cyst, microlithiasis, cyst of the tunica albugiínea, intratesticular cyst, hydrocele, tubular ectasia of the rete testis, scrotal calcifications, cystic testicular dysplasia.Take home points.

GUEE-10   Prostate MRI: Why Are We Missing Clinically Significant Cancer?

Participants
Joan C. Vilanova, MD, PhD, Girona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

a) Recognize different causes of missing clinically significant prostate cancer (csPCa) on mpMRI. b) Understand the radiobiopathology mechanisms supporting the m/bpMRI visibility and invisibility of csPCa. c) Identify other types of prostate cancer beyond the typical appearance of adenocarcinoma or other atypical prostatic disease. d) Recognize technical & protocol & biopsy issues related to false negative diagnose of prostate cancer. e) Show and review the ambiguities in image interpretation related to PI-RADS 2.1 that might develop false negative results

TABLE OF CONTENTS/OUTLINE

1.- Introduction to Prostate MRI 2.- Histopathology of prostate cancer 3.- Causes of missing and limitations for clinically significant prostate cancer on MRI: a) Pathological-Clinical/MRI features. b) Technical acquisition. c) Biopsy issues/under-sampling. d) Interpretation MRI. It will be illustrated different and multiple causes that can cause invisible clinically significant prostate cancer on m/bpMRI. It will be correlated MRI/ histopathological features that explain the invisible csPCa (Gleason grade, volume, cellular density, microvessel density, stromal tissue, cribriform pattern and intraductal carcinoma) with clinical data (PSA). It will be described technical & interpretation issues on MRI protocol, DWI-ADC, limitation on PI-RADS and biopsy under-sampling for false negative results on csPCa detection. It is important to know why csPCa is missed to reduce the false negative rates and improve PCa detection.

GUEE-100   An Insight Into The Revised Bosniak Classification For Renal Cysts: Version 2019

Participants
Suryansh Bajaj, New Haven, Connecticut (*Presenter*) Nothing to Disclose

TEACHING POINTS

Cystic lesions in the kidney are common occurrences and it is important to differentiate the benign cysts from the malignant lesions on the basis of radiological imaging. For this purpose, Dr. Morton A Bosniak proposed a classification system for different renal cystic lesions in 1986 on the basis of the imaging characteristics on CT. Reviewing the data showing the overdiagnosis and aggressive treatment of renal cell carcinoma and with a view of standardizing the classification to reduce the interreader variability, the Bosniak classification was revised in 2019 introducing major changes to the classification. The revised classification formally included the MRI imaging into the classification for the first time. This exhibit will review the revised 2019 version of the Bosniak classification for renal cysts, its clinical application, and the differences from the previous classification. We will also review images of different CT and MRI sequences for all Bosniak types.

TABLE OF CONTENTS/OUTLINE

Limitations of the previous classification The need for the revised Bosniak classification - 2019 version. Updated definitions and

Limitations of the previous classification. The need for the revised Bosniak classification - 2019 version. Updated definitions and descriptions of classes I-IV. MRI and CT features of each class. Standardized descriptions of terms used in the classification system. How to classify equivocal lesions. Limitations of the 2019 version.

GUEE-101 Multimodality Diagnosis Of Borderline Epithelial Ovarian Tumors: Radiologic-pathologic Correlation And Pitfalls In The Diagnosis.

Awards
Identified for RadioGraphics

Participants
Takahiro Tsuboyama, MD, Suita, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Borderline epithelial ovarian tumors (BEOT) are characterized by cellular proliferation with mild nuclear atypia, but without destructive stromal invasion. Preoperative diagnosis of BEOTs is important because treatment strategy is different from that for benign and malignant tumors. Although MR is the established method for characterization of ovarian masses, CT and PET can also provide useful information for the diagnosis of BEOTs. Learning objective of this presentation is to describe useful multimodality imaging findings correlated with pathological findings and pitfalls in the diagnosis of BEOTs, as well as to describe the revised points in the WHO 2020.

TABLE OF CONTENTS/OUTLINE

1, MR imaging findings of BEOTs and radiologic-pathologic correlation - Serous borderline tumor - Seromucinous borderline tumor - Mucinous borderline tumor - Clear cell borderline tumor - Endometrioid borderline tumor - Borderline Brenner tumor - Peritoneal implant 2, Multimodality diagnosis of BEOT - Role of CT - Role of PET 3, Pitfalls - Benign lesions mimicking BEOT - Malignant lesions mimicking BEOT

GUEE-102 Surgical And Interventional Management Of Renal Cell Carcinomas: A Primer For Radiologists

Participants
Aditi Chaurasia, MBBS, Bethesda, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

Invasive management of renal cell carcinoma (RCC) includes various surgical and interventional procedures. Surgical resection represents the standard of care for most RCCs. Surgical options include radical nephrectomy for larger renal masses, nephron-sparing surgery for smaller tumors, cytoreductive nephrectomy and metastasectomy/extirpation of local recurrence in advanced RCC. Moreover, interventional radiology has an increasingly popular role in the treatment of small renal masses, and options include cryoablation, microwave ablation, and radiofrequency ablation. Since adequate radiologic assessment and accurate staging is critical for planning any intervention, it is imperative for radiologists to be familiar with the imaging characteristics to determine and plan the appropriate procedure. This educational exhibit will review the existing guidelines and illustrate the key preoperative imaging findings & criteria necessary to plan the various surgical strategies and interventional procedures. It will also compare these features with the post-operative imaging characteristics.

TABLE OF CONTENTS/OUTLINE

1.Criteria and pre-and post-operative imaging characteristics for surgical strategies:?Radical nephrectomy ?Partial nephrectomy •Role of intraoperative ultrasound ?Cytoreductive nephrectomy ?Metastasectomy2.Criteria and pre- and post-procedural imaging characteristics for interventional radiological methods: 1.Cryoablation 2.Microwave ablation 3.Radiofrequency ablation 4.Embolization

GUEE-103 Improd and Multi-improd Server: Free Public Access To 499 Prostate MRI Scans, MRI Reports, Biopsy Findings, Scanned Whole Mount Prostatectomy Sections and Much More

Participants
Ivan Jambor, MD,PhD, New Haven, Connecticut (*Presenter*) Institutional Research Grant, Siemens AG

TEACHING POINTS

- to learn how to use IMPROD (http://petiv.utu.fi/improd/) MULTI-IMPROD servers (http://petiv.utu.fi/multiimprod/) for teaching purposes - to provide access to an optimized MRI acquisition protocol, including a scanned importable format - to learn how to detect prostate cancer using biparametric MRI (bpMRI) - to differentiate prostate cancer from common confounders such as benign prostatic hyperplasia using biparametric MRI (bpMRI)

TABLE OF CONTENTS/OUTLINE

IMPROD (Improved Prostate Cancer Diagnosis - Combination of Magnetic Resonance Imaging and Biomarkers) was a prospective registered clinical trial evaluating the role of a novel bpMRI and targeted biopsy in men with a clinical suspicion of prostate cancer. The validation 4 institutional trial using the same method was MULTI-IMPROD trial (ClinicalTrials.gov Identifier: NCT02241122). All anonymised bpMRI data sets and prospective bpMRI reports, biopsy and prostatectomy reports, follow up information, and results of additional analyses are freely available at the following address http://petiv.utu.fi/improd/ and http://petiv.utu.fi/multiimprod/ . Strength and limitation of bpMRI will be highlighted by provided direct link to all bpMRI data sets, biopsy and prostatectomy findings. Whole mount prostatectomy sections were digitalized and allow correlation of pre-biopsy bpMRI enhancing the learning experience.

GUEE-11 Urinary Diversions: Main Normal And Abnormal Findings With Special Focus On Hemorrhagic Complications

Participants
Amaia Perez, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

To describe the different surgical techniques used to create urinary diversion after radical cystectomy. To show the normal

radiological findings after radical cystectomy.To explain the main complications of urinary diversions.

TABLE OF CONTENTS/OUTLINE

Introduction: Main indications of radical cystectomy. Bladder cancer staging.The role of imaging in bladder cancer. Surgical techniques:Incontinent urinary diversions.Continent urinary diversions. CT-protocol.Normal radiological findings.Image-based review of main complications after radical cystectomy:Early complications:Alterations of bowel transit. Urinary leakage.Collections.Urinary fistula formation.Urinary obstruction.Vascular complications: arterio-ureteral fistula. Late complications: Urinary infection.Lithiasis.Parastomal herniation.Stenosis of the ureteral anastomosis.Granuloma of the anastomosis of the ureter and conduit or reservoirTumor recurrence.Special review of hemorrhagic complications through a case series. Take-home messages.

GUEE-12   Think Outside The Testicle: Extra-testicular Causes Of Acute Scrotal Pain And Swelling

Awards
Cum Laude

Participants
Adam Yen, MD, San Francisco, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Discuss causes of acute scrotal pain and swelling apart from testicular torsion and epididymitis-orchitis, with a focused discussion on often missed extra-testicular entities to prevent delay in diagnosis and patient morbidity.2. Review extra-testicular anatomy, particularly of the vas deferens and pampiniform plexus, to increase familiarity with these structures which may often be overlooked by technologists and radiologists.3. Develop a systematic anatomy-based approach to review extra-testicular structures as a framework for recognizing these entities.4. Analyze sonographic images of extra-testicular entities with discussion of pearls and pitfalls.

TABLE OF CONTENTS/OUTLINE

1. Overview- Review of anatomy- Anatomy-based framework for case review2. Skin- Acute idiopathic scrotal edema (AISE)- Cellulitis/abscess- Fournier's gangrene3. Tunica vaginalis- Hematocele- Pyocele4. Epididymis and vas deferens- Torsed appendage- Complicated epididymitis5. Spermatic Cord- Corditis/funiculitis- Spermatic vein thrombosis- Postoperative hematoma (vasectomy, hernia repair)6. Non-scrotal causes- Renal calculus- Inguinal hernia with strangulation7. Scrotal Pearls and Pitfalls- Diffuse scrotal wall edema, always check for subcutaneous gas.- Always evaluate testicular vascularity, even when the main finding is extratesticular, as it may be secondarily compromised.

GUEE-13   PI-RR And Beyond: A Practical Guide To Local Recurrence Of Prostate Cancer.

Awards
Magna Cum Laude

Participants
Paulo Antunes, MD, Niteroi, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To gain awareness of the clinical background of the main indications of radical prostatectomy and radiotherapy.To review the relevant anatomy of the male pelvis before and after radical prostatectomy.To discuss the main findings of prostate cancer local recurrence.To learn the new Prostate Magnetic Resonance Imaging for Local Recurrence Report (PI-RR) system.

TABLE OF CONTENTS/OUTLINE

Introduction From diagnosis to treatment - What the radiologists should know about the main guidelines recommendations? Basic concepts like PSA density, PSA doubling time, and biochemical recurrence.DiscussionFirst things first - Getting familiarized with the relevant male pelvis anatomy before and after radical prostatectomy.What to expect? What to look for? - A discussion of the normal and abnormal findings on multiparametric prostate magnetic resonance imaging after RP em radiotherapy.Fresh news - Learning how to apply the new PI-RR system.SummaryGrab and go - A brief review with take-home schematic drawings.

GUEE-15   Contrast Media In And Out The Urinary System - From Parenchymal Enhancement To MR Urography

Participants
Daniel Montel, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

- How contrast media cruises through the urinary system and the normal nephrogram pattern in MR and CT. - When to use MR Urography with and without contrast media enhancement to diagnose different pathologies - The broad differential diagnosis of an altered nephrogram focusing on most frequent pathologies.

TABLE OF CONTENTS/OUTLINE

- Description of a normal nephrogram (unenhanced, corticomedullary, nephrographic, excretory phases). - Exemplify and illustrate CT and MR Urography technique - Altered nephograms (Absent nephrogram, delayed nephogram, striated nephrogram, spotted nephrogram, persistent nephrogram, reversed nephrogram).- Evaluation of urinary tract with MR Urography - Take-home messages

GUEE-16   Spectral CT In Renal Imaging: Cutting Edge Applications

Participants
Kevin Neville, DO, Andover, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Spectral CT (also referred to as Dual Energy or Multi Energy CT) is a technology that is steadily increasing in use, with many applications in renal imaging2. Spectral CT can reliably distinguish between enhancing and non-enhancing renal masses, with greater accuracy than traditional CT3. Advanced analysis with Spectral CT shows promise in differentiating between different renal tumor subtypes, possibly allowing patients to avoid biopsy4. Iodine selective imaging with Spectral CT can be used to assess

response of renal tumors to systemic therapy

GUEE-17 Imaging Characteristics Of Retroperitoneal Tumors: Differential Diagnosis And Histopathological Correlation - What A Radiologist Needs To Know

Participants
Martin Halicek, PhD, Augusta, Georgia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To demonstrate diagnostic challenges including localization of the mass, extent of invasion and characterization of specific pathology such as liposarcoma, leiomyosarcoma, extragonadal germ cell, paragangliomas and sarcoma. 2. To illustrate patterns of spread, tumor components, tumor vascularity, helping narrow the differential diagnosis. 3. Added value of MR imaging.

GUEE-18 VIRADS In Bladder Cancer - A Practical Approach

Participants
Chooi Yan Anna Lois Lai, MD, Singapore, Singapore (*Presenter*) Nothing to Disclose

TEACHING POINTS

VIRADS IN BLADDER CANCER - A PRACTICAL APPROACHTEACHING POINTSA. To review aspects of bladder cancerB. To review radiological evaluation of bladder cancer on mpMRIC. To illustrate VIRADS scoring using case reviewD. To discuss practical challenges and pitfalls in mpMRI bladder analysis and in the use of VIRADS scoring

GUEE-19 Deep Infiltrative Pelvic Endometriosis: Image Based Review

Participants
Stuti Chandola, MBBS, New Delhi, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Define the various patterns of endometriosis.2. Review the common locations and imaging features of DIE on dynamic transvaginal USG (TVUS) and MRI through a multimodality image based review. 3. Highlight the importance of cross sectional imaging in surgical management of DIE. 4. Outline a step wise algorithm to approach a patient with endometriosis to avoid overlooking DIE lesions.

GUEE-2 Nuances Of Radiation In Prostate Cancer: Treat And Protect!

Participants
Rebekah Padilla, DO, Jacksonville, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

Basics of radiation therapy for prostate cancerTypes of prostate cancer treatment including external beam radiation with fiducial markers and internal radiation utilizing brachytherapyUnderstand protection mechanisms for radiosensitive pelvic structuresImaging

characteristics of the pre- and post-radiated prostateSpecific placement of safety devices such as hydrogel spacersComplications of and contraindications for the use of safety devices

TABLE OF CONTENTS/OUTLINE

Male pelvic anatomy and anatomic variants on magnetic resonance imagingTypes of prostate cancer treatmentsThe role of MRI for evaluation of primary prostatic cancer, re-evaluation of disease and the post-radiotherapy prostateIndications and contraindications for prostate radiation therapy and hydrogel spacersCommon complications of prostate radiationThe role of spacer placement to reduce post-radiation complicationsDescription of spacer placement procedureCases of optimal versus suboptimal hydrogel spacer placement and spacer complications on MR images

GUEE-20   Pelvic Floor Ultrasound: A Primer For Radiologists

Participants
Anirudh Nair, MBBS, Doha, Qatar (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Pelvic floor disorders (PFD) affect about 50% of women in different stages of their lifetime. 2. These are either due to relaxed pelvic floor muscles that result in pelvic organ prolapse, urinary or fecal incontinence; or due to non-relaxing pelvic floor muscles that lead to pyriformis syndrome, puborectalis dyssynergia, etc. 3. Diagnosis of PFD is sometimes challenging when patients present with clinical symptoms attributable to sexual dysfunction, chronic pelvic pain, coital difficulties. 4. The radiologists should be aware of the utility of pelvic floor ultrasound as a useful tool in the diagnosis, classification, and quantification of pelvic floor disease.

TABLE OF CONTENTS/OUTLINE

1. Discuss the ultrasound anatomy of the female pelvic floor. 2. Literature review on utility of pelvic floor ultrasound (PFUS) in the imaging of PFD.3. Discuss indications, equipment, and techniques required to perform a PFUS.4. Classify PFD. 5. Demonstrate the common and challenging PFD involving anterior compartment (stress urinary incontinence, vaginal sling imaging, Fowler's syndrome, urethral stricture, cystocele with Green classification, etc); Central compartment (Congenital anomalies, vaginal inclusion cysts, Bartholin's cysts, levator ballooning/tears, pelvic congestion syndrome and varices, clitorial doppler for sexual dysfunction, genital mutilations, vulval lesions), and Posterior compartment diseases (rectocele, enterocele, anorectal dyssynergia). Other miscellaneous pathologies causing perineal symptoms.

GUEE-21   Imaging Of The Cowper's (Bulbourethral) Gland - Its Abnormalities And Differential Diagnosis

Awards
Identified for RadioGraphics
Magna Cum Laude

Participants
Hiroaki Takahashi, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

TEACHING POINTS

Owing to increasing utilization of cross-sectional imaging, abnormalities of the Cowper's (Bulbourethral) gland and duct are more commonly depicted. While its function and anatomy are well-established, reports on imaging findings of the Cowper's gland are scarce. This exhibit will review the anatomy, physiology, and pathology of the Cowper's gland along with imaging assessment of the various abnormalities. In addition, common periurethral lesions that mimic Cowper's gland pathology on imaging will be discussed. Familiarity with these imaging findings will improve diagnostic confidence and accuracy when evaluating Cowper's gland, resulting in better patient outcomes. The purposes of this exhibit are to: 1. Review the anatomy, physiology and imaging findings of normal Cowper's gland. 2. Review the clinical and imaging findings of the abnormalities of the Cowper's gland with treatment options. 3. Discuss the differential diagnosis of the periurethral lesions about the bulbar and membranous urethra that could mimic the Cowper's gland abnormality.

TABLE OF CONTENTS/OUTLINE

1. Overview of Cowper's gland and its abnormality. 2. Fundamental anatomy, physiology and imaging of normal Cowper's gland. 3. Systematic review of clinical and imaging findings of the abnormalities of the Cowper's gland. 4. Differential diagnosis of periurethral lesions mimicking the Cowper's gland abnormality. 5. Summary

GUEE-22   Ovarian-adnexal Reporting Data System MRI (O-RADS MRI), Learning From Challenges In Our Clinical Practice.

Participants
Lledo Cabedo Esteve, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review how to perform the MR protocol for the O-RADS MRI score system . To recognize the imaging findings described in the O-RADS MRI score system, correctly stratify adnexal masses , depict differential diagnosis and pitfalls of these adnexal masses. Identify and know how to deal with the most common problems with the O-RADs MRI score system in the clinical practice.

TABLE OF CONTENTS/OUTLINE

O-RADS MRI protocol, mass characterization, differential diagnosis and pitfalls; O-RADS 1-No mass or non-adnexal mass: How to deal with serosal myomas mimicking ovarian fibromas and neighboring intestinal or urinary diseases considered ovarian masses by ultrasound; O-RADS 2 and 3-Benign adnexal masses: Hemorrhagic cysts and endometriosis disease. Not always ovarian cysts: other cyst-like findings. Rule out the solid component in hemorrhagic or proteinaceous multilocular cysts. Solid ovarian masses with type I enhancement curve. Dark-dark masses and other presentations of ovarian fibromas. Other benign tumors with typical radiological findings; O-RADS 4 and 5-Malignant adnexal masses: Definition and types of solid tissue. Non-enhancing ovarian masses torsion, clue findings. Non-solid ovarian cystic nodules that mimic solid tissue . DCE-MRI types of enhancement curves: meaning and pitfalls. Mucinous tumors, MRI findings and searching for another primary origin. Tips to avoid overlooking pelvic peritoneal implants. How to differentiate normal ovarian parenchyma from tumor solid tissue. Benign ovarian tumors with small areas of malignancy.

GUEE-23   Imaging Biomarkers Relevant For Prostate Cancer Management: Introduction

Participants
James Diss, PhD,FRCR, Epping, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

(1) Biomarkers (BM) are measured indicators of normal biological processes, pathogenic processes, or biological responses to interventions. BM are not assessments of how individuals feel or function; and are not survival surrogates or quality-of-life measures (but maybe correlated). (2) There are multiple classes of imaging BM of clinical relevance to the advancing prostate cancer state (Diagnostic, Prognostic, Predictive, Response). (3) Diagnostic imaging BM can become prognostic and/or predictive BM, serving different functions. (4) Prognostic BM are used to identify patients who do not need therapy intensifications and/or those with very poor outcomes (not benefiting from therapy intensifications). (5) Predictive BM are needed when outcomes are suboptimal to determine which therapy option provides the best benefit.

TABLE OF CONTENTS/OUTLINE

(1) Define and give examples of image-based diagnostic, prognostic, predictive and response BM used in the clinical management of prostate cancer. (2) Explain how BM are relevant to precision care using the advancing clinical states model of prostate cancer. (3) Describe how to distinguish between BM with prognostic or predictive properties using Kaplan Meier survival curves. (4) Show the clinical utility of prognostic and predictive BM to address the challenges contributing to diagnostic and therapy outcomes heterogeneity. The presentation will include a mini-quiz and take-home points.

GUEE-24   Pelvic Endometriosis: A Systematic Ultrassonographic Approach With MRI Correlation

Awards
Certificate of Merit

Participants
Merval Franklin Britto, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Discuss the role of transvaginal US compared to MR imaging in endometriosis diagnosis and managementBriefly review the US and MR technique and patient preparationDescribe systematic approach of US and MR imaging for endometriosis assessment, highlighting usual and unusual presentationsRecognize the importance of structured reports for endometriosis assessment

TABLE OF CONTENTS/OUTLINE

INTRODUCTIONOverview of endometriosisTransvaginal ultrasound accuracy, reliability and applicability, and comparison to MRIANATOMIC CONCEPTS Pelvic compartmentsUS AND MR IMAGING TECHNIQUEPatient preparation US and MR protocolsSYSTEMATIC US AND MR IMAGING APPROACH Comparison between the both methods (pros and cons)Compartment-based evaluationAssessment of usual and unusual sitesULTRASOUND FINDINGS WITH MRI CORRELATIONAnterior Compartment Uterus and AdnexaPosterior compartmentSliding signSoft markersUnusual presentationsPOST TREATMENT IMAGING Imaging role in post-treatment evaluationCritical spots that may be missed during surgeryHOW DO WE REPORT Sample cases to illustrate and solidify the conceptsStructured report

GUEE-25   Gas In The Genitourinary System: When To Worry,- A Cased-Based Review

Participants
Abhay Dhaliwal, Bloomfield Hills, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

To use an unknown case-based approach to highlight key imaging features of entities that can result in genitourinary system gas.To review the categories of inciting conditions that can lead to genitourinary gas.To emphasize the relevant clinical history and ancillary findings that may aid in making the correct diagnosis. To review the management of these entities, including the emergent conditions.

TABLE OF CONTENTS/OUTLINE

Gas in the genitourinary tract is a rare imaging finding and can vary in volume. However, its detection in even small amounts is crucial, as some causes of gas require emergent management. Determining the etiology of genitourinary system gas is as essential as its detection, and a category-based approach can aid in accurate diagnosis. Categories include infection, inflammation, ischemia, surgical, percutaneous, endourologic or endoscopic interventions, trauma, and neoplasm. The inciting process can originate in the genitourinary system or in an adjacent organ with secondary involvement of the genitourinary system. Multi-modality cases will be presented as unknowns with accompanying multiple-choice questions, as well as explanations that emphasize the relevant presentation, imaging findings, and management of each entity. The upper and lower urinary tract, and the male and female genital tracts will be included in this case-based review.

GUEE-26   Sonographic Assessment Of Penile Vascular Pathology: What The Urologist Needs To Know

Awards
Certificate of Merit

Participants
Christopher Fung, MD, Edmonton, Alberta (*Presenter*) Stockholder, Mikata Health

TEACHING POINTS

1. Normal sonographic anatomy of the penis. 2. Approach to color Doppler ultrasonography (CDUS) techniques in evaluating vascular pathology of the penis.3. Key imaging findings of erectile dysfunction, priapism, and Peyronie disease: what the urologist needs to know.4. Logistics of incorporation of penile CDUS in clinical practice 5. Future use of penile CDUS for detection of peripheral vascular disease (PAD) and coronary artery disease (CAD).

TABLE OF CONTENTS/OUTLINE

1. Introduction - Brief overview of penile imaging and the role of ultrasound in assessment of common and uncommon penile

vascular disease.2. Sonographic anatomy of the penis - Review vascular and non-vascular anatomy in standard imaging planes.3. Prostaglandin injection method and color Doppler ultrasonography techniques- Prostaglandin dosing, options, and risks of procedure- Protocol overview pre- and post-injection, with discussion of imaging timing and expected findings.4. Review of imaging characteristics in erectile dysfunction, arterial priapism, veno-occlusive priapism, Peyronie disease, and Mondor's disease. - Key findings the urologist needs to know for common and uncommon vascular pathology with discussion of treatment implications.5. Illustrative cases 6. Troubleshooting postoperative ED and non-responders to PDE5-I- Common issues during the examination and how to overcome them.7. Future use of penile CDUS for detection of PAD and CAD- Role of penile CDUS in patient lifestyle management and potential additional medical workup.8. Summary

GUEE-27　　Postoperative Complications In Urological Surgery: How Do We Face This Challenge?

Participants
Marina Herrero Huertas, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To learn the most frequent genitourinary types of surgery. - To understand the expected appearance of the normal postoperative image findings. - To become familiar with the different imaging modalities and protocols that can be used to diagnose postoperative complications. - To recognize potential postoperative complications and avoid common pitfalls.

TABLE OF CONTENTS/OUTLINE

1. A quick review of genitourinary normal anatomy and types of surgery. 2. Diagnostic imaging studies of choice for evaluation postoperative genitourinary tract: CT protocols (contrast material-enhanced CT with delayed imaging, CT cystography) and other types of urological imaging techniques (retrograde urethrography, antegrade or retrograde pyelography, nephrostomy studies).3. We illustrate the main urological postoperative complications through a case-based review, organized by its location and/or type of complication: vascular, infectious, urinary... - Renal Surgery: Partial and radical nephrectomy, renal transplant.- Cystectomy: urinary diversions.- Prostatectomy.- Others: as urinary derivations.4. Key points 5. Conclusions 6. Bibliography

GUEE-28　　Magnetic Resonance Hysterosalpingography: A Complete And Promising Imaging Method In The Work-up Of Female Infertility

Participants
Fernanda Goncalves, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Magnetic resonance hysterosalpingography (MR-HSG) is a promising imaging method that can provide important information in the assessment of female infertility, through the combination of an excellent anatomical characterization of the pelvis with tubal permeability evaluation.The use of contrast in the uterine cavity, may also have other indications, such as the investigation of uterine fistulas, post ectopic tubal conditions, and others. The purpose of this exhibit is to: 1. Explain the indications and utility of Magnetic Resonance Hysterosalpingography (MR-HSG). 2. Detail the MR-HSG imaging protocol. 3. Discuss the advantages and disadvantages of MR-HSG in comparison with the main and well-established imaging modalities, including conventional hysterosalpingography and laparoscopy with chromopertubation.

TABLE OF CONTENTS/OUTLINE

1. Brief review of the most common causes of female infertility. 2. Discussion of the most used imaging methods in the work-up of female infertility. 3. Indications and utility of MR-HSG, highlighting its advantages and disadvantages. 4. A detailed explanation of the MR-HSG protocol. 5. Selection of interesting cases using MR-HSG, some of them compared with conventional hysterosalpingography or laparoscopy with chromopertubation: normal tubes, endometriosis associated with hydrosalpinx, tubal obstruction, uterine fistula with Nabothian cyst, tubal entrapment by the endometrioma, and endometrial polyp.

GUEE-29　　Radiogenomics In Genitourinary Malignancies

Participants
Matthew Mason, Miami, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review the genomic profiles of genitourinary (GU) malignancies; to describe the imaging features associated with various genetic mutations in GU malignancies; to display the clinical correlates of selected genetic mutations and imaging features

TABLE OF CONTENTS/OUTLINE

Renal cell carcinoma: Genomic characterization (TCGA); Imaging correlation: PBRM1, KDM5C-renal vein invasion;VHL-Well-defined margins, nodular tumor enhancement and intratumoral vascularization; BAP1-Ill-defined margins, calcifications and renal vein invasion; RUNX3 methylation-intratumoral vascularity, unclear margins and left-sided tumor; MUC4-exophytic growth; Clinical correlates: Associations with Radiogenomic Risk Score and BAP1, SETD2, KDM5C, MUC4 and TP53, RUNX3 methylation. Urothelial Carcinoma: Genomic characterization (TCGA); Imaging correlation: TP53-nodal and osseous metastases; RB1- peritoneal metastases; Clinical correlates: Associations with RB1, TP53, STAG2, ARID1A and High-risk Mutational Group. Ovarian Carcinoma: Genomic characterization (CLOVAR); Imaging correlation: CLOVAR mesenchymal subtype-Peritoneal involvement and mesenteric infiltration; Cyclin E1-Texture heterogeneity; BRCA 1/2-Gastrohepatic ligament metastases; BRAF-Bilateral ovarian masses; Clinical correlates: Associations with CLOVAR mesenchymal subtype, Cyclin E1, BRCA1/2, BRAF. Others: Endometrial Carcinoma, Cervical and Prostate Cancer, Testicular Germ Cell Tumors. For every cancer type, imaging examples will be provided.

GUEE-3　　Spectrum Of Testicular Lymphoma; Grey-scale And Color Flow Doppler Evaluation

Participants
Priyanka Garg, Rochester, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

Testicular lymphoma is the most common tumor involving the testes above the age of 50 and familiarity with its sonographic features is important to differentiate it from other diseases that involve the testes diffusely. The attendee will be able to learn the

following from this exhibit:1. Various presentations of testicular lymphoma involving the testes 2. Color flow Doppler imaging of testicular lymphoma will be emphasized 3. Histopathological correlation as well as other modality correlation such as PET imaging will presented correlating the disease. 4. Other disease entities that mimic lymphoma will be presented as a differential diagnosis

TABLE OF CONTENTS/OUTLINE

1. Normal Grey-scale and Color Flow Doppler of the Testes 2. Images demonstrating spectrum of lymphomatous involvement of the testes with histopathological correlation and other imaging correlations 3. Color Flow Doppler features of testicular lymphoma 4. Images of diseases that mimic testicular lymphoma

GUEE-30   Treatment Strategies For Benign Prostatic Hyperplasia And Post-treatment MR Imaging Appearances

Awards
Identified for RadioGraphics

Participants
Elizabeth Han, MD, Royal Oak, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Patients suffering from lower urinary tract symptoms (LUTS) caused by benign prostatic hyperplasia (BPH) have minimally invasive, surgical, and endovascular treatment options in addition to standard medical options for symptom relief. 2) Non-medical treatment options cause significant changes to the MRI appearance of the prostate. This poses challenges to post-procedure lesion detection by multi-parametric MRI (mpMRI). 3) Familiarity with commonly encountered procedures and expected post-treatment changes will aid in lesion detection on mpMRI and management if clinically significant prostate cancer (csPCa) is detected.

TABLE OF CONTENTS/OUTLINE

1) Review of BPH classification on mpMRI (e.g. overall gland volume, histologic findings, and lobar distribution). 2) Review of treatment options and expected post-treatment appearances on prostate MRI: a) Surgical (simple vs radical prostatectomies) b) Minimally invasive surgery i) Transurethral approaches (ablations, vaporizations, laser enucleations) ii) Transrectal approaches (high intensity focused ultrasound) iii) Endovascular (prostate artery embolization) iv) Medical implants (e.g. urolift) c) Medical therapies (e.g. hormonal, alpha-adrenergic antagonists) and the effect on PSA density 3) Discussion on management after detection of csPCa. 4) Perspective: Role of pre-procedure mpMRI and MR predictors of BPH severity.

GUEE-32   A Didactical Radiologic Approach To Testicular And Paratesticular Lesions

Participants
Juliana Valdrighi, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Testicular and paratesticular masses mainly affect men 20 to 35 years of age and diagnostic workup begins with clinical history, physical examination, and followed by imaging. Along with this, imaging plays an increasingly important role in initial diagnosis, staging, and imaging surveillance of testicular malignancies. With that in mind, we aim to provide our colleagues with a complete guide to properly evaluate the anatomy, different image methods in the evaluation and identify the radiological findings of benign and malignant testicular and paratesticular pathologic conditions. The purpose of this exhibit is: (1) To review imaging appearances of the normal scrotum. (2) Discuss the role of the different imaging methods in the evaluation of testicular and paratesticular masses. (3) Identify and discuss the radiological findings of benign and malignant extratesticular and testicular pathologic conditions. (4) Propose an algorithm to narrow the diagnosis of testicular and paratesticular masses.

TABLE OF CONTENTS/OUTLINE

1. Anatomy and imaging appearance of the normal scrotum with didactic illustrations. 2. Epidemiology and imaging features of testicular and paratesticular lesions on ultrasound, computed tomography, magnetic resonance images. 3. A comprehensible guide to evaluating testicular and paratesticular masses: US, CT and MRI. 4. Case-based approach to discussing the radiological and histopathological findings of benign and malignant extratesticular and testicular pathologic conditions.

GUEE-33   Imaging Biomarkers Relevant For Prostate Cancer Management: Clinical Development

Participants
James Diss, PhD,FRCR, Epping, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

(1) The clinical development of imaging biomarkers (IBM) for healthcare is a multistep process. The IBM type, context of use and clinical risk determines the level of evidence needed to support regulatory approvals (2) Higher levels of evidence are needed for more clinically impactful IBM in a risk-based approach (surrogate>predictive>prognostic>diagnostic) (3) Trials of diagnostic or prognostic IBM should assess changes in diagnostic/therapeutic management. Secondarily, IBM-driven management decisions may favorably impact on oncologic endpoints (4) Trials of predictive IBM should be evaluated as therapeutic studies against standard of care, focusing on the quality and quantity of life endpoints.

TABLE OF CONTENTS/OUTLINE

Outline the governing principles of the regulatory process regarding Context of Use and Levels of Evidence for IBM qualification that incorporates a patient risk based approach. Outline and show examples of the essential steps of IBM qualifications, including: (1) Defining use in settings where change in management is possible from IBM results (2) Ensuring that IBM are independently diagnostic/prognostic when incorporated into multivariable models (3) Ensuring that IBM improve the discrimination of clinically meaningful endpoints (4) Estimating both relative and absolute benefits for diagnostic & prognostic IBM (5) Demonstrating that IBM use increases diagnostic confidence and changes management via improved risk stratifications, and that quantity and/or quality of life is improved for predictive IBM.

GUEE-34   Utility Of Diffusion Weighted Sequence In Gynecological Imaging

Participants
Apurva Bonde, MBBS, MD, San Antonio, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

Diffusion weighted imaging is functional imaging (DWI) technique with wide range of applications in malignant and non-malignant gynecological conditions. We describe basics of technique, pitfalls, major clinical applications and future trends in diffusion weighted imaging in gynecological entities.

TABLE OF CONTENTS/OUTLINE

Functional imaging with diffusion weighted imaging (DWI): complementary tool to conventional MRI sequences, wide range of clinical applications in malignant and non-malignant gynecological condition, describe the detailed technique and discuss problems encountered during DWI interpretation. The main implications in non-malignant conditions: differentiation of degenerated fibroids from uterine sarcomas, monitoring uterine fibroids after treatment, assisting diagnosis of adnexal torsion, tubo-ovarian abscess and endometrioma.The implications in malignant gynecological conditions: diagnosis and staging of endometrial, cervical, ovarian, and vulvar cancers, tumor response assessment, early detection of tumor recurrence/pelvic peritoneal disease, differentiation between tumor and post radiation fibrosis, quantitative assessment with ADC measurement with various tumor parameters.Pitfalls: T2 shine through, diffusion restriction in hemorrhage, melanin and in normal structures, lack of diffusion restriction in some malignant tumors.Newer techniques: DWIBS, DTI, and DSI, potential use in pelvic nerve mapping preoperative planning and fertility preserving surgeries.

GUEE-35   Reporting O-RADS MRI: How We Do It. Practical Application Of The ACR Reporting Template.

Awards
Cum Laude
Identified for RadioGraphics

Participants
Krista Suarez-Weiss, MD, Chestnut Hill, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Discuss the O-RADS MRI key descriptors and risk stratification Illustrate the use of O-RADS MRI through a standardized reporting template Discuss pitfalls and challenges in use of O-RADS MRI Provide various educational and clinical resources for use of O-RADS MRI in routine clinical practice

TABLE OF CONTENTS/OUTLINE

Outline: 1. MRI of Adnexal Lesions. 2. Introduction to O-RADS. 3. ACR Reporting Template for O-RADS MRI. 4. Case Examples. 5. Educational and Clinical Resources: O-RADS calculator, ACR E-Learning Module, RadAssist, RadiopaediaMRI of Adnexal Lesions 1. MRI can further characterize adnexal lesions deemed indeterminate on initial ultrasound. 2. Characterization by MRI can clarify the benignity of lesions that do not require further monitoring or surgical resection 3. Studies have shown that specific imaging characteristics, such as multilocularity of a cystic lesion or enhancing solid tissue, portend a higher risk of malignancy.ORADS MRI Reporting Components 1. Adnexal lesion A. Size B. Lesion type: Unilocular cyst without enhancing solid tissue; Multilocular cyst without enhancing solid tissue; Lesion with lipid content with/without large volume enhancing solid tissue; Lesion with enhancing solid tissue C. Cystic component characteristics: Wall enhancement; Fluid content D. Solid tissue component characteristics: T2 and DWI signal; Enhancement pattern 2. Extra-adnexal findings: Lymph nodes; Peritoneal, mesenteric or omental nodularity or thickening. 3. Impression: Adnexal lesion description with ORADS MRI score

GUEE-36   Get The Ball Rolling: A Pattern-based Approach For Imaging Diagnosis Of Testicular Lesions

Participants
Natália Cavalcante, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To exhibit general anatomic aspects of the testis and adjacent structures correlated with magnetic resonance imaging. To bring a diagnostic thought for testicular lesions with a step-by-step approach. To demonstrate focal and diffuse testicular lesions. To show inflammatory and neoplastic conditions that can occur at the testicle. To present the imaging appearance of usual and unusual cases.

TABLE OF CONTENTS/OUTLINE

•Pathological lesions of the testis are very frequently found. They consist of tumoral lesions, inflammatory lesions, and miscellanea. They can pose a diagnostic challenge for non-specialized radiologists.•Anatomical knowledge is essential for a good diagnostic reasoning and will be reviewed through educational illustrations and correlated with imaging exams.•A didactic approach of differential diagnoses is presented, based on imaging aspects, addressed as a focal, diffuse and miscellaneous pattern.•Most tumoral lesions have a focal presentation, including seminoma, rhabdomyosarcoma, mixed germ cell tumor, liposarcoma, and lymphoma, whose image presentations will be exposed, with clinical key information.•On the other hand, inflammatory lesions usually occur in a diffuse pattern, as well as in tuberculosis and epididymo-orchitis in general.•However, some lesions are not suitable in these two patterns, and the radiologist might be aware of atypical presentations and diagnostic challenges, such as infarction, microlithiasis, cryptorchidism, ectopic testis, vanishing testis, and burned-out tumor.

GUEE-37   ESRD: Evolving Guidelines, Sonographic Problem Solving, And Imaging Of The Patient With Renal Disease In 2021

Awards
Identified for RadioGraphics

Participants
Mary J. Clingan, MD, Ponte Vedra Beach, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Patients with Stage 4 or 5 chronic kidney disease have a very low risk of NSF with group II gadolinium- based contrast agents and the benefits may outweigh the risk for indicated examinations.-Contrast enhanced ultrasound is a useful problem- solving tool for indeterminate renal lesions detected in the native kidneys of patients undergoing pre-transplant evaluation. There is also a role for CEUS in patients with renal transplants.-Ultrasound mapping is useful for preoperative planning of dialysis access. Indications of

fistula maturity include a draining vein diameter of 4-6 mm, a depth under the skin of 5 mm or less, and a flow rate of at least 500-600cc/min.-Hemodialysis access stenosis is indicated by an Increased peak systolic velocity ratio of greater than 3:1 at the anastomosis or greater than 2:1 for the graft and draining vein.

TABLE OF CONTENTS/OUTLINE

1. Goals and Objectives2. Background3. Review of current iodinated and gadolinium-based contrast consensus recommendations as they relate to chronic kidney disease4. Multimodality case-based examples:-a. Pre-transplant evaluation imaging i. Ultrasound ii. NCCT-b. Contrast Enhanced Ultrasound Problem Solving i. Native Kidneys ii. Transplant kidney-c. Dialysis access work-up and surveillance i. Vein mapping ii. AV Fistula/Graft imaging/complications iii. Peritoneal Dialysis imaging/complications-d. Renal and Extrarenal findings specific to ESRD/Dialysis patients i. Acquired cystic kidney disease ii. Musculoskeletal findings iii. Cardiovascular findings

GUEE-38   The Prostate Cancer Clinical Trials Working Group 3 (pcwg3): What You Need To Know - An Overview Of Tumor Metrics Criteria

Participants
Halyna Pokhylevych, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

Rapid development of novel therapeutics, recognition of new disease phenotypes, better understanding of disease biology and an evolving regulatory environment warranted the need to revise castration-resistant prostate cancer (CRPC) clinical trial recommendations in prior Prostate Cancer Clinical Trials Working Groups. Key new recommendations in Prostate Cancer Working Group 3 (PCWG3) include distinguishing histologic subtypes of the disease and considering the lines of therapy a patient has received as well as using blood-based assays of tumor material and imaging (or biopsy) to enable treatment selection based on disease biology. For trial outcome measures, new recommendations include the time to event end point of symptomatic skeletal events, as well as time to first metastasis and time to progression for trials in the non-metastatic CRPC state. PCWG3 focuses drug development on disease manifestations that are most likely to change prognosis unfavorably for new treatments in CRPC populations.

TABLE OF CONTENTS/OUTLINE

• A review of the PCWG3 and why it is essential in evaluating tumor response. • Image-based approach with educational points of tumor metrics criteria in prostate cancer. • Evaluation of the therapeutic response, recurrence, and complications. • Pitfalls: pseudoprogression. • Take-home messages.

GUEE-39   Cross-sectional Imaging Of Renal Masses: Potential Pitfalls And Possible Solutions

Participants
Adam Sierra, MD, San Antonio, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

Describe the role of different imaging techniques in the evaluation of adult renal masses Review potential image acquisition-related pitfalls and suggest possible solutionsDiscuss potential image interpretation-related errors and provide possible solutions

TABLE OF CONTENTS/OUTLINE

IntroductionAppropriate imaging technique: Ultrasound, CT & MRIImage acquisition-related pitfalls Ultrasound (failure to detect a mass & operator dependency), CT (partial volume effects, pseudo-enhancement, pitfalls related to phase of CT data acquisition, image display format, and rendering technique) & MRI (respiratory misregistration artifacts).Image interpretation-related pitfalls Renal pseudotumors (Hypertrophied column of Bertin, focal acute pyelonephritis & abscess, renal infarct, localized cystic disease, vascular pathologies), Misinterpretation of fat containing solid renal masses (angiomyolipoma and mimics, perirenal liposarcoma, and RCC), and inappropriate assessment of contrast enhancement (papillary RCC, hemorrhagic cyst & calcified masses)ConclusionSummary and Clinical Implications: Recognizing and understanding various imaging-related pitfalls in the characterization of renal masses is necessary to avoid misdiagnosis and thus management. Improved knowledge regarding potential pitfalls along with their solutions will help radiologists to choose a different imaging modality or repeat the same study with technique modifications.

GUEE-4   A Must Know For Radiologists: A Pictorial Review Of Cystourethrography Imaging In The Diagnosis Of Genitourinary Pathology

Participants
Yumi Kimura Sandoval, BMBS, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Recognize the importance of cystourethrography in the diagnosis of genitourinary pathology.- Learn about the epidemiology, risk factors, and clinical presentation of genitourinary diseases.-Identify specific radiological signs of genitourinary pathology through cystourethrography.- Case-based review of the main radiologic features of genitourinary diseases observed in cystourethrography.

TABLE OF CONTENTS/OUTLINE

1. Normal genitourinary anatomy correlating with demonstrative cystourethrograms: A) Male urethral anatomy Portions of the urethra: anterior (penile and bulbar urethra) and posterior (membranous and prostatic urethra)B) Urethral glands: - Glands of Littré - Glands of Cowper C) Prostatic ducts2. Indications of cystourethrography3. Techniques - Retrograde urethrography - Voiding cystourethrography4. Urethral pathology - Strictures - Membranes - Diverticula - Calculi5. Bladder pathology - Bladder herniation - Colovesical fistula - Diverticula - Stress bladder - Cystocele6. Ureter pathology - Vesicoureteral reflux - Postsurgical changes

GUEE-40   Update In Comprehensive Imaging In ADPKD - What's New

Awards
Identified for RadioGraphics

Participants

Devang Odedra, MD, Burlington, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Role of radiologist in diagnosis & screening of ADPKD 2. Role of radiologist in detecting complications of ADPKD including RCC 3. Role of radiologist in predicting renal function decline 4. Imaging in ADPKD - what is the future?

TABLE OF CONTENTS/OUTLINE

1. Diagnostic criteria for ADPKD - Is it based on ultrasound or MRI? What is the Unified criteria? 2. What is the current imaging classification (Class 1-typical (A,B,C,D,E), Class 2- atypical (2A- unilateral, segmental, asymmetric, lopsided; 2B - bilateral with acquired unilateral or bilateral atrophy) 3. Can we differentiate PKD1 and PKD2 mutations on imaging? 4. What is hypomorphic ADPKD? Why is it important? 5. Screening - when to start, how often, what modality? 6. How to differentiate mimickers? 7. What does approval of Tolvaptan to treat rapidly progressive disease mean for the radiologist? How to risk stratify ADPKD on imaging for treatment? 8. Why is renal volume measurement important? What is height-adjusted TKV? 9. What is the best method of renal volume segmentation? 10. Can renal blood flow analysis with phase contrast/arterial spin labeling predict renal function decline? 11. Can texture analysis/radiomics predict renal function decline? Answer: Yes 12. Complications in ADPKD - infection/hemorrhage/fistulization 13. Treatment - what is the current role of sclerotherapy? 14. Does ADPKD have increased risk of RCC? Challenges in diagnosing RCC in ADPKD 15. ADPKD in pregnancy - considerations 16. Role of 3D printing? Intraoperative ultrasound? 17. Suggested reporting template

GUEE-41   Post Vasectomy Changes In Scrotum: Spectrum Of Ultrasound Findings

Participants
Pramod K. Gupta, MD, Plano, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Vasectomy is a popular method of male contraception where small portion of vas deferens is excised and ends are sealed with sutures or clip.2. Epididymal thickening, epididymal tubular ectasia, sperm granulomas, tubular ectasia of rete testis and mediastinal cysts occur more frequently in post vasectomy patients, believed to be due to increased intraluminal pressure in efferent ducts, epididymal duct and sperm stasis due to vas deferens interruption.3. Medial rotation of testis is occasionally seen in vasectomy patients which is likely due to iatrogenic changes in the structural support mechanism of the testis with resultant increased motility.4. Familiarity with post vasectomy changes makes interpretation of scrotal ultrasound easy and in some cases help in avoiding unnecessary follow up or work up.

TABLE OF CONTENTS/OUTLINE

-Introduction -Scrotal Anatomy -Various post vasectomy ultrasound findings with several illustrative examples and short discussion -Conclusion -References

GUEE-42   Renal Transplant Ultrasound: Primer On Vascular Evaluation And Complications

Participants
Sai Chennupati, BA, Nashville, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Renal transplant is the treatment of choice for end stage renal disease. While nearly 23,000 transplants are done yearly in the US, demand still far outweighs availability and graft survival is of the utmost importance. Attentive surveillance with ultrasound plays an important role in the monitoring of these patients. Vascular complications are particularly important. While uncommon, several are potentially catastrophic and if caught early may result in the salvage of the transplant. In this exhibit, we will review normal post-transplant anatomy, normal sonographic appearance of the kidney, and review key vascular complications utilizing a case-based approach. Recognition of the imaging features of these complications, typical time-frames and differential diagnosis will help radiologists guide the appropriate management of these transplant patients.

TABLE OF CONTENTS/OUTLINE

A. Review normal post-transplant anatomy. B. Review normal sonographic appearance of the transplant kidney. C. Review key vascular complications via a case-based approach including renal artery thrombosis, renal vein thrombosis, renal artery stenosis, arteriovenous fistula, pseudoaneurysm, compartment syndrome and transplant torsion. D. Review potential mimics of these complications as well as treatment.

GUEE-43   Mesenchymal Neoplasms Of The Urinary Bladder:2021 Update And Comprehensive Review

Participants
Rashmi Balasubramanya, MD, Philadelphia,, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

Mesenchymal neoplasms of the urinary bladder are rare, comprising 5% of tumors. A diverse spectrum of smooth muscle, neurogenic, fibrous, vascular and miscellaneous tumors with distinct histopathology and tumor genetics occur in the bladder. We present cross-sectional imaging findings of a wide spectrum of these tumors.To review taxonomy, epidemiology, clinical features, histopathology & biology of a wide spectrum of mesenchymal tumors of the urinary bladder.To describe multimodality, cross-sectional imaging findings of these tumors.To discuss biological behavior, management and prognosis of diverse mesenchymal tumors of the urinary bladder.

TABLE OF CONTENTS/OUTLINE

OrganizationIntroduction, classification, epidemiology, clinical manifestations, pathological features, CT, MRI, PET-CT findings, management, prognosis, conclusion.Entities discussedLeiomyoma, smooth muscle tumor of uncertain malignant potential, leiomyosarcoma, angiosarcoma, rhabdomyosarcoma, solitary fibrous tumor, inflammatory myofibroblastic tumor, undifferentiated sarcoma, pheochromocytoma.

The ABCDEs Of Fibroids

Awards
Certificate of Merit

Participants
Iris Chen, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

Fibroids are benign neoplasms that represent the most common pelvic tumor in women with a lifetime risk of 70-80% and are classified using the FIGO system. While ultrasound (US) is often the first-line imaging for pelvic pathology including fibroids given its broad availability, cost-effectiveness, and real-time evaluation, MR provides the best assessment of fibroid size, number, and location. Fibroid variants include degenerated fibroids and lipoleiomyomas. Fibroids can often mimic the appearance of other pelvic pathologies on imaging. Distinguishing fibroids from these mimics can inform appropriate clinical management. Management should be tailored to the patient's age, symptoms, and desire to maintain fertility, along with consideration of the chances of success, limitations, and possible treatment complications. While management of symptomatic fibroids has largely been surgical, uterine artery embolization and MR-guided focused US are nonsurgical alternatives with comparable outcomes. Post-treatment complications include prolapse, devascularization, and post-surgical infection and hemorrhage.

TABLE OF CONTENTS/OUTLINE

This exhibit will include a comprehensive review of the FIGO classification for fibroids and fibroid variants, with examples of each type on US and MR and tips on how to classify them accurately. We will review common mimics of fibroids and recommendations for distinguishing the pathologies in real-time. We will also review the current literature on surgical and non-surgical treatment options.

GUEE-45 **Retroperitoneal Masses In Adults: A Pattern-based Imaging Approach On CT And MRI**

Awards
Certificate of Merit

Participants
Akira Yamamoto, MD, Kurashiki, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this study is1) To illustrate the anatomy of retroperitoneal space2) To indicate a pattern-based imaging approach on retroperitoneal lesion3) To demonstrate the CT and MR imaging appearances of various retroperitoneal mass.

TABLE OF CONTENTS/OUTLINE

1) Retroperitoneal space- Three compartments• Anterior pararenal (or paranephric) space• Perirenal (or perinephric) space• Posterior pararenal (or paranephric) space- Lymphatic system• Distribution of lymph node2) Pattern-based imaging approach on retroperitoneal lesion- Peritoneal lesions? or Retroperitoneal lesions?- Massive lesions? or Non-massive lesions?- Masses arising from retroperitoneal organ? or not organ?3) Image findings of cystic mass- Lymphangioma- Cystic mesothelioma- Bronchogenic cyst- Schwannoma, Neurofibroma4) Image findings of mass with fat- Lipoma, Liposarcoma- Teratoma- Extramedullary hematopoiesis5) Imaging findings of mass with calcification- Schwannoma- Ganglioneuroma- Teratoma- Sarcoma (dedifferentiated liposarcoma)- Bronchogenic cyst- Lymphangioma6) Imaging findings of hyper-vascular mass- Paraganglioma- Castleman disease- Hemangioma- Sarcoma (leiomyosarcoma)

GUEE-46 **What Radiologists Need To Know About Diagnosis Of Endometriosis**

Awards
Cum Laude

Participants
Hideyuki Fukui, Suita, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Endometriosis is defined as the presence of endometrial epithelium and stroma outside the uterine lumen and muscle layer. It is thought that repetitive bleeding and inflammation cause high fibrosis and adhesion. The accurate preoperative assessment of the spread of endometriosis is critical because surgery is the best treatment option for patients. MRI has the superiority for detecting blood components and plays an important role in detecting and diagnosing endometriosis due to repeated bleeding. In addition, it helps to plan a surgical approach. The purpose of this presentation is to become familiar with the image findings of endometriosis.

TABLE OF CONTENTS/OUTLINE

This article describes the clinical features and imaging findings on MR images of endometriosis and makes further reference to the hot topics concerning these diseases. 1. Endometriotic lesions of the anterior compartment - Bladder - Prevesical space - Vesicovaginal septum - Ureter 2. Endometriotic lesions of the middle compartment - Ovaries - Fallopian tubes - Uterus - Uterine ligaments 3. Endometriotic lesions of the posterior compartment - Pouch of Douglas (MR-Laparoscopic correlation) - Uterosacral ligaments - Rectovaginal septum - Rectum 4. Extrapelvic endometriosis - Subcutaneous endometriosis - Inguinal endometriosis - Thoracic endometriosis

GUEE-47 **Takes One To Know One: Imaging Features Of Non-syndromic Bilateral Renal Masses With Pathological Correlation**

Awards
Certificate of Merit

Participants
Amer Alaref, MD, Thunder Bay, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

[[Unsupported Character - Symbol Font &·]] Review common and uncommon adult non-syndromic bilateral renal

[[Unsupported Character - Symbol Font &;]] Review common and uncommon adult non-syndromic bilateral renal masses[[Unsupported Character - Symbol Font &;]] Describe clinical and radiological signs of bilateral non-syndromic renal masses[[Unsupported Character - Symbol Font &;]] Discuss histopathological features and their prognostic significance

TABLE OF CONTENTS/OUTLINE

Multifocal masses can involve the kidney bilaterally. A large number of non-syndromic conditions exist that can pose a diagnostic dilemma for radiologists leading to potentially unnecessary biopsies, redundant imaging follow-up and incorrect workup. In this presentation, clinical and imaging findings are reviewed with multiple case examples. Strategies for management are discussed. Disease categories include: Malignant: metastases, lymphoma, primary renal cell carcinomasBenign neoplasms: oncocytosis, angiomyolipomasInfectious: pyelonephritis, tuberculosis, abscessesVascular: infarcts, hematomasInfiltrative: IgG4 disease, amyloidosis, plasmacytomas, sarcoidosis, non-langerhans cell histiocytosis ConclusionThis educational exhibit provides a systematic approach to bilateral non-syndromic renal masses, a topic currently underrepresented in the literature. Upon completion of this exhibit, the participant will have an advanced level of knowledge of these lesions including an approach to workup and management.

GUEE-48   Ovarian Cancer Reporting: Pearls And Pitfalls

Participants
Krista Suarez-Weiss, MD, Chestnut Hill, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Understand FIGO 2018 staging of ovarian cancerDiscuss role of imaging in determining the initial managementUnderstand the easy to miss areas of spread on imaging and those predisposing to suboptimal cytoreductionDiscuss standardized CT/MRI report template that provides the referrers all the necessary information needed to make initial management decisions

TABLE OF CONTENTS/OUTLINE

OutlineBackground/epidemiology of ovarian cancerFIGO 2018 staging system and role of imagingEasy to miss areas of spread and sites predisposing to difficult or suboptimal cytoreductionElements of standardized reporting template for initial staging of ovarian cancerCase examplesFIGO 2018 Staging System- 2018 FIGO staging system is the most widely used staging system for ovarian cancer, classifying disease into one of four stages based on the primary tumor, nodal involvement, and presence and location of metastases based on surgical findings.-Imaging assists with lesion location (confirming ovarian origin), relative likelihood of benign versus malignant, and stage of the primary.-While US and MR play a key role in initial characterization of adnexal lesions, CT is the radiologic workhorse for staging and surveillance in ovarian cancer.-CT can also be used to assess the likelihood of a suboptimal surgical outcome in higher stage patients, with optimal cytoreduction defined as no residual tumor deposit measuring > 1 cm. - Accurate and thorough reporting of ovarian cancer at diagnosis is critical for optimal further management.

GUEE-49   MRI in Endometrial Carcinoma: An Illustrated Guide To 2018 Figo Staging

Participants
Juan Quintana Perez, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

The aims of this education exhibit are: (1) to review the indications of MRI in endometrial carcinoma and to propose an MRI protocol for daily practice; (2) to revise the 2018 FIGO staging through illustrations and real-life histologically-proven cases; (3) to point at potential problems and mistakes in MRI interpretation and to suggest useful tips for successful staging.

TABLE OF CONTENTS/OUTLINE

1. Indications of MRI in endometrial carcinoma 2. Technical aspects 3. MRI anatomy of the female pelvis 4. MRI staging: an illustrated stage-by-stage review 5. Pitfalls and pearls in MRI staging 6. Conclusions 7. References

GUEE-5   MRI-guided Transurethral Ultrasound Ablation (Tulsa) Of Prostate: From Basic Technology To Clinics

Participants
Roberto Luigi Cazzato, Strasbourg, France (*Presenter*) Proctor, Medtronic plc

TEACHING POINTS

- To present TULSA technology - To list current indications and contraindications to TULSA - To present TULSA devices and ablation procedure - To summarize the available TULSA literature

TABLE OF CONTENTS/OUTLINE

- TULSA technology - Indications and contraindications - TULSA devices and step-by-step procedure - Summary of TULSA literature

GUEE-50   Imaging In Uterine Fibroids With An Emphasis On The FIGO Classification Of Fibroids

Participants
Aishwarya Ghate, MBBS, Mumbai, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To discuss the imaging features of fibroids with an emphasis on FIGO classification. 2. To review the important imaging features while reporting a case of uterine fibroid.3. Knowing the exact anatomical location and extent of fibroids is important. 4. FIGO class is important in deciding the management of fibroid disease.

TABLE OF CONTENTS/OUTLINE

1. Discussion regarding the FIGO classification of fibroids. 2. Description of MR imaging features of different FIGO classes with examples of each class. 3. Role of FIGO classification in management of disease. 4. Various complications of uterine fibroids with their imaging features.

GUEE-52   Easy Access: Radiology Primer For Dialysis Workup And Surveillance

Daniela Garcia, MBBS, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Diagnostic and interventional radiology play an important role during pre-procedural evaluation and monitoring of optimal peritoneal and vascular access. 2. Ultrasound, fluoroscopy and CT are modalities available for the assessment of peritoneal and vascular accesses. 3. Development of new ultrasound and fluoroscopy-guided endovascular techniques project promising outcomes focused in improvement quality of life and overall survival.

TABLE OF CONTENTS/OUTLINE

End stage kidney disease is a major cause of morbidity and mortality in the United States and dialysis is the most common method of renal replacement therapy in this population. Thus, the need to improved patient's outcomes requires integration of a multidisciplinary medical team. The role of the radiology department includes both diagnostic and interventional planning and regular assessment of peritoneal and vascular accesses, according to patient's needs. Radiologists must be able to recognize different types of access, as well as common complications utilizing different imaging modalities in order to guide appropriate clinical management. This exhibit will serve as a comprehensive imaging based review of a radiologist's role in dialysis work up and surveillance. We will provide pictorial examples of various access routes with their imaging correlates, an overview of the complications and their management, and a guide to pre- and post- procedural surveillance.

GUEE-53   Be Sceptical, Save A Testicle: Sonographic Features Of Benign Intratesticular Lesions That Can Mimic Malignancy

Participants
Elise Chua, MBBS, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

As ultrasound has high sensitivity but poor specificity in the diagnosis of testicular tumours, a commonly accepted practice in the management of suspected testicular malignancy is radical orchidectomy and histological assessment. However, the increasing availability of ultrasound has led to detection of a greater proportion of benign lesions, prompting the need for a more conservative approach.The purpose of this exhibit is to:• Illustrate ultrasound appearances of common and rare benign testicular lesions• Identify features which enable confident differentiation of benign from malignant lesions, facilitating management and preventing unnecessary surgery• Discuss appropriate follow up and role of advanced techniques

TABLE OF CONTENTS/OUTLINE

1. Overview of testicular lesions2. Case presentations of benign lesions that can simulate malignancy with distinguishing features:• benign cystic lesions (intratesticular cyst, tubular ectasia of the rete testis)• trauma (haematoma) and vascular pathology (segmental infarction, necrosis) and evolution of appearances with time• infection (abscess, chronic orchitis)• granulomatous disease (tuberculous orchitis, sarcoidosis, cholesterol granuloma)• benign neoplasms (cystadenoma of the rete testis, Leydig cell hyperplasia, epidermoid cyst, lipomatosis)3. Management or follow-up options for testicular lesions identified on ultrasound and role of advanced imaging techniques (MRI, elastography, contrast-enhanced ultrasound)

GUEE-54   Etiology And Imaging Traits Of Bilateral Renal Cell Carcinoma And Mimics

Participants
Weibo Fu, BS, Augusta, Georgia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) To review the epidemiology, etiology, imaging traits, and management of bilateral renal cell carcinoma + mimics 2) To highlight key distinctions between synchronous and metachronous bilateral renal cell carcinoma 3) To review the role of radiologists in diagnosing and guiding management of bilateral renal cell carcinoma and other bilateral renal tumors

TABLE OF CONTENTS/OUTLINE

Bilateral RCC is a rare manifestation of RCC, accounting for 3-4% of sporadic RCC. Synchronous tumors occur within 6 months of the primary cancer, whereas metachronous tumors occur after 6 months. Although most bilateral tumors present synchronously, a small number of cases present metachronously. Risk of metachronous RCC is significantly higher in younger patients presenting with RCC, suggesting a strong hereditary link. Inherited and familial causes of bilateral RCC include loss of chromosome 3 and diseases such as von-Hippel-Lindau and Birt-Hogg-Dube. Because treatment of bilateral RCC involves both kidneys, surgical management and planning may be challenging. Physicians must consider both preservation of cortex function and tumor eradication as similarly important goals. Thus, over time treatment has shifted from bilateral radical nephrectomy to nephron sparing partial nephrectomy. A clear understanding of bilateral RCC features and mimics is required for radiologists to inform appropriate management. 1) Epidemiology, etiology 2) Causes of bilateral RCC 3) Mimics 4) Imaging features 5) Diagnosis 6) Treatment considerations 7) Conclusion

GUEE-55   Mesenchymal Tumors In The 'Adult Diaper' Distribution: Genetics ; Imaging Update

Participants
Steven Chua, MD, PhD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review taxonomy, epidemiology, clinical features, histopathology & biology of a wide spectrum of mesenchymal tumors that occur in the inguino-genital-perineal regions.2. To describe multimodality, cross-sectional imaging findings of these tumors.3. To discuss biological behavior, management and prognosis of diverse mesenchymal tumors that occur in the 'adult diaper' distribution.

TABLE OF CONTENTS/OUTLINE

1. Introduction, epidemiology and clinical features.2. Histopathological features, immunocytochemistry & molecular pathology.3. CT, MR and PET-CT findings as well as tumor biology of the rich diversity of mesenchymal tumors of the inguino-genital-perineal region, which include:* Cellular angiofibroma* Angiomyofibroblastoma* Aggressive angiomyxoma* Myolipoma* Liposarcoma* Solitary fibrous

tumor* Fibrosarcoma* Angiosarcoma* Myxoid sarcoma* SMARCB1 sarcoma4. Prognosis.5. Conclusion.

GUEE-57   Fibrous Pseudotumors Of Scrotum

Participants
Seyed Mohammad Seyedsaadat, MD, Jacksonville, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

Fibrous pseudotumor of scrotum is a rare and benign condition encountered in young men, which might clinically mimic a testicular malignancy. Pre-operative diagnosis of these tumors can be challenging due to the lack of specific clinical and imaging characteristics. Understanding the differential diagnosis and determining the benign or malignant nature of the tumor will help guide clinical management and surgical options, thereby obviating radical orchiectomy and consider a testis-sparing intervention. After reviewing the educational exhibit, the learner will be able to: - Understand the different imaging characteristics of fibrous pseudotumors of the scrotum - Review the classification and types of fibrous pseudotumors of the scrotum based on their location and pathology - Recognize that the fibrous nature of the tumors as a preoperative diagnosis can guide management based on benignity

TABLE OF CONTENTS/OUTLINE

I. Objectives II. Background III. Classification of Fibrous pseudotumors of scrotum IV. Types a. Fibrous Pseudotumor of Epididymal Tail b. Fibrous Pseudotumor of Tunica vaginalis c. Multiple nodular Fibrous Pseudotumors of testis d. Bilateral Fibrous Periorchitis e. Calcified Fibrous Pseudotumor of Epididymal Tail f. Fibrous Pseudotumor of the Testicular parenchyma g. Tumor Mimics V. Conclusions

GUEE-58   Wunderlich Syndrome: Clinical And Imaging Review

Awards
Identified for RadioGraphics

Participants
Jignesh N. Shah, MD, Germantown, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review the pathological spectrum of renal lesions leading to Wunderlich Syndrome 2. To discuss imaging approach and to review imaging features of these entities 3. To discuss implications of imaging on management

TABLE OF CONTENTS/OUTLINE

Review anatomy of retroperitoneal spaces; Introduction of Wunderlich Syndrome; Etiologies of Wunderlich Syndrome; Imaging approach; Imaging features of various pathologies leading to Wunderlich Syndrome including but not limited to Neoplasms such as angiomyolipoma, renal cell carcinoma, Vascular causes such as polyarteritis nodosa, renal artery aneurysm/pseudoaneurysm, renal arteriovenous malformation, renal arteriovenous fistula, renal vein thrombosis, Cystic renal diseases such as acquired cystic renal disease, renal hemorrhagic cyst, autosomal dominant polycystic kidney disease, Infectious causes such as acute pyelonephritis, emphysematous pyelonephritis, and Miscellaneous causes such as anticoagulation, reperfusion injury, end-stage renal disease, hemophilia, ureteric obstruction, nephritis; Discuss implications of imaging on management

GUEE-59   Unraveling Scrotal Pathology: Acute, Chronic, Congenital And Neoplastic Manifestations

Participants
Jennifer Hanak, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

Scrotal and testicular pathology varies widely and often presents in a similar fashion: with pain, swelling or a mass. It is important to be able to distinguish the various etiologies based on imaging and clues in the patient history to assist clinicians in appropriate treatment. It is important to recognize benign, congenital and malignant causes of testicular mass to appropriately treat those with malignancy and prevent unnecessary procedures in those with benign masses.

TABLE OF CONTENTS/OUTLINE

Acute Torsion Torsion of appendage testes Infarct Epididymitis/epdidymorchitis Trauma Rupture/fracture Hematocele Abscess Emphysematous infection Chronic Chronic granulomatous epididymitis Epidermoid cyst Sarcoidosis Varicocele Inguinal hernia Calculi Congenital Undescended testes Polyorchidism Adrenal Rests Neoplastic Seminomas Nonseminomatous germ cell tumors Lymphoma Zebras - angiosarcoma, etc Metastasis

GUEE-6   Two Roads Diverged: Anomalies Of Mullerian And Wolffian Duct Development

Awards
Certificate of Merit

Participants
Neha Udayakumar, BS, Riverside, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is to:1) Examine the normal embryological development of the Müllerian, Wolffian, and Metanephric ducts.2) Provide a case-based review of commonly encountered genitourinary development anomalies.3) Recognize the important MRI findings that guide the diagnosis and treatment of infertility related to development anomalies.

TABLE OF CONTENTS/OUTLINE

Embryological Development of Genitourinary Structures- Müllerian (Paramesonephric) ducts- Wolffian ducts- Metanephric ductsMüllerian Duct Anomalies - Uterine agenesis/hypoplasia (class I)- Unicornate uterus (class II)- Uterine didelphys (class III)- Herlyn-Werner-Wunderlich syndrome (OHVIRA)- Bicornuate uterus (class IV)- Septate uterus (class V)- Arcuate uterus (class VI)- T-shaped uterus (class VII)- Müllerian duct cystWolffian Duct Anomalies - Zinner syndrome- Gartner duct cystMetanephric Duct

Anomalies - Renal agenesis

Radiogenomics In Cancers Of The Genitourinary Tract

Participants
Aishah Azam, BSC,MBBS, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

(1) Radiogenomics is the combination of diagnostic imaging and genomic signatures to improve tumor phenotyping. (2) Radiogenomics extracts features from images including shape and texture, using mathematical modelling, as well as quantitative parameters from functional/molecular imaging e.g. apparent diffusion coefficient, perfusion, or standardized uptake value; and features from gene expression analysis requiring advanced statistical or deep learning approaches for data integration. (3) Radiogenomic signatures can be used to predict prognosis and response to treatment, and may allow more individualized patient care. (4) Standardization of study methodology and reporting is required for all radiogenomic studies, as described by the Image Biomarker Standardization Initiative.

TABLE OF CONTENTS/OUTLINE

(1) Introduction to radiomics and radiogenomics. (a) Using CT, MRI and PET. (b) Statistical and deep learning approaches to data handling. (2) Roles of radiogenomics. (a) Correlation/association between radiomic features and genomic signatures. (b) Combination of radiomic and genomic signatures to form predictive models (tumor phenotyping; response to chemo-/radio-/immuno-therapy; prognosis). (3) Radiogenomics in practice. (a) Renal cancer. (b) Prostate cancer. (c) Bladder cancer. (4) Challenges for implementation. (a) Segmentation. (b) Statistical overfitting. (c) Standardization of reporting for studies. (5) Potential areas for future use.

GUEE-61 **Cortical Renal Tumors: Correlation Of Radiologic And Histopathologic Features**

Awards
Certificate of Merit

Participants
Ruggeri Guimaraes, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

1 - To show features of the most common renal tumors in adults. 2 - To correlate the radiologic features with histopathologic findings. 3 - To provide a guide using the imaging-histologic correlation to narrow diagnosis and support management of these renal tumors.

TABLE OF CONTENTS/OUTLINE

1 - Prevalence of cortical renal tumors in adults. 2 - Typical imaging characteristics of the most common renal tumors. 3 - Correlations between radiological and histopathological findings supported by the use of didactic illustrations as well as radiological and pathological images. 4 - Diagnostic tools, including computed tomography (CT) and magnetic resonance imaging (MRI). 5 - Imaging protocols. 6 - Description of atypical imaging features of these renal tumors, and how to avoid the misdiagnosis. 7 - Didactic diagnostic approach for solid cortical renal masses.

GUEE-62 **No Man Left Behind - MRI Diagnostic Workup of Male Infertility**

Awards
Certificate of Merit

Participants
Milton B. Muniz JR, DO, Teresina, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Anatomical review of the male reproductive system 2. Imaging evaluation of the anatomy of ejaculation process. 3. MRI n post-testicular cystic obstructive lesions: - cysts of the Wolffian duct, - ducts of the Cowper gland, - prostatic utricle, - Müller's duct cysts - seminal vesicle cysts. 4. Congenital genitourinary anomalies related to infertility: - Agenesis of the vas deferens - Zinner syndrome - Persistent Mullerian Ducto Syndrome - Testicular agenesis - Cryptorchidism

TABLE OF CONTENTS/OUTLINE

Among infertile couples, the cause of infertility is related to male partner in approximately 50% of cases and involves conditions related to production, function and distribution of sperm, in addition to anomalies of the reproductive system. The main role of imaging exams in diagnosis of male infertility factor is identification of congenital malformations and disorders that obstruct sperm transport and are potentially correctable. Magnetic resonance imaging (MRI) is useful for assessing the ductal system and male accessory sexual glands, being able to characterize the genito-urinary anatomy, identifying malformations and related injuries.

GUEE-63 **Vaginal Malignancies And MRI: What Radiologists Should Know**

Participants
Maria Clara Fernandes, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

* Primary malignant diseases of the vagina are rare, accounting for about 1-2% of all gynecological malignancies. The secondary involvement of the vagina is much more common, mainly due to direct extension cervical, endometrial, or rectal tumors. * MRI is the imaging method of choice for depicting and characterizing the lesion and locoregional staging. Therefore, the proper protocol is essential for the characterization. * Radiologists should be aware of the anatomic repairs, the pattern of spread, and possible differential diagnosis in order to correctly characterize these lesions. * This exhibit aims to review the literature and illustrate the imaging features of primary and secondary vaginal malignancies, the relevant pelvic anatomic structures for diagnosis and staging.

TABLE OF CONTENTS/OUTLINE

GUEE-64   P.E.N.I.S. T.: A Mnemonic Approach To Imaging Evaluation Of The Penis

Awards
Cum Laude

Participants
Joao Manoel Santos, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:- To propose the mnemonic P.E.N.I.S. T. to imaging approach in the evaluation of the penis.- To review usual and unusual cases of penile conditions and its differential diagnoses.- To correlate important findings with the anatomy and pathophysiology.- To discuss image findings in order to enhance radiologists' skills.- To review MRI protocols in the evaluation of patients with acute and chronic penile conditions.- To highlight their characteristics in order to familiarize radiologists with these conditions, preventing unfavorable patient outcome.

TABLE OF CONTENTS/OUTLINE

- Applied anatomy of the penis.- MRI protocols in the evaluation of the penis.- The mnemonic P.E.N.I.S. T. (interactive touch-based panel).P: prosthesis, phimosis.E: external traumaN: neoplasm.I: infection, inflammation, induratio penis plastica (Peyronie's disease), impotence.S: sexuality, stenosis (urethra)T: thrombosis and vascular disorders.- Sample cases of pearls, pitfalls, diagnostic difficulties, and mimics.- Summary and take-home messages.

GUEE-65   The Role Of Ultrasound In Uterine Cervical Cancer

Participants
Paula Perroni, MD, Buenos Aires City, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

Abstract Examination of the cervix is often cursory during pelvic US, such that cervical disease may be overlooked or misdiagnosed Cervical cancer is a common gynecologic malignancy worldwide and the most frequent cause of cancer-related death in women younger than age 35, it is prevalent condition in poor contries .Ultrasound has gained increased attention in recent years; it is faster, cheaper, and more widely available than other imaging techniques, and is highly accurate in detecting tumour presence and evaluating local extension of disease. The familiarity with the imaging feature of uterine cervical lesions will facilitate prompt and accurate diagnosis and treatment Accurate staging is critical because risk stratification and treatment of clinically visible lesions varies depending on size of the tumor, presence and extent of local invasion, and presence of metastases This review describes the normal appearance of the cervix at US, the appearance of cervical cancer and FIGO 2018 staging system by ultrasound Teaching points Describe the normal appearance of the cervix at US Recognize us and color Doppler findings in uterine cervical cancer Review FIGO 2018 staging system for uterine cervical cancer by ultrasound

TABLE OF CONTENTS/OUTLINE

1. Normal US appearance of the cervix2. US findings in uterine cervical cancer3. Color Doppler findings in cervical cancer 4. Staging of cervical cancer

GUEE-66   Pathways Of Lymphatic Spread In Prostate Cancer: What The Radiologist Needs To Know

Participants
Camila Cifuentes, MD, Santiago, Chile (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Describe the anatomy of the pelvic nodal groups by using standard terminology. 2. Identify the different pathways of nodal metastasis in prostate cancer: lateral, posterior and anterior routes. 3. Learn the therapeutic implications of the involvement of different nodal groups

TABLE OF CONTENTS/OUTLINE

1. Pelvic lymphatic anatomy. 2. Imaging-based criteria for identifying nodal metastases with Ga-68 PSMA PET-CT: Lymph node size, nodal location, internal nodal architecture, tracer uptake and SUV max values. 3. Common pathways of nodal metastasis: Lateral route, for which the sentinel nodes are the obturator nodes, part of the external and internal iliac nodal group. The second most common pathway is the perirectal rout whose drainage is in to the inferior mesenteric nodes. 4. Uncommon pathways of nodal metastasis: Anterior rout, lymph nodes located anterior to the urinary bladder. From these nodes, metastases can spread to the internal iliac nodes. 5. Important staging system considerations (non-regional lymphadenopathy are considered M1). 6. Our local experience of staging patients with prostate cancer since the use of Ga-68 PSMA PET-CT in our institution. 7. Illustrative cases for each pathway of nodal metastasis. 8. Therapeutic considerations in prostate cancer (extended pelvic lymph node dissection)

GUEE-68   Big Ovaries? Big Deal: Non-mass Causes Of Ovarian Enlargement

Awards
Certificate of Merit

Participants
Rishabh Agarwal, MD, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

TEACHING POINTS

In the setting of ovarian enlargement without an ovarian mass, radiologists often invoke the diagnosis of acute ovarian torsion, particularly in the setting of pelvic pain. However, there are many other causes of ovarian enlargement that the practicing radiologist should be aware of, some of which have imaging overlap with acute torsion. The purpose of this educational exhibit is to present a comprehensive differential diagnosis for non-mass causes of ovarian enlargement using multiple modalities, with a focus on the underlying pathophysiology and relevant clinical scenarios in which they arise.

GUEE-69   Renal Bleeding In Cancer Patient Cross Sectional Imaging And Role Of Intervention In Management

Participants
Khaled M. Elsayes, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Introduction to general causes of hemorrhage in cancer patients.2. Identify common benign lesions that bleed.3. Identify common malignant lesions that bleed.4. Recognize vascular causes of hemorrhage.5. Explain the role of intervention radiology in management of bleeding

TABLE OF CONTENTS/OUTLINE

1) Cross sectional and ultrasound appearance of blood. 2) Hemorrhage from malignant renal neoplasms. 3) Hemorrhage from benign renal lesions. 4) Bleeding from urothelial neoplasms: 5) Vascular causes of bleeding: Aneurysms, pseudo-aneurysms, AV fistulas and vascular outflow obstruction. 6) Traumatic causes of renal hemorrhage. 7) Procedure related bleeding: Percutaneous biopsies, nephrostomy, and nephron sparing surgeries. 8) Role of intervention in management of renal hemorrhage.

GUEE-7   A Pictorial Review Of Ultrasonography Of The Revised FIGO Classification For Uterine Leiomyomas.

Participants
Suryansh Bajaj, New Haven, Connecticut (*Presenter*) Nothing to Disclose

TEACHING POINTS

Uterine leiomyomas are the most common gynecological and pelvic neoplasm, occurring in up to 80 percent of women by age 50.Ultrasonography remains the first-line radiological investigation for the diagnosis of leiomyomas and is the most appropriate imaging modality for the initial assessment of AUB.To standardize nomenclature and identify causes of AUB, FIGO developed a classifications system - PALM-COEIN which was last revised in 2018.For the L category of leiomyoma, when present, a secondary and tertiary subclassification system is described distinguishing submucosal masses from others and categorizing the relationship of the mass to the endometrium and serosa. Pelvic USG usually consists of a combined approach to include both transabdominal (TAS) and transvaginal (TVUS) imaging. Complementary techniques include the use of color Doppler, 3D USG, USG elastography, contrast-enhanced ultrasound, and USG sonohysterography. A uniform characterization, mapping, and classification of leiomyomas are necessary to decide the optimal therapeutic approach. We present a pictorial review of USG images of all the FIGO categories of leiomyomas to provide a standard guide for radiology reporting.

TABLE OF CONTENTS/OUTLINE

Role of USG: TVUS vs TAS, use of color Doppler, 3-D USG, USG elastography, contrast-enhanced ultrasound, and USG sonohysterography.Comparative analysis of USG and MRIFIGO classification of AUB with 2018 revisions:USG of Submucosal leiomyomasUSG of Other LeiomyomasUSG of Hybrid leiomyomasLimitations of USG

GUEE-70   MRI/TRUS Fusion In Prostatic Cancer. What The Radiology Resident Needs To Know.

Participants
Piedad Acosta Mora, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

-To improve the knowledge of the normal anatomy of the prostate, the PIRADS 2.1 system, and indications for transrectal biopsy.-To describe the limitations offered by systematic biopsy TRUS-To know the advantages and disadvantages of TRUS biopsy by fusion of MRI/TRUS imaging.-To show the step-by-step MRI/TRUS fusion-guided biopsy

TABLE OF CONTENTS/OUTLINE

Introduction:-Normal anatomy-PI-RADS 2.1 system-Indications for biopsy Technique-Systematic transrectal biopsy -MRI/TRUS Fusion Advantages and benefits (case-based) Complications Conclusions

GUEE-71   A Colorful Matching Game Of Ovarian Tumors: From Easy Winning To Game Over

Participants
Jessica Marchi, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Primary ovarian neoplasms can be categorized on the basis of histopathologic features into epithelial surface cell tumors, germ cell tumors and sex cord-stromal tumors. • Imaging findings of ovarian neoplasms are often overlapping and nonspecific, although some subtypes have distinguishing imaging features and clinical data that approach to an accurate diagnosis.

TABLE OF CONTENTS/OUTLINE

To make a diagnostic approach of the most common ovarian tumors in a fun and different way• To make a diagnostic approach to the most common ovarian tumors through a flowchart drawn in a tetris and puzzle game model. • To illustrate the main features of the most common ovarian tumors• To highlight when the diagnostic hypothesis can be formulate based on the imaging features and clinical data and when the overlapping features can make it impossible. • To list the imaging tumor findings through specifics colors and then try to match it to the board of the game table that contain the most common ovarian tumors with it respective color combination (features combination). When the diagnostic hypothesis can be formulate, the "next" button will highlight, when it's not ,the "hold" button will highlight and the success must be tried with another ovarian tumor.

GUEE-72   Participants

MRI Imaging Findings Of Papillary Necrosis - The Utility Of Non-contrast MR Imaging Of The Pelvicalyceal System Including The Importance Of Papillary Diffusion Restriction.

Denver Pinto, MD, Miami, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

*To identify various calyceal findings of papillary necrosis*To recognize diffusion restriction of the calyx as an important precursor sign to the the occurrence of papillary necrosis and its pathophysiological basis.*To recognize that intravenous administration of contrast is not necessary to image papillary necrosis.

TABLE OF CONTENTS/OUTLINE

* Demographic data, epidemiology and disease burden of papillary necrosis* Etiology* Imaging modalities used for papillary necrosis and the role of intravenous contrast in imaging* Non-contrast MR Urogram findings of papillary necrosis, Calyceal findings seen in papillary necrosis. Special focus on diffusion restriction in the calyx as a sign of papillary necrosis, pathophysiologic basis of diffusion restriction as a cause for papillary necrosis.* Imaging of papillary necrosis (case discussions) due to various etiologies.* Comparison of static MR Urogram versus other modalities of imaging.

GUEE-73   Deep Infiltrating Endometriosis: A Structured Approach

Awards
Certificate of Merit

Participants
Jihyun Kang, Staten Island, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Review and illustrate three distinct female pelvic compartments. 2. Discuss a structured approach to evaluating pelvic endometriosis within the framework of pelvic compartments. 3. Describe MR imaging characteristics of deep infiltrating endometriosis and discuss structured reporting system.

TABLE OF CONTENTS/OUTLINE

1. Introduction2. Anatomic illustrations: -Female pelvis -Pelvic compartments (anterior, middle, posterior)3. Diagnosis of endometriosis: -Clinical aspects -Subtypes of endometriosis (ovarian, deep infiltrating, superficial) -MR imaging characteristics of deep infiltrating endometriosis -Categorization of endometriosis within different pelvic compartments4. Discussion of structured reporting system with summary table5. Conclusion

GUEE-74   Imaging Of Urinary Bladder Masses And Mass-like Lesions

Awards
Identified for RadioGraphics

Participants
Mark Hoegger, MD, PhD, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is to:1. Illustrate the urinary bladder normal anatomy and appearance with multimodal imaging, including CT urography and MR urography, and describe techniques for image optimization.2. Highlight features of bladder malignancy including those described by current standardized reporting systems (i.e. VI-RADS).3. Provide a case-based review of various masses and mass-like lesions including intrinsic and extrinsic etiologies.

TABLE OF CONTENTS/OUTLINE

1. Anatomy:i. Urinary bladder layersii. Normal urinary appearance with CT and MR urographyiii. Urinary bladder inflow and outflow anatomyiv. Adjacent structures including comparative anatomy between males and females2. Techniquei. Compare CT modalities: cystography, urography, and standard CTii. Describe MR techniques for bladder imagingiii. Optimizing bladder imaging across modalities3. Urothelial malignancyi. Multimodal appearance of urothelial malignancyii. Description and application of VI-RADS4. Non-urothelial masses and mass-like lesions - malignant and benigni. Mesenchymal tumorsii. Metastatic lesionsiii. Benign extravesical masses and mass-like lesionsiv. Malignant extravesical and mass-like lesionsv. Hemorrhagic pathologiesvi. Inflammatory pathologies - Infectious and non-infectionsvii. Calcification and crystalline disease5. Pitfalls and special considerationsi. Suboptimal bladder distensionii. Optimal contrast usageiii. Age related changes and variant anatomyiv. Iatrogenic

GUEE-75   It's As Easy As 1,2,3: Three-step Approach To Cystic Renal Mass 2019 Bosniak Classification

Awards
Certificate of Merit

Participants
Dana Galvan, MD, Albuquerque, New Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is: 1. To familiarize radiologists and in-training radiologists on the use of a simple three-step approach to characterize all cystic renal masses to aid with consistent classification. 2. To demonstrate the "Magic 4" simplified rule for distinguishing nodularity, thickness, and septa. 3. To provide examples using the unique three-step approach to demonstrate classification of different Bosniak lesions such as 2F, 3, and 4.

TABLE OF CONTENTS/OUTLINE

Introduction and Importance of the 2019 Bosniak Classification. 2019 Bosniak Classification Summary. Overview of our Three Step Approach to the Bosniak Classification. Explanation with figures of the "Magic 4" simplified rule for distinguishing nodularity, thickness, and septa. Example Classifications of Bosniak Lesions using the Three-Step Approach: Bosniak 2F Lesion classification,

Bosniak 3 Lesion classification, Bosniak 4 Lesion classification. Summary Table of Three Step Approach to 2019 Bosniak Classification.

GUEE-76   Ovarian Torsion Revisited - Untwisting The Truth

Participants
Aman Kahlon, MBChB, Manchester, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

Describe the appearances of ovarian torsion of a normal ovary. Differentiate between a torsion of a normal and pathological ovary. Describe the appearances of torsion in cystic pathologies including simple ovarian cyst, dermoid cyst and cystadenofibroma. Recognise commonly encountered complications, imaging pitfalls and mimics of ovarian torsion.

TABLE OF CONTENTS/OUTLINE

Torsion of a normal ovary although rare is often encountered in clinical practise. It occurs most often in adolescents and is an important differential in young patients presenting with acute pelvic pain. Conversely, torsion of ovaries with pre-existing pathologies is a well-recognised entity. Early recognition by the radiologist is vital to allow prompt intervention and preservation of ovarian function.We present a series of cases that highlight the imaging features of ovarian torsion in normal and pathological ovaries and the commonly encountered complications and pitfalls that radiologists should be aware of.

GUEE-77   Ultrasound Of Scrotal Masses: 10 Pearls And Pitfalls

Participants
Cindy Mai, MD, Leuven, Belgium (*Presenter*) Nothing to Disclose

TEACHING POINTS

Ultrasound is still the preferred imaging modality when it comes to scrotal pathology. It is widely available, inexpensive and non-invasive. Also, the extracorporeal and superficial position of the testicles make high resolution evaluation by ultrasound possible. It is widely performed among sonographers, radiologists and non-radiologists. However, as in other body areas ultrasound is very operator dependent.The purpose of this educational exhibit is:- To provide the most important concepts in scrotal ultrasound when evaluating intrascrotal masses (the pearls)- To familiarize the radiologist/ultrasonographer with common mistakes when an intratesticular lesion is seen (the pitfalls)

TABLE OF CONTENTS/OUTLINE

Pearl 1: Testicular microlithiasis, when to sound the alarm Pearl 2: First things first, is it extratesticular or intratesticular? Pearl 3: Second, is it cystic or solid? Pearl 4: Color doppler comes to the rescue Pearl 5: It is mostly germ cell tumor, but not always Pearl 6: It is mostly seminoma, but not always Pitfall 1: Anamnesis is important, but? never trust the patient Pitfall 2: Suboptimal doppler settings Pitfall 3: Conditions that can mimic tumor Pitfall 4: Underestimating experience in ultrasonography, it is not always a textbook case

GUEE-78   Endometriosis In The Chest And Upper Abdomen: Little-explored Territory

Participants
Cristiane Costa, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

1 - Review the usual and unusual location of endometriosis of the chest and upper abdomen, imaging characteristics, theories of dissemination, and clinical manifestations. 2 - Provide the radiologist with the main information he must report and correlate the characteristics of MRI and US images with the findings of laparoscopy. 3 - Illustrate the cases of endometriosis in the chest and upper abdomen, demonstrating the therapeutic surgical options.

TABLE OF CONTENTS/OUTLINE

1 - Theories of dissemination of endometriotic implants. 2 - Location and imaging aspects of the lesions. 3 - Imaging protocols. Advantages and disadvantages of US and RM. 4 - More relevant information should the radiologist report to the surgeon. 5 - Correlation of imaging characteristics (US and MRI) with laparoscopy. 6 - Demonstrate surgical treatment options for lesions.

GUEE-79   A Radiological Advice: Tips About Gynecological Pelvic Devices

Participants
Flavia M. Starling, MD, Belo Horizonte, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

• The female pelvis is made up of a complex anatomy and understanding it can be challenging sometimes, especially if there are unknown devices inside the pelvic cavity, including the uterus or the vagina.• There are many contraceptive methods that have intravaginal and intrauterine delivery systems, such as the vaginal ring and intrauterine device (IUD) copper or hormones releasing. In addition, there are other devices that can be found in the female pelvis, for example the slings or vaginal pessaries, each one with their own function and purpose, or even foreign bodies.• Questionnaires are often vague when referring to these devices and most women forget to mention actively whether they have or are using them.• An understanding of the radiological appearance of some of these devices in the many imaging methods such as X-ray, ultrasound, CT and MRI is useful to avoid misinterpreting them, as well as knowing their correct positioning and possible complications, obtaining a diagnosis more quickly and accurately.

TABLE OF CONTENTS/OUTLINE

• Clinical and epidemiological aspects.• Case-based review illustrating the findings of different methods of women's vaginal and uterine devices, including normal and inappropriate positioning and complications.• Take-home messages.• References.

GUEE-8   A Panoply Of PEComas

Participants

Adam Kinzel, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

Perivascular epithelioid cell tumors (PEComas) are a group of rare mesenchymal tumors composed of distinct perivascular epithelioid cells (PECs). First described in 1992 by Bonetti et al. due to distinct morphologic similarities between angiomyolipomas (AML) and clear cell "sugar" tumors of the lung (CCTL). These tumors were found to be immunoreactive to melanocyte markers, contain clear-acidophilic cytoplasm, have an unusual cell type, and were organized in a perivascular distribution. Bonetti et al. were also the first to suggest a connection between PEComas and Tuberous Sclerosis. Since that time, other tumors have been added to the PEComa family including lymphangiomyomatosis, abdominopelvic sarcoma of PECs, and other related tumors at various sites simply called PEComas. This educational exhibit will provide a comprehensive overview of PEComas by discussing the epidemiology, morphology, and radiographic appearance of the most common PEComas as well as describe therapeutic interventions in the treatment of these tumors. Finally, this exhibit will review the associated entities commonly seen with PEComas such as Tuberous Sclerosis and Lymphangioleiomyomatosis.

TABLE OF CONTENTS/OUTLINE

Background;General Pathology;Epidemiology, histology, imaging features, and treatment considerations for the most common PEComas (Angiomyolipomas, Lymphangiomyomatosis, Abdominopelvic sarcoma of PECs);Associated Entities (Tuberous Sclerosis, Lymphangioleiomyomatosis);Newer Treatments/Research;Summary and Conclusion

GUEE-80   MRI Of The Female Urethra

Awards
Certificate of Merit

TEACHING POINTS

The female urethra is well delineated on pelvic MRI due to the excellent soft tissue and spatial resolution of MRI. The utilization of pelvic MRI has rapidly increased over the last decade (eg. pre-operative imaging of patients with endometrial/cervical cancer). Therefore, incidental urethral pathology is more commonly detected and thus increases the need for accurate image interpretation and diagnosis. MRI also has an evolving role in the primary assessment of the female urethra for both benign and malignant pathology. Retrograde urethrography and voiding cystourethrography are typically the primary imaging modality of choice in the male urethra, but provide less information concerning the female urethra. MRI provides vital information regarding the anatomy and pathology of the female urethra which can guide clinical management and provide a road map for surgical procedures. Goals: 1. Describe the embryological development and anatomy of the female urethra 2. Highlight the female urethra imaging techniques with an emphasis on pelvic MRI 3. Exemplify the female urethra pathology: a.Benign - Congenital : malformations - Inflammatory/infective - urethritis, vasculitis - Post-surgical - urethral bulking agents - Tumour - leiomyoma - Other - diverticulum, Skene gland cyst, cecoureterocele b.Malignant - Rare primary urethral carcinoma - Secondary malignancy involving the urethra 4. Discussion of each category, including complementary imaging methods

TABLE OF CONTENTS/OUTLINE

1. Embryology and anatomy 2. MRI 3. Pathology 4. Summary

GUEE-81   Local Staging On Prostate MRI: What The Urologist And Radiation Oncologist Want To Know

Awards
Identified for RadioGraphics

Participants
Ravi Gottumukkala, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Prostate MRI findings regarding local tumor extent are increasingly incorporated into treatment planning. Surgical techniques have evolved to optimize continence and potency following radical prostatectomy, but rely on a detailed understanding of tumor extent and relationship to critical anatomic landmarks, in part derived from imaging assessment. Additionally, decisions regarding the logistics of radiation and androgen deprivation therapy rely on risk stratification that incorporates imaging-derived local staging features alongside other biomarkers. This clinically oriented exhibit aims to 1) Review key anatomic principles pertaining to local staging of prostate cancer, 2) Illustrate via case examples the spectrum of local staging features on prostate MRI, 3) Discuss inflection points where imaging findings may modify clinical management.

TABLE OF CONTENTS/OUTLINE

-Brief clinical overview of surgical and radiation therapy for localized prostate cancer-Anatomic principles and imaging assessment of extraprostatic extension (EPE)-Anatomic principles and imaging assessment of seminal vesicle invasion (SVI)-Discussion of how EPE and SVI modify the radiation oncologist's treatment approach-Discussion and imaging appearance of key anatomic/surgical landmarks where EPE may modify the urologist's technical approach

GUEE-82   Imaging Characteristics Of Post-partial Nephrectomy: Expectations And Complications

Awards
Certificate of Merit

Participants
Aditi Chaurasia, MBBS, Bethesda, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

Nephron-sparing surgery is the standard treatment in many patients with small renal tumors. Complication rates for such procedures are variable and can range from 4%-37% depending on factors such as patient's health status, tumor size and technique performed. Complications usually occur in the early post-op period, & include urinary leak/fistula, bleeding, acute renal failure, infection, fat necrosis, ischemic changes in the renal parenchyma and ureteral/ renal pedicle stricture. Most of these complications can be managed conservatively or with endoscopy or interventional radiology. As nephron-sparing surgery gains popularity, it is crucial for radiologists to be familiar with imaging characteristics of postoperative complications and distinguish them from normal

postoperative findings. This educational exhibit will illustrate the key imaging findings of complications after partial nephrectomy and describes the features that can help radiologists to distinguish them from expected postoperative changes and tumor recurrence. We will also discuss management strategies for postoperative complications.

TABLE OF CONTENTS/OUTLINE

1. Expected post-partial nephrectomy imaging characteristics • Enumeration of different normal imaging findings• US, CT and MRI findings2. Post-partial nephrectomy complications• Enumeration of different complications• US, CT and MRI findings3. Management of post-partial nephrectomy complications • Conservative options• Role of interventional radiology• Imaging of management strategies

GUEE-83   Ultrasound Of Pelvic Pain In A Fertile Woman: Characteristic Signs To Guide The Diagnosis

Participants
María Loyola, Santiago, Chile (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Review the ultrasound diagnostic approach in patients with pelvic pain of childbearing age.-Classify the differential diagnosis in defined clinical settings.-Recognize the different ultrasound signs that we find in different clinical scenarios.

TABLE OF CONTENTS/OUTLINE

Introduction. - Epidemiology. - Possible clinical scenarios in ultrasound of pelvic pain in a fertile woman.Ultrasound signs present in the different scenarios (Description of B-mode signs and color Doppler signs): - Clinical Scenario 1: Unilateral ovarian volume enlargement. - Ovarian torsion: - Clinical Scenario 2: Normal size ovary + contralateral adnexal cyst-mass in patients without increased inflammatory parameters or bhcg levels. a)Hemorrhagic cyst. b)Ruptured hemorrhagic cyst. c)Endometrioma. d)Mature cystic teratoma. e)Torsion of the Fallopian Tube. - Clinical Scenario 3: Normal size ovary + contralateral adnexal cyst-mass in patients with elevated inflammatory parameters without increased bhcg levels. in a patient with elevated inflammatory parameters. a)Salpingitis-piolsalpinx. b)Tubo-ovarian abscess.- Clinical Scenario 4: Normal size ovary + contralateral adnexal cyst-mass in a patient with elevated BHCG. -Ectopic tubal pregnancy.Conclusions.

GUEE-85   Penis Fracture: Cowgirl, Decrease The Rhythm!

Participants
Evelyn Torres Gomez, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

Penile fracture is described as the rupture of the tunica albuginea and/or corpus spongiosum in the erect penis caused by rapid blunt force. The tunica albuginea covers the corpora cavernosa and sponge, has a normal thickness of 2 mm when the penis is flaccid, it stretches during erection and its thickness is reduced to 0.25 mm. Penile fracture generally occurs in the proximal or middle shaft and results in a transversal tear. The most common sexual position associated with penile fracture is the reverse cowgirl. US is an ideal technique for evaluating patients with penile trauma and can be routinely used in an emergency. It is a non-invasive method that gives results faster than cavernosography and MRI. Ideally, US of the penis is performed with a high-frequency (7-12.0 MHz) linear transducer, anatomic orientation, and ample gel to provide high-quality images. The examination should include different angles of insonation to identify hidden lesions due to edema of the penis.Tunica albuginea is easily represented as a hyperechoic linear line. It can show the integrity of the tunica albuginea as well as the extent and location of a tunical tear or to see any hematoma on either side of the tunica. The radiological report should include the location of the rupture, the major axis, hematoma diameters, and a description of findings that suggest a ruptured urethra.

TABLE OF CONTENTS/OUTLINE

Normal anatomy of the penis. Ultrasonographic findings of penile fracture. Frequency of sexual positions as a mechanism of injury. Ultrasound evaluation technique.

GUEE-86   Typical And Atypical Fibroids And Figo Classification: Old Disease And New Perspectives

Participants
Júlia Miranda, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Understand current concepts and management of uterine leiomyomas- Recognize uterus anatomy- Review the Magnetic Ressonance Imaging (MRI) technique- Comprehend FIGO classification- Recognize the most important imaging features to report and differential diagnosis

TABLE OF CONTENTS/OUTLINE

INTRODUCTION- Uterine leiomyoma prevalence, risk factors and clinical significance ANATOMIC CONCEPTS- Key anatomical landmarks demonstrated by illustrations with MRI correlation- MRI appearance of different subtypes of leiomyomas- MRI appearance of leiomyoma degenerationMRI TECHNIQUE- Preparation-MRI protocol-Difficulties and how to overcome themTYPES OF LEIOMYOMA DEGENERATION FIGO CLASSIFICATIONDIFFERENTIAL DIAGNOSIS- Adnexal lesions- Non-fibroid uterine lesions- Pitfalls TYPES OF TREATMENT- Briefly review the role of MRI on therapeutic planning SYSTEMATIC APPROACH- Systematic approach to evaluate uterine leiomyomas- Template reporting system INTERACTIVE CASE-BASED DIDACTICS- Sample cases to illustrate and solidify the concepts CONCLUSION

GUEE-87   Multidetector Computed Tomography (MDCT) With Tridimensional And Functional Reconstruction Modeling For Partial Nephrectomy: A Tool To Improve Surgery And Renal Function Outcomes

Participants
Giovanna Torre, Sao paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

I. Understand the concepts and applications of 3D kidney reconstruction for partial nephrectomyII. Comprehend the main

techniques used to outline the tumours as well as the kidney blood vesselsIII. Demonstrate through cases how 3D kidney reconstruction can improve post-treatment renal function, enhancing the the surgical planning and reducing the duration of renal ischemia IV. Discuss the future directions of 3D kidney reconstruction for partial nephrectomy

TABLE OF CONTENTS/OUTLINE

INTRODUCTION• Understand the benefits of 3D reconstructions in partial nephrectomyIMAGING TECHNIQUE• CT protocol and software management• Calculate the renal cortex volume and parenchymal volume with an imaging software program (Synapse 3D - FUJIFILM Corporation, Tokyo, Japan)• Assess the extrarenal and intrarenal vascular road map of renal artery tree• Characterize the tumor-specific vascularization• Estimate volumetry of the renal parenchyma and cortex volume of the anticipated remnant renal volumeIMAGING EVALUATION• What information the surgeon needs to know in a preoperative planning for partial nephrectomy• Illustrative cases of partial nephrectomies planned through 3D reconstructionFUTURE DIRECTIONS• What's on the horizon for 3D kidney reconstruction for partial nephrectomy

GUEE-88   Imaging Findings Of Succinate Dehydrogenase Subunit B (sdhb) Gene Mutation

Participants
Aditi Chaurasia, MBBS, Bethesda, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

Succinate Dehydrogenase Subunit B (SDHB) mutation-related cancer is a recently defined inherited syndrome characterized by increased risk of multiple paragangliomas, pheochromocytomas, and renal cell carcinoma. SDHB is associated with several subtypes of RCC, including clear cell, chromophobe carcinomas, and oncocytomas. These renal tumors present at an early age, and have a high tendency toward overtly malignant disease. Considering their early tendency to metastasize, SDHB tumors should be managed promptly with surgery.There is no clear consensus regarding the best time to initiate imaging surveillance, its frequency, and modalities of choice in these patients. This educational exhibit reviews the mechanism, clinical, and imaging findings as well as management and imaging surveillance in patients with SDHB mutation

TABLE OF CONTENTS/OUTLINE

This educational exhibit will illustrate the following features of patients affected with SDHB mutation:Genomics and underlying pathophysiology• Inheritance pattern• Gene involved• Gene function• Mechanism of tumorigenesis• Potential targeted therapyClinical presentation • Epidemiology• Onset, clinical signs, and symptoms• Natural course of the disease Imaging characteristics on CT, MRI, FDG-PET• Imaging findings of renal lesions • Imaging findings of extra-renal lesions Treatment options and potential management strategies • Role of surgery and/or interventional radiologyImaging surveillance- Current NCI guidelines regarding onset, frequency, and modality

GUEE-89   MRI Of Prostatitis: The Great Mimicker

Participants
Antonio Luna, MD,PhD, Jaen, Spain (*Presenter*) Speaker, General Electric Company

TEACHING POINTS

Review the classification of prostatitis Analyze their different presentations on MRI Provide tips and tricks to differentiate prostatitis and prostate cancer

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Classification of prostatitis -NIH classification -Radiological classification 3. Appearance on multiparametric MRI of prostatitis and its complications -Acute prostatitis +Complications: Abscess -Chronic prostatitis +Glandular atrophy +Postinflammatory scar -Granulomatous prostatitis 4. Prostatitis vs prostatic cancer on mpMRI using PIRADS v2.1 5. Conclusions

GUEE-9   Imaging Of Chronic Urinary Tract Infections

Participants
Mindy Horrow, MD, Philadelphia, Pennsylvania (*Presenter*) Spouse, Employee, Bristol-Myers Squibb Company

TEACHING POINTS

1. Appreciate the variety of underlying medical conditions that may predispose a patient to chronic urinary tract infections 2. Differentiate chronic pyelonephritic scarring and pseudotumors from fetal lobation and true renal masses 3. Demonstrate the typical findings of xanthogranulomatous pyelonephritis including renal enlargement, non-function, dilated calyces with constricted renal pelvis, staghorn calculus and discuss unusual manifestations and variations 4. Relate the pathophysiology of renal TB to the imaging findings of "autonephrectomy", ureteral strictures and bladder wall thickening with decreased capacity 5. Demonstrate ureteral and bladder findings of ureteritis and cystitis cystica and malakoplakia

TABLE OF CONTENTS/OUTLINE

1) Background 2) Chronic pyelonephritic scarring i) CT urography, US ii) Differentiate from fetal lobation iii) Appearance of pseudotumors iv) Association with papillary necrosis 3) Xanthogranulomatous pyelonephritis A) Pathophysiology B) Classic imaging findings 1) Contrast and non-contrast CT 2) Ultrasound 3) Retrograde urethrography C) Complications and variants 1) Extrarenal extension 2) Focal 3) Emphysematous 4) Replacement lipomatosis 4) Chronic inflammatory conditions of ureters and bladder A) Ureteritis cystica B) Cystitis cystica C) Malakoplakia 5) Tuberculosis of the urinary tract A) Renal 1) Granulomatous cavities and calcifications 2) Hydronephrosis 3) Auto nephrectomy- "putty kidney" B) Ureter and Bladder

GUEE-90   Gynecological Malignancy In Pregnancy: What Radiologists Should Know?

Participants
Arthur Uchoa Pacheco, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Malignancy during pregnancy is relatively rare. The overlap of the symptoms of pregnancy and malignant disease, delay the diagnosis, leading to higher stages of disease at diagnosis. Imaging of pregnant patients with cancer is challenging because conflict

between maternal benefit and fetal risk needs to be addressed. There are important considerations and challenges for the radiologist in this context. The purpose of this exhibit is to:1 - Review the general principles and approach to imaging the pregnant patient with suspected malignancy.2- Discuss the imaging strategies for staging, pitfalls and limitations.3- Discuss the effects of pregnancy on tumor biology and presentation of specific tumors.4- Illustrate the cases of gynecological malignancy in pregnancy.

TABLE OF CONTENTS/OUTLINE

- Brief review of the most common tumors in pregnancy with an emphasis on gynecological tumors.- Discussion about the imaging methods that should be used in pregnancy and the timing that it should be made, including follow-up. - Review the imaging protocols and its limitations in pregnancy.- Discuss the relevant information that the radiologist should report for staging.- Selection of interesting cases of gynecological malignancy in pregnancy with it's differential diagnosis.- Discuss safety and strategies of surgical and chemotherapy treatment planning in pregnant patients

GUEE-91   CT Subtraction For Renal Lesion Evaluation

Participants
Veronica Teixeira, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:Describe the protocol and image manipulation to perform a single energy CT subtraction.Show how CT subtraction can aid radiologist detect subtle lesions, whether there is enhancement within a lesion and how it may add value to imaging surveillance after ablation therapy.

TABLE OF CONTENTS/OUTLINE

Introduction presenting literature review in diagnosis of incidental renal lesions.Review imaging-guided percutaneous ablation of renal cancer treatment.Present the challenges of post-ablation follow-up and diagnosis of residual lesions and recurrences after local treatment.CT subtraction protocol. Case-based examples on how CT subtraction can improve radiologist diagnosis of undetermined renal lesions in conventional CT, avoiding further imaging studies.Discuss the perspectives for CT subtraction in a routine.Conclusions and key points to consolidate the acquired knowledge.Bibliographical references.

GUEE-92   Imaging Of Female To Male Transexuals

Participants
Ajay K. Singh, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

There are multiple surgeries that transgender men can undergo, including hysterectomy, oophorectomy, vaginectomy, phalloplasty, metoidioplasty, and scrotoplasty.The surgical techniques are more complicated and therefore not always performed in transgender men. Limited use of surgery translates in to relatively less awareness of the imaging findings by the radiologist.Phalloplasty is a complex procedure with high complication rates, which often requires additional corrective surgery

TABLE OF CONTENTS/OUTLINE

Surgical techniques for transgender men:1. Phalloplasty.2. Metoidioplasty3. Scrotoplasty4. Hysterectomy and oophorectomy.Prevalence of surgery in male versus female transgenderPhalloplasty techniques: Forearm flap, abdominal flap, thigh flap and latissimus dorsi flap: Infection, hematoma and ischemiaSurgical complications

GUEE-93   Testicular Neoplasm: A Systematic Approach For Radiologist

Participants
Laise Silveira, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Describe the epidemiology of the main histological subtypes of testicular tumor.- A brief review of guidelines treatment for testicular tumor.- Discuss the role of image in diagnostic, staging, and follow-up of patients with testicular tumor.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION- Testicular cancer epidemiologyMANAGEMENT OF TESTICULAR CANCER- Management guidelines and algorithmMR AND CT IMAGING TECHNIQUE- MRI protocol- CT protocolIMAGING EVALUATION- Imaging modalities in diagnosis, staging and follow-up- Landing zones for lymphatic spread- What information should be reported in the primary staging and restaging- The role of PET imagingMIMICS- Epidermoid cyst- Testicular hematoma- Testicular Lymphoma- Infectious diseases

GUEE-94   High-Intensity Focused Ultrasound (HIFU) For Prostate Cancer: A Practical Guide To MR Imaging Evaluation

Participants
Laise Silveira, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Describe the current indications of high-intensity focused ultrasound (HIFU).- Briefly review the HIFU procedure techniques- Discuss the expected and unexpected post-HIFU MR imaging findings.

TABLE OF CONTENTS/OUTLINE

INTRODUCTION- Brief overview of high-intensity focused ultrasound (HIFU)- Current clinical applicationsHIFU TECHNIQUE- Description of the procedure- Tissue effects post-HIFU- Limitations of HIFUIMAGING EVALUATION- MRI protocol- Systematic approach to evaluate prostate mpMR imaging- Describe post-HIFU MR imaging findings--- Discuss the importance of DCE--- Review the role of PET-PSMA- Didactic case-based learning

GUEE-95   Multimodality Imaging Review Of Fibroids With Emphasis On Work Up And FIGO Classification

Participants
Mohamed Badawy, BMBCh, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Discuss the epidemiology, risk factors, and clinical manifestations of uterine fibroids • Describe FIGO classification, typical and atypical imaging features of fibroids • Illustrate a recognition approach to reach diagnosis with emphasis on differentiation from its mimics and related pitfalls • Discuss the role of interventional radiology and magnetic resonance imaging in management and follow up of uterine fibroid

TABLE OF CONTENTS/OUTLINE

• Introduction • Risk factors: (race, endocrine factors, medication, obesity, special habits and genetics) • Clinical manifestations: heavy menstrual bleeding, compression symptoms, infertility, torsion) • FIGO classification • Imaging characteristics o X-ray o Ultrasound o CT o MRI: § Protocols (recent guidelines) § Typical features § Atypical features (edema, different types of degeneration, cellular, lipoleiomyoma variants) § Unusual locations: cervix, board ligament, pelvic organs, intravenous, metastasizing, peritoneal, retroperitoneal and parasitic § Role of MR diffusion and ADC images o Hystrosalpingiography • Differential diagnosis such as: leiomyosarcoma, endometrial carcinoma and pitfalls of imaging • Treatment options o Quality of life after various types of management o Magnetic resonance-guided ultrasound and uterine artery embolization (difference of materials used, indication, contraindication, side effects, relation with pregnancy) o Role of MRI after embolization • Conclusion

GUEE-96   Complications In The Pregnancy-puerperal Cycle: A Case Based Review

Participants
Roberto Freitas, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Complications during pregnancy, childbirth and the puerperium are associated with an increase in maternal and perinatal morbidity and mortality. Many of these changes require evaluation using imaging methods. Identifying and characterizing them correctly is essential for proper clinical management. The purpose of this exhibit is: 1. Review the pathophysiology of complications related to the pregnancy-puerperal period and its main risk factors. 2. Review, through cases and illustrations, the main imaging findings present in gestational and puerperal complications, such as hemorrhages, uterus-placental structural alterations and iatrogenic lesions related to the method of delivery. 3. Discuss practical challenges in the image evaluation of complications related to pregnancy and the puerperium.

TABLE OF CONTENTS/OUTLINE

1. General aspects of pregnancy and the puerperium. 2. Risk factors for the development of complications of the pregnancy-puerperal cycle. 3. Pathophysiology of complications related to the pregnancy-puerperal period. 4. Maternal complications in pregnancy and in the early and late puerperium: a case based review. 5. Challenges and limitations in the imaging evaluation of complications of the pregnancy-puerperal cycle. 6. Final considerations.

GUEE-97   Prostatic Cancer Radiopathological Diagnostic Pitfalls. What Are They And How To Approach Them?

Participants
Lidia Alcala, MD, Jaen, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Raise awareness of the potential radio-pathological diagnostic pitfalls in prostatic cancer (PCa).- Review different approaches to these potential errors with integrated PCa diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Introduction2. Pitfalls due to MRI technique. Are there any solutions?3. The PI-RADS v2.1 system: potential problems and how to avoid them.- Peripheral zone.- Transitional zone.- Anterior Fibromuscular Zone.- Central Zone.4. Biopsy sampling errors in PCa diagnosis:- Different biopsy types, their pros and cons: systematic biopsy, cognitive biopsy, target-biopsy (ultrasound-guided biopsy types, in-bore MRI Biopsy).- Approaching difficult locations such as the AFM zone. -Approaching difficult locations such as the AFM zone5. Pathology sample diagnosis: what can go wrong?- Is pathology ready to go digital?-Artificial Intelligence helps pathologists be more sensitive and specific.6. Integrated radiopathological diagnosis: here to help resolve errors in PCa diagnosis.7. Conclusion

GUEE-98   What Did I Epididy'miss'?: Extratesticular Scrotal Masses And Pseudomasses

Awards
Certificate of Merit
Identified for RadioGraphics

Participants
Mathew Smith, MD, Phoenix, Arizona (*Presenter*) Nothing to Disclose

TEACHING POINTS

Imaging plays a crucial role in the work up of painful and painless scrotal masses. Ultrasound is the first-line imaging modality owing to its low cost, high spatial resolution, and wide availability. Magnetic resonance (MR) imaging provides a useful, noninvasive adjunct imaging option. Extratesticular masses lead to significant patient anxiety. Benign and malignant lesions exist in the extratesticular space and are sonographically and MR-apparent. It is important for radiologists to recognize the sonographic appearance of both common and rare extra-testicular masses/pseudo-masses and ascertain when MR may be warranted. It is helpful to organize extra-testicular scrotal masses and pseudo-masses according to their anatomic compartment, namely those that arise form the scrotal wall, the tunica vaginalis, spermatic cord, epididymis, and tunica albuginea.

TABLE OF CONTENTS/OUTLINE

Overview of scrotal anatomy. Overview of extratesticular masses/pseudomasses. Scrotal wall.Hemangioma. Subcutaneous inclusion

Overview of scrotal anatomy Overview of extratesticular masses/pseudomasses Scrotal wall Hemangioma Subcutaneous inclusion cyst Tunica vaginalis Cyst Scrotolith Hernia Hematocele Spermatic cord lipoma varicocele liposarcoma leiomyosarcoma Epididymis Head Leiomyoma Papillary cystadenoma Spermatocele Body Cyst Epididymitis (sarcoid/nodosa) Lymphoma Tail Adenomatoid tumor Tuberculoid epididymitis Tunica albuginea Fibrous pseudotumor Other Epidermoid Polyorchidism

GUEE-99   The Evaluation Of Obstructive Renal Disease By MRI- The Wonders Of A Static MR Urogram

Participants
Denver Pinto, MD, Miami, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

At the end of this exhibit the reader should be able to* Identify classic MR Urogram appearances of obstructive uropathy due to intraluminal obstruction, obstruction due to mural / ureteral wall involvement and extrinsic compression* Recognize that papillary necrosis can be imaged without administration of intravenous contrast* Be able to identify mimics like vascular impressions and air foci as a cause of diagnostic error

TABLE OF CONTENTS/OUTLINE

Utility of MR UrogramBenefits of MR URogram - using intrinsic contrast of the urine, no need for intravenous contrastCase discussion with imaging findings ofAnatomical variants like malrotated kidneys, ectopic location, duplex kidneys and ectopic ureteral insertionsIntraluminal obstruction: Papillary necrosis, Hematoma, Calculi, TuberculosisMural Obstruction Ureteral stricture, PUJ obstruction, Radiation fibrosis, Urethral obstruction, ureteric mass, Primary megaureter, Ureterocoele.Extrinsic compression: Mass lesions, Genitourinary prolapse, Retroperitoneal fibrosis, metastases, collections.Imaging in papillary necrosis and infections including TuberculosisConclusion statement regarding how MR Urogram is a superior modality that can be used safely in patients with renal dysfunction

Sub-Events

ROEE-1   Role Of MRI In Work-up And Radiation Therapy Treatment Of Endometrial Cancer

Participants
Edina Wang, MD, Washington, Dist. of Columbia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Discuss the role of obtaining a pelvic MRI in endometrial cancer 2. Discuss the use of pelvic MRI in radiation treatment planning for inoperable endometrial cancer 3. Discuss how MRI findings affect the treatment planning for radiation therapy 4. At the completion of this course, the participant will be able to: -Understand the role of pelvic MRI in endometrial cancer-Understand how findings on MRI may affect target delineation and radiation treatment for endometrial cancer

TABLE OF CONTENTS/OUTLINE

1. Evaluation of the role of pelvic MRI in endometrial cancer work-up based on evidence-based literature 2. Overview of treatment planning considerations when using primary CT simulation with secondary MRI for inoperable endometrial cancer 3. Segmentation considerations when using MRI in endometrial cancer radiation therapy planning 4. Summary

ROEE-10   The Application Of 3D Printing Personalized Surgical Guide Plate In Gynecologic Brachytherapy

Participants
Ya Li I, Zhengzhou, China (*Presenter*) Nothing to Disclose

TEACHING POINTS

Step 1 The basic workflow of a 3D printing personalized surgical guide plate in gynecologic brachytherapy. Step 2 Segmentation imaging software to generate the target anatomic structures. 2.1 Image acquisition Transferring the CT images to the post-processing workstation. 2.2 Patient-specific Surgical guide plate design 2.2-4 Anatomy segmentation- skeleton, vascular, skin, and tumor structures using Region Growing technique and 3D software mimics. 2.5 Digital imaging modeling. Step 3 Learn how to print a 3D printing product, including the selection of 3D printer, material, parameters etc. 3.1 Equipment of Medical 3D Printing 3.2 3D printing Products 3.3Clinical application of 3D printing

TABLE OF CONTENTS/OUTLINE

Learning objective Step 1 Step2 Step 3

ROEE-2   Collateral Damage: Radiation Therapy-related Changes And Complications In Neuroradiology

Participants
Jeet Patel, MD, St. Augustine, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Radiation therapy is an important modality of the multidisciplinary approach to treatment of neoplasms of the CNS and head and neck. Different forms encountered in neuroimaging include stereotactic radiosurgery, intensity-modulated radiation therapy, whole brain radiation therapy, and proton therapy. 2) Radiation-induced changes range from expected commonplace pathology (e.g. oral mucositis) to severe complications that might require surgical management (e.g. osteoradionecrosis). 3) The radiologist plays an important role in monitoring for and diagnosing complications of radiation therapy on surveillance imaging.

TABLE OF CONTENTS/OUTLINE

1) Mechanism of radiation-induced injury. 2) Overview of radiation therapy modalities. 3) Radiation necrosis: Brain; spinal cord. 4) Radiation-induced vasculopathy: Capillary telangiectasia / cavernous malformation; Moya-Moya syndrome; Mineralizing microangiopathy; Accelerated large vessel atherosclerosis. 5) Radiation-induced optic neuropathy. 6) Leukoencephalopathy. 7) Radiation-induced mucositis. 8) Osteoradionecrosis. 9) Radiation-induced tumors: Meningioma; Sarcoma

ROEE-3   Radiomics And Artificial Intelligence To Predict Response To Chemotherapy In Primary Brain Tumors

Participants
Edward Florez, PhD, Jackson, Mississippi (*Presenter*) Nothing to Disclose

TEACHING POINTS

• To understand the principles and different MRI pulse sequences used in the diagnosis of primary brain tumors. • To discuss the role of radiomics as quantitative biomarkers in the process of identification and characterization of brain tumors, as well as in the evaluation of the response to chemotherapy. • To review the best applications of the use of radiomics features together with artificial intelligence (AI) models in the evaluation and prediction of tumor response to chemotherapy, particularly anti-angiogenic

therapies. • To review response criteria in oncologic neuroimaging.

Glioblastoma multiforme (GBM) is the most frequent and aggressive primary tumor of the central nervous system with a dismal prognosis (median progression-free survival [PFS] = 6.9 months and median overall survival [OS] = 14.2 months) with limited treatment options. Currently, the gold standard therapy is the Stupp protocol consisting of surgical resection (but only possible in 40% to 45% of patients) and chemotherapy with temozolomide. In addition, MRI is the standard of care to monitor brain tumors. We will discuss the role of radiomics and AI as crucial factors to quantify initial changes in multiparametric MRI of primary brain tumor to predict PFS as well as response in recurrent GBM patients eligible for second-line chemotherapy.

ROEE-4   Abbreviated MRI Protocol For Brachytherapy Of The Cervical Cancer: Case-based Review With Serial Follow-up

Participants
Jigarkumar Rangunwala, MD, Flowood, Mississippi (*Presenter*) Nothing to Disclose

TEACHING POINTS

• To describe an optimized abbreviated magnetic resonance imaging (MRI) protocol for brachytherapy cervical cancer planning and follow up • To review the latest updates on cervical cancer staging according to the FIGO classification • To comprehend the brachytherapy procedure technique, appropriate applicator positioning and dosing selection • To recognize the role of MRI and PET-CT in cervical cancer staging, brachytherapy planning, applicator positioning, complication assessment and surveillance

TABLE OF CONTENTS/OUTLINE

MRI has an established role in diagnosis, characterization, staging, treatment guidance and surveillance of cervical cancer. Moreover, given its excellent soft tissue contrast resolution, MRI is indispensable in brachytherapy planning, post implantation assessment, and dose estimation. In this presentation we will review the imaging features of cervical cancer staging and corresponding treatment selection. We will describe the essential components of MRI assessment in brachytherapy planning and monitoring including a structured report template. We will provide a case-based review covering a wide range of presentations on MRI and PET-CT including post radiotherapy complications.

ROEE-5   Expect The Best, Prepare For The Worst: Unusual Complications Of Immunotherapy In Oncological Patients.

Participants
Ines Podadera, Pilar, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review the interaction between the immune system and cancer development. To assess the different immunological therapies available to avoid cancer progression and its mechanism of action. To evaluate unusual immune-related adverse effects and its most relevant radiological findings. To emphasize the radiologist role in the treatment of oncological patients with immunotherapy and the importance of interdisciplinary work.

TABLE OF CONTENTS/OUTLINE

Introduction Immunoediting Cancer immunotherapy Adverse effects and its radiological findings Differential diagnosis Conclusion

ROEE-6   Is It Treatment Related Change Or Disease Progression? - Looking Beyond Size With Diffusion And Perfusion Imaging

Awards
Cum Laude

Participants
Shivaprakash Hiremath, DMRD,FRCR, Toronto, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

The teaching points include: • Review the basic concepts of radiotherapy planning and treatment • Describe the early and delayed imaging changes based on the duration post radiotherapy • Illustrate the role of diffusion and perfusion imaging in differentiating treatment-related changes and disease progression in monitoring a glioma and metastatic tumor. • Depict the common presentations post-therapy including pseudoresponse, pseudoprogression, radiation necrosis, and tumor recurrence along with uncommon manifestations such as peri-ictal pseudoprogression (PIPG), stroke-like migraine attacks after radiation therapy (SMART) and post-radiation vasculopathy

TABLE OF CONTENTS/OUTLINE

Ø Importance of the initial radiation planning treatment map for the interpretation of the subsequent imaging Ø Radiation associated changes mimicking tumor progression Limitations of RANO criteria in the assessment of small lesions (<1cm) and non-enhancing lesion Imaging pattern on conventional and advanced MR imaging of: o Lesions seen in the acute to subacute period following radation § Pseudoprogression § Pseudoresponse § Radiation necrosis § Tumor recurrence o Lesions seen in the delayed period following radiation § Benign punctate enhancement § Peri-ictal pseudoprogression § Stroke-like migraine attacks after radiation therapy (SMART) Ø Flow chart for assessment of a new lesion seen following radiation treatment using a combined approach of conventional and advanced MR imaging

ROEE-7   Imaging Features In The Liver Post Stereotactic Body Radiation Therapy (SBRT)

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Patrick Navin, MBBCh,MRCPI, Rochester, Minnesota (*Presenter*) Nothing to Disclose

Learn the technique of SBRT delivery to the liver and indications for treatment. Understand post SBRT changes in the tumor and surround liver parenchyma. How to evaluate tumor response post SBRT delivery and avoid pitfalls in assessment Understand common complications following SBRT.

TABLE OF CONTENTS/OUTLINE

1. SBRT technique Discuss evolution of SBRT as a viable treatment option for liver masses. Discuss indications and fundamentals of radiation delivery Patient selection Simulation, motion management and target delineation Dose prescription and fractionation Treatment planning, delivery Types X-ray Photon beam 2. Post SBRT changes in liver tumors and Assessment of tumor response Response of liver tumors to SBRT- how is it different from other treatments Typical features on imaging (CT/MRI/PET) which predict tumor response Response assessment tools and their limitations (mRECIST, EASL, LIRADS) 3. Parenchymal changes post SBRT Evolution of typical post SBRT changes on imaging - acute, subacute and chronic Discuss potential complications and related imaging features o Radiation Induced Liver Disease (RILD) o Prediction of RILD i. Child-Pugh score, MELD score ii. Imaging 1. Hepatocellular contrast 2. MR Elastography Injury to surrounding structures (radiation enteritis, radiation pneumonitis)

ROEE-8   Endometrial Cancer Revisited: What Radiologists Should Know

Participants
Giovanna Torre, Sao paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

I. Review of endometrial cancer histopathological subtypes and integrated genomic characterizationII. Understand current concepts of the prognosis of endometrial cancer and its clinical impactIII. Describe our institutional protocol of MR imaging acquisition for endometrial cancerIV. Discuss the most important imaging features to report in preoperative staging of endometrial cancerV. Review the role of functional imaging in follow-up and detection of recurrent disease

TABLE OF CONTENTS/OUTLINE

INTRODUCTION- Brief discussion of epidemiologyMR IMAGING TECHNIQUE- Preparation- MRI protocol and how to optimize itMANAGEMENT OF ENDOMETRIAL CANCER- Histological type- Integrated genomic characterization- FIGO classification- Treatment guidelines and algorithm- Discuss fertility-sparing in low-grade tumorsIMAGING EVALUATION- Systematic approach to evaluate MR imaging for endometrial cancer (pre- and post-treatment)- Didactic case-based approach for FIGO classification- Pitfalls, challenges, and how to overcome theseFUTURE DIRECTIONS- PET imaging- Radiomics

ROEE-9-HC   What Information Can We Derive From In-vivo Rectum Dose Measurement During RALS Irradiation?

Participants
Hiroaki Hayashi, PhD, Kanazawa, Japan (*Presenter*) Research collaboration, Meditec Japan Co., Ltd;Research collaboration, JOB Corporation

TEACHING POINTS

1. In radiation therapy, it is unlikely that the patient will stay in their original position during finalization of their treatment planning. Therefore, we should evaluate the effects of movement.2. During RALS irradiation for the cervical cancer treatment, we measured the rectum dose which is known as OAR using our novel OSL dosimeter.3. When performing in-vivo measurement of 64 patients, 21 cases (33%) of planned dose were not in agreement with the experimental data with the differences of approx. 10%. The cause of the difference was evaluated as due to incomplete medical imaging such as (a) patient movement, (b) presence of intestinal gas, and (c) artifacts.4. For general cases of the other 43 patients, the measured values were in good agreement with the planned values.5. Medically dangerous levels of exposure are not performed, therefore the traditional RALS irradiation method can be achieved at low-cost and simple systems that can be said to be robust.

TABLE OF CONTENTS/OUTLINE

Although dose control is very important in radiotherapy, most evaluations are static phantom studies, and there are only a few cases of actual dose measurement. Recently, we made a novel rectum dosimeter using OSL dosimeter and established the manufacturing method and dose calibration method. In this presentation, we will demonstrate in-vivo measurement of rectum dose, and analyze the robustness of the traditional irradiation method without using a dynamic tracking function.

Abstract Archives of the RSNA, 2021

Sub-Events

MSEE-1   Deep Gluteal Syndrome: Dark Corner

Participants
Rodrigo Loto, MD, Rosario, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

Learning objectives - To describe the anatomy and CT/MRI appearance of the subgluteal space (SS). - To review known etiologies of deep gluteal syndrome and introduce new ones. - To describe the management of pathologic conditions of the SS and the role of the radiologist in the diagnosis, treatment and postoperative evaluation.

TABLE OF CONTENTS/OUTLINE

By 1947 the terminology and clinical description of piriformis syndrome was established in the medical literatura.Research in hip kinematics has identified a number of areas within the deep gluteal space where the sciatic nerve may be susceptible to entrapment. Although the designation piriformis syndrome is still used, these observations lead to the introduction of the term deep gluteal syndrome (DGS) which better distinguishes the pathophysiology and clinical symptoms of hip and buttocks pain as well as radicular pain caused by non-discogenic and extrapelvic entrapment of the sciatic nerve.A broad spectrum of known pathologies may be located nonspecifically in the subgluteal space and can therefore also trigger DGS. these can be classified as traumatic, iatrogenic, inflammatory/infectious, vascular and tumor pseudotumors.The present communication is interesting given the low frequency of cases.

MSEE-10   Multimodality Imaging In Paraneoplastic Syndromes And Related Neoplasms

Awards
Certificate of Merit

Participants
Prabhakar Rajiah, MD, FRCR, Rochester, Minnesota (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review the spectrum of paraneoplastic syndromes (PNS)2. To review tumors associated with common PNS3. To discuss an approach for the imaging of PNS4. To illustrate the imaging appearances of PNS and the associated tumors

TABLE OF CONTENTS/OUTLINE

Paraneoplastic syndromes- DefinitionImaging- Radiograph, ultrasound, fluoroscopy, whole body CT, MRI, PET/CT, bone scan, angiographyDiscussion and illustration of the following PNS. The most common tumor associated with these syndromes is listed in parenthesis.A. Endocrine-SIADH (lung)-Ectopic ACTH (lung)-Cushing's (lung)-Hypercalcemia (Epithelial tumors)-Hypoglycemia (Mesothelioma)-Gonadotrophin excess- (Germ cell)-Oncogenic osteomalacia (Fibroma)B. Musculoskeletal-Hypertrophic osteoarthropathy (Lung)-Dermatomyostiis (Lung)C. Hematological-Venous thromboembolism (Pancreas)-Trosseau's syndrome (Lung)-Autoimmune hemolytic anemia (lymphoma)-Migratory thrombophlebitis (pancreas)-Idiopathic thrombocytopenic purpura (Lung)- Erythrocytosis (RCC)-Marantic endocarditis (Mucinous adenocarcinoma)-Giant cell myocarditis (germ cell)D. Neurological-Limbic encephalitis (Lung)-Myasthenia gravis (Thymoma)-Cerebellar degeneration (Lung)-Brainstem encephalitis-Lambert-Eaton syndrome (Squamous)-Myelopathy/neuropathyE. Dermatological-Necrolytic migratory erythema (Glucagonoma)-Seborrheic keratoses(Lymphoma)- Poyphyria cutanea tarda (HCC)Diagnostic algorithm and approach

MSEE-100   Vascular Injuries In Blunt Torso Trauma. Image-based Classification

Participants
Gorka Arenaza Choperena, San Sebastian, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

-To review the traumatic vascular injury classification with emphasis on imaging findings -To present these injuries in different organs that are part of the torso. showing some specific characteristics for each organ-To convey the importance of detecting them to avoid complications -To show several cases of vascular injuries involving the torso and discuss some teach key points to achieve the most accurate diagnosis

TABLE OF CONTENTS/OUTLINE

Patients with multiple trauma can present a wide spectrum of injuries. Most of them can be treated conservatively. Therefore, it is key to identify those injuries that require intervention, such as vascular injuries, which are associated with hypotensive shock and higher mortality rates. We propose an image-based classification for vascular injuries in which different injuries can appear with the same imaging features and, also, the same condition can appear with different image findings. We present several vascular injuries

in great vessels, solid viscera, mesentery and pelvis: -Active bleeding -Pseudoaneurysm -Occlusion-Intimal tear/dissection -AV fistula -Intramural hematoaAlso, indirect signs that can help to identify vascular injuries are presented:-Hematoma -Perivascular stranding -Distal non-enhancement-Vasospasm

MSEE-101   Modifiers In Spine Trauma Reporting

Participants
Meena Nedunchelian, MBBS, Coimbatore, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To describe the various imaging findings in spine trauma, newly categorized as modifying factors in the AO spine trauma classification system.2. Discuss the clinical and surgical relevance of these modifiers in patient management using multimodality imaging in a case-based approach.

TABLE OF CONTENTS/OUTLINE

Multimodality imaging plays a crucial role in the management decision for spine trauma. AO Spine classification system is widely accepted and is based on CT scan, although MRI is performed in patients with neurological deficits. In the current AO Spine Classification system, spinal injuries in each segment are classified mainly as axial compression, distraction and translation injuries. It also includes clinical and imaging modifiers for each segment, denoted by the letter M followed by a number. The presence of modifiers changes management. Examples of specific modifiers in the upper cervical segment include mid substance transverse ligament tear and type 2 odontoid fractures; however vertebral artery injury, critical disc herniation with bilateral locked facets in the sub axial spine. Rigid spine and metabolic diseases are thoracolumbar modifiers whereas SI joint disruption and pelvic-ring injuries are modifiers in the sacral segment. Summary:Radiologists should be aware of these modifiers to guide optimal management. We describe the various modifying factors in a case based approach with a checklist for each segment.

MSEE-102   To Err Is Human: Comprehending And Learning From My Mistakes-The Viewpoint Of A Resident Trainee In Radiology

Participants
Ankit Arora, MBBS, Jodhpur, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

• To be aware of the difference between error and bias.• To know about the various errors and bias in radiology , and the commonly followed Kim-Mansfield classification of radiological errors.• To understand the workflow of radiology reporting , the final communication of report with the clinician and its impact on patient management.• To understand the human cognition behind reporting and the concept of Type 1 and Type 2 thinking• Comprehending each error with the help of real-life case examples.• How to avoid errors

TABLE OF CONTENTS/OUTLINE

• Introduction and Brief History• Error and Bias• Kim Mansfield radiology error classificationo Type 1 Error: Complacencyo Type 2 Error: Faulty Reasoningo Type 3 Error: Lack of Knowledgeo Type 4 Error: Under-readingo Type 5 Error: Poor Communicationo Type 6 Error: Techniqueo Type 7 Error: Prior Examinationo Type 8 Error: Historyo Type 9 Error: Locationo Type 10 Error: Satisfaction of searcho Type 11 Error: Complicationo Type 12 Error: Satisfaction of Report• Workflow of Radiology Reporting • Human cognition in reporting• Case examples of each error and the learning points from the same.• How to avoid mistakeso Structured reportingo Computer aided detection

MSEE-103   MSK Imaging Manifestations Of Recreational Drug Use

Awards
Certificate of Merit

Participants
Joshua Gu, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Recreational drug use is an increasing problem worldwide, contributing to significant morbidity and mortality, as well as economic impact. 2. Recreational drug use may lead to numerous acute and chronic health consequences, including infections of the musculoskeletal system. 3. Clinical presentations are challenging. Imaging provides depth and severity of the infection to allow for appropriate diagnosis and treatment of musculoskeletal infections related to recreational drug use. 4. Early diagnosis of pathologies such as necrotizing fasciitis and septic arthritis impacts morbidity and mortality. 5. Knowledge of advanced MR imaging techniques (DWI) is key in solving complex cases.

TABLE OF CONTENTS/OUTLINE

1. Status of worldwide recreational drug and recent trends. Explore infections directly and indirectly related to drug use. 2. Description of various imaging modalities available to the radiologist, and their advantages and disadvantages. 3. Discussion of MRI protocols for evaluating disease process and their respective advantages. Utility of diffusion weighted imaging.4. Multimodal demonstration of disease processes, including: Cellulitis, Abscess, Pyomyositis, Necrotizing fasciitis, Osteomyelitis Tenosynovitis, Septic arthritis, Discitis, Mycotic aneurysm, Chondritis, Granuloma5. Image guided management of drug related disease processes.6. Pitfalls. 7. Summary

MSEE-104   Imaging Of Acute Mesenteric Pathologies

Participants
Borna Dabiri, MD, PhD, Milton, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

• - Review of the anatomy of the mesentery and its relationship to other abdominopelvic structures. • - Briefly discuss the MDCT protocols used in the emergency setting and highlight the role of Dual Energy CT (DECT). • - Review the imaging findings of acute mesenteric pathologies classified as primary and secondary entities with case examples. • - Underscore mesenteric pathologies and

their pattern of involvement of the adjacent abdominopelvic structures.

TABLE OF CONTENTS/OUTLINE

• - Brief overview of the anatomy of the mesentery and its relationship to adjacent structures as well as its role in the inflammatory and immune response. • - Discuss the most common imaging protocols used to diagnose mesentery pathologies in the acute setting, with emphasis on the role of DECT. • - Highlight examples of primary mesenteric pathologies o Acute mesenteric ischemia o Internal hernia o Volvulus o Traumatic mesenteric injury o Epiploic appendagitis o Omental infarct o Idiopathic sclerosing mesenteritis o Primary mesenteric tumors • - Highlight examples of secondary mesenteric pathologies o Infection (complication from acute appendicitis) o Inflammation (Crohn's disease) o Neoplasms (carcinomatosis; ruptured mucocele) o Endometriosis o Hepatic congestion o Secondary sclerosing mesenteritis

MSEE-105   Imaging Of The Multi-organ Diabetic Complications

Participants
Madiha Aslam, MBBS, Darby, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

Diabetes mellitus is a commonest endocrine disorder with multiple devastating end organ complications. Radiologists play decisive role by making an early diagnosis and guiding further management of acute diabetic complications with increased morbidity and mortality like acute limb ischemia associated with PAD and especially due to increased risk of infection like emphysematous cholecystitis, emphysematous pyelonephritis, and Fournier's gangrene. We will provide a pictorial review of the usual and unusual, acute and chronic multi-organ diabetic complications.

TABLE OF CONTENTS/OUTLINE

Diabetes mellitus is a chronic epidemic disease and its prevalence is expected to increase by 54% by 2030. It results in a variety of multi-organ, clinically important complications, which account for major morbidity and mortality associated with this disease. Radiological manifestations of diabetic complication are proportional to the duration of the disease e.g. micorangiopathy and macroangiopathy complications, however increased risk of infection in diabetics result in some acute complications with increased mortality like emphysematous cholecystitis, emphysematous pyelonephritis/pyelitis/cystitis, acute osteomyelitis, Fournier gangrene. Sound knowledge of the imaging characteristics of multi-organ acute and chronic diabetic complications is of paramount importance for accurate management of diabetic patients. Using several imaging examples we will present wide variety of head to toe diabetic complications.

MSEE-106   Iron Man's Face: MDCT Evaluation In Post-operative Traumatic Facial Bone Injuries: Imaging Features Of Satisfactory Repair And Related Complications

Participants
Gaurav Chauhan, MD, Coimbatore, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

• To describe most common facial bone fractures which warrant surgical intervention. • To illustrate the imaging findings indicating the satisfactory placement of post-operative stabilizing hardware and various mesh used in facial bone injuries. • To familiarize the reader about immediate and delayed post-operative complications and their clinical and imaging features.

TABLE OF CONTENTS/OUTLINE

Facial bone fracture repair is one of the commonest facial surgeries. There is a spectrum of orthopedic hardware and various types of mesh used in facial bone fracture repair, both for functional and cosmetic purposes. Although clinical findings and radiographs are adequate in a post-operative follow-up, there are certain complications for which MDCT plays a crucial role owing to its superior resolution of the intricate details. The radiologist should be aware of the imaging features indicating the satisfactory facial bone repair using the hardware or the mesh. Knowledge of the clinical features and chronology of the occurrence of various complications helps in accurate diagnosis. Based on the facial buttress system and surgical intervention in each of the station, contributing imaging features will be described along with complications.SUMMARY This pictorial review provides comprehensive knowledge on acceptable outcome and complications following facial bone fracture repair by clinical and radiological findings.

MSEE-107   Non-traumatic Gastrointestinal Emergency Conditions That A Radiology Resident Must Identify - A Hot Seat Presentation!

Participants
Denver Pinto, MD, Miami, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

After completion of this exhibit you should be able:*To identify life threatening gastro-intestinal conditions in the ER reading room and discuss the imaging findings*To understand the epidemiology, evaluation and management of these patients.*To recognize indirect imaging signs of life threatening conditions

TABLE OF CONTENTS/OUTLINE

ObjectivesEpidemiology of life threatening gastro-intestinal conditions seen in the ER reading room.The cases will be presented in a quiz format. Key imaging findings, pearls and differential diagnostic points will be highlighted in each case discussion. The list of cases and key findings include* Aortic aneurysm with rupture into the lower esophagus causing massive gastrointestinal hemorrhage - no pleural effusion, exact site of hemorrhage could not be demonstrated.* Focal intraluminal bleeding branch of gastroduodenal artery - extremely subtle and hard to pick finding that was prospectively picked up.* Bleeding gastroduodenal artery pseudo-aneursym - secondary to pancreatitis* Peptic ulceration with bleed - hard to pick focus of bleed that was prospectively picked up.* High grade portal vein stenosis with variceal bleed - one of the causes of elevated portal venous pressure* Boerhaave syndrome* Oesophageal neoplasm, Gastric neoplasm with bleed - important and common cause of bleed* Diffuse esophageal spasm* Midgut and gastric volvulusImpending life threatening hemorrhage* Duodenal ulcer almost eroding into the gastroduodenal artery - impending massive gastrointestinal hemorrhage

MSEE-108   Next Generation Imaging For Evaluating Advanced Prostate Cancer: WBMRI/PSMA PET

Complementarity

Participants
Andra Curcean, MD, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

Next generation imaging (NGI) including whole-body MRI (WBMRI) and PSMA PET/CT has superior accuracy for advanced prostate cancer (APC) compared with standard imaging (CT and bone scan) and is increasingly used in clinical practice. MET-RADS-P for WBMRI and PSMA PET progression (PPP) reporting criteria have been recently published. In parallel, there is emerging evidence of complementarity between NGI techniques that is addressing: a. technique-specific limitations b. tumour heterogeneity c. disease response challenges and d. early detection of complications.

TABLE OF CONTENTS/OUTLINE

1. Introduction a. Definition of APC disease states b. Use of next generation imaging (WBMRI and PSMA PET-CT) in APC 2. Limitations of PSMA PET-CT a. Tracer urinary excretion masking disease b. False positive uptake benign bone marrow lesions c. False positive uptake benign soft tissue lesions (nodes/hemangiomas) d. PSMA expression heterogeneity e. FLARE phenomenon f. Malignant spinal cord compression 3. Potential limitations of WBMRI a. Poor specificity in nodal disease b. Low sensitivity in setting of early biochemical relapse c. Subcentimetre lung metastases d. Subcentimetre rib lesions e. Suboptimal image quality due to artefacts 4. How to optimally combine NGI for evaluating patients with advanced prostate cancer according to disease states

MSEE-109   The Role Of Radiologists In Reporting Non Accidental Injuries In Elderly

Awards
Identified for RadioGraphics

Participants
Mohamed Badawy, BMBCh, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

- The unrecognized detection of elder abuse despite its wide prevalence in the US - What radiologist should report - Illustrating the red flags for elder abuse from patients' history and imaging - Future directions for the radiologist training and imaging correlations with elder abuse

TABLE OF CONTENTS/OUTLINE

- Introduction - Prevalence of elder abuse - Radiologist role in non-accidental injuries - Challenges in diagnosis compared to the pediatrics population - Common site of injuries o upper extremity as axilla lateral aspect of the arm (most common) o face or neck (2nd most common) o skull/ brain o Torso o Lower extremity - Red flags in patient history o Injury occurred > 24 hour prior to the presentation o Dementia o Multiple ED visit for the same complaint - Factors increase suspicion from imaging review o Site and type of fractures § Multiple fractures with or without head trauma § Ribs (upper, posterior) § Distal Ulna § Maxillofacial area § Spiral fracture o Different healing stages of patent's injury o Hematomas § Small bowel hematomas § Multiple subdural hematomas o Unusual findings for the mechanism of injuries narrated in the history (e.g fall) o Brain volume loss due to malnutrition o Decubitus ulcer - How Radiologist- ED communication - What radiologist should know about their elder patient o Functional capability o Social circumstances o Mechanism of injury - Future directions o for radiologist training o Large studies that identify the imaging correlates for elder abuse - Conclusion

MSEE-11   Body MRI Lessons Learned: Pearls And Pitfalls From Training To Remember As An Attending

Awards
Identified for RadioGraphics

Participants
Anup Shetty, MD, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

TEACHING POINTS

This exhibit is targeted towards resident and fellows, as a solicited topic of interest from the RadioGraphics Editorial Board, with the following goals:1. Discuss nuances and subtleties in body MRI sequences, physics, protocols, search patterns, interpretive pitfalls, and problem solving from the perspective of the trainee2. Show the key teaching points for these concepts through a series of illustrative cases

TABLE OF CONTENTS/OUTLINE

1. Protocols and Contrast: Liver contrast timing, algorithm and considerations; contrast timing; Eovist nuances2. Artifacts as Problems: Misregistration between free-breathing sequences and breath-hold sequences; parallel imaging artifact; Subtraction misregistration; "bouncy" images on interleaved versus respiratory-navigated; susceptibility mimicking pathology3. Artifacts as Solutions: THID as a clue; chemical shift sequences for hemosiderin; the value of India ink4. Fat as friend and foe: Background liver steatosis and lesion assessment; DIXON for bone evaluation; intrapancreatic fat as an IPMN fooler; fat-containing adrenal nodules; infiltrative steatohepatitis5. Moving patient techniques: Compressed sensing; radial acquisition; CAIPIRINHA; respiratory gating6. Search Pattern/Interpretive Tips: How to use clinical history; value of reviewing prior imaging; minimizing errors of detection and interpretation; optimal use of DWI7. Blind spots/pain points: Body wall; peritoneum; bones; lower thorax; liver left lateral section

MSEE-110   Imaging Of Immune Related Adverse Effects Emergencies From Head To Toe.

Participants
Felipe Amorim SR, MD, Salvador, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review the most common immune-related adverse effects of immune checkpoint inhibitors for different types of cancer at the emergency department, classified by their system of origin. To propose a diagnostic workflow based on initial clinical presentation. To discuss the role of imaging evaluation in the initial approach of patients with suspected toxicity syndromes. To describe and illustrate the main imaging features of each immune-related adverse effect by organ. To discuss the essential information of the

radiologic report in the emergency setting.

TABLE OF CONTENTS/OUTLINE

1. Major toxicity syndromes related to immune checkpoint inhibitors by organic system: Central nervous system: encephalitis, meningitis and transverse myelitis. Head and neck: uveitis. Endocrine system: hypophysitis. Cardiovascular system: myocarditis, vasculitis and acute coronary syndrome. Pulmonary system: pneumonitis. Musculoskeletal system: inflammatory arthritis and myositis. Gastrointestinal system: colitis, pancreatitis and hepatitis. 2. The role of different imaging techniques (US/CT/MRI/PET-CT) in evaluating immuno-related urgencies and main radiologic findings of: Ultrasound/ echocardiogram Computed tomography (CT) Magnetic Resonance Imaging (MRI) PET/CT 3. Radiology report structure in the emergency department. Oncologic background: tumor type, immune checkpoint inhibitor type and dates "Red flag" imaging findings ComparisonFollow-up

MSEE-111   What Else Can Go Wrong? Multisystemic Complications In Patients With Covid-19

Awards
Certificate of Merit

Participants
Marcus Vinicius Silva Ferreira, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

? Review the pathophysiology of SARS-CoV-2 infection and its impact on different systems ? Recognize multisystemic complications related to Covid-19 disease ? Understand the role of different imaging modalities in the diagnostic approach ? Recognize complications due to invasive and noninvasive treatment modalities ? Be familiar with possible sequelae related to severe disease or prolonged hospital stay

TABLE OF CONTENTS/OUTLINE

INTRODUCTION- Epidemiology- Mechanisms of disease / pathologic pathwaysPULMONARY COMPLICATIONS- Exacerbated inflammatory response- Thrombotic and embolic complications- Treatment-related complications CARDIAC COMPLICATIONS-Exacerbated inflammatory response- Thrombotic complicationsABDOMINAL COMPLICATIONS- Exacerbated inflammatory response on parenchymatous viscera- Hypoxic-ischemic complicationsNEUROLOGIC COMPLICATIONS- Cerebrovascular events- Diffuse leukoencephalopathy and microhemorrhages- Treatment-related complications MUSCULOSKELETAL COMPLICATIONS- Peripheral neuropathies- Hemorrhagic complicationsSEQUELAE POST SEVERE INFECTION- Late post-inflammatory findings on lung parenchyma-Persistent symptoms after infection resolution- Chronic sequelae due to prolonged hospitalization

MSEE-112   What Is This? - Imaging Of Unusual Complications In An Oncologic Hospital

Participants
Andre De Freitas Secaf, MD, Barretos, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Oncological patients can present several clinical and surgical complications that may or may not be associated with the underlying disease, as well as complications due to invasive procedures. These may result in a myriad of imaging findings which, if misinterpreted, can significantly affect clinical outcome. Therefore, imaging plays a crucial role both in the initial diagnosis and in the therapeutic management of these acute conditions. The objectives of this Educational Exhibition are to describe and discuss the radiological findings of patients with complications related to treatment of cancer, whether invasive or not; to make radiologists aware of these findings, deemed uncommon even in large cancer centers; and to perform a literature review related to each reported complication, through a series of cases. Radiologists must be familiar with these diagnoses, as it may prove helpful when interpreting challenging imaging findings in the acute setting at cancer treatment centers.

TABLE OF CONTENTS/OUTLINE

1. Introduction; 2. Case reports of unusual oncology complications such as intestinal pneumatosis due to esophageal mucositis; infected liver metastases; gas in the portomesenteric system after rectal endoprosthesis; fistula between the colon and L5-S1 disc space; migrated esophageal stent evolving with discitis; jejunogastric intussusception after abdominal surgery; radiation-induced large-vessel arteritis; fracture and migration of a venous catheter; 3. Discussion.

MSEE-113   Photon Counting Detector CT A New Powerful Addon Tool To Forensic Autopsy.

Participants
Anders Persson, MD, PhD, Linkoping, Sweden (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of these lecture is to present the potential superiority of new high resolution photon counting detector prototype CT (PCD-CT) in comparison with a standard CT (EID-CT) for postmortem imaging.The lecture will present the new technology and image examples from several forensic cases were PCD-CT may contribute important new information in cases such as identifications, battered children, gunshot wounds, traffic accidents, and air embolisms.

TABLE OF CONTENTS/OUTLINE

Photon Counting Detector CT has many advantages such as significantly higher resolution and reduced blooming artifacts from metal. K-edge imaging provides potential for tissue quantification and accurate volume determinations of foreign bodies such as bullets and other non-body materials. The technology is currently only available for research.We have used a prototype PCD-CT system from Siemens (PCD-CT; SOMATOM CounT Plus; Siemens Healthineers, Forchheim, Germany) since more that a year for postmortem imaging. The PCD-CT has been used in comparison with an energy integrating detector CT (EID-CT; SOMATOM Force; Siemens Healthineers, Forchheim, Germany) for forensic examinations.The PCD-CT allows visualisation of implant-bone interface and non-body material with higher resolution. It also provides superior delineation of trabecular bone compared to conventional CT due to smaller detector elements allowing for thinner slice thickness and a large image matrix of 2048 x 2048 pixels and 9 microns resolution.

MSEE-114   Interpreting Whole Body MRI In Oncological Imaging: A How-to Guide For The Novice

Participants
Naami McAddy, MBBS, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

There are recognised roles for whole-body diffusion-weighted MRI (WB-DWI-MRI) in staging and response assessment, especially in tumours where bone disease predominates.The combination of DWI and Dixon derived T1W relative fat fraction sequences allows differentiation between normal bone marrow, active disease and post treatment scarring. By combining DWI with anatomical sequences, WB-DWI-MRI has increased accuracy in detection of liver, peritoneal and serosal bowel disease. It allows prompt detection of complications such as metastatic spinal cord compression (MRI gold standard), fractures, hydronephrosis (does not require contrast) and local tumour complications.The radiologist should be aware of limitations and pitfalls of WB- DWI- MRI such as low accuracy for subcentimetre nodes and lung metastases. Familiarisation with well know MRI artefact such as those due to prostheses is also essential. A systematic approach facilitated by template reporting can highlight review areas e.g. skull base and hypophysis, reducing the risk of overlooking disease or complications.

TABLE OF CONTENTS/OUTLINE

1) Imaging protocol and optimisation 2) Detecting disease a) Bone marrow i) Identifying normal bone marrow & variants ii) Identifying active disease b) Viscera c) Peritoneal & Nodal disease d). Local disease 3). Assessing response a) Bone marrow specific response patterns b) Systemic response 4) Pitfalls and Limitations 5) Template reporting

MSEE-116   Paraneoplastic Syndromes From Head To Toe; Pathophysiology, Imaging Features And Workup

Awards
Certificate of Merit
Identified for RadioGraphics

Participants
Mohamed Badawy, BMBCh, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

• • List most common paraneoplastic syndromes associated with various neoplasms • Discuss the clinical and multimodality imaging features of the various paraneoplastic syndromes • Illustrate an algorithmic approach for the most common paraneoplastic syndromes by anatomical body systems • Describe pitfalls in imaging diagnosis

TABLE OF CONTENTS/OUTLINE

• Introduction: definition, epidemiology, pathogenesis • Clinical significance of paraneoplastic syndromes • Incidence and onset of paraneoplastic syndromes related to pertinent malignancy • Paraneoplastic syndromes: Ø Target patient population Ø Clinical manifestations Ø Radiological features Ø Most common neoplasms associated with; o Nervous system: § Cerebellar degeneration § Limbic encephalitis § Cranial and peripheral neuropathy § Spinal myelopathy § Lambert Eaton Myasthenic Syndrome, Myasthenia Gravis o Endocrinal § ACTH dependent and independent Cushing syndrome § Parathyroid hormone-related peptide and its effect on bones o Polymyositis/Dermatomyositis o Musculoskeletal § Oncogenic osteomalacia § Hypertrophic osteoarthropathy, § palmar fasciitis, arthritis o Autoimmune like manifestations (e.g. panniculitis, scleroderma, rheumatoid arthritis) o Summary o Conclusion

MSEE-117   Autoimmune Diseases Of The Gastrointestinal Luminal Tract; Pathophysiology, Imaging Findings And Workup

Participants
Mohamed Badawy, BMBCh, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

Discuss multi-modality imaging features of autoimmune diseases affecting the gastointestinal luminal tract Algorithmic approach to the differential diagnosis of findings in each affected organ Potential imaging pitfalls

TABLE OF CONTENTS/OUTLINE

• Introduction • Anatomical background • Pathophysiology of Immune-mediated gut disorders• Epidemiology, risk factors and types of immune response • Common clinical presentation of bowel involvement in autoimmune disease • Role of diagnostic imaging in the evaluation of bowel disease.o Fluoroscopyo Computed tomography (CT) o Utility of dual-energy CT maps in evaluation of bowel diseaseo MRI/CT enterography techniques• Anatomical-based approach to immune-mediated bowel diseases.(Foregut, Midgut, Hindgut)• Primary intestinal autoimmune diseases (Clinical manifestations and imaging findings)o Celiac disease o chronic intestinal pseudo-obstructiono Crohn's diseaseo Ulcerative colitis• Secondary intestinal involvement in autoimmune conditions (Diagnostic approach, Common imaging features) o Esophagus (scleroderma; achalasia, Chagas disease)o Stomach (autoimmune gastritis)o Small bowel (celiac disease, inflammatory bowel disease)• Large bowel (inflammatory bowel disease, Hirschsprung's disease)• The immunocompromised patiento Graft versus host disease • Conclusion

MSEE-12   End-stage Kidney Disease: Renal And Extrarenal Imaging Features

Participants
Dyan V. Flores, MD, Ottawa, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

End-stage kidney disease occurs when GFR is permanently lower than 15 ml/min/1.73 m2. Imaging features of end-stage renal disease include both renal and extrarenal findings. Renal findings include chronic kidney failure, polycystic kidney disease, acquired cystic renal disease and transplant-related complications. Extrarenal findings involve a wide spectrum of abnormalities from the more common musculoskeletal manifestations (i.e. renal osteodystrophy, brown tumors, osteosclerosis) to the much rarer encapsulating peritoneal sclerosis. Thrombosis and pseudoaneurysms are potential vascular access complications.

TABLE OF CONTENTS/OUTLINE

Renal • Polycystic kidney disease • Chronic renal failure • Acquired cystic renal disease • Renal neoplasms • Transplant-related

Renal • Polycystic kidney disease • Chronic renal failure • Acquired cystic renal disease • Renal neoplasms • Transplant-related complications Extrarenal Musculoskeletal Secondary hyperparathyroidism Osteosclerosis, osteoporosis Osteomyelitis Avascular necrosis Thoracic Interstitial and alveolar edema Pleural effusion Lung atelectasis Calcifications of the bronchial walls, pleura and chest wall vessels Ground-glass opacity Bronchiectasis Cardiovascular CHF, left ventricular afterload Neurologic Focal white matter lesions Hypertensive encephalopathy, PRES Cerebral infarction Intracerebral hemorrhage Gastrointestinal Spontaneous hemorrhage Encapsulating peritoneal sclerosis Vascular and soft tissues Metastatic calcifications Dialysis access complications Thrombosis, pseudoaneurysms

MSEE-120   Imaging Of Systemic Vasculitis: A Multimultimodality Review

Participants
Mariano Volpacchio, MD, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

TEACHING POINTS

Teaching points 1. To review current nomenclature and classification of systemic vasculitis 2. To review imaging modalities and discuss strenghs and limitations thereof in diagnosis and follow-up 3. To discuss imaging findings of various systemic vasculitides with clinical information relevant to diagnosis 4. To offer diagnostic clues to proper interpretation with a pattern-based approach considering underlying pathophysiologic basis

TABLE OF CONTENTS/OUTLINE

Table of Contents • An Introduction to systemic vasculitis • Role of Different Imaging Modalities • Large Vessels Vasculitides • Medium-sized Vessels Vasculitides • Small Vessels Vasculitides • Conclusion Outline Systemic vasculitides represent an heterogeneous group of entities affecting different organ systems with varied clinical presentation thus, posing a diagnostic dilemma for clinicians. Further compounding this limitation, imaging findings, particularly in small vessel vasculitides, are often nonspecific. Nevertheless, a systematic, pattern-based imaging approach integrated with active interdisciplinary discussion is key to hone in on the right direction regarding diagnosis and management. The role of the radiologist has become of utmost importance provided that He or She is familar with the array of clinical and imaging presentations. Our goal is to review nomenclature and current classification scheme of systemic vasculitis, to describe imaging findings in various organs systems with a systematic, pattern-based approach on different modalities.

MSEE-121   Imaging Histiocytosis Cell´s Diseases. From Head To Toe.

Participants
Daniel Sebastian Chaves Burbano, MD, , Colombia (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Recognize the different types of dendritic cells, their origin and some pathologies that can be diagnosed and followed by imaging findings. - Identify the different imaging modalities that can be used in the histiocytosis cells disease.- Describe the findings of the post infiltrative and proliferative changes caused by the dendritic cells, especially the Langerhans cells. - The dendritic cells disease approach is not easy, but with anatomy distribution identified in images the approach can be improved.

TABLE OF CONTENTS/OUTLINE

- Introduction. - Pathophysiology of the dendritic cells disease. - Imaging modalities. - X-ray.- Nuclear medicine.- PET-CT.- CT.-
MRI.Anatomy distribution of the disease.- Brain.- Lung.- Gastrointestinal.- Genitourinary.- Musculoskeletal.- Spine.-
Others.Conclusions.Bibliography.

MSEE-123-HC   Looks Can Be Deceiving: Imaging Findings Of Cosmetic Procedures For Gluteal Augmentation

Participants
Maria Lucia Brun, MD, Bogota, Colombia (*Presenter*) Nothing to Disclose

TEACHING POINTS

• To outline the normal anatomy and surgical pockets of the gluteal region on different imaging modalities, essential for gluteal augmentation.• To explain the usefulness of the different imaging modalities in the assessment of gluteal augmentation.• To review the role of the radiologist in the diagnosis and recognition of complications derived from gluteal augmentation procedures.• To exemplify, through representatives cases, the normal appearance of different gluteal augmentation techniques and its postprocedural complications.

TABLE OF CONTENTS/OUTLINE

1. Introduction2. Essential anatomy3. Types of gluteal augmentation procedures and techniques4. Role of the radiologist. 5. Imaging modalities in assessment of gluteal augmentation procedures (US, CT, MR, PET-CT)6. Normal appearance of different gluteal implants and fillers7. Imaging evaluation of the most common complications8. Summary and conclusions9. References

MSEE-13   Multisystemic Imaging Manifestations Of Connective Tissue Diseases

Participants
Dyan V. Flores, MD, Ottawa, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

The connective tissue diseases or disorders (CTDs), also known as collagen vascular diseases, form a heterogeneous group of conditions that are linked by a disease process that mainly affects the connective soft tissues and vasculature of the body. These abnormalities may share not only derangements of structural proteins such as collagen and elastin, but multisystemic imaging findings. The objectives of this educational exhibit are: • To briefly review basic pathologic concepts of classic and hereditary CTDs • To discuss multisystemic imaging findings common to CTDs • To highlight imaging findings characteristic or unique to each disease

TABLE OF CONTENTS/OUTLINE

Review of basic pathologic concepts: • Systemic lupus erythematosus (SLE) • Systemic sclerosis (SSC) • Sjogren syndrome (SS) • Mixed connective tissue disease (MCTD) • Polymyositis • Dermatomyositis • Marfan syndrome • Ankylosing spondylitis Multisystemic

imaging findings: Neurologic Cerebrovascular disease Intracranial hemorrhage Neuritis, myelitis Dural ectasia Pulmonary Interstitial lung disease Pneumonias Cardiac Pulmonary arterial hypertension Myocardial fibrosis GIT Esophageal dilatation Bowel derangement (dilatation and inflammation) Vascular Aneurysms, ectasias Thrombosis Vasculitis Extremities and soft tissues Arthropathy Myositis and fasciitis Osteomyelitis and septic arthritis Calcifications

MSEE-14   Emergencies In Congenital Heart Disease

Participants
Prabhakar Rajiah, MD, FRCR, Rochester, Minnesota (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review the common and uncommon emergency presentations in congenital heart disease (CHD)2. To understand the role of multimodality imaging, especially CT and MRI in the management of these patients3. To illustrate the CT and MRI appearances of emergent CHD presentations4. To provide a diagnostic algorithm in the management of these patients

TABLE OF CONTENTS/OUTLINE

IntroductionCauses of emergent presentation in CHDImaging approach- Chest radiograph, echocardiography, CT, MRICT and MRI protocols for the emergent presentation of CHDDiscussion and illustration of the following emergencies in congenital heart disease, focusing on imaging findings and scan techniquesA. Acute chest pain- Prevalence of CAD same as in general population- ACS in anomalous coronary origins, repaired coronary arteries including TGA, Bentall procedureB. Arrhythmias- Identifying substrateC. Heart Failure- Cardiac cirrhosisD. Infective endocarditis in conduits/prosthetic valvesE. Thromboembolic complications-- Fontan shunt, prosthetic valves, stents, grafts, chronic cyanosis (Eisenmenger syndrome)- Fontan circuit thrombus vs contrast mixing-----CT scanning techniques- Foot and upper extremity injection; Delayed scan-----MRI scanning technique- Feraheme- Pulmonary embolism- Paradoxical embolism- Air embolismF. Constrictive pericarditisG. Baffle complications- Stenosis-- LeakH. RuptureI. Aortic dissection, rupture in Bicuspid/quadricuspid valvesJ. Pulmonary AVMsK. MAPCAsL. Pulmonary or mediastinal abnormaliteis

MSEE-15   Astronomy And The Classical Elements Signs In Radiology

Participants
Raquelle El Alam, MD, Beirut, Lebanon (*Presenter*) Nothing to Disclose

TEACHING POINTS

When interpreting findings on imaging, radiologists rely on their sense of pattern recognition to establish either a pathognomonic diagnosis or a comprehensive differential diagnosis. These patterns can come together to resemble objects or phenomena encountered in everyday life. We present in this pictorial review a group of radiological disease manifestations resembling cosmic and celestial bodies, as well as ones seen in nature around us, providing a broad collection of classic signs aiming to assist training radiologists in the recognition and diagnosis of a multitude of pathologies. In this review we discuss several signs seen on different imaging modalities, spanning all fields of radiology. For every sign, we included an image from the database of our institution with a description of the pathology, coupled with an illustration of the corresponding sign seen in nature to highlight the resemblance between the two.

TABLE OF CONTENTS/OUTLINE

I. Introduction/background II. Cosmic signs 1. Celestial bodies in motion (comet tail, twinkling) 2. Our galaxy and beyond (galaxy, milky way) 3. The night sky (loss of halfmoon overlap, crescent, pie in the sky) 4. Among the stars (star field, starry sky, sunburst, halo) III. Terrestrial signs 1. Earth (the earth heart, no man's land, matterhorn, mount fuji, rolling stone) 2. Ice (tip of the iceberg, snowstorm, snowman, snowcap) 3. Water (chain of lakes, whirlpool, whirl, fluid fluid, air fluid, geyser) 4. Fire (flame shape, ring on fire, brain on fire) IV. Conclusion

MSEE-16   Adverse Effects In The Brain, Head ; Neck, And Spine Associated With Immune-checkpoint Inhibitors And Molecularly Targeted Drugs

Awards
Certificate of Merit

Participants
Ryo Kurokawa, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

We summarize the variety of clinical and radiological findings of the adverse effects associated with immune checkpoint inhibitors (ICIs) and molecularly targeted drugs (MTDs) in the brain, head & neck, and spine.

TABLE OF CONTENTS/OUTLINE

I. What are ICIs and MTDs? The concept of ICIs and MTDs; Types of ICIs and MTDs; Types of adverse effects associated with ICIs and MTDs II. ICI-associated adverse effects Brain: Encephalitis; Cerebellitis; Aseptic meningitis; Guillain-Barre syndrome; PRES; Vasculitis; Demyelination; Hypophysitis; Ataxia; Polyneuropathy; Infection Head & Neck: Optic neuritis; Thyroiditis; Scleritis; Vogt-Koyanagi-Harada disease-like uveitis; Sjogren syndrome Spine: Myelitis; Aseptic meningitis; Demyelination III. MTD-associated adverse effects Brain: Tumor pseudoprogression/pseudoresponse; Leukoencephalopathy; PRES; Cerebral hemorrhage; ANCA-associated vasculopathy; Demyelination; RPLS; PML Head & Neck: DRONJ; Nasal septal perforation; Cervical artery dissection; Brachial neuritis; Guillain- Barre syndrome; Optic neuritis; Hypothyroidism Spine: Meningitis; Demyelination; CIDP Summary 1. Patients receiving ICIs or MTDs can develop various types of adverse effects in the brain, head & neck, and spine. Summary 2. Knowledge of clinical and radiological findings can help differentiate adverse effects from tumor metastasis or dissemination. Summary 3. The development of ICIs and MTDs is rapidly advancing, so we should keep up with the relevant clinical and radiological findings.

MSEE-17   One Space, Many Pathologies: A Pictorial Case Based Review Of The Presacral Space.

Awards
Cum Laude

Participants
Sean Mendonca, MD, Morristown, New Jersey (*Presenter*) Nothing to Disclose

TEACHING POINTS

The presacral space is an important pelvic extraperitoneal space posterior to the rectum and anterior to the sacrococcygeal spine. A wide variety of pathological processes can occur given its unique location and internal contents. These range from developmental/congenital masses to a variety of benign and malignant tumors as well as pseudotumors and infectious/inflammatory processes. Post-surgical alterations and complications can also frequently be seen. This exhibit aims to:Review anatomic relations of the presacral space.Review common and uncommon presacral pathologic processes utilizing a case-based approach.Review common surgical procedures and complications involving the presacral space.

TABLE OF CONTENTS/OUTLINE

-Anatomy of the presacral space.-Case based approach review the following common and uncommon pathologies:Congenital/Developmental: Tailgut cyst, Sacrococcygeal teratoma.Benign Tumors: Neurogenic Tumors, Extra-Adrenal myolipoma, giant cell tumor.Malignant Tumors: Chordoma, lymphoma, neuroendocrine tumor, metastasis.Miscellaneous: Fibrosis, Ulcerative Colitis, Extra-medullary hematopoiesis.-Infectious/Inflammatory: Abscesses, fistulas.-Post surgical alterations and complications.

MSEE-18   Keys To The Zoo: Body Imaging Manifestations Of Zoonotic Infections

Awards
Identified for RadioGraphics

Participants
David Kraft, MD, Carrollton, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

Objective: To review the clinical pearls and key radiologic findings that can aid the body imager in the evaluation of zoonotic infections. Each infection is presented as an unknown case with an exposure history and key radiology images, followed by the diagnosis and discussion slides with additional cases and teaching points.

TABLE OF CONTENTS/OUTLINE

1. Bacterial infections: Case-based review of Pasteurella multocida, Bartonella henselae (Cat-scratch disease), Coxiella burnetii (Q fever), Brucella spp., Francisella tularensis (tularemia), and Leptospira spp. infections in humans highlighting helpful clinical clues (including exposure histories) and key radiology findings on cross-sectional imaging studies (including ultrasound, computed tomography, and magnetic resonance imaging) with a focus on thoracic, cardiovascular, abdominal, and musculoskeletal findings2. Parasitic infections: Case-based review of Echinococcus spp., Paragonimus spp., Toxocara spp. (visceral larva migrans), and Dirofilaria immitis infections in humans highlighting helpful clinical clues (including exposure histories) and key radiology findings on cross-sectional imaging studies (including ultrasound, computed tomography, and magnetic resonance imaging) with a focus on thoracic, cardiovascular, abdominal, and musculoskeletal findings

MSEE-19   Forensic Post-mortem CT To Investigate The Cause Of Death: Pictorial Essay

Participants
Wataru Fukumoto, Hiroshima, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Post-mortem computed tomography (PMCT) is valuable for forensic investigations. We present some forensic cases in which PMCT was useful for investigating the cause of death. In dead burn victims, PMCT permits individual identification by revealing the shape of vascular prostheses and dental fillings. The detection of intratracheal soot helps to determine whether death occurred before or during the fire. Heat hematomas, a kind of epidural hematoma, are a specific burn-related finding. In case of strangulation, volume-rendering images facilitate the identification of ligature marks. Laryngohyoid fractures are more easily detected by PMCT than by classic autopsy. Fluid and froth in the airway are usually observed in drowning cases. Swallowed water distends the stomach and the inflow of water fills the paranasal sinuses. Differences between fresh- and salt water affect lung findings and the density of the sinus fluid. In cases with multiple injuries from traffic accidents and falls, PMCT facilitates the detection of organ damage and multiple bone fractures.

TABLE OF CONTENTS/OUTLINE

TABLE OF CONTENTS/OUTLINE 1. Burned bodies •Identification of severely burned bodies •Intratracheal soot •Heat hematoma •Chicken fat clots 2. Strangulations •Ligature marks •Laryngohyoid fractures 3. Drownings •Fluid and froth in the airway, stomach and paranasal sinuses •Difference between fresh- and salt water drownings 4. Multiple injuries in traffic accidents and fall injuries •Organ damage and multiple bone fractures •Vanishing aorta

MSEE-2   Standardized Reporting In Lymphoma Radiology (CT, PET-CT, MRI): SIHMIR, A Paradigm Shift

Participants
Sara Zafar, MBChB, MRCP, Toronto, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

•Review the need for standardized reporting in lymphoma radiology. •Introduce the original 'Specialist Integrated Hematological Malignancy Imaging Reporting' (SIHMIR) framework to radiologists; highlight clinical and research utility.

TABLE OF CONTENTS/OUTLINE

•Lymphoma encompasses a wide, complex spectrum of disorders with over 40 non-Hodgkin's and 5 Hodgkin's lymphoma categories currently recognized by the revised WHO classification. •Highlight need for accurate diagnosis of precise histological subtype, as this is vital in ensuring appropriate patient management and optimizing outcome. •Standardized reporting templates already mandated in UK pathology laboratories as per NICE Guidelines and Quality Standards, in an attempt to improve accuracy of histopathological lymphoma diagnosis. •Recognize analogous issues in imaging, with the need for better integration and specialist

interpretation of complex multi-parametric anato-functional imaging (CT, PET-CT, MRI); providing key data-items at staging, interim and 'end-of-treatment' response assessment. •Highlight key prognostic indicators during the patient pathway, including secondary CNS lymphoma risk factors; a high degree of inter-observer variability being a current issue with regards to reporting these items. •Present the original SIHMIR framework, designed as a comprehensive yet practical reporting tool for radiology departments globally, for use in daily clinical practice and research studies together with artificial intelligence applications.

MSEE-20   Lymph Node Anatomy With A Case Review Perspective: A Trip From Neck To Inguinal Region

Participants
Luis Frias Mendez SR, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

The human body is composed of approximately 800 lymph nodes. Knowing the nodal anatomy is essential in identifying the pattern distribution in neoplastic lymph node metastases, systemic disease and local inflammatory process which helps to narrow the final diagnosis.Various attempts have come to a consensus on the evaluation of the regional metastasic disease such as the IASLC node map and the pathways of dissemination of gastric cancer according to the Japanese Gastric Cancer Association and others like RECIST that gives a reproducible way to measure the treatment response during the follow-up of these patients.Systemic diseases like tuberculosis are capable of affecting from neck to the gastrointestinal tract, especially in immunocompromised patients with necrotic centre adenopathies as a hallmark feature.In benign settings, the presence of inflammatory lymph node in specific locations helps in the diagnosis such as appendicitis and now with vaccinated patients in the COVID-19 era.

TABLE OF CONTENTS/OUTLINE

Introduction to lymph node, Inflammatory lymph node vs Adenopathy, Lymph node levels of the neck, Thoracic IASLC lymph node map, Extrathoracic lymph nodes, Abdomen lymph node anatomy, pelvic lymph node anatomy

MSEE-21   Emergence Of AI In Emergency Radiology: Applications, Approaches, Benefits ; Challenges

Participants
John Zhu, BSC, Vancouver, British Columbia (*Presenter*) Nothing to Disclose

TEACHING POINTS

By viewing this exhibit, participants will be able to: 1) Recognize that radiological artificial intelligence (AI) has the potential of becoming a powerful tool to increase efficiency and accuracy in patient care in the age of mounting radiologist burden. 2) Describe how AI can potentially be integrated into the emergency radiology workflow. 3) List acute conditions to which machine learning (ML) techniques have been applied, in terms of detection, segmentation & classification of neurovascular, thoracic, orthopedic & abdominal pathologies. 4) Recognize that while a wide variety of AI algorithms exists, the same goal can be accomplished by vastly different approaches. 5) Describe challenges faced by current AI technologies related to development, ethics & adoption. 6) Recognize that while radiological AI is rapidly developing, it is not expected to replace all roles of radiologists in the foreseeable future. 7) Describe the roles radiologists play in the uptake of AI technologies, and how to get involved.

TABLE OF CONTENTS/OUTLINE

1) Overview & definitions of common AI terms 2) Potential benefits of AI in emergency radiology 3) Stages of workflow benefitted by AI 4) AI approaches being explored 5) Applications in acute conditions - neurovascular, thoracic, orthopedic, abdominal 6) Current & future challenges 7) Outlook of AI

MSEE-22   Expect The Unexpected When They're Expecting: Imaging Of Acute Non-Traumatic Abdominal Pain In Pregnancy

Participants
Koween Vencatasawmy I, MBChB, Leicester, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

Imaging is vital to elucidate the cause of non-traumatic abdominal pain in pregnancy as accurate clinical diagnosis is hampered by anatomic and physiologic factors. Delayed diagnosis can confer worse neonatal and maternal outcomes.Ultrasound is often used as the first line modality, with MRI suitable at all gestational ages as a second line tool - gadolinium is relatively contraindicated.Diffusion-weighted imaging and fat-saturated SSFSE sequences allow detection of inflammation and fluid, gradient echo for appendix patency and T1 sequences for haemorrhage.Diagnoses involving multiple organ systems may be made, enabling prompt treatment.Dilatation of the ovarian vein and proximal ureter are physiologic but may be mistaken for appendicitis.

TABLE OF CONTENTS/OUTLINE

Outline of imaging modalities available and their strengths and weaknesses.Description of MRI protocol with rationale for sequence choice.Examples of normal studies with focus on identifying key structures and an approach to a non-visualised appendix.Appearances of uncomplicated and complicated acute appendicitis.Multimodality review of other diagnoses involving different systems: (a) Gastrointestinal: bowel obstruction, intestinal ischaemia, epiploic appendagitis (b) Gynaecologic: degenerating fibroids, ectopic/heterotopic pregnancy, ovarian mass and torsion (c) Hepatobiliary: cholecystitis, acute pancreatitis (d)Urologic: pyelonephritisExpected normal findings such as ovarian vein distension and physiologic hydronephrosis.

MSEE-23   Periarticular Calcifications

Participants
Mayuran Saththianathan, MBChB,MS, Westmead, Australia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Differentiating between calcifications and ossification followed by systemically reviewing different etiologies is a method of generating a list of differential diagnoses when assessing peri-articular mineralization.2. A list of conditions leading to peri-articular calcifications can be further subdivided into multi-regional and single region involvement to assist in diagnosing.3. Ossifications tend to be post-traumatic whereas calcifications although having variable etiologies, are associated with crystalline causes. 4. Mineralization can be broadly categorised into dystrophic and metabolic causes.

Periarticular calcification and ossification is a frequent finding on imaging and may sometimes pose a diagnostic challenge. The differential diagnoses for this radiological finding can be classified into broad groups such as idiopathic, developmental (accessory ossicles/sesamoids), trauma (myositis ossificans & avulsion fracture), burns, infection, tumor (synovial sarcoma, soft tissue chondroma & intracapsular chondroma), connective tissue disease (scleroderma), crystalline (gout, CPPD & HADD), metabolic (end stage renal disease, vascular (atherosclerotic plaques, Monckeberg media sclerosis & vascular malformation) and foreign bodies. This presentation aims to review the clinical-radiologic findings of periarticular calcified or ossified lesions as well as mimickers of periarticular mineralisation with relevant imaging illustrations.

MSEE-24   Globe Injuries In Emergency Radiology

Awards
Certificate of Merit

Participants
Matthew Lee, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review normal ocular anatomy on CT.To review different types of globe injuries.

TABLE OF CONTENTS/OUTLINE

Normal Globe Anatomy on CTAnterior Chamber InjuriesCorneal lacerationHyphemaLens InjuriesPartial lens dislocationComplete lens dislocationPosterior Segment InjuriesVitreous hemorrhageRetinal detachmentChoroidal detachmentGlobe RuptureDirect signs of open-globe injuries: altered globe contour/volume, scleral discontinuityIndirect signs of open-globe injuries: altered anterior chamber depth, foreign body/air

MSEE-25   Revisiting Hyper Dense Lesions On Unenhanced Head CT- Correlation With Brain MRI And Contrast Enhanced CT Imaging

Participants
Alka Gupta, MBBS, Syracuse, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

Unenhanced head CT is a commonly utilized study in varied clinical settings. In emergency settings, it acts as a sensitive tool for detecting lesions that require immediate neurosurgical intervention with added value as a screening tool for triage. Hyper attenuation on CT is a commonly encountered and often non specific finding with broad differentials ,that needs to be interpreted in appropriate clinical context for efficient confident diagnosis. Substantial overlap in imaging appearances of these lesions can often confound diagnosis. Further evaluation with advanced imaging including contrast enhanced CT, CT angiography, dual energy CT and brain MRI is important for narrowing down the differential diagnoses, thus enabling timely intervention.

TABLE OF CONTENTS/OUTLINE

Hyperattenuation on unenhanced head CT is a commonly encountered and often non specific finding with broad differentials. A comprehensive list of acute and chronic brain diseases and conditions, that can present as hyper attenuation on unenhanced CT will be presented. The imaging findings of these lesions on head CT will be systematically evaluated based on their pattern of distribution, multiplicity, location and anatomic relationship to formulate a differential diagnosis. The lesion characteristics will be further illustrated utilizing contrast enhanced CT, CT angiography, dual energy CT or Brain MRI for problem solving thus classifying them into broad categories such as traumatic, infectious, vascular, neoplastic, metabolic and congenital disorders.

MSEE-26   Treatment Response Assessment In Lymphoma Radiology: Utility Of PET-CT, Deauville Classification, The New RECIL And LyRIC Criteria.

Participants
Sara Zafar, MBChB, MRCP, Toronto, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

•Identify clinical indications for CT and FDG-PET CT imaging in interim and end-of-treatment (EOT) response assessment in non-Hodgkin's lymphoma (NHL).•Review currently utilized tools in assessing disease response, including the Deauville classification (DC) and newer criterion, such as the Response Evaluation Criteria in Lymphoma (RECIL) and Lymphoma Response Criteria in Immunomodulatory Therapy (LyRIC).•Understand concepts of disease tempo and potential low-high transformation.

TABLE OF CONTENTS/OUTLINE

•Accurate response assessment is essential for optimizing patient management. •Highlight specific utilities of FDG-PET CT in interim and EOT response assessment, for example being advocated at EOT response in high-grade NHL subtypes including diffuse large B-cell and Burkitt's lymphoma, whilst not routinely recommended in low-grade NHL or at interim response in DLBCL due to false-positive activity, particularly observed with rituximab-based regimens; CT imaging instead advised. •Utility of DC in allocating overall response category at EOT response assessment, based on FDG-avidity of lesions.•Importance of stating Deauville score (DS) in all PET-CT reports. •Limitations and nuances of DS, specifically the DS 'X' score. •Simplified new RECIL response assessment methodologies, including new response category of 'minor response,' with case-based examples of its utility. •Review new LyRIC modification, with 3 'indeterminate response' categories, in the context of novel immunomodulatory therapy in the lymphomas.

MSEE-27   An Outsider In The Emergency Room: An Overview Of The Abdominal Foreign Bodies In The Acute Setting, Differentiating Expected Findings From Complications

Participants
Daniel Montel, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Recognize the importance of active search for foreign bodies, mainly after positive history.• Identify and characterize the

different kinds of foreign bodies, looking for the optimum window, to avoid missing non-radiopaque objects.• Demonstrate the main imaging findings in emergencies related to foreign body complications such as perforation, occlusion and infection.• Demonstrate how to recognize normal findings in therapeutic materials in the gastrointestinal and genitourinary tracts, not classified as incidental foreign bodies.

TABLE OF CONTENTS/OUTLINE

1. Introduction.2. Expected attenuation of the different foreign body materials (metal, plastic, wood, glass, bones, etc).3. Foreign bodies in the gastrointestinal and genitourinary tract arising from ingestion or introduction through natural orifices, such as anus, vagina, and, less frequently, the urethra.4. Foreign body complications such as perforation, gastrointestinal occlusion, and infection.5. Iatrogenic post-surgical foreign bodies.6. Demonstration of normal aspects of foreign bodies after therapy and eventual ectopia.7. Take home messages.

MSEE-28   **How To Get Through The Night-Diagnostic Approach To Acute Intracranial Hemorrhage**

Participants
Nicolas Murray, MD, Vancouver, British Columbia (*Presenter*) Nothing to Disclose

TEACHING POINTS

Differential diagnosis of acute intracranial hemorrhage (AIH) is broad. A compartmental/distribution approach is key in narrowing the differential diagnosis. In the trauma setting, AIH is commonly the result of the traumatic injury, but may also represent or may point towards a causative factor precipitating a trauma. Vascular studies are key in identifying a vascular lesion (aneurysm, vasospasm, extravasation, AVM, venous thrombosis) as a cause of AIH. Potential complications related to AIH must be assess on every study with AIH.

TABLE OF CONTENTS/OUTLINE

This poster will present the various types of traumatic and spontaneous AIH, including hemorrhage related to trauma (epidural, subdural, subarachnoid, intraventricular, diffuse axonal injury, Kernoan notch, Duret hemorrhage), vascular lesions (aneurysm, arterio-venous malformation), venous thrombosis, vascular dysregulation (hypertensive hemorrhage, PRES, RCVS), vasculitis, benign perimesencephalic hemorrhage. Examples will be provided as well as summary decisional trees in order to help the radiologists navigate through the potential causes of AIH, and determine when a vascular study (CT/MR angiogram +/- venogram) is needed. Complication of acute intracranial hemorrhages will also be discussed (intracranial herniation syndromes, secondary ischemic changes, extension of hemorrhage into the adjacents spaces, active extravasation and delayed expansion, vasoconstriction), as well as utility of dual-energy CT in detection and characterization.

MSEE-29   **Chondrosarcoma From Head To Tail : A Pictorial Review Of Chondrosarcomas Outside The Appendicular Skeleton**

Participants
Margaret Adejolu, FRCR,MRCP, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Overview of 2020 WHO pathological classification of chondrosarcomas 2. Recognizing the Imaging appearances of chondrosarcomas presenting at uncommon sites and their differential diagnosis 3. Understanding the clinical course and patterns of metastases.

TABLE OF CONTENTS/OUTLINE

1. 2020 WHO pathological classification of chondrosarcomas. 2. Secondary Chondrosarcomas. 3. Typical imaging appearances of chondrosarcomas and correlation between tumor grade and MRI appearances 4. Chondrosarcoma of the skull base 5. Chondrosarcoma of the Nasal septum 6. Chondrosarcoma of the maxillary antrum 7. Laryngeal and tracheal chondrosarcoma 8. Chondrosarcoma of the costal cartilages 9. Chondrosarcoma of the sternum 10. Chondrosarcomas involving thoracic and abdominal viscera 11. Chondrosarcomas involving the pelvis and perineum.

MSEE-3   **A Walk To Not Remember: A Detailed Review Of Pedestrian Versus Motor-vehicle Injuries At A Level 1 Trauma Center**

Participants
Andrew Mitchell, MD, Memphis, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Review most common injuries associated with automobile vs pedestrian trauma. Data will be from over 150 cases reviewed at our trauma center and from previously published data. 2. Show examples of common resident "misses" and what subtle radiographic injuries to evaluate for. Common misses include vascular injury, bowel/mesenteric injury, and relevant additional fracture findings. 3. Examples of cases that needed advanced imaging (MRI/DSA) to confirm results or identify associated injuries. 4. Show examples of initially normal scans that later demonstrated traumatic findings.

TABLE OF CONTENTS/OUTLINE

1) Background: Epidemiology and general overview of auto vs pedestrian traumatic findings, which often include pelvic, extremity, bowel, and intracranial injuries. 2) Case based review of common auto vs pedestrian/blunt trauma injuries and a review of recent research on the topic. 3) Case based presentations of common resident/community misses and pitfalls, including pearls to improve detection. Cases include secondary findings that require advanced imaging or delayed findings found on follow-up imaging. 4) Summary: Conclusions/References

MSEE-30   **Imaging Foreign Bodies In Trauma**

Participants
Ivica Bratanovic, MSc, Port Moody, British Columbia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Foreign body (FB) deposition can result from various types of penetrating trauma?. Traumatic FB diversity and their common

1. Foreign body (FB) deposition can result from various types of penetrating trauma2. Traumatic FB diversity and their common clinical and imaging presentations are important to recognize3. Understand the importance of the traumatic mechanism and its anatomical location is key in establishing a plan to evaluate FBs with imaging4. Recognition of the imaging signs of common complications of traumatic FBs is essential

TABLE OF CONTENTS/OUTLINE

- Introduction to foreign body (FB) imaging, modality selection, and utility- Overview of trauma mechanisms that can lead to deposition of FBs- FB diversity and the impact of composition on imaging modality selection- Evaluating patients with suspected traumatic FB based on clinical signs and mechanism of trauma- Imaging traumatic FBs based on anatomical location- Imaging characteristics of common complications of traumatic FBs based on mechanism- Utility and safety of MRI in evaluating patients with FBs in an emergency trauma setting- Clinical Cases- Summary and key points moving forward

MSEE-31   Who Are You Calling Fat? A Review Of Fat-containing Lesions In The Abdomen And Pelvis

Awards
Certificate of Merit

Participants
Anthony Larder, DO, Milford, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Review multimodality imaging findings of fat-containing lesions in the abdomen and pelvis including pearls and pitfalls to aid in diagnosis-Discuss pathophysiology and clinical implications of various fat-containing lesions-Review imaging findings of syndromes associated with fat-containing lesions

TABLE OF CONTENTS/OUTLINE

General Concepts:-Identifying macroscopic vs. microscopic fatDiscussion of imaging findings and clinical implications of fat-containing lesions. Modalities include CT, MRI, US, fluoroscopy, angiography, and PET-CT. Case examples include:-Adenomas-Angiomyolipoma of the kidney, liver, and spleen-Fat-containing hepatocellular carcinoma-Fat-containing renal tumors-Fatty infiltration/replacement -Fibrofatty proliferation-GI tract lipomas including associated intussusception -Lipoleiomyoma-Liposarcoma including retroperitoneal and scrotal-Myelolipoma, adrenal and extra-adrenal-Omental infarct-Solid organ lipomas-Steatosis-Teratomas-Testicular lipomatosisReview of syndromes associated with fat-containing lesionsCase examples include:-Tuberous Sclerosis-Lymphangioleiomyomatosis-Cowden syndromeSummary and Clinical Implications-Fat-containing lesions are commonly encountered in the abdomen and pelvis-Knowledge of imaging findings of various fat-containing lesions and associated syndromes to is essential to guide diagnosis and management

MSEE-32   Imaging Trauma During Pregnancy

Awards
Cum Laude

Participants
Asir Chishti, Lexington, Kentucky (*Presenter*) Nothing to Disclose

TEACHING POINTS

I. Radiography, Sonography and CT play a crucial role in evaluating the traumatically injured pregnant patient. II. The risk of radiation to the pregnancy is small compared with the risks of missed or delayed diagnosis. III. Placenta abruption is characterized by a large, contiguous retroplacental and/or full-thickness area of hypo enhancement that forms an acute angle with the myometrium. IV. Fetal Injuries are generally uncommon due to afforded protection by maternal body; however, fetal skull injuries are possible in the 3rd trimester with cephalic presentation, often in the setting of maternal pelvic fractures.

TABLE OF CONTENTS/OUTLINE

I. Background (Epidemiology, special considerations in maternal physiology, review of normal pregnancy imaging anatomy) II. Imaging Algorithm (Radiography, sonography (maternal/fetal), computed tomography, fetal dose concerns) III. CT and US imaging examples (Traumatic placental findings, traumatic uterine findings, fetal trauma, maternal trauma) IV. Conclusion (Radiologist should be comfortable evaluating traumatically injured pregnant patients. Knowledge of normal anatomy, injury patterns, imaging limitations and pitfalls can help radiologist avoid diagnostic error.)

MSEE-33   The Leading Role Of The Radiologist In The Assessment Of Retroperitoneal Haematoma: From Diagnosis To Endovascular Treatment

Participants
Dario Herran de la Gala, MD, Santander, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

This exhibit will: 1) Review the retroperitoneal anatomy and its appearance on CT. 2) Describe CT protocol for evaluating retroperitoneal haematomas. 3) Review the different etiologies of retroperitoneal haematoma. 4) Describe the role interventional radiology has in the treatment of retroperitoneal haematomas.

TABLE OF CONTENTS/OUTLINE

Retroperitoneal hemorrhage can be the source of significant but clinically occult blood loss. There are different conditions that can lead to retroperitoneal haematoma (RH) and it is recommended to evaluate RH in multi-phase CT scan, where non-enhanced acquisitions are key. Trauma is the leading cause of RH. In the absence of trauma history, underlying conditions must be scrutinized in order to justify the haematoma: iatrogenic, abdominal aorta aneurysms, inferior vena cava rupture, renal or suprarenal lesions, hemorrhagic pancreatitis or, lastly, spontaneous retroperitoneal bleeding. Evaluating the presence of active bleeding is imperative to discuss whether the patient might benefit from endovascular treatment or not.

MSEE-34   The Manifold Manifestations Of Pheochromocytomas And Paragangliomas, From Head To Pelvis

Participants
Karen Man, BS,MD, Morristown, New Jersey (*Presenter*) Nothing to Disclose

TEACHING POINTS

After viewing this exhibit, the learner will be familiar with:1. The pathophysiology of pheochromocytomas and paragangliomas, as well as major sympathetic and parasympathetic nervous system anatomy.2. Imaging characteristics of adrenal pheochromocytomas across multiple modalities.3. Imaging characteristics and signs of extra-adrenal pheochromocytomas and paragangliomas across a variety of locations in the body, from head to pelvis.4. Multi-system syndromes in which pheochromocytomas and paragangliomas may manifest.5. Pre-treatment optimization and therapeutic options for patients, which may vary according to location or other characteristics of tumors seen on imaging.

TABLE OF CONTENTS/OUTLINE

I. Pheochromocytoma and Paraganglioma Anatomy & PathophysiologyII. Adrenal Pheochromocytomas A. Classic Imaging Characteristics on CT, MRI, and ultrasoundB. Exceptions to the Rule: Cystic PheochromocytomaC. Imaging with Radiotracers Specific to Neuroendocrine TumorsIII. Extra-adrenal Pheochromocytomas and Paragangliomas A. Carotid Body TumorB. Glomus JugulareC. Glomus TympanicumD. Organ of Zuckerkandl TumorE. Miscellaneous Extra-adrenal TumorsIV. Multi-System Syndromes A. Von Hippel-LindauB. Multiple Endocrine Neoplasia SyndromesV. Management and Therapeutic Options

MSEE-35   A Comprehensive Imaging Review Of Elbow Injuries In The Emergency Department

Awards
Identified for RadioGraphics

Participants
Jean Sebastien Rowe, MD, Atlanta, Georgia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Understand the functional anatomy of the normal elbow joint, its intrinsic stability, and the biomechanical forces required to result in a fracture or dislocation.2. Identify the major types of elbow fractures and dislocations, with complications and appropriate recommendations for additional imaging.3. Recognize common injury classification systems used by orthopedic surgeons and what clinically relevant material to add to the radiology report.

TABLE OF CONTENTS/OUTLINE

Elbow injuries are common, representing 15% of upper extremity injuries in the Emergency Department (ED). The elbow joint is a complex hinge-type synovial joint, with several types of common injury patterns. Radial head and neck fractures are the most common elbow fractures in adults; however, distal humeral fractures, ulnar fractures, and complex fracture-dislocations occur with elbow trauma. Radiologists should be aware of the clinically relevant injury classification systems used by orthopedic surgeons, such that they can include relevant information in their reports. This exhibit will review the functional anatomy of the elbow using multimodality imaging. A brief discussion of the common biomechanical forces required to cause a fracture or dislocation will follow. Subsequently, multiple common elbow injuries seen in the ED will be presented on multi-modality imaging. Clinically relevant injury classification schemes and terminology will be discussed, and imaging complications will be reviewed.

MSEE-36   MR Imaging Of Non-obstetric Acute Abdominal Presentations In Pregnancy.

Participants
Elizabeth Robinson, MD, Bristol, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Have a low threshold for performing MRI in acute abdominal presentations in pregnancy. At our institution, the cause of pain was identified >50% of patients.- Scan from diaphragm to pubic symphysis as symptoms may be difficult to localize.-Consider both black blood and white blood sequences - these help to differentiate appendix from parametrial veins, ureters from vessels, and for detecting thrombosed vessels.

TABLE OF CONTENTS/OUTLINE

We present our experience of using MRI to investigate non-obstetric causes of acute abdominal presentations in pregnancy. We illustrate our learning points with cases from our institution.1) Introduction and Objectives-Our experience- findings from a 5 year cohort of 35 pregnant women with acute abdominal presentations-Safety and consent-MRI techniques- key sequences and implementation.2) Appendicitis-Acute appendicitis-Pitfalls of identifying the appendix in pregnant patients.3) Gastrointestinal-Inflammatory bowel disease-Bowel obstruction4) Hepatobiliary-Cholecystitis-Choledocholithiasis5) Genitourinary-Pregnancy-related hydronephrosis-Obstructive hydronephrosis-Acute pyelonephritis6) Vascular-Gonadal vein thrombosis7) Gynaecological-Ovarian torsion-Cervical cancer-Mature cystic ovarian teratoma8) Endocrine-Bilateral adrenal hemorrhage9) Summary of learning points

MSEE-37   Uncovering The Dark Side Of Melanin: Pictorial Depiction Of Head To Toe Imaging Spectrum In Malignant Melanoma

Participants
Ankush Jajodia, DMRD,MBBS, New Delhi, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Melanoma accounts for 50% of deaths related to skin cancer and can spread by direct extension, lymphatic, or hematogenous routes and can involve virtually every organ system. The prognosis is dismayed with a median survival of 6-10 months in metastatic disease. 2. T1 hyperintensity on MR imaging gives us clue to the melanotic pattern which is the dominant variety. The amelanotic variety appears as iso or hypointense on MRI. 3. We have largely incorporated the rarer amelanotic type in our pictorial depiction of this entity. This is done to make readers keep in mind this ghastly entity while encountering such cases. 4. Multiple masses with similar signal intensity are characteristic of this entity. However, in few cases, we have presented multiple lesions exhibiting different signal intensities in metastatic uterine cervix cancer. 5. This review serves to present an embodiment of the typical and

atypical multi-modality imaging manifestations of malignant melanomas from head to toe. 6. We have incorporated 18- FDG PET-CT imaging and MR imaging which hasn't been undertaken in previous studies.

TABLE OF CONTENTS/OUTLINE

Aims I. Head A. Scalp B. Brain C. Duramater II. Neck A. Nasal cavity B. Sinus C. Orbit D. Nasopharyngeal E. Cervical spinal canal F. Skull base III. Chest A. Pre-sternal region B. Lungs and pleura C. Breast IV. Abdomen A. Liver B. Spleen C. Gall bladder D. Pancreas E. Peritoneum F. Mesentery V. Pelvis A. Rectum B. Cervix C. Vagina D. Vulva and Clitoris VI. Extremity A. Forearm B. Femur C. Toe

MSEE-38   Imaging IVDU Complications: A Review Of The Most Common Abdominopelvic Imaging Findings.

Participants
Abbas Charlie, DO, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

Recognize the increasing incidence of recreational intravenous drug use (IVDU) in the United States and its clinical presentations. Using a multi-modality imaging approach, review some of the most common abdominopelvic imaging findings attributable to IVDU from a busy inner-city hospital that the radiologist may encounter in the emergency setting. Discuss practical imaging tips for aiding and narrowing the differential diagnosis as well as strategies to avoid diagnostic pitfalls.

TABLE OF CONTENTS/OUTLINE

Incidence of intravenous drug use in the United States. Review case examples of soft tissue/musculoskeletal infections including cellulitis, abscess, necrotizing fasciitis, discitis/osteomyelitis, and retained foreign body; vascular complications including arterial aneurysm, arteriovenous fistula, thrombophlebitis, and septic emboli; gastrointestinal complications including stercoral colitis/perforation.

MSEE-39   Imaging Features Of The Ectopic Tissues With Embryologic Approach For Correct Diagnosis.

Awards
Identified for RadioGraphics
Cum Laude

Participants
Mariko Kurokawa, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Understand normal and abnormal human development causing the ectopic tissues or organs.• Recognize clinical and radiological features of these ectopic tissues focusing on the anatomical correlations and genetic factors.• Identify the complications, the differential diagnoses and key findings of the ectopic tissues for the correct diagnosis.

TABLE OF CONTENTS/OUTLINE

I. Introduction to fetal developmentFetal development from zygote to each organ.How does the ectopic tissue develop? - Embryonic rests, Impaired migration, Dissemination, Metaplasia, Iatrogenesis Signaling pathway and gene mutations which cause malformations or affect the development of organ systems.II. Normal and abnormal fetal development Divided into five areas. Brain, Head and neck, Chest, Abdomen, Bone and soft tissue. What is an important point with the aspect of diagnostic radiology?III. Case based review1. Brain: Periventricular nodular heterotopia, Focal cortical dysplasia, Ectopic posterior pituitary, Ectopic pituitary adenoma, Ectopic brain tissue, Nasal glioma2. Head and neck: Ectopic thyroid tissue, Ectopic parathyroid gland, Ectopic thymic tissue, Branchial cleft cyst3. Chest: Ectopic tissues in the lung, Ectopic mammary gland, Ectopic thymus4. Abdomen: Ectopic pancreatic tissue, Annular pancreas, Wandering spleen, Intrahepatic accessory spleen, Adrenal rest tumors, Ectopic kidney, Heterotopic endometriosis, Ectopic tissue in Meckel's diverticulum, Ectopic ureters5. Bone and soft tissue: Ectopic bone formationIV. Summary

MSEE-4   Lymph Node Evaluation In Imaging Response Assessment Criteria: Similarities And Differences

Participants
Tagwa Idris, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

• -To describe lymph node assessment across imaging response criteria • -To compare the criteria to determine nodal assessment similarities and differences • -To recognize the challenges of applying these criteria

TABLE OF CONTENTS/OUTLINE

• -Timeline of imaging criteria using lymph node for treatment response assessment • -Terminology and rules for nodal response assessment • -Similarities and differences across various response assessment criteria • -Case-based scenarios to demonstrate nodal assessment variations in response criteria/categories • -Challenges in image metrics assessment using these different criteria • -Summary and future directions • -References

MSEE-40   Primary Tumors And Tumor-like Lesions Of The Mesothelium And Their Mimics: Cross-sectional Imaging Spectrum

Awards
Identified for RadioGraphics

Participants
Apurva Bonde, MBBS, MD, San Antonio, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

Discuss anatomy, embryology & functions of mesothelium covering pleura, pericardium, abdominal organs & testiclesReview imaging spectrum of primary benign and malignant tumors and tumor-like lesions of mesothelium & role of imaging in managementDescribe

the spectrum of non-mesothelial mimics & role of imaging in appropriate diagnosis

TABLE OF CONTENTS/OUTLINE

IntroductionAnatomy, Embryology & Physiology of MesotheliumMesothelium to mesenchymal transition: What is the role in cancer developmentRole of ImagingPericardium: Malignant Pericardial Mesothelioma, benign pericardial proliferations & pericardial cyst; Mimics:Sarcoma, metastases, pericardial lymphoma & tuberculous pericarditisPleura: Malignant pleural mesothelioma; Solitary fibrous tumor, pleural fibrosis secondary to tuberculosis & actinomycetes. Mimics: Metastases, lung cancer & Extrapleural hematoma.Peritoneum including serosal covering of Uterus & Ovaries: Malignant peritoneal mesothelioma & Well-differentiated papillary mesothelioma, solitary fibrous tumor, adenomatoid tumor & benign multicystic mesotheliomaMimics: omental infarction, epiploic appendagitis, primary peritoneal serous carcinoma, peritoneal carcinomatosis, tuberculous peritonitis, peritoneal inclusion cyst pseudomyxoma peritonei, cystic lymphangioma, neurofibromatosis & lymphangiomatosis Tunica vaginalis: Mesothelioma & adenomatoid tumors; Mimics: Hematocele, metastases, lipoma, sarcoma, epididymitis & supernumery testesConclusion

MSEE-41 Tonight I'll Be Eating And Reading: A Review Of Radiology Food Signs

Participants
Jonathan Revels, DO, Albuquerque, New Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Familiarize radiologists with the multimodality imaging appearance and diagnoses associated with "food signs" in radiology. 2. Provide multimodality images of food signs and illustrations to improve their recognition by using pareidolia (ability to perceive random images or patterns as an object or pattern known to the observer).

TABLE OF CONTENTS/OUTLINE

Introduction to pareidolia and patternicity and its radiological application Thoracic radiology food signs with case examples and illustrations: Honeycomb-Head Cheese-Mitral Annular Caseous Calcifications-Cheerios Abdominal radiology food signs with case examples and illustrations: Cottage Loaf sign-Nutmeg Liver sign-Lollipop sign-Honeycomb sign-Liver Scalloping sign-Sausage sign-Bean sign-Pancake sign (kidney, adrenal)-Apple core sign- Coffee bean sign-Donut sign-Mushroom sign-Pear shape bladder sign Female pelvis radiology food signs with case examples and illustrations: Swiss Cheese sign-Boba sign-Bagel sign Male pelvis radiology food signs with case examples and illustrations: Onion Skin sign-Eggplant sign-Pie sign Fetal radiology signs with case examples and illustrations: Lemon sign, Strawberry sign, Banana sign Other radiology signs with case examples and illustrations: Omental caking-Lymph node eggshells-Rice Bodies Musculoskeletal and Neuroradiology food signs with case examples and illustrations: Celery stalk metaphysis -- Sausage digits- Onion skin periosteal reaction - Hamburger sign - Carrot stick fracture Summary Table

MSEE-42 Behcet's Disease From Head To Toe

Awards
Certificate of Merit

Participants
Furkan Ufuk, MD, Denizli, Turkey (*Presenter*) Nothing to Disclose

TEACHING POINTS

? To review the entire spectrum of clinical and imaging findings of Behçet's disease. ? To review the Behçet's disease-associated complications and imaging findings.

TABLE OF CONTENTS/OUTLINE

Vascular Involvement: Venous occlusion (most common), arterial occlusion, and arterial aneurysm can be seen in patients with Behçet's disease (BD). Vascular involvement is the most important cause of morbidity and mortality in BD patients.Thoracic Involvement: In patients with BD, both systemic and pulmonary vessels (arteries and veins) can be involved. Moreover, lung parenchyma, mediastinum, and pleura can be involved.Neurologic Involvement: Neurological involvement in BD is rare, and both parenchymal (brain stem, spinal cord) and non-parenchymal (cerebrovascular disorders, aseptic meningitis, and intracranial hypertension) involvement can be seen.Gastrointestinal involvement: Behçet's disease can involve the intestinal venules and cause mucosal ulceration, and mostly involve the ileocecal region. Bowel ischemia can be seen due to mesenteric vein or artery thrombosis.Cardiac Involvement: Cardiac involvement of BD is rare, and myocarditis, pericarditis, and intracardiac thrombosis are the most common presentations.Musculoskeletal Involvement: BD may cause sacroiliitis, avascular necrosis, enthesopathy, and myositis. Hepatobiliary Involvement: BD may cause Budd-Chiari syndrome, portal vein thrombosis, portal hypertension, and sclerosing cholangitis.

MSEE-43 Optimising 3D Printed Physical Models From Imaging: Learning Points, Tips ; Tricks

Participants
Mark Tan, MBBS,FRCR, Singapore, Singapore (*Presenter*) Nothing to Disclose

TEACHING POINTS

This educational exhibit describes various pointers in optimising 3D printed models from CT/MRI imaging. Applications of high resolution physical anatomical models created using additive manufacturing techniques from medical imaging include the rehearsal of complex patient-specific surgeries, the pre-sizing and pre-shaping of surgical plates and screws, the employment of custom made targeting guides, as well as the reconstruction of osseous defects post tumour resection, craniotomy, or joint surgery. Various domains of this process are covered in this exhibit, including image acquisition, image segmentation, image transformation, print protocolling. This exhibit may be of interest to the teams involved in such tasks i.e. radiologists, radiographers, surgeons and biomedical engineers.

TABLE OF CONTENTS/OUTLINE

Optimising 3D models from imaging:The following are non-exhaustive and include:Image acquisitionMetal artefact reduction techniquesDual energy CTMetal Artefact Reduction AlgorithmImage segmentationUtilising multiplanar reconstructions to improve segmentationMultimodal lesion analysisImage transformation (i.e. 3D model manipulation)Closing of large mesh defectsCreating structures to model non critical regions of anatomy to increase print efficiencyModelling tubular structuresPrint protocollingPrinter

technique choice for different applicationsMaterial choice for different applicationsPrint bed sizingOptimising model orientations for print efficiency

MSEE-44   MR Imaging In Ob/Gyn Emergencies: A Practical Guide

Participants
Bernardo Oliveira, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Understand the role of MR imaging in the evaluation of gynecologic emergencies. Proficiently recognize pelvic gynecologic emergencies by MR imaging. Be able to evaluate acute abdominal pain during pregnancy by MR imaging. Be aware of safety issues regarding MR imaging contrast media during pregnancy and lactation.

TABLE OF CONTENTS/OUTLINE

Gynecological emergencies and pregnancy-related complications are frequent causes of hospital care among women of reproductive age. Although ultrasonography remains the first-line imaging modality in this setting, when a definite diagnosis is not obtained, Magnetic resonance (MR) imaging plays a role by increasing diagnostic accuracy. Therefore, the emergency radiologist may be aware of MR imaging presentation in gynecologic emergencies, such as adnexal disorders (torsion, hemorrhagic cyst, ectopic pregnancy); complication of uterine fibroids; inflammatory pelvic disease; as well as nonobstetric causes of acute abdominal pain during pregnancy, such as appendicitis and urinary disorders. Eventually, it is also important to address considerations related to safety of contrast media during pregnancy and lactation.

MSEE-45   Imaging In Histiocytic Disorders In Adults: Hard Work But, Let's Make Some "imaging Teamwork".

Participants
Ana Santos Angel, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

Histiocytic disorders can rarely affect adults and present nonspecific image findings. The role of the radiologists in the diagnosis is relatively limited but, familiarity with typical radiographic features and putting together with histological findings may promote accurate and timely diagnosis.

TABLE OF CONTENTS/OUTLINE

Histiocytic disorders are defined as non-malignant disorders that include some rare multisystem diseases with a wide and heterogeneous clinical radiological spectrum. Langerhans cell histiocytosis is the most common disease and its imaging features are better known. But there are other uncommon diseases in this category such as Erdheim-Chester disease, Rosai-Dorfman disease, juvenile xanthogranuloma, and hemophagocytic lymphohistiocytosis, that should be included in the differential diagnosis. Focusing on CT images and correlating with microscopic histologic images, we present some cases of our hospital including adult patients with histiocytic disorders. We review image findings including locations of involvement and some key radiographic features as "hairy" margins of the kidneys in Erdheim-Chester disease or locations of massive lymphadenopathy in Rosai-Dorfman disease, among others. We also review microscopic histologic images with some clues for the histopathological diagnosis. These findings are nonspecific, but on the whole, its knowledge is important for radiologists and pathologist to get them into account in the differential diagnosis.

MSEE-46   "Why-RADS", A 2021 Update On The Standardized Reporting And Data Systems

Awards
Certificate of Merit

Participants
Kyle Unsdorfer, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

TEACHING POINTS

• The American College of Radiology (ACR) Reporting and Data Systems (RADS) are a set of dynamic documents created to address a specific need, but all aim to unify standardized imaging assessment, classification, terminology and reporting • Formal processes are underway to determine the extent and ways in which RADS should be collectively standardized

TABLE OF CONTENTS/OUTLINE

Review• Explore "why" each RADS exist and the historical context behind each RADS creation and adoption • Compare and contrast RADS systems regarding prior biopsy, role of interval change, multiple lesions, and lexiconLearning and Tools• Provide an update on guidelines and reporting systems since prior RadioGraphics Fundamentals article 39:1435-1436 (2019).• Review of ACR RADS: BI-RADS, C-RADS, CAD-RADS, GI-RADS, LI-RADS, Lung-RADS, NI-RADS, *PI-RADS, *O-RADS, and TI-RADS, and Non-ACR/International "RADS": *BT-RADS, CO-RADS, MY-RADS,*VI-RADS, and *PSMA-RADS (*new/updated since 2019) • Provide educational resources and web-based calculator appsFuture• Discuss future directions and potential synergy among current and future RADS • Discuss pros and cons of ACR affiliation-resources, processes, degree of organization involvement, adoption and legitimizing • Discuss aims for consistent scales, terminology, description of lesion biopsy status between systems • Discuss collaboration with clinicians to further improve standardized language and patient management across multiple disciplines

MSEE-47   Lymphoepithelial Carcinoma And Lymphoepithelioma-like Carcinoma: Imaging And Clinicopathological Features Within And Beyond The Head And Neck

Participants
Koji Takumi, MD,PhD, Kagoshima, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Lymphoepithelial carcinoma and lymphoepithelioma-like carcinoma (LEC/LELC) are rare histologic types of solid tumors that arise most frequently in the head and neck and also occur in other anatomic sites such as the lung, thymus, stomach, uterine cervix, bladder, etc. LEC/LELC is characterized by undifferentiated malignant epithelial cells with a prominent lymphocytic infiltration. LEC/LELCs have been reported to be associated with viral infection such as EB virus and HPV. In spite of a high incidence of

regional and distant metastasis when diagnosed, the prognoses for LEC/LELCs are generally better than those of other malignancies in each organ because of high sensitivity to irradiation and antitumor drugs. It is important for radiologists to understand the clinicopathological and radiological features of LEC/LELCs to avoid misdiagnosis and improper patient management as they may be mistaken for metastatic nasopharyngeal carcinoma or lymphoma on biopsy histopathologic specimens. Therefore, we should review and clarify the clinical and imaging features of LEC/LELC of nasopharyngeal and non-nasopharyngeal region. The purpose of this exhibit are: 1. To illustrate the etiology and epidemiology of LEC/LELCs 2. To review the histopathological and radiological imaging features of clinical cases of LEC/LELCs 3. To discuss the differential diagnosis of LEC/LELCs in each organ

TABLE OF CONTENTS/OUTLINE

1. Overview of LEC/LELCs 2. Clinicopathological and imaging features of LEC/LELCs in each organs 3. Limitations of imaging in LEC/LELCs

MSEE-48   Lower Back Pain: Not So Innocuous After All - A Guide For ER Radiologist

Participants
Baran Vardar, MD, Worcester, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Lower back pain (LBP) is a symptom, not a disease, and is one of the most common causes of emergency room (ER) visits in the United States. It is estimated that at least 80 percent of adults have one episode of low back pain during their lifetime. Although most LBP results from a lumbar strain and does not warrant further workup, more emergent or serious underlying conditions, including cancer, infection, fracture, cauda equina syndrome, and ruptured abdominal aortic aneurysm, may present to the ER with LBP. High level of clinical suspicion with imaging study done in a timely fashion significantly impacts patient management and prognosis. This educational exhibit reviews the imaging manifestations of possible serious LBP causes with ER presentation.

TABLE OF CONTENTS/OUTLINE

1) Overview of normal imaging anatomy of the lumbar spine 2) Red flags in the management of LBP and possible imaging indications per American College of Radiology Appropriateness Criteria 3) Multimodality imaging examples of LBP with complicated underlying conditions: a) Infection: Osteomyelitis/discitis, paraspinal abscess, epidural abscess, arachnoiditis b) Neoplasia: Metastatic carcinoma, multiple myeloma, lymphoma, myxopapillary ependymoma, schwannoma c) Fractures: Vertebral compression fracture, burst fracture, sacral insufficiency fracture d) Cauda equina syndrome: Degenerative herniated disc, spinal canal stenosis, epidural hematoma, facet joint cyst e) Visceral disease: Nephrolithiasis, pyelonephritis, ruptured aortic aneurysm, pancreatitis.

MSEE-49   Imaging Challenges And Considerations Of The Obese Trauma Patient

Participants
Julia Saltalamacchia, MD, Portland, Oregon (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Imaging obese patients present specific challenges in trauma/emergency settings.2. Body habitus plays a role in traumatic injury pattern, injury severity, morbidity, and mortality.3. Implement strategies to mitigate the effect of obesity on image quality to ensure the best possible trauma care for all patients, regardless of body habitus.

TABLE OF CONTENTS/OUTLINE

1. Review obesity demographics 2. General trauma imaging challenges are more complex in obese patients, including: a. Spine precautions b. Patient stability c. Unknown past medical history 3. Challenges of imaging an obese patient a. CT: Technical/scanner characteristics, positioning and risk of airway compromise, and obesity related artifacts b. Ultrasound c. Radiograph 4. Obese trauma patient imaging: special considerations during hospital stay a. Mechanism and injury pattern: increased likelihood of MVC, increased risk of chest, extremity, and pelvis fracturesb. Increased risk of infection, VTE, and post-operative complication 5. Optimizing imaging modalities: strategies and solutionsa. Modality specific i. CT: increase tube current, increase peak voltage, increase reconstruction section thickness, and bundling ii. US: Tissue harmonic imaging, patient positioning iii. Radiography - Antiscatter grid, tight collimationb. Technologist education and compassionate care c. Reporting language and clinician communication

MSEE-5   Dixon Technique In Musculoskeletal And Spine MRI - Beyond The Bone Marrow

Participants
Robert W. Morris, MD, Jackson, Mississippi (*Presenter*) Nothing to Disclose

TEACHING POINTS

Much has been written about utilizing the Dixon technique to evaluate the bone marrow, but this imaging method has applications in musculoskeletal and spine MRI outside of the bone marrow. These applications include: 1. Improved fat suppression on fluid-sensitive and contrast-enhanced sequences. 2. Enhanced lesion detection in the soft tissues. 3. Fat fraction quantification. 4. Characterization of soft tissue lesions. 5. Evaluation and quantification of muscle atrophy.

TABLE OF CONTENTS/OUTLINE

Table of Contents: 1. Review of the Dixon method. 2. Use in fat suppression: fluid-sensitive sequences. 3. Use in fat suppression: contrast-enhanced sequences. 4. Enhanced lesion detection. 5. Quantification of fat fraction using the Dixon method. 6. Lesion characterization: lipid-containing lesions. 7. Lesion characterization: lesions with little to no lipid content. 8. Evaluation and quantification of muscle atrophy. 9. Conclusion.

MSEE-50   Don't Forget To Look Up: Clues To Abdominal Diagnoses In The Lower Thorax

Participants
Matthew McCann, MD, Jacksonville, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. A careful search of the lower thorax at abdominal CT may reveal important clues for a unifying diagnosis of abdominal findings 2.

Abdominal pathologies may manifest with predictable patterns of lower thoracic involvement 3. Abdominal findings may be attributable to a primary thoracic disease process, such as congestive hepatopathy related to cardiac dysfunction 4. Various disease processes may involve both the thorax and abdomen; for example, Lymphangioleiomyomatosis (LAM) and Birt-Hogg-Dubé are both cystic lung diseases associated with renal lesions and cutaneous findings

TABLE OF CONTENTS/OUTLINE

Formatted as Interactive unknown cases first showing abdominal findings, then click to MCQ, then click for lower thorax findings that seal the unifying diagnosis + teaching points.Pulmonary: a. LAM b. Birt-Hogg-Dubé c. Alpha-1 antitrypsin deficiency d. Metastases from abdominopelvic tumors (metastasizing leiomyoma, choriocarcinoma, gestational trophoblastic disease)Pleura: a. Ovarian hyperstimulation b. Meigs syndrome (Triad: pleural effusion, ascites, ovarian tumor) c. Thoracic endometriosis d. SplenosisCardiovascular: a. CHF & constrictive pericarditis hepatopathy "nutmeg liver", cardiac cirrhosis b. Tumor thrombus c. Hepatopulmonary syndrome d. Erdheim-Chester disease e. Carcinoid heart from liver mets f. Abdominal infarcts with cardiac thrombus

MSEE-51   Imaging Ingested And Aspirated Foreign Bodies

Participants
Ivica Bratanovic, MSc, Port Moody, British Columbia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Ingested and aspirated foreign bodies (FBs) are commonly encountered in the Emergency Radiology setting and understanding the epidemiology and patient's risk factors is essential2. A thorough clinical history is important to determine the best imaging modality to evaluate aspirated and ingested FBs3. FB composition and anatomical location will influence the selection of the appropriate imaging modality to investigate ingested and aspirated FB4. Ingested and aspirated FB can be associated with complications and recognizing their imaging characteristics is key for the radiologist

TABLE OF CONTENTS/OUTLINE

- Brief introduction to FB imaging and imaging modality utility- Overview of ingested and aspirated FBs and their epidemiology- Key anatomical locations to evaluate with imaging for ingested and aspirated FBs- Patient profile and history on determining imaging modality selection- Imaging characteristics of common ingested or aspirated FBs- Review of common complications associated with ingested and aspirated FBs and imaging considerations- Clinical Cases- Summary and key points moving forward

MSEE-52   Beyond The Lungs: Abdominal Involvement By Tuberculosis

Awards
Certificate of Merit

Participants
Bianca Coimbra, BMedSc, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Tuberculosis remains the leading cause of death from infectious diseases among adults worldwide, especially in developing countries.The abdomen is the most common site of extrapulmonary tuberculosis, being a diagnostic challenge, due to several presentations of the disease, we may have delays in the diagnosis and development of complications. Early diagnosis, initiation of anti-tuberculosis therapy and surgical treatment, in some cases, are essential to prevent morbidity and mortality. It is important that the Radiologist recognizes the imaging findings, allows the establishment of a more effective strategy to confirm the diagnosis and institute the appropriate treatment as soon as possible.

TABLE OF CONTENTS/OUTLINE

Clinical and epidemiological aspects. To review presentations of abdominal tuberculosis in computed tomography (CT) and magnetic resonance (MRI), especially in immunocompromised patients, based on our service's digital archive: pulmonary, lymph node, renal, splenic, adrenal, peritoneal and testicular involvement. Take-home messages. References.

MSEE-53   Sonography Made Simple: A Case-based Review

Participants
Brian Tsui, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

Ultrasound technology and tools constantly evolves, giving radiologists new methods to make more accurate diagnoses on ultrasound alone. Understanding these ultrasound modes and tools can help trainees, fellows, and general radiologists recognize when to use them and how to troubleshoot in order to confidently make a diagnosis. 1. 1. Case-based review with multiple choice questions of common ultrasound tools and modes 2. 2. Demonstrate through cases how these tools and modes work, including physics 3. 3. Discuss common scenarios when to use these tools and common pitfalls

TABLE OF CONTENTS/OUTLINE

1. 1. Introduction2. 2. Transducer and Grey scale optimization 3. 3. Doppler and Microvascular Imaging4. 4. Harmonic imaging5. 5. Contrast-enhanced ultrasound6. 6. 3-D ultrasound7. 7. Chroma maps 8. 8. Panoramic imaging9. 9. Elastography10. 10. M-mode imaging11. Summary and conclusion

MSEE-54   The Radiologist'S Role In Thread Lifts Evaluation With High Frequency Ultrasound:how To Detect, Recognize And Access Complications

Participants
Luciana Zattar, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Facial aesthetic procedures are increasingly being performed, and minimal invasive types are preferable. In this context, the

radiologist has been requested to recognize their usual aspects as well as to assess possible complications.To achieve accurate and timely detection and appropriate approach of each case, High frequency ultrasound (HFUS/24-33MHz) is the most effective method since it provides optimal anatomical information of the skin and allows identification of thread lifts and its complications.This study aims to discuss and illustrate the radiologist's role in the evaluation of thread lifts with HFUS.The purpose of this exhibit is:-To describe the pre procedure evaluation-To illustrate the anatomy of the skin and facial layers-To show the main image patterns of thread lifts that allows its identification-To list, classify and describe the procedure complications-To highlight the importance of HFUS guidance in thread lifts procedures/removal-To keep in mind a practical chart that may help reaching the correct patient's approach

TABLE OF CONTENTS/OUTLINE

1.PREPROCEDURE EVALUATIONAnatomical variantMaterials2.LOCALIZATIONSkin/facial layers3.THREAD LIFT IDENTIFICATION4.COMPLICATIONS5.PROCEDURE GUIDANCE

MSEE-55   An Emergency Radiologist's Guide To The Acute Breast

Participants
Douglas Katz, MD, Mineola, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

To review the spectrum of potential breast emergencies and the settings where they can occur To recognize the clinical and imaging features of breast emergencies and their differential diagnosis, based on various imaging modalities, including radiography, ultrasound, and CT To discuss the current literature on the imaging and management of breast emergencies

TABLE OF CONTENTS/OUTLINE

Although breast emergencies are infrequently encountered, these acute situations require urgent management, and may be encountered by both the general and the emergency radiologist, in addition to the breast imager, whom is much more familiar with these entities. It is important to recognize the clinical signs and imaging appearances for timely diagnosis and treatment. We will review the multi-modality imaging appearances of breast emergencies, and will show multiple examples including trauma, infection, malignancy, and iatrogenic etiologies, and their potential mimics and pitfalls. We will also discuss the treatment and follow-up of acute breast disease, to ensure continuity of care and facilitate timely disease management. Entities to be demonstrated and discuss will include complications from percutaneous biopsy or trauma, as well surgery (hematoma, fat necrosis, pseudoaneurysm and/or AV fistula); infection (mastitis, abscess, Mondor disease); malignancy (inflammatory carcinoma, emergency presentations of locally advanced/metastatic breast cancer); and other breast lumps presenting emergently (Phylloides tumor and gynecomastia).

MSEE-56   Facial Fat Compartments Evaluation With High Frequency Ultrasound

Participants
Luciana Zattar, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Facial aging is a multifactorial process. Physiological and morphological changes occur in both skeletal and soft tissue composites. Most available therapeutic options are aimed at restoring the redistributed volume of superficial and deep facial fat layers. The correct evaluation and measurement of these fat compartments is essential to determine which structure is the key player in the presenting clinical scenario of ageing and wrinkles formation, since a wrong manipulation might yield an aesthetically undesirable result. In this context, the radiologists may be requested to recognize and evaluate the layers, compartments and their contents, crucial for safe and effective minimally invasive rejuvenation procedures. To achieve accurate and timely detection and appropriate approach of each case, High frequency ultrasound (HFUS/24-33MHz) is the most effective method since it provides optimal anatomical information of the skin and allows skin layers differentiation and changes monitoring. This study aims to discuss and illustrate the radiologist's role in the evaluation of fat-pads with HFUS.The purpose of this exhibit is:- To illustrate the anatomy of the skin and facial layers- To describe the most important facial aging changes- To highlight the importance of HFUS in fat-pads characterization- To show the dynamic fat-pads evaluation and measurements with HFUS

TABLE OF CONTENTS/OUTLINE

1.ANATOMY:Skin/facial layers2.FACIAL AGEING PROCESS3. FAT-PADS EVALUATIONBICHATEYELIDROOFSOOF4.CONCLUSION

MSEE-57   Abdominal Tuberculosis: Untangling The Great Mimicker

Participants
Wider Landim Filho, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The incidence of tuberculosis has increased mainly as a consequence of HIV infection and use of immunosuppressive drugs. The abdomen is the most common site of extrapulmonary tuberculosis. Owing to the multiplicity of abdominal organs, there are many forms and patterns of occurrence, representing a diagnostic challenge for radiologists. Abdominal presentation may involve structures such as gastrointestinal tract, genitourinary tract, liver, spleen, pancreas, gallbladder, aorta, peritoneum and lymph nodes, frequently with simultaneous involvement of those organs.Abdominal tuberculosis may be mistaken as several different conditions, such as inflammatory bowel disease, cancer and other infectious diseases. A delay in the correct diagnosis may result in significantly increased morbidity, and an early recognition is essential for proper management.

TABLE OF CONTENTS/OUTLINE

• Discussion of the different forms of presentation of abdominal tuberculosis, describing the most typical radiological findings in each type. • Discussion on the performance of each imaging modality in tracking and detecting the disease. • Presentation of rare imaging features found in unusual cases. • Take-home messages and provision of a didactic approach of differential diagnoses, based on imaging features, addressed to each abdominal system/ organ.

MSEE-58   **Arterial Injuries Associated With Superior Pubic Rami Fractures: Variants, Cross-talk, Collaterals, And Conventional Anatomy**

Participants
Ethan Speir, MD, San Francisco, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Superior pubic rami fractures can result in hemorrhage from multiple arterial vascular territories.2) The corona mortise is a common anatomic variant to consider during pelvic angiography.3) Limited pelvic angiography in the traumatic setting can result in failure to recognize life-threatening hemorrhage.

TABLE OF CONTENTS/OUTLINE

Pubic rami are the most frequently fractured pelvic ring elements in the setting of blunt force trauma and are the most common osteoporotic pelvic fracture. Superior pubic rami fractures are of particular importance as they can result in hemorrhage from multiple arterial vascular territories including the obturator artery, medial circumflex femoral artery, and corona mortise, a common anatomic variant present in nearly half hemi-pelvises. Furthermore, heavy atherosclerotic burden can result in extensive collateralization. Clinically, this poses a challenge to the interventionalist as life-threatening hemorrhage can arise from internal and/or external iliac branches originating from the ipsilateral and/or contralateral side.In this exhibit, we will review cases from our institution, a Level I Trauma Center, which highlight these anatomic implications. We will also review data from our cohort and compare incidence of culprit vessels and patient outcomes to those reported in the literature

MSEE-6   **Bowel And Mesenteric Injuries In Trauma - Correlation With Intraoperative Findings/ Follow-up Imaging: Where An Early Diagnosis Can Save Lives.**

Participants
Denver Pinto, MD, Miami, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

This exhibit aims to help the ER radiologist or resident to:* Identify subtle signs of bowel injury.* Identify signs of mesenteric injury necessitating operative repair.* Demonstrate bowel related remote complications of trauma.* Evaluate the imaging findings of bowel and mesenteric injury caused by varying mechanisms

TABLE OF CONTENTS/OUTLINE

Objectives.Epidemiology of bowel and mesenteric trauma.Importance of prospectively picking up subtle findings.Evaluation and Imaging findings (cases and discussion)Blunt trauma: Peri colonic hematoma with interval development of hemoperitoneum, Ascending colon hematoma (sub serosal tear) with mesenteric injury, Mesenteric injuries with and without active extravasation, Pseudoaneurysm in the mesocolon inferior to the liver.Stab injury: Peritoneal violation without bowel injury, Perforated bowel, Perforated stomach, Psoas and mesenteric hematoma, Omental hematoma, Retroperitoneal hematoma.Gun-shot wound: Colon hematoma with full thickness perforation, Jejunal and sigmoid colon perforation - be wary of satisfaction of search. Air may act as a negative contrast.Importance of analysis of trajectory of a projectileSpecial cases: Non-viscus/ non-renal retroperitoneal injury, Foreign body perforating the rectum.Complications: Diaphragmatic hernia and closed loop obstruction following a remote stab injury to the diaphragm, Adhesions causing bowel obstruction S/p colonic repair.Teaching points. References

MSEE-60   **Contrast-enhanced Ultrasound As A Problem-solving Tool: A Guide To A Successful Integration Into Clinical Routine**

Participants
Lucas Roberto Lelis Oliveira, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Discuss how contrast-enhanced ultrasound (CEUS) is performed, focusing on setup and workflow issues.• Summarize dosing and safety questions related to the microbubble contrast administration in adults and pediatric patients.• Present different clinical scenarios in which CEUS can be used as a problem-solving tool, including "off-label" indications.• Improve the knowledge of current and potential applications of CEUS among radiologists, aiming to facilitate the integration of this technique into their clinical routine.

TABLE OF CONTENTS/OUTLINE

Introduction - General concepts of CEUS• How microbubble contrast works.• Advantages of CEUS over other imaging modalities• Indications and contraindications.CEUS Technique• A step-by-step explanation of how to perform CEUS.• Common CEUS artifacts and pitfalls.• Tips and tricks for beginners and veterans.Case-Based Review• Sample cases demonstrating how CEUS can be used as a problem-solving tool in clinical practice.This section will present illustrative cases of:o Hepatic and renal focal lesions o Gynecological diseaseso Organ Transplantationo Vascular pathologieso Pediatric imagingo Abdominal Traumao CEUS in Interventional RadiologyFuture Directions: What is on the horizon for CEUS?Conclusion and key takeaways.

MSEE-61   **Eye Got It: Orbital Trauma**

Participants
Jason A. Pietryga, MD, Warren, Rhode Island (*Presenter*) Consultant, Radiostics LLC

TEACHING POINTS

Review normal orbital and globe anatomyReview common traumatic pathologies of the globe. Review common mimics of acute globe trauma.Review orbital traumatic pathologies.

TABLE OF CONTENTS/OUTLINE

Introduction: Present statistics regarding orbital/globe traumaNormal globe & orbit anatomyTraumatic pathologies of the globe: corneal laceration, traumatic cataract, vitreous hemorrhage, lens dislocation, and globe ruptureMimics of globe trauma: staphyloma, silicone injection, trochlear apparatus calcification, post operative changes (e.g. pseudophakia, scleral buckle)Traumatic orbital pathologies: orbital fractures, extra-ocular muscle entrapment, retrobulbar hemorrhage, orbital compartment syndrome, orbital foreign body.

MSEE-62   Polycystic Neotropical Echinococcosis: Imaging Review Of A Rare Variant Of Hydatid Disease

Awards
Certificate of Merit

Participants
Jose Wilson Trindade, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

• To describe the epidemiology and pathophysiology of neotropical polycystic echinococcosis, a rare variant of hydatid disease • To discuss differential diagnosis of hepatic cystic lesions and calcification, emphasizing key points to consider Echinococcus infection in patients from endemic regions • To illustrate different imaging features of polycystic echinococcosis on CT • To present a proposed CT staging system for echinococcosis after initial treatment, to provide further adequate therapeutic decisions and improve outcomes

TABLE OF CONTENTS/OUTLINE

1) Introduction and overview of polycystic neotropical echinococcosis, including epidemiology, imaging features and differential diagnosis 2) Discussion of various confirmed cases, emphasizing the most common hepatic and extra-hepatic imaging findings on CT and their correlation with patients' prognosis and outcomes 3) Proposed CT staging system for polycystic echinococcosis

MSEE-63   CT Of Sacral Fractures: Classification Systems, Management, And Complications

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Elana Smith, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

After reviewing this exhibit, readers will be able to: i. Describe common classification systems for sacral fractures. ii. Explain how injury grade affects surgical decision-making iii. Discuss post-traumatic or post-surgical complications by fracture type.

TABLE OF CONTENTS/OUTLINE

I. CT-based classification1. Isler and Denis• based on violation of neural foramina/spinal canal• zone 3 subclassification- considers orientation, angulation, translation, and comminution2. AO spine for sacral fractures• Need for universal system identified through worldwide survey of 474 spine surgeons.i. Type A: lower sacrococcygeal- no instabilityii. Type B: posterior pelvic instabilityiii. Type C: spinopelvic instability3. Insufficiency fractures:• No trauma/low impact trauma (esp women > 55 yrs)• typically non-ambulatory• Bone scintigraphy/MRI complementary (H-sign)II. Management considerationsi. Indications/types of stabilization/instrumented fusionii. Indications/types of neural decompressioniii. Sacroplasty/kyphoplasty for insufficiency fracturesiv. Conservative mgmtIII. Complications:i. neural compression symptomsii. neural compression: CT findingsiii. post-operative complications:o screw malpositiono wound complications/infectiono loosening requiring revision surgery

MSEE-64   Ankylosing Spondylitis: A Review From Head To Toe

Awards
Certificate of Merit

Participants
Vamsi Meka, MD, Charlottesville, Virginia (*Presenter*) Nothing to Disclose

TEACHING POINTS

Ankylosing spondylitis (AS) is a prototype of HLA B27+ve axial spondyloarthritis. It is a chronic, potentially debilitating, inflammatory disorder with multisystem involvement. Musculoskeletal manifestation is characterized by 'enthesitis' (inflammation at the ligament or tendon insertion site on to the bone) or synovitis. Bilateral sacroiliitis, spondylitis, spinal fusion and ankyloses are characteristic musculoskeletal imaging findings. The purpose of this exhibit is to review the multimodality imaging appearance of typical and atypical imaging findings of AS with focus on different organ system involvement. It is important to differentiate AS from other inflammatory spondyloarthropathies on imaging to aid in early diagnosis. We briefly discuss the diagnostic criteria for AS, current role of imaging in the diagnosis and follow up, and management.

TABLE OF CONTENTS/OUTLINE

Introduction Epidemiology and Pathophysiology of AS Imaging and clinical manifestations of AS - a) Musculoskeletal: Sacroiliitis, Spondylitis, Peripheral arthritis. b) Cardiovascular: Aortitis, aortic regurgitation c) Pulmonary: Parenchymal abnormalities, Apical fibrosis. d) Gastrointestinal: Inflammatory bowel disease. e) Miscellaneous: Anterior uveitis, Psoriasis.Diagnostic criteria Differential diagnosis Disease related complications Summary References

MSEE-65   High Energy Lower Extremity Trauma: Beyond Fracture Lines

Participants
Ane Ugarte Nuno, MD, San Sebastian, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To explain how to acquire CT images in high energy trauma patients including lower limbs. - To describe pathologic findings related to vascular system, musculotendinous structures and soft tissue. - To convey the importance of detecting these findings to improve pacient management

TABLE OF CONTENTS/OUTLINE

Patients that undergo high energy trauma usually present to the ER with multiple injuries affecting the head, thorax and abdomen. These lesions can be life-threatening. Associated injuries to lower extremities often take second place. However, it is crucial to

evaluate them because high energy fractures promote a systemic inflammatory response that makes even more difficult management of these patients. Stabilization of fractures is mandatory. Moreover, beyond the fracture lines, it is essential to evaluate sorrounding soft tissues, neurovascular system and musculotendinous structures. This presentation will emphasize evaluation of these forgotten structures following these index: - Introduction - CT protocol - Vascular injuries associated to high energy fractures - Injuries to musculotendinous structures - Subcutaneus tissue and skin injuries in high energy fractures - Few fracture classifications of use in high energy fractures

MSEE-66   Teratoma: From Head To Toe.

Participants
Samyra Medeiros, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Teratomas are a common form of GCT. They are defined histologically as containing tissues derived from all 3 germ cell layers: ectoderm, mesoderm (most teratomas contain fat, an imaging hallmark, which is a mesodermal derivative), and endoderm. Teratomas are also classified as mature or immature, depending on the degree of differentiation of its components. Teratoma is an uncommon neoplasm with an incidence of 0.9/100,000 population. Common sites for teratomas in infancy and children are extra-gonadal like mediastinal, sacro-coccygeal and pineal regions. In adults, they are mainly gonadal. Retroperitoneal teratoma is rare and comprises of about 1% of all teratomas. In more than 50% of cases, mature teratomas have no symptoms at initial diagnosis and are detected by chance. Teratomas have already been reported in different locations, ranging from intracranial, thoracic, abdominal compartments, to ostiomuscular and spinal compartments.

TABLE OF CONTENTS/OUTLINE

Present a brief review of teratoma and its possible locations. Demonstrate, through imaging, some common and rare sites of teratomas, available in our digital archive.

MSEE-67   Musculoskeletal Involvement In Marfan Syndrome: An Imaging Overview

Participants
Mariana Batista Rosa Pinto, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is to: 1. Briefly approach the pathophysiology and epidemiology of Marfan Syndrome. 2.Remember the diagnosis criteria and point the importance of musculoskeletal radiologist. 3.Review and didactically illustrate the most frequent musculoskeletal manifestations of Marfan Syndrome with imaging findings in a multimodality approach (radiographs, computed tomography scans and magnetic resonance imaging).

TABLE OF CONTENTS/OUTLINE

Introduction: General presentation of the pathophysiology, epidemiology, clinical findings and diagnostic criteria of Marfan Syndrome. Present a schematic table with the main musculoskeletal imaging findings in Marfan Syndrome, as well as didactically divide them to facilitate the approach. Provide didactic and illustrative cases of each site of musculoskeletal involvement (spine, pelvis, chest wall, hands and feet). Conclusions. Bibliographical references.

MSEE-68   Imaging Of Pregnant Patients In The Trauma Setting: A Case-based Review

Participants
Helena Bentley, MD, Vancouver, British Columbia (*Presenter*) Nothing to Disclose

TEACHING POINTS

Trauma is the leading cause of non-obstetric mortality of pregnant patients. Timely, high-quality imaging evaluation of pregnant patients who sustain trauma is essential for patient & fetal outcomes.Using illustrative cases from our tertiary, high-volume level 1 trauma center upon review of this educational exhibit the reader will be better able: (1) to recall the epidemiology of trauma sustained by pregnant patients; (2) to understand the general principles of imaging evaluation of pregnant patients in the trauma setting; (3) to recognize the unique pattern of traumatic injury sustained by pregnant patients; & (4) to discuss notable imaging findings of obstetrical complications arising from trauma sustained by pregnant patients & associated do not miss diagnoses.

TABLE OF CONTENTS/OUTLINE

While non-pregnancy related injuries may arise, we will emphasize potential obstetrical complications & injuries. General principles of imaging evaluation of pregnant patients in the trauma setting will be described, with a particular focus on study selection as well as radiation dose and contrast concerns. The increased incidence of abdominal injury will be outlined as well as the physiologic rationale for same. Obstetrical complications associated with trauma, including internal hemorrhage, placental abruption, & uterine rupture, shall be reviewed.

MSEE-69   "Non Vascular Uses Of Ultrasound Contrast" - Unexplored Territories And Unfamiliar Utilities

Participants
Pooja Vyas, MBBS, Mumbai, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

Use of ultrasound contrast agents in diagnosis of various non vascular gastrointestinal or genitourinary pathologies is a relatively unfamiliar territory. Local instillation of ultrasound contrast via oral/urinary catheter/ drainage catheter into intraluminal or intracavitatory spaces further augments the utility of ultrasound with microbubble agents and opens a new spectrum of real time visualization of various pathologies that can be diagnosed, in addition to the routine intravascular ultrasound contrast studies.

TABLE OF CONTENTS/OUTLINE

1. Introduction to USG Contrast 2. Case series -Gastrointestinal(GI) applications:Oesophageal strictures, Hiatus hernia, Gastric malignancy, Pyloric mass, upper GI Perforation4. Case series -Genitourinary applications- Vesicoureteric reflux,Urethrogram,5. Case series-applications in Fistulae/ sinuses-Vesicovaginal fistula,Vesicocolonic fistula, Perianal abscess and fistula,Sinogram6.Sentinel

lymph node detection post intraductal contrast instillation in breast malignancy

MSEE-7   **Imaging Of Non-traumatic Renal Hemorrhage In The Emergency Department - Where The Radiologist Saves Lives!**

Participants
Denver Pinto, MD, Miami, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

This exhibit aims to help the ER radiologist or resident to:* Identify subtle findings related to the type and etiology of renal hemorrhage.* Identify high risk conditions predisposing to renal hemorrhage.* Identify the different imaging findings in non-traumatic renal hemorrhage

TABLE OF CONTENTS/OUTLINE

Objectives.Epidemiology and pathophysiology of renal hemorrhage.Importance of prospectively picking up subtle findings on Plain CT and Ultrasound.Evaluation and Imaging findings (cases and discussion)Intrinsic renal hemorrhage: Spontaneous subcapsular hematoma with an active bleeding vessel, Renal neoplasm with hemorrhage, Renal AML with pseudoaneurysm and hemorrhage, ADPKD with hemorrhage, Transplant kidney with pelvicalyceal hemorrhage.Vascular causes: Renal aneurysm and pseudoaneurysm, Renal vein thrombosis/ infarct.Extrinsic causes of hemorrhage: Retroperitoneal lipomatosis causing renal compression and hemorrhage, Post-operative Page kidney.Iatrogenic cause (non-biopsy): Renal stone causing deviation of nephrostomy tube causing hemorrhage.Special cases:Complication: Renal hemorrhage with urinoma and communication with the subhepatic space.Endograft leak.Conditions that are high risk for life threatening hemorrhage1. Renal AV shunting in a vascular tumor.2. Renal vascular malformation.3. Renal mass with an IVC thrombus.Teaching points.References.

MSEE-71   **Trauma: Ao Classification Pocket Guide For Residents**

Participants
Camila Justino, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To simplify by schematic drawings and clinical cases the different types of fractures in the Ao classification as terminal segment fractures, diaphyseal, spine and special cases.To emphasize which important aspects of fractures should be included in the radiologist's report to assist the orthopedic surgeon's decision.

TABLE OF CONTENTS/OUTLINE

Throughout history there have been numerous classifications of bone lesions proposed to create a common language among the members of the healthcare team.The lack of consensus can limit communication between doctors and hinder the complete understanding of the lesion, making it difficult to plan and develop treatment algorithms.A study group was created in 1958 in Switzerland, entitled Ao, which means in english Association for the Study of Internal Fixation. For a better understanding of each fracture, this group initiated several lines of research associated with innovations in surgical techniques that have allowed a change in the treatment of fractures. It is essential that the radiologist understands the Ao classification, since the definition of the treatment of these fractures will be based on their report, impacting the recovery of function and the patient's morbimortality. The clinical application of this classification will be illustrated later in schematic drawings and a case-based approach.

MSEE-72   **Standardizing Whole Body MRI In Myeloma: Myeloma Response Assessment And Diagnosis System (MY-RADS)**

Participants
Khalil ElGendy, PhD,MBBCh, Brentford, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

Purpose of the exhibit: • To be aware of the international guidelines for Whole-body diffusion weighted MRI (WB-DW-MRI) for imaging patients with myeloma. • To review the Myeloma Response Assessment and Diagnosis System (MY-RADS) guidance into standardization of acquisition and reporting of WB-DW-MRI in multiple myeloma patients. • To recognize the five Response assessment categories (RAC) according to the response to the intervention based on objective parameters (including lesion size, number, ADC measurements and bone marrow signal). • To review a series of RAC case examples

TABLE OF CONTENTS/OUTLINE

• Role of WB-DW-MRI in multiple myeloma with a focus on response assessment • MY-RADS: • Overview • Standardized acquisition • Structured reporting • RAC descriptions: objective criteria for assessment. • Case examples for RAC descriptions (RAC1 to RAC5)

MSEE-73   **Atypical Chest Pain: Role Of Cardiac MRI Beyond Myocardial Infarct**

Awards
Certificate of Merit

Participants
Juliana Sitta, MD, Jackson, Mississippi (*Presenter*) Nothing to Disclose

TEACHING POINTS

• To review the differential diagnosis and classification of atypical chest pain• To describe MRI findings and useful sequences to narrow the differential diagnosis• To review interesting common and uncommon cardiothoracic pathologies in which MRI is useful to guide clinical management

TABLE OF CONTENTS/OUTLINE

Acute chest pain is one of the most common presentations in the Emergency Department. Cardiac magnetic resonance imaging (CMRI) has an established role in the risk stratification of patients with acute coronary syndrome (ACS). However, when initial clinical workup excludes ACS, MRI aids in assessing differential diagnoses and mimickers. In this presentation, we will discuss the

role of CMRI in the assessment of atypical chest pain. We will discuss the advantages of different MRI protocols compared to other imaging modalities by describing sequence specific findings and their role in each pathology. We will provide case samples covering cardiac, vessels, lung, chest wall, and miscellaneous topics, including various etiologies such as cardiomyopathies, inflammation, infection, congenital malformations, malignancy, trauma, and incidental findings.

MSEE-74 Beyond The Aorta: Mimics Of Aortic Dissection On CT

Participants
Richard D. White, MBChB, FRCR, Cardiff, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Demonstrate alternative explanations in cases of suspected aortic dissection on CT across a range of body systems 2) Highlight pearls and pitfalls from imaging of suspect aortic dissection, including key artefacts which can masquerade as aortic dissection

TABLE OF CONTENTS/OUTLINE

1) Clinical presentation2) Pathologiesa. Cardiacb. Vascularc. MSKd. Pulmonarye. Miscellaneous3) Pearls, pitfalls and artefacts

MSEE-75 Vascular Causes Of Abdominal Emergencies: What The Radiologist Needs To Know

Participants
Richard D. White, MBChB, FRCR, Cardiff, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Appreciate pearls and pitfalls when evaluating the abdominal vasculature system on portovenous phase CT2) Be aware of key vascular review areas3) Highlight a spectrum of vascular causes of abdominal emergency of different mechanisms, with clinical correlation and management strategies, drawn from cases from two tertiary vascular centres

TABLE OF CONTENTS/OUTLINE

1) Pearls and pitfalls2) Key vascular review areas3) Vascular causes of abdominal emergencya. ischemiai. arterial vs venousii. atheroscleroticiii. thromboemboliciv. dissectionv. miscellaneousb. rupturec. hemorrhaged. AV fistulae. inflammatoryf. extrinsic compressiong. miscellaneous

MSEE-76 Cryptococcosis Not Hidden Anymore: Growing And Showing Up In Immunocompetent And Imunosuppressed Patients

Participants
Jessica Marchi, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To illustrate the general image aspects of cryptococcosis in multiple systems, address the main organs affected by it and recognize their most common involvement patters; To present cryptococcal infeccions image findings, both in immunocompetent and immunosuppressed patients

TABLE OF CONTENTS/OUTLINE

A review of cryptococcosi's epidemiology, pathophysiology and systemic manifestations; An assessment of the main imaging findings of cryptococcosis in multiple systems, both in immunocompetent and immunosuppressed patients, focusing on the possible differences and similarities between them;Case based review with illustrative cryptococcal infections represented by image methods.

MSEE-77 Neurofibromatosis From Head To Toe: What The Radiologist Needs To Know

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Mindy Wang, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Describe and distinguish the clinical presentations of neurofibromatosis types 1 and 2.2) Identify the imaging features of neurofibromatosis types 1 and 2 in various modalities.3) Discuss the impact of imaging features on management.

TABLE OF CONTENTS/OUTLINE

1) Neurofibromatosis type 1a) Pathophysiology and diagnosisb) Clinical presentations and imaging featuresi) Cutaneous manifestations(1) Neurofibromas and plexiform neurofibromasii) Central nervous system manifestations(1) Focal areas of signal intensity(2) Optic pathway gliomas and astrocytomas(3) Malignant peripheral nerve sheath tumor(4) Sphenoid wing dysplasia(5) Plexiform neurofibromas(6) Meningocelesiii) Thoracic manifestations(1) Interstitial lung disease(2) Bullae formationiv) Abdominopelvic manifestations(1) Neurofibromatosis(2) Various neoplasms such as gastrointestinal tumors and pheochromocytomav) Musculoskeletal manifestations(1) Kyphoscoliosis(2) Posterior vertebral scalloping(3) Dural ectasia(4) Rib abnormalities(5) Bony dysplasias(6) Non-ossifying fibromasvi) Vascular manifestations(1) Vascular dysplasias such as moya-moya arteriopathy and renal artery stenosis(2) Aneurysms/arteriovenous malformationsc) Management2) Neurofibromatosis type 2a) Pathophysiology and diagnosisb) Clinical presentations and imaging featuresi) Schwannomaii) Meningiomaiii) Ependymomac) Management

MSEE-78 Technical And Methodological Issues Which Influencty Ceus Examination

Participants
Irene Campo, Conegliano, Italy (*Presenter*) Nothing to Disclose

TEACHING POINTS

Knowledge of the basic physical and technical principles of ultrasound is needed to understand sonographic images and findings and to be able to evaluate the possibilities and limitations of the method. Like the B-mode ultrasound, the quality of the Contrast Enhancement Ultrasound (CEUS) is also subject not only to the well-known manual skills of the operator but also to a deep knowledge of the technique, to improve image quality and avoid misleading artifacts. CEUS technique, technical errors and possible solutions are described.

TABLE OF CONTENTS/OUTLINE

Although CEUS is a widespread and easily manageable technique, image interpretation errors are often due to the operator's inexperience and / or lack of knowledge of the pitfalls it can offer, causing uncertain diagnosis and misdiagnosis. The pitfalls can be simplified as follows: pitfalls of acoustic windows; pitfalls arising from the methodological approach of US equipment; pitfalls of inadequate visualization of the depth and location of the structure; Pitfalls arising from equipment malfunction. Content organization: 1. Introduction 2. CEUS technical parameters 3. Pitfalls resulting from acoustic windows 4. Pitfalls resulting from metodological setting of us equipment 5. Pitfalls resulting from inadequate visualization of the deep and seat of structure 6. Pitfalls resulting from malfunction of the equipment 7. Conclusion 8. Reference

MSEE-79   Doppler Ultrasound Of Peripheral Vascular Emergencies: A Beginner's Guide To Riding Waves

Participants
Francesca Iacobellis, MD, Naples, Italy (*Presenter*) Nothing to Disclose

TEACHING POINTS

To provide a practical learning guide of color Doppler ultrasound applications to recognize acute vascular emergencies, including technical and interpretative approaches. To review color-Doppler parameters regulation techniques to avoid artifacts and pitfalls, in order to optimize the quality of Doppler waveform for a correct data interpretation. To examine the role of innovative vascular ultrasound technologies useful in the emergency setting. To identify the spectral waveform alterations of the commonly-encountered vascular peripheral conditions in the emergency department. To learn a standardized nomenclature to be used in describing peripheral arterial and venous waveforms, according to recent expert consensus statements.

TABLE OF CONTENTS/OUTLINE

Technical and interpretative principles of Doppler: Technical parameters. Artifacts. Innovative techniques in Vascular Ultrasound. Normal arterial and venous spectrograms. Reporting of Doppler waveform alterations. Peripheral vascular emergencies· Acute ischemic conditions. Trauma-related conditions. Iatrogenic injuries. Deep Vein Thrombosis.

MSEE-8   When Anatomical Variants Mimic Trauma Or Pathology In The Upper Extremity - How To Differentiate Them: A Radiographic Review For The Emergency Radiologist!

Participants
Denver Pinto, MD, Miami, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

To help the ER Radiologist or resident identify anatomical variants mistaken for pathology or fractures

TABLE OF CONTENTS/OUTLINE

Objectives.Imaging of fractures and fracture mimics.Importance of identifying the variant anatomy.Evaluation and Imaging findings (cases and discussion)Shoulder: Suprascapular foramen, Irregular ossification centre of the acromion, unfused coracoid process vs fractures in this region, prominent bicipital aponeurosis, infra scapular bone.Arm and elbow: Delayed fusion of ossification centers vs fractures (Ex: Triceps avulsion fracture), supracondylar process.Forearm: Delayed fusion of ossification centers vs fractures (Ex: Radial head and neck fractures), notch of radial neck.Wrist and hand: Unfused ossification centers vs avulsion fracture, variant ossification centers Ex: Pisiform bone, carpal coalition, dense metaphyseal bands.Special cases* Focus on hard to pick Salter-Harris fractures (cases and discussion)* Don't touch me lesions: Melorheostosis, Enchondroma, Fibrous dysplasia, Non-ossifying fibroma, Simple bone cyst.Teaching points.References

MSEE-80   Mesenteric And Intestinal Lesions In Blunt Abdominal Trauma, A Common Cause Of Underdiagnosis

Participants
Javier Cuetos, MD, Donostia-San Sebastian, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To understand the anatomy and pathophysiological mechanisms.- To know what findings require urgent surgery.- To know how to identify the specific and less specific findings of intestinal and mesenteric traumatic injuries.

TABLE OF CONTENTS/OUTLINE

Bowel and mesenteric injuries in blunt abdominal trauma continue to constitute one of the most frequently underdiagnosed pathologies by radiodiagnosis services.The underdiagnosis or delay in diagnosis has vital implications since a delay of only eight hours has been associated with increased morbidity and mortality mainly related to bleeding, peritonitis, and sepsis.Computed tomographic scan is considered as the most reliable method for diagnosis of bowel or mesenteric injuries and has become the preferred diagnostic test for the evaluation of blunt abdominal trauma in hemodynamically stable patients.There are certain imaging findings that require urgent surgical exploration and others that are very specific for a traumatic mesenteric or abdominal injury. The objective of this presentation is to emphasize imaging findings that may be useful in identifying mesenteric and intestinal lesions as well as in correctly describing and classifying lesions given the differences that may exist in therapeutic implications.

MSEE-81   Anastomosing Hemangioma: A New Kid On The Block?

Awards
Certificate of Merit

Participants
Krishna Prasad Shanbhogue, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

--To review epidemiology, clinical features, & histopathology of anastomosing hemangiomas, newly described benign vascular neoplasms with distinct histopathology.--To describe multimodality, cross-sectional imaging findings of these tumors.--To discuss tumor biology and management of anastomosing hemangiomas

TABLE OF CONTENTS/OUTLINE

Introduction Clinical features Pathology: Gross pathology, Histopathology and Immunohistochemistry Imaging features: Ultrasound, CT and MRI of anastomosing hemangiomas from head-to-toe. Differential diagnosis: Imaging features of other vascular lesions that can mimic anastomosing hemangiomas such as angiosarcoma, Kaposi sarcoma, Angiomyolipoma, and hypovascular lesions such as hepatocellular carcinoma and renal cell carcinoma will be discussed. Implications on Diagnosis and Management

MSEE-82   Neuro And Head And Neck Imaging: What The Musculoskeletal Radiologist Should Know

Participants
Tatiane Moriwaki, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is to: Highlight the main points to look for in the neuro and head and neck imaging for a musculoskeletal radiologist; Provide a systematic way not to miss important and critical findings; Illustrate and show didactically challenging cases, classified according to pathophysiology (vascular, trauma, neoplasm, congenital/malformations and inflammatory/infectious conditions).

TABLE OF CONTENTS/OUTLINE

Introduction: illustration of the main practical points for the musculoskeletal radiologist to be aware about neuro and head and neck imaging; Present a schematic illustration with didactic cases of different pathologies, classified according to pathophysiology (vascular, trauma, neoplasm, congenital/malformations and inflammatory/infectious conditions); Summary with tips of how to look beyond musculoskeletal findings not to miss and/or forget to report a critical finding; Bibliographical references.

MSEE-83   Beyond Blood And Bone: Rare Cerebrovascular Complications At A Level I Trauma Center

Participants
Ashanth Thomas, MD, MEng, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. An in-depth understanding of cerebrovascular anatomy is essential to identify potentially life-threatening injuries in penetrating head trauma. 2. Unique mechanisms of injury and unusual complications of trauma are important to become familiar with outside of Level I Trauma centers. 3. Dural venous sinus thrombosis, pseudoaneurysm, carotid-cavernous fistulae, and cerebrovascular dissections are difficult to identify in the presence of confounding findings that are often present in trauma cases. Radiologists must be aware of the imaging pitfalls of penetrating trauma, to avoid missed diagnoses that may benefit from additional imaging.

TABLE OF CONTENTS/OUTLINE

The primary goals of this exhibit are to provide a review of cerebrovascular anatomy and provide guidance on recognizing unusual cases of cerebrovascular complications after penetrating injury. Cases will include unusual mechanisms of injury as well as less common complications, focusing on dural venous sinus thrombosis, psuedoaneurysm, carotid-cavernous fistulae, and multiple cerebral arterial dissections. CT findings for these cases will highlight difficult and subtle abnormalities in the presence of larger confounding findings, such as intracranial hematomas and calvarial fractures. Finally, the pitfalls and numerous mimics of these cases will be explored, to educate radiologists on the limitations of post-traumatic imaging, and to increase sensitivity for these rare findings.

MSEE-84   Immune-related Adverse Events Associated With Cancer Immunotherapy: A Review For Radiologists

Participants
George Veloso Filho, DDS, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Advances in the use of immune response modulation in cancer treatment have led to exceptional responses in patients with advanced-stage tumours. However, the non-specific activation of the immune system can cause significant adverse effects in multiple organ systems. The purpose of this exhibit is to review the radiological features of immune-related adverse events (IrAE), highlighting Immune checkpoint inhibitors (ICIs), in a multisystemic approach, including musculoskeletal, pulmonary, cardiac, neurological and gastrointestinal disorders. In a didactic and illustrative way, we will discuss the multimodality imaging findings of such adverse events and differential diagnosis.

TABLE OF CONTENTS/OUTLINE

IntroductionImmune-related adverse events concept and epidemiology Pathophysiology Concepts: Main immunotherapy drugsImmune system and tissue damage consequencesClinical presentationToxicities phenotypes and their mais complaintsCase-based review CT, MRI and PET/CT imaging findingsMusculoskeletal (inflammatory arthritis, adhesive capsulitis, myositis, eosinophilic fasciitis) Pulmonary (pneumonitis, sarcoid-like granulomatosis, pleural effusion)Cardiac (myocarditis)Neurological (meningitis, hyphophysitis)Gastrointestinal (hepatitis, colitis, pancreatitis)OthersSummary and conclusionIrAE can cause serious complications during immunotherapy. Radiologists should be aware of imaging features and help to recognize and properly treat these patients

MSEE-85   Don't Step In The Puddle: Challenges And Mimics Of Mucin-containing Lesions In Abdomen And Pelvis

Awards
Certificate of Merit

Participants
Ekta Maheshwari, MD, Pittsburgh, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

Mucin-containing neoplastic intrabdominal lesions broadly include mucinous adenocarcinoma, signet ring cell carcinoma, post treatment change in a non-mucinous carcinoma and premalignant and malignant mucinous neoplasms of pancreas and biliary tree. Mucinous malignancies arising from or secondarily involving multiple intraabdominal and pelvic organs and spaces demonstrate characteristic imaging findings on US, CT, MRI/MRCP and FDG-PET scan. Mucinous neoplastic lesions can mimic and may be mistaken for several benign entities resulting in delayed diagnosis, complications and adverse outcomes.

TABLE OF CONTENTS/OUTLINE

Review the histology and functional and clinical significance of mucin. Review imaging appearance of mucin content on ultrasound, CT, MR and PET scans. Describe the typical imaging findings of mucin-containing neoplasms in abdomen and pelvis. Present the spectrum of imaging appearances of mucin-containing neoplasms mimicking benign entities such as cysts, abscesses, fistulae, hydrosalpinx, lymphangioma etc., and alternate cystic and necrotic malignancies.

MSEE-86   Fluid In The Belly: A Patterned Approach To Encountering Unexpected Abdominopelvic Ascites

Participants
Kira Melamud, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Discuss an approach to evaluating unexpected (nontraumatic) large volume abdominopelvic fluid on CT. 2. Review potential causes of free simple and complex fluid in the abdomen. 3. Discuss potential pitfalls which may lead to misdiagnosis of sources of fluid and tips for avoiding such mistakes.

TABLE OF CONTENTS/OUTLINE

Patterned Approach to Encountering Unexpected Abdominopelvic Fluid:1. Measure the Attenuation of Fluid and Narrow Windows 2. Evaluate for Ancillary Findings 3. Evaluate Location/Distribution of Fluid 4. Evaluate for Presence of Hemoperitoneum (i.e. look at the most dependent portions of the abdomen and pelvis; search for a sentinel clot) 5. Use dual energy CT to your advantage to problem solve to differentiate blood from soft tissue 6. Look for free air and extraluminal oral contrast in the setting of bowel perforation with large volume ascites, but be aware of pitfalls (i.e. RYGB). 7. Assess pattern of peritoneal abnormality (i.e. smooth and uniform, irregular, or nodular)

MSEE-87   Diabetes-related Complications In The Abdomen And Pelvis: Spectrum Of Imaging Findings

Participants
Ayman H. Gaballah, MD, FRCR, Columbia, Missouri (*Presenter*) Nothing to Disclose

TEACHING POINTS

Overview of the pathophysiology of diabetes mellitus (DM) Multi-modality imaging features of DM involving multiple organs in the abdomen/pelvis and potential related complications Algorithmic approach to the differential diagnosis of findings in each affected organ Diabetes and organ transplant Potential pitfalls in imaging diagnosis

TABLE OF CONTENTS/OUTLINE

Pathophysiology of DM (I and II), and how it affects organs in the abdomen and pelvis Discussion of multi-modality imaging evaluation of abdominal/pelvic organs that can be affected by DM GI tract (reflux, dysmotility, ulcer disease), hepatobiliary (fat infiltration, non-alcoholic steatohepatitis, acute liver failure, cirrhosis, and hepatocellular carcinoma, gallstones and various type of cholecystitis, sphincter dysfunction), pancreas (pancreatitis, fat infiltration, insufficiency, atrophy), adrenals (insufficiency, hemorrhage, hyperplasia), kidneys (chronic/end-stage renal disease, papillary necrosis, various stages of infection, calculi), vasculature (atherosclerosis and stenosis), and reproductive organs (vas deferens calcification, erectile dysfunction, ovarian failure, polycystic ovaries) Potential complications (various types of infections, organ failure, transplantation) Relation of diabetes to organ transplantation and subsequent complications Potential pitfalls in imaging diagnosis (use of IV contrast and options, use of alternate imaging modalities) Management options

MSEE-88   Imaging Of Sequelae Of Eating Disorders

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Nadia Solomon, MD, New Haven, Connecticut (*Presenter*) Nothing to Disclose

TEACHING POINTS

Eating disorders are common and linked with high morbidity and mortality, yet they tend to be underdiagnosed and undertreated due to societal stigma and associated poor patent compliance. Imaging findings may suggest the diagnosis and identify complications. We aim to provide a review of imaging findings seen in patients with eating disorders as well as findings associated with their complications. Teaching points: • Familiarize the radiologist with the spectrum of eating disorders • Discuss the clinical presentation of eating disorders and their medical complications/sequelae • Describe the imaging features associated with common and uncommon sequelae • Provide a brief overview of management and treatment of eating disorders

TABLE OF CONTENTS/OUTLINE

• Diagnostic criteria of spectrum of eating disorders including epidemiology • Life-long potential complications of eating disorders • Role of imaging and imaging features associated with sequelae of eating disorders • Neurologic (e.g., volume loss, osmotic myelinolysis) • Head and Neck (e.g., dental caries, patulous eustachian tube) • Pulmonary (e.g., aspiration/infection/abscess, lipoid pneumonia) • Cardiac (e.g., right ventricular dilatation, pericardial effusion) • Gastrointestinal (e.g., patulous GE junction, bezoar) • Urogenital (e.g., female genital tract immaturity) • Musculoskeletal: (e.g., osteopenia, delayed skeletal growth) • Brief overview of management of eating disorders and their sequelae

MSEE-89   High-value Radiologic Diagnosis In Acute Post-partum Pathologies In The Abdomen And Pelvis

Participants
Kheng L. Lim, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

Present pearls in diagnosing common acute abdomen in females of reproductive age regardless of whether the patient is pregnant or not such as appendicitis, pyelonephritis, obstructive uropathy from stone disease, acute cholecystitis, and diverticulitis. Differentiate bladder flap hematoma from normal post-operative findings Pearls in diagnosing endometritis at ultrasound by incorporating clinical and laboratory findings from normal recent cesarean appearance of the uterus, and correlation to CT. Pearls in diagnosing ovarian thrombosis (filling-defect within an enlarged ovarian vein with peripheral rim-enhancement).

TABLE OF CONTENTS/OUTLINE

Various pathologies categorized by clinical signs and symptoms. Postpartum hemorrhage: Pelvic hematoma after vaginal delivery. Bladder flap hematoma after c-section. Pain/fever: Endometritis. Retained product of conception. Ovarian vein thrombosis. Pyelonephritis. Appendicitis. Iatrogenic complications from C-section. Rupture of a large myoma. Bladder injury. Normal appearance of recent C-section changes (ascites, hemoperitoneum, echogenic sutures at ultrasound mimicking gas). Normal appearance of recent post-partum uterus (e.g. engorgement of vessels and heterogenous myometrium).

MSEE-90 Cardiac Pacemaker Safety And Imaging Features Of Complications

Awards
Identified for RadioGraphics
Cum Laude

Participants
Rishabh Agarwal, MD, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. An estimated one million adults in the United States are equipped with a pacemaker. Pacemakers are commonly encountered by a radiologist on imaging studies. 2. This exhibit will review the imaging basics of pacemakers and some of their immediate and long-term complications. 3. This exhibit will also discuss MRI safety of pacemaker devices, appropriateness criteria and approach.

TABLE OF CONTENTS/OUTLINE

1) Types of cardiac pacemakers and their radiographic appearance a. Defibrillating vs non-defibrillating devices b. Intra-vascular leads, extra-vascular leads, unusual lead positioning (ex: "His" lead), leadless 2) Basics of cardiac pacemaker components, specifically defibrillating capacitor and lead function 3) Discuss common and identifiable pacemaker complications on multimodality imaging a. lead fracture, lead displacement, lead perforation, Twiddler's syndrome, infection 4) Discuss MRI safety of pacemaker devices and develop an approach for determining appropriateness of performing MRI on patients with pacemakers

MSEE-91 All We Need To Know About Gaucher Disease

Participants
Juliana Duarte, Porto Alegre, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are: • Review the main imaging findings of Gaucher disease. • Describe the main imaging patterns of Gaucher Disease type 1, 2 and 3, highlighting the role of MRI imaging since the diagnosis, follow-up and monitoring the response of the enzyme therapy.

TABLE OF CONTENTS/OUTLINE

Imaging patterns of Gaucher Disease: - VISCERAL MANIFESTATIONS: - Massive splenomegaly - Splenic nodules - Hepatomegaly - Hepatic ischemia - Iron deposition - Brain atrophy - Pulmonary involvement: - Ground glass pattern - Reticulonodular infiltration - Air retention -SKELETAL MANIFESTATIONS: -Osteopenia -Osteonecrosis -Metaphyseal notching of humerus -Pathological fracures - Erlenmeyer flask deformity -Involved bone marrow shows reduced T1 and T2 signals due to infiltration of Gaucher cells - Salt and pepper pattern in MRI due to scattered involvement -H-shaped vertebra -Bone marrow burden score in MRI (semi-quantitative MRI scoring system for assessing the extent of bone marrow involvement). Treatment results in improvement of marrow infiltration however it takes much longer than the visceral and hematologic manifestations. Imaging plays a key role in both initial diagnosis and treatment monitoring. MRI of the abdomen is used to monitor liver and spleen volumes. MRI of the femoral and lumbar spine is used for evaluation of bone marrow infiltration burden. Final remarks.

MSEE-92 Hit A Nerve? Perineural Invasion In The Abdomen And Pelvis

Awards
Identified for RadioGraphics
Magna Cum Laude

Participants
Wendy Tu, MD, Edmonton, Alberta (*Presenter*) Nothing to Disclose

TEACHING POINTS

Perineural invasion (PNI), while commonly discussed in head and neck cancers, is less appreciated as a mechanism of disease spread in the abdomen and pelvis despite multiple common abdominopelvic cancers exhibiting a proclivity for it. Though much more frequently a histopathologic finding, PNI can be evident radiologically and, when identified, has the potential to indicate more aggressive tumor biology, modify oncologic management, and suggest a possible cause for patient-reported pain disproportionate to tumor extent. This exhibit aims to 1) Review the anatomic and pathologic principles pertaining to abdominopelvic PNI, 2) Illustrate appearances of PNI on cross-sectional imaging for specific cancers, and 3) Discuss how PNI may impact clinical management.

TABLE OF CONTENTS/OUTLINE

Review pathologic principles of PNI. Overview of anatomic principles of PNI, including illustration of nerve plexuses in the upper

abdomen and posterior pelvis most susceptible to PNI. Identify abdominopelvic cancers with propensity for PNI, with case examples and suggested cancer-specific search patterns, and brief discussion of perineural involvement in endometriosis. Discuss how PNI identified on imaging may potentially modify oncologic management including surgery, radiation therapy, and pain management.

MSEE-93   Acute Ankle Tendon Tears, Dislocations And Associated Lesions

Awards
Magna Cum Laude

Participants
Ricardo De Carli SR, BMBS, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Review the normal anatomy of the ankle tendons and retinaculum using ultrasound and MRI Explain how dynamic maneuvers can be done on ultrasound to improve accuracy for ankle tendon lesions and dislocations Elucidate the most important imaging findings and report goals

TABLE OF CONTENTS/OUTLINE

Ankle acute trauma is one of the most common injuries presenting to emergency rooms. Most of the orthopedic and radiology literature about ankle trauma is focused on ligaments and osseous abnormalities due to its high prevalence and morbidity. Although less prevalent, acute ankle tendon injuries can be present in the setting of acute trauma, and its early diagnosis can prevent tendon dysfunction and foot deformity. The ankle clinical exam is limited in the setting of acute trauma by the presence of edema and local pain, impairing physical examination. Ultrasound and MRI are the imaging methods of choice to identify tendon lesions. Ultrasound has the advantage for its accessibility, low cost, and the possibility to dynamic evaluate using maneuvers such dorsiflexion, plantar flexion, calf compression and ankle eversion. MRI can identify ligamentous and intra-articular lesions. Tendon injuries vary from subtle tenosynovitis to a tendon complete tear and can be associated with retinaculum injuries and tendon dislocations. It is important to the radiologist to be familiar with these injuries, their appearance on MRI and ultrasound, and the report goals.

MSEE-94   Imaging Approach To Ballistic Injury In Pediatric Patients

Participants
Mohammed Abdeen, FRCR, MSc, Memphis, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Background:Ballistic injuries account for the majority of penetrating trauma in pediatric patients and lead to high mortality. We will be discussing key imaging findings in various body areas and their role in imaging protocols/workups related to gunshot injuries, with emphasis on findings consistent with injuries requiring immediate surgical intervention.Teaching points:1. Knowledge of imaging findings for various modalities and protocols can improve diagnosis for ballistic injuries.2. Demonstrate the spectrum of imaging features for various types of gunshot injuries.3. Understand the imaging findings that require surgical intervention.

TABLE OF CONTENTS/OUTLINE

1. Mechanisms and statistics on U.S.A. gunshot injuries in children2. Intracranial gunshot injuries and imaging analysis3. Head and neck gunshots4. Thoracic gunshots5. Abdominopelvic gunshots6. Musculoskeletal gunshots including spine

MSEE-95   Crash Course On Calcifications: Classifying The Common, Concerning, And Critical

Participants
Lyndon Luk, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Abdominopelvic calcifications are commonly encountered and can result from a variety of disease processes. 2. Morphology, location, and mobility of calcifications can be used to narrow the differential 3. Incidentally discovered calcifications on different imaging modalities can lead to diagnosis of malignant and potentially life-threatening conditions 4. Radiologists should be aware of the variety of calcifications in the abdomen and pelvis and use them to help guide management when appropriate

TABLE OF CONTENTS/OUTLINE

1. Review of calcification types and mechanisms 2. Review abdominopelvic calcifications on radiographs, ultrasound, CT, and MRI 3. Identify calcification patterns and locations that require further workup for potentially malignant or life-threatening etiology 4. Discuss different methods of classifying abdominopelvic calcifications

MSEE-96   Vascular Anomaly Syndromes: Current Update Of I.S.S.V.A. Classification Of Imaging Findings And Role Of Intervention

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Mindy Wang, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Describe the ISSVA classification of vascular anomalies and its relation with various syndromes.2) Identify the imaging features of vascular anomaly syndromes in various modalities.3) Discuss the management and role of interventional radiology in treatment.

TABLE OF CONTENTS/OUTLINE

1) Updated ISSVA classification2) Multimodality imaging features of specific vascular anomaly syndromesa) Hereditary hemorrhagic telangiectasiab) Blue rubber bleb nevus syndromec) Gorham-Stout syndromed) Primary lymphedemae) Klippel-Trenaunay syndromef)

Parkes Weber syndromeg) Servelle-Martorell syndromeh) Sturge-Weber syndromei) Maffucci syndromej) Macrocephaly-capillary malformationk) CLOVES syndromel) Proteus syndromem) Bannayan-Riley-Ruvalcaba syndromen) CLAPO syndromeo) Kasabach-Merritt phenomenonp) PHACE syndrome3) Management and role of interventional radiology

MSEE-99   Artificial Intelligence (AI) In The Emergency Department: Incorporating Into The Work Flow And Clinical Applications

Participants
Babina Gosangi, MD,MPH, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Artificial intelligence (AI) reads through the studies and identifies cases with acute findings such as intracranial hemorrhage, pulmonary embolism, rib or cervical spine fractures. It marks the cases as important and moves them higher up in the worklist so that the radiologists can read these cases immediately and improves patient care. 2. Post processed images from the AI highlight the abnormal findings and color code them so that the radiologists can review these images. 3. AI can overcall findings or miss findings and radiologists need to closely review the findings and dispose the case according to their acumen.

TABLE OF CONTENTS/OUTLINE

1. Introduction to Artificial intelligence (AI)- How is AI applied to radiology- How are images obtained- How are the images post processed and color coded2. How is AI incorporated into the workflow in the emergency department (ED)- Review cases- Identify abnormal cases- Prioritize the cases in the worklist by coding them or moving them to the top of worklist3- Various applications of AI in the ED- Intracranial hemorrhage- Pulmonary embolism- Rib fracture- Cervical spine fracture4. Pitfalls- Missed diagnosis - Overcalls

Printed on: 06/28/22

Abstract Archives of the RSNA, 2021

Sub-Events

PDEE-1   Evolution And Long Term Sequelae Of Chronic Non-bacterial Osteomyelitis

Participants
T. Shawn Sato, MD, Iowa City, Iowa (*Presenter*) Research Grant, Bracco Group

TEACHING POINTS

- Chronic non-bacterial osteomyelitis (CNO) is a rare auto-inflammatory condition characterized by multifocal bone pain with a waxing and waning course.- Untreated or incompletely treated disease can result in complications including pathologic fractures, vertebral body collapse, hyperostosis and physeal bars.- Despite development of these complications, with adequate treatment in some cases these damages resolve.

TABLE OF CONTENTS/OUTLINE

- Clinical features of CNO- Imaging appearances of CNO on plain film, CT and MRI- Typical disease course of CNO- Importance of whole body MRI for diagnosing and monitoring CNO- Review cases of patients that develop pathological fractures of the axial and appendicular skeleton, hyperostosis and physeal bars and demonstrate follow up to demonstrate how adequate treatment can in some cases resolve these complications

PDEE-10   Inflammatory Myopathies In Children: Tips And Tricks

Participants
Maria Navallas, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

After reviewing this exhibit, the learner should be able to:1. Discuss the main inflammatory myopathies that occur in children2. Describe the most common imaging findings of inflammatory myopathies in children, with special emphasis on MRI3. Discuss the differential diagnosis of inflammatory myopathies in children

TABLE OF CONTENTS/OUTLINE

1. Background2. Clinical and demographics of inflammatory myopathies in children3. Imaging techniques for the diagnosis and follow-up of inflammatory myopathies, with special emphasis on the use of whole-body MRI3.1. Whole-Body MRI: abbreviated and fast protocol to avoid anesthesia4. Myopathies in children:4.1. Idiopathic inflammatory myopathies: Juvenile dermatomyositis, Juvenile polymyositis, Overlap myositis, Immune-mediated necrotizing myopathies4.2. Myositis associated with other connective tissue diseases such as scleroderma, systemic lupus erythematosus, systemic juvenile idiopathic arthritis, and mixed connective tissue disease4.3. Infectious inflammatory myopathies: viral, bacterial and parasitic4.4. Neoplastic related inflammatory myopathies4.5. Trauma4.6. Drug-induced myopathies4.7. Rhabdomyolysis4.8. Neuromuscular diseases: Muscular dystrophies, Congenital myopathies, Metabolic myopathies5. Management of the most common inflammatory myopathies in children6. Summary

PDEE-11   Current And Emerging Applications Of Computer-assisted Reporting And Decision Support (CAR/DS) Tools In Pediatric Radiology

Awards
Cum Laude

Participants
Eric Tung, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Computer-assisted reporting and decision support (CAR/DS) tools are a developing technology in radiology reporting that provide real-time assistance to improve accuracy, efficiency, reproducibility, and clinical utility of radiology reports. Many CAR/DS modules have either been developed or are being developed that have clinical applications in pediatric radiology. This exhibit aims to highlight the value of CAR/DS tools in the practice of pediatric radiology, including a) their value to pediatric radiologists through improved adherence to evidence-/consensus-based guidelines, promotion of clinically useful categorization, rapid access to educational materials, and performance of laborious calculations and b) their value to pediatric referring providers and deep learning tool developers through incorporation of standardized report language.

TABLE OF CONTENTS/OUTLINE

CAR/DS benefits pediatric radiologists: 1. Guideline adherence (i.e. AAST solid organ injury grading, SAR/SPR/AGA Crohn's disease reporting, perinatal UTD grading); 2. Clinically useful categorization (i.e. Papile germinal matrix hemorrhage classification, AO-ASIF distal humeral fracture classification, acute pancreatitis Balthazar Score); 3. Educational material access (i.e. ossification center graphic, foot alignment measurements, Mullerian duct anomaly spectrum); 4. Calculations (i.e. bone age evaluation, measurement

comparison to reference standards). Standardized language benefits referring providers and AI tool developers.

PDEE-12   Complications Of Cancer Therapy In Children: A Comprehensive Review

Awards
Cum Laude

Participants
Elizabeth Snyder, MD, Nashville, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Although progress has been made in reducing toxicity associated with cancer treatment in children, many complications may be unavoidable. Moreover, children are living longer after therapy as cancer survival rates have improved. Treatment-related complications may occur acutely after initiation of therapy or years following remission and can affect any organ system. Pediatric radiologists often play an important role in the diagnosis and evaluation of these complications, and thus, awareness of their imaging findings is essential to guide management and avoid misdiagnosis. The aim of this educational exhibit is to provide a comprehensive review of potential complications of cancer therapies, both short-term and long-term, from head to toe.

TABLE OF CONTENTS/OUTLINE

1. Introduction2. Brain, Head & Necka. Short-term: e.g. Methotrexate toxicity, pseudoprogressionb. Long-term: e.g. Secondary neoplasm, moyamoya vasculopathy, microsomia3. Chesta. Short-term: e.g. Infection, pulmonary edemab. Long-term: e.g. Pulmonary fibrosis, bronchiolitis obliterans, GVHD4. Abdominopelvic:a. Short term: e.g. enteritis, pancreatitis, veno-occlusive diseaseb. Long term: e.g. Focal nodular hyperplasia, hepatic fibrosis, GVHD5. Musculoskeletala. Short term: e.g. myositisb. Long-term: e.g. Avascular necrosis, secondary osteochondroma6. Conclusion

PDEE-13   RASopathies: The Imaging Spectrum

Participants
Yuko Tsujioka, MD, Tokyo, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

RAS genes are common oncogenes that encode signaling molecules regulating cell proliferation, differentiation, and survival. Recent investigations have shown that abnormal activation of RAS signaling due to germinal mutations of RAS and RAS-related genes causes a group of congenital disorders, collectively termed RASopathies. The group of disorders is divided into two subgroups. The first subgroup includes Noonan syndrome and allied syndromes (cardio-facio-cutaneous syndrome and Costello syndrome) caused by overactivation of RAS activators, RAS proteins, and downstream molecules. The second comprises capillary malformation-arteriovenous malformation (CM-AVM) and neurofibromatosis type 1 (NF1) caused by inactivation of RAS inhibitors. It may be odd to most clinicians to address the Noonan group and NF1 together; however, there are a number of patients who show characteristics of both disorders. It is noteworthy that somatic mutations of RAS and RAS-related genes may manifest as atypical RASopathies. Clinical trials of RAS-signal inhibitors for affected individuals have provided promising results. The advances in therapeutic intervention may increase an opportunity for imaging examinations of RASopathies. We present here on the imaging spectrum of RASopathies.

TABLE OF CONTENTS/OUTLINE

- Concept of RASopathies - Noonan group/CM-AVM/NF1 - disorders bridging a gap between NF1 and Noonan syndrome (Jaffe-Campanacci syndrome, Noonan-like multiple giant cell lesion syndrome, etc.) - disorders due to somatic mutations

PDEE-14   Strategies To Help Optimize Fetal MRI Image Quality

Participants
Gregory A. Vorona, MD, Henrico, Virginia (*Presenter*) Nothing to Disclose

TEACHING POINTS

Appropriate sequence selection and optimization is essential to perform quality fetal MRI. The "three-point tool" can be used to create in-plane images from oblique images in a moving fetus. Optimizing the shim mode can minimize delays between running sequences, mitigating the chance of the fetus repositioning itself. Adjusting the settings of parallel imaging can impact image quality factors including image sharpness and noise. Adjusting the number of concatenations can help to improve image quality by mitigating artifacts such as cross-talk.3.0 Tesla MRI imaging of the fetus presents technical challenges, which in part can be mitigated by hardware and software optimization.

TABLE OF CONTENTS/OUTLINE

Fetal MRI studies can be some of the most challenging MRI examinations to perform. The purpose of this educational exhibit is to share and discuss some of the technical factors that we identified as being useful to modify at our institution using a single vendor MR platform (Siemens). The exhibit will begin with a brief discussion of sequence selection, particularly focused on fetal brain MR evaluation. We will then discuss potential strategies that can be employed to optimize obtaining diagnostically acceptable multiplanar sequence acquisitions when the fetus is moving. We will then discuss other strategies that can be attempted to optimize image quality, including the use of parallel imaging and adjusting the number of concatenations. Finally, we will briefly discuss our experience performing fetal MR at 3.0T.

PDEE-15   Evaluation Of Extracardiac Complications Of Fontan Circulation Using Non-invasive Imaging

Awards
Certificate of Merit

Participants
Sowmya Balasubramanian, MD,MSc, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Fontan circulation can result in long term cardiac and extracardiac complications- Radiological studies play an important role in

the evaluation of end-organ dysfunction- Emerging techniques play a critical role in the detection and interventions of extracardiac complications

TABLE OF CONTENTS/OUTLINE

Background: Fontan circulation carries long term burden of cardiac, pulmonary and visceral organ dysfunction and aberration in lymphatic drainage due to increased central venous pressure and low cardiac output warranting routine, detailed diagnostic imaging. Diagnostic Imaging Options: Ultrasonography, magnetic resonance (MR) and computed tomography (CT) with advanced techniques can detect early and late sequelae. Extracardiac Complications: Lungs - Presence of veno-venous collaterals and arteriovenous malformations can be shown by CT or MR. Veno-lymphatic complications - Lymphatic congestion and abnormal lymphatic channels may contribute to plastic bronchitis and protein losing enteropathy. T2 weighted MR angiography with and without contrast can delineate flow dynamics and guide interventions to improve lymphatic function. Fontan associated liver disease - Findings include passive congestion, fibrosis, regenerative nodules, cirrhosis, hepatocellular carcinoma and intra- and extrahepatic veno-venous collaterals. Hepatocyte-specific contrast can differentiate regenerative nodules from hepatocellular carcinoma, while elastography allows for quantification of fibrosis.

PDEE-16   Pigmented Villonodular Synovitis In Children: A Comprehensive Review Of Entities And Differential Diagnosis

Awards
Certificate of Merit

Participants
Emilio Inarejos Clemente, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

1.Describe the use of ultrasound, radiography, CT and MRI for diagnosis and follow-up in children with pigmented villonodular synovitis (PVNS).2.Explain the different entities that are included in the term PVNS.3.Discuss the most common imaging findings of pigmented villonodular synovitis in children and compare with corresponding surgical and gross pathology.4.Describe the most frequent differential diagnosis depending on patient's age and disease location.

TABLE OF CONTENTS/OUTLINE

1. Background.2. Clinical findings and demographics of PVNS in children.3. PVNS includes the following entities: diffuse intraarticular form, localized intraarticular form, diffuse extraarticular form and localized extraarticular form (also known as giant cell tumor of the tendon sheath).4. Conventional and advanced imaging techniques in the study of PVNS in children, emphasizing on the role of US and MRI (diffusion-weighted imaging and perfusion) for diagnosis and follow-up.5. Ultrasound, radiography, CT, and MRI findings of PVNS in children, including illustrative examples with clinical, surgical and histopathological correlation.6. Novel targeted treatment options for non-surgical forms and recurrent PVNS: Imatinib.7. Use of contrast-enhanced MRI in treatment response assessment with illustrative examples.8. Summary.

PDEE-17   Cranial Sutures: Methods, Analysis And How Far Ultrasound Can Go. A Review.

Participants
Alessandra Chiovatto, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The objectives of this study is to analyse the main cranial sutures, with the aim of differentiation from craniosynostosis and positional skull deformities, emphasizing the role of ultrasound in the frontline. This manuscript intends to outline the normal anatomy of the newborn skull, technique of the sonographic exam to evaluate cranial sutures and to demonstrate the major types of craniosynostosis as well as the sonographic differential diagnosis from positional skull deformities.

TABLE OF CONTENTS/OUTLINE

1. Exam technique2. Sonographic anatomy a. by age group b. which age that close the sutures3. Epidemiology;4. Common presentation;5. Positional deformity X Craniosynostosis;6. Ultrasound, X-Ray and CT imaging limitations.

PDEE-18   Imaging The Cerebral Veins In Pediatric Patients: Beyond The Dural Venous Sinuses

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Asha Sarma, MD, Nashville, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Pediatric cerebral venous pathologies are a diverse group of entities with numerous underlying causes. This educational exhibit will prepare the radiologist to: a) compare and consider pros and cons of various cross-sectional imaging techniques used for evaluating pediatric patients with cerebral venous pathologies; and b) recognize and understand a broad variety of superficial and deep venous pathologies in children. Less-frequently discussed topics such as pathologies involving the cortical/bridging veins and the deep veins will be emphasized.

TABLE OF CONTENTS/OUTLINE

1. Anatomy, embryology, and normal variants 2. Cross-sectional imaging and post-processing techniques: CTV, MRI, MRV 3. Pathologic entities: A. Primarily superficial venous pathology: 1. Dural venous sinus pathologies (e.g., thrombosis, stenosis) 2. Traumatic bridging vein injury (acute, chronic with collateralization, subdural hemorrhage complicating arachnoid cyst) 3. Anomalous tortuous superficial cerebral veins 4. Cephalocele with anomalous drainage 5. Sinus pericranii (e.g., isolated and associated with other anomalies) 6. Isolated cortical vein thrombosisB. Primarily deep venous pathology: 1. Deep medullary vein thrombosis and white matter injury in infants 2. Complicated developmental venous anomalies 3. Sturge-Weber (spectrum of venous abnormalities) 4. "Vein of Galen" malformation 5. Cerebral venous metameric syndrome

PDEE-19   **Temporal Bone Tumors In Pediatric Age Group: A Pictorial Review.**

Participants
Mohammad Alwatban, MBBS, Khobar, Saudi Arabia (*Presenter*) Nothing to Disclose

TEACHING POINTS

Review the anatomy of the temporal bone.Discuss the clinical presentations associated with temporal bone lesions.Describe imaging features of some of these lesions and how to distinguish based on imaging findings.

TABLE OF CONTENTS/OUTLINE

The temporal bones comprise the lateral skull base, forming portions of the middle and posterior fossa. They are composed of five osseous parts and contain important structures such as the ossicular chain, osseous labyrinth, nerves, vessels, between others.The clinical manifestation of lesions of the temporal bones can be very variable, depending on the involvement of the adjacent intra- and extracranial structures, can present as a visible/palpable mass, or even be an incidental finding. The specific diagnosis by imaging can be challenging. CT and MRI are complementary in providing an appropriate differential diagnosis, the relation with important structures and in aiding surgical planning.There are numerous conditions that can affect the temporal bone region, including inflammatory and neoplastic. The tumors can originate from the diverse different structures that are seen in this region.We will briefly review the anatomic architecture of the temporal bone and present a pictorial review of 8 cases of temporal bone tumors, with discussion and illustration of the imaging features.

PDEE-2   **The Ductus Arteriosus: A Review Of Embryology, Fetal Imaging, Pathophysiology, And The Role Of Advanced Imaging In PDA Management And Intervention In Children And Adults**

Participants
Lauren May, MD, Wilmington, Delaware (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. The ductus arteriosus (DA) is a key structure in fetal circulation that shunts blood from the pulmonary artery to the aorta to bypass the lungs. The fetal DA is highly amenable to assessment by ultrasound. 2. The DA typically closes after birth but can remain patent (PDA) causing pathophysiology as a result of shunting from the aorta to the pulmonary artery. 3. Depending on symptomatology and patient age a PDA can be closed with medication, occlusive devices, or surgical ligation. 4. Ductal-dependent congenital heart disease may require non-invasive and minimally-invasive interventions to maintain DA patency prior to palliative or definitive treatment. 5. An understanding of DA anatomy and function is crucial in the assessment and management of vascular rings and aortic malformations. 6. The DA can develop complications like aneurysm or thrombus for which advanced imaging techniques like CT and MRI are helpful in management and surgical planning.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Embryology and Maturation of the DA 3. DA Prenatal Imaging 4. PDA Clinical Presentation and Pathophysiology 5. PDA Imaging and Management 6. DA in Vascular Rings, Aortic Coarctation and Interrupted Arch 7. Ductal-Dependent Congenital Heart Disease 8. Conclusion

PDEE-20   **CT Report: Understanding The Staging System For Hodgkin's Lymphoma**

Participants
Warda Limaye, MD, Halifax, Nova Scotia (*Presenter*) Nothing to Disclose

TEACHING POINTS

By the end of this exhibit, the reader should be able to : 1- Understand the staging system of lymphoma. 2- The definition of bulk disease, measurable disease, and non-measurable disease. 3- Calculate the perpendicular product PPD and SPPD (sum of perpendicular products). 4- Be confident in assessing response to treatment (complete response versus very good partial response, versus partial response versus no response)

TABLE OF CONTENTS/OUTLINE

- Staging of HD.- Definitions: bulk disease, measurable, non-measurable disease.- Treatment response.

PDEE-21   **Contrast-enhanced Ultrasound In Pediatric Radiology: Why, How And When.**

Participants
Luca Basso, MD, Genova, Italy (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To explain the safety of intravenous application of UCAs - To mention current indications of UCAs in child - To discuss indications and limits of intravenous application of UCAs in different radiological settings in pediatric population (i.e. characterization of focal organ lesion, blunt abdominal trauma, pyelonephritis, vasculitis, etc.) - To make Radiologists aware of advantages of CEUS in diagnosis and follow-up in different radiological settings in children being a radiation-free and repeatable imaging technique

TABLE OF CONTENTS/OUTLINE

a) Physical Principles of Contrast-enhanced Ultrasound (CEUS) - b) Safety-profile of Ultrasound Contrast Agents (UCAs) - c) Acquisition technique of CEUS - d) Indications and off-label application of CEUS in pediatric population - e) Case series in pediatric population: I. Contrast-enhanced Voiding Urosonography (CEVUS) for Vesicoureteral Reflux (VUR) through endocavitary administration - II. Intravenous administration for: a. Characterization of focal organs lesions b. Blunt abdominal trauma c. Pyelonephritis d. Vascular pathologies (i.e. vasculitis) e. Inflammatory Bowel Disease (IBD) assessment f. Testicular lesions

PDEE-22   **Establishing A Non-sedate Pediatric MRI Program: Awake Or Asleep...Both Options Are On The MRI Table**

Awards
Certificate of Merit

Participants
Samantha Harrington, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Building blocks Ensure correct processes, people and workflows are in place. 2. Options Tailor non-sedate strategies to patients and their MRI scans. 3. Optimization Optimize MRI protocol for targeted, faster, quieter imaging with sequence order prioritized.

TABLE OF CONTENTS/OUTLINE

1. Departmental Processesi) referrals - who and how, ii) scheduling - when, where and with whom, iii) bookings - if it works AND if it doesn't. 2. Non-sedate Practices - General Considerations: i) environment, ii) education, iii) patient preparation.3. Non-sedate Practices - Specific Options: (including process, inclusions and exclusions) i) feed and swaddle, ii) natural sleep, iii) animal assisted therapy, iv) MRI simulation - real and virtual, v) Child Life Specialists - alone or in combination with other options, vi) non-sedating medications e.g. antianxiolytic agents, melatonin, vii) distracters e.g. music, movies. 4. MRI scanning - General Considerations: i) faster sequence strategies, ii) shorter protocols, iii) quiet MRI technology, iv) motion compensation strategies, v) advanced sequences. 5. MRI Scanning - Specific Considerations: i) indication-specific protocols, ii) protocols in prioritized order, iii) minimize use of intravenous gadolinium, iv) complementary modalities e.g. contrast enhanced ultrasound for cystic vs. solid lesions.

PDEE-23   CT In Tetralogy Of Fallot: Pre- And Postoperative Evaluation

Participants
Evan Zucker, MD, Palo Alto, California (*Presenter*) Research Consultant, F. Hoffmann-La Roche Ltd

TEACHING POINTS

1. To review the current and evolving indications for CT in tetralogy of Fallot (TOF). 2. To illustrate the broad spectrum of CT applications in pre- and postoperative TOF. 3. To emphasize the expanding role of CT for diagnosis, monitoring, and management of TOF, including emerging techniques.

TABLE OF CONTENTS/OUTLINE

TOF is the most common cause of cyanotic congenital heart disease, characterized by a subaortic ventricular septal defect (VSD), overriding aorta, right ventricular hypertrophy, and pulmonary stenosis. Yet, the anatomy and clinical course are in fact greatly heterogeneous. Echocardiography, supplemented by MRI, remains the primary imaging modality in TOF. Yet, in recent years, CT has become increasingly important. The growing indications for CT in TOF are reviewed, highlighting newer techniques (e.g., dual-energy, 3D printing, augmented reality). The broad spectrum of CT applications in TOF is illustrated through preop examples of conventional TOF, TOF with absent pulmonary valve, and TOF with pulmonary atresia / major aortopulmonary collaterals and postop examples of volumetry surveillance, right ventricular outflow tract aneurysm and recurrent obstruction, VSD patch leak, recurrent pulmonary arterial and conduit stenosis, aortic dilation, stent and implanted device-related complications, and repeat intervention planning (e.g., redo sternotomy, transcatheter pulmonary valve). In summary, CT has emerged as an essential tool in TOF evaluation, helping to facilitate precise diagnosis and tailored management.

PDEE-24   Hope For The Best, Prepare For The Worst - Pediatric Arthralgia: A Practical And Complete Guide For Rheumatic Pediatric Conditions

Participants
Andre Y. Aihara, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Joint pain in children is a common complaint. Although there are more frequent causes of joint pain, rheumatic causes should always be considered due to their high morbidity. In according to this,this exhibit aims to:Review every rheumatic disease in pediatric population, including clinical presentation, diagnostic criteria, image findings, complications, and differential diagnosis for these conditions in a multimodality approach;Illustrate with didactic cases the presentations of rheumatological diseases in children;Highlight and discuss specific findings that could help to determine the correct diagnosis/narrow down the differential diagnosis.

TABLE OF CONTENTS/OUTLINE

Overview about pediatric arthralgia,including clinical assessment. Propose a structured report with essential information that must be included in the report to help rheumatologists to approach the correct diagnosis.Demonstrate didactically the CR,CT,US and MRI findings of each rheumatic disease in children,including:Juvenile Idiopathic arthritis,Chronic nonbacterial osteomyelitis,Systemic lupus erythematosus,Scleroderma,Dermatomyositis/Polymyositis,Reactive arthritis,Inflammatory bowel disease.Differential diagnosis: infection, neoplasms, transitory synovitis. Propose a diagnostic algorithm for articular pain in children, which exams to be requested and according to the findings and clinical-laboratory correlation, narrow down the differential diagnosis and determine the correct diagnosis.

PDEE-25   The New Age Of Medulloblastomas: Imaging Features Of The Molecular Subgroups Of Medulloblastomas

Awards
Certificate of Merit

Participants
T. Shawn Sato, MD, Iowa City, Iowa (*Presenter*) Research Grant, Bracco Group

TEACHING POINTS

Medulloblastomas are the most common pediatric brain tumors. While historically considered a single entity, distinct molecular subgroups of medulloblastomas have emerged with implications for prognosis and optimal therapy. Although these tumor subgroups are often definitively characterized by molecular features, they can often be distinguished by distinct imaging features in conjunction with patient demographics, and the radiologist can play a larger role in diagnosis when tissue sampling is inconclusive due to sample variance. It is therefore important for radiologists to be familiar with these ongoing developments in medulloblastoma classification, specifically the most recent WHO classification, and typical imaging findings to provide intelligent consultation for our

oncology colleagues and provide the best care for our patients with medulloblastomas.

TABLE OF CONTENTS/OUTLINE

1. Overview of medulloblastomas 2. Review of embryological development of the hindbrain 3. Discussion of proposed embryological origins of medulloblastoma subtypes 4. Overview of each medulloblastoma subgroup (WNT, SSH, Group 3, and Group 4) 5. Review of multiple cases within each subgroup of medulloblastoma with emphasis on imaging characteristics unique to each subgroup

PDEE-26   Pediatric Right Lower Quadrant Ultrasound: Appendicitis And Beyond

Participants
Chris O'Sullivan, Temple, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Understand indications for right lower quadrant ultrasound 2. Perform appropriate scan technique 3. Identify normal appendix on ultrasound 4. Identify abnormal appendix on ultrasound 5. Identify complications of appendicitis 6. Recognize alternative diagnoses 7. Incorporate a standardized radiology report into practice

TABLE OF CONTENTS/OUTLINE

I. Indications for RLQ US a. ACR Criteria II. Scan Technique a. Preparation b. Technique c. Positioning d. Documentation III. Normal Appendix a. Measurements b. Morphology c. Compressibility IV. Abnormal appendix a. Measurements b. Morphology c. Noncompressible d. Vascularity e. Appendicolith V. Complications a. Abscess b. Perforation VI. Alternative diagnoses a. Ileitis b. Mesenteric adenitis c. Omental infarct d. Urachal remnant e. Meckel's diverticulum VII. Standard report

PDEE-27   Ectopic Thymic Tissue Masquerading As A Mass In Children - Tips And Tricks For The Radiologist.

Participants
Maura E. Ryan, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

TEACHING POINTS

The thymus is normal lymphoid tissue, typically prominent in childhood and classically located in the anterior mediastinum.However, thymic tissue can be encountered in other locations along the path of the thymopharyngeal ducts from which the thymic tissue arises.Ectopic or accessory thymic tissue, frequently encountered in the cervical soft tissues can be mistaken for pediatric malignancies such as neuroblastoma.Thymic tissue in ectopic regions retains imaging characteristics of lymphoid tissue on MR, CT and US imaging.Recognizing the typical imaging features, morphology and locations of ectopic thymic tissue to avoid unnecessary workup or surgery.

TABLE OF CONTENTS/OUTLINE

Embryology, anatomy and natural history of thymic tissue.Imaging appearance of normal thymic tissue on US, CT and MR.Case based pictorial review of children with ectopic thymic tissue, including superior extension of thymic tissue, ectopic thymic tissue in the thyroid gland, central neck and carotid space and in the posterior mediastinal space.Examples and discussion of ectopic thymic tissue associated with DiGeorge Syndrome (22q11.2 deletion).Discussion rare instances of symptomatic ectopic thymic tissue, management and follow-up

PDEE-28   A Radiologist's Lexicon For Reporting In Child Abuse

Awards
Magna Cum Laude
Identified for RadioGraphics

Participants
Asha Sarma, MD, Nashville, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Child abuse is a common and critical problem that may be encountered by radiologists in multiple disciplines. Optimal radiological terminology for suspected abuse-associated injuries in young children may differ from that used in other scenarios, including reporting in older patients and in cases of accidental trauma. Variable terminology for the same finding in the literature may also lead to confusion. Child abuse pediatricians' expert evaluation of injury-mechanism correlation relies on precise, appropriately detailed, and consistent use of radiological terminology for clinical, forensic, and medicolegal applications. This exhibit aims to catalog child-abuse related injuries from head to toe, with emphasis placed on preferred terminology from the child abuse pediatrics literature. More recently described entities (e.g., bridging vein injury), potential terminological pitfalls (e.g., inadequate description of fracture morphology), and mimics (e.g., coagulopathy, benign extra-axial fluid collections) will be highlighted.

TABLE OF CONTENTS/OUTLINE

1. Abusive CNS Trauma: a. Scalp injury b. Skull fractures and sutural widening c. Extra-axial collections (e.g., bridging vein injury, dating considerations) d. Parenchymal injury e. Retinal hemorrhage f. Spinal cord injury 2. Skeletal injuries: a. Fracture morphology (appropriate terminology, biomechanics) b. Fracture by site of injury c. Fracture dating d. Potential mimics of child abuse 3. Thoracoabdominal injuries

PDEE-29   Pediatric Airway Obstructions That Will Take Your Breath Away

Participants
Bruno Peres, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To display and discuss several teaching cases of congenital and acquired upper airway obstructive conditions from our hospital's 15-year database, mostly through computed tomography (CT) and magnetic resonance (MR) scans.

TABLE OF CONTENTS/OUTLINE

1. Brief introduction of pediatric upper airway anatomy and obstructive conditions. 2. Cases: unilateral and bilateral choanal atresia - unilateral and bilateral congenital dacryocystocele - pyriform aperture stenosis - arhinia (Bosnam syndrome) - retropharyngeal lymphadenitis - retropharyngeal suppurative lymphadenitis - congenital cervical teratoma - epiglottitis - juvenile nasopharyngeal angiofibroma - nasal cavity foreign body - oral cavity foreign body - infantile hemangioma - tracheobronchitis - aberrant left pulmonary artery (pulmonary sling) - tracheobronchial papillomatosis - tracheal stenosis tracheomalacia - tracheoesophageal fistula. 3. Conclusion.

PDEE-3   Lung Ultrasound For The Pediatric Radiologist

Participants
Thomas Marini, MD, Rochester, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Understand the basic physics of lung ultrasound and image acquisition. 2) Understand the broad spectrum of applications for lung ultrasound in pediatric radiology. 3) Identify basic imaging features of common and uncommon pediatric pulmonary conditions on lung ultrasound. 4) Discuss the use of lung ultrasound in the context of the larger health system.

TABLE OF CONTENTS/OUTLINE

1) Introduction to lung ultrasound: a) Basic physics to contextualize clinical findings including discussion of "A-Lines" and "B-Lines" b) Lung ultrasound image acquisition in pediatric patients c) Indications for lung ultrasound and its sensitivity and specificity for conditions d) Discussion of current use of lung ultrasound including point of care ultrasound and future directions 2) Lung ultrasound imaging findings in pediatrics: a) Asthma b) Viral illness including bronchiolitis and COVID-19 c) Bacterial pneumonia d) Pleural fluid (effusion/empyema) e) Pulmonary edema f) Abscess g) Miscellaneous cases including vaping and bronchopulmonary dysplasia 3) Future uses and directions in pediatric lung ultrasound a) Alternative to chest x-ray utilization b) Point of care versus diagnostic lung ultrasound c) Lung ultrasound health policy and global outreach

PDEE-31   Neurological Findings In Down Syndrome: What Every Radiologist Should Look For

Participants
Juliana Benez, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibition is to: • Demonstrate the most frequent neuroradiological findings in Down syndrome. • Illustrate through didactic cases and different imaging modalities the main manifestations according to brain/spine/vascular/head and neck. • Help young radiologists to perform an active search of these changes.

TABLE OF CONTENTS/OUTLINE

• Introduction • Main imaging findings in DS, according to - Brain: overall reduced brain volume, progressive brain atrophy, basal ganglia calcifications, malformations of the corpus callosum, syndrome) - Spine: craniocervical instability, flattened surface of the occipital condyles, bifid C1 arches, atlantooccipital assimilation, "Os Odontoideum" and, "Mickey Mouse" pelvis.- Vascular: aberrant subclavian artery and Moyamoya syndrome. - Head and neck: microcephaly/microcrania, brachycephaly without craniosynostosis, platybasia, macroglossia, stenotic external auditory canal, ossicular chain abnormalities, and hypoplasia/aplasia of the bony island of the lateral semicircular canal. • Objectively delineate what findings radiologists should look for. • Provide didactic and illustrative cases in a challenging format to test and consolidate the knowledge acquired. • Conclusions. • References.

PDEE-32   Ultrasonography As A Diagnostic Tool In The Evaluation Of Congenital And Acquired Duodenal Obstruction: Anatomy, Usual And Unusual Cases

Participants
Natalia Lima, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:1. To review the normal duodenal anatomy by ultrasound;2. To show the importance and effectiveness of ultrasound as a method of choice for the diagnosis of obstructive pathologies of the duodenum in neonates and children;3. To show usual and unusual cases of congenital and acquired duodenal obstruction from our pediatric radiology group;4. To show the main sonographic findings, classic signs and tips in the assessment and diagnosis of duodenal obstruction in neonates and children.

TABLE OF CONTENTS/OUTLINE

1. Sonographic technique in duodenal evaluation;2. Sonographic duodenum anatomy and adjacent structures;3. Illustrated teaching cases from our pediatric radiology group showing sonographic images of usual and unusual causes of congenital and acquired duodenal obstruction:- Duodenal web;- Annular pancreas;- Intestinal malrotation;- Duodenal hematoma after upper digestive endoscopy.

PDEE-33   Optimizing Imaging Of Pediatric Liver Tumors: Guidelines From The Pediatric LI-RADS Workgroup

Awards
Identified for RadioGraphics

Participants
Govind Chavhan, MD, Toronto, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

Differential diagnosis of pediatric focal liver lesions should be based on age, underlying history, and AFP level. Children vary significantly in age, size, ability to stay still, and ability to breath-hold. Choosing and tailoring imaging techniques for each indication and age group is important. The need for sedation can be obviated using techniques like feed and bundle, contrast-enhanced ultrasound, and motion-insensitive sequences for MRI. Hepatobiliary contrast media enables detection of satellite lesions and helps radiologists to refine their differential diagnosis.

PDEE-34 Abnormalities Of Placental Blood Flow: What The Radiologist Needs To Know

Awards
Certificate of Merit

Participants
Morgan McLuckey, MD, Indianapolis, Indiana (*Presenter*) Nothing to Disclose

TEACHING POINTS

There is a growing body of literature which suggests that placental hemodynamics are related to common gestational problems such as maternal hypertension, intrauterine growth restriction, and preterm delivery. The increasing availability of prenatal MR allows radiologists to assess in vivo placental vasculature more clearly than ever before. There is a need for radiologists to have a more thorough understanding of placental imaging to better predict which vascular anomalies are problematic and which are incidental findings.

TABLE OF CONTENTS/OUTLINE

1. Review placental vascular anatomy and embryology // 2. Highlight examples of placental extravascular blood // a. Intraplacental // b. Retroplacental // c. Subchorionic // d. Subamniotic/Intra-amniotic // e. Aging hematoma // f. Comparison of hematoma and ongoing hemorrhage // g. Comparison of hematoma and transient myometrial contraction // 3. Illustrate examples of placental ischemic lesions // a. Placental infarction // b. Generalized ischemia // c. Intervillous thrombi (with comparison to placental lakes) // 4. Address imaging findings of the placenta in intrauterine growth restriction in the setting of perfusion abnormality // 5. Assess the clinical significance of these findings and how they relate to systemic gestational disease processes // 6. Summarize the diagnostic value of placental MRI and how findings are related to perinatal outcome.

PDEE-35 Ultrasound: A Noble Technique For The Diagnosis Of Gastroesophageal Reflux In Children

Participants
Evelyn Torres Gomez, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

Gastroesophageal reflux is a physiological condition in patients under one year, however, when the quantity or intensity of these episodes increases, it conditions a gastroesophageal reflux disease. A good history and physical examination are usually sufficient for the clinical diagnosis of gastroesophageal reflux.However, in the presence of complications or suspected GERD, some of these patients will require additional diagnostic studies, among which are phmetry, endoscopy with or without biopsy, esophageal manometry, barium fluoroscopic studies, scintigraphy abdominal and abdominal ultrasound.Abdominal ultrasound is a safe, non-invasive, ionizing radiation-free and reliable procedure, with a sensitivity that exceeds 68%; which can be used in the assessment of GERD patients.Ultrasound allows evaluation of morphological characteristics of the esophagogastric junction, diagnose gastroesophageal reflux and classify the severity of the reflux according to the number of episodes in a given time.Abdominal ultrasonographic evaluation also makes it possible to identify differential diagnoses with pathologies that may have a similar clinical presentation, among which is pyloric hypertrophy and hiatal hernia.

TABLE OF CONTENTS/OUTLINE

Normal anatomy of the esophagogastric junction.Ultrasound technique for the evaluation of the distal esophagus.Main imaging findings in patients with gastroesophageal reflux.Ultrasonographic classification of the severity of gastroesophageal reflux.

PDEE-36 Diffusion MRI (DW-MRI) In Pediatric Soft Tissue Tumors And Pseudotumors: Technical Considerations, Pitfalls, Current And Evolving Applications

Participants
Maria Clara Lorca, MD, Pittsford, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Diffusion weighted imaging MRI (DW-MRI) role in evaluation of pediatric soft tissue masses, both as complement and alternative to traditional MR pulse sequences 2. Artifacts associated with DW related to hardware, pulse sequence or the composition of the assessed soft tissue mass; radiologists must recognize and when possible, mitigate these artifacts 3. DW-MRI role in characterization and post-therapy assessment of pediatric soft tissue masses 4. 4. Intravoxel incoherent motion (IVIM), an advance in DW-MRI separates microcirculation/perfusion-related effects from pure tissue diffusion, thereby allowing for derivation of pure diffusion coefficients and improving accuracy of characterization of pediatric soft tissue masses

TABLE OF CONTENTS/OUTLINE

1. Physics, technique, pitfalls of pediatric musculoskeletal DW-MRI exams 2. Whole body MRI: tool to examine multifocal soft tissue tumors 3. WHO classification of soft tissue tumors 4. Institutional acquisition protocols of single body part / whole body MR imaging 5. Scanner considerations and pulse sequences used for DW acquisition with relative merits and demerits of each; strategies to optimize single-shot echoplanar imaging (SS-EPI) 6. Current and evolving applications of DWI-MRI for assessment of pediatric soft tissue tumors/pseudotumors on an image-based template, with histologic correlation where applicable

PDEE-37 Pediatric Hepatic Cystic Lesions: Differential Diagnosis And Multimodality Imaging Approach

Awards
Identified for RadioGraphics

Participants
Erica Riedesel, MD, Atlanta, Georgia (*Presenter*) Nothing to Disclose

TEACHING POINTS

The differential diagnosis of cystic hepatic lesions seen in the pediatric population can be divided into developmental, infectious, post-traumatic/iatrogenic, and malignant lesions. Familiarity with key radiologic findings and understanding of specific clinical associations can assist the practicing radiologist in definitive diagnosis. In this educational exhibit, we will present a comprehensive differential diagnosis for pediatric hepatic cystic lesions with an emphasis on imaging findings on multiple modalities.

TABLE OF CONTENTS/OUTLINE

• Introduction • Developmental o Simple cystso Biliary cysts § Choledochal cysts § Caroli's disease o Foregut cysts • Infectious o Pyogenic abscess o Hydatid cyst • Post-Traumatic/Iatrogenic o Hematoma o Seroma o Biloma o UVC-related extravasation o Post-ablation changes • Malignant o Mesenchymal hamartoma o Undifferentiated embryonal carcinoma • Mimics o Fungal microabscess o Vascular tumor (infantile or congenital hepatic hemangioma) o Diaphragmatic mesothelial cyst

PDEE-38 Diagnostic And Therapeutic Utility Of Contrast Enema In Pediatric Patients: What Does The Radiologist Need To Know?

Participants
Khem R. Uprety, MD, Memphis, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Educational Goals1. To review the appropriate indications and contraindications of contrast enema in the pediatric patients.2. To become familiar with the technique and appropriate choice of contrast while performing contrast enema.3. To review imaging features of various conditions causing distal intestinal obstruction in neonates. 4. To review therapeutic utility of contrast/air enema in various emergent conditions such as Volvulus, Ileo-Colic Intussusception and Meconium Ileus.

TABLE OF CONTENTS/OUTLINE

Indications and contraindications of contrast enema; Appropriate technique and choice of contrast while performing contrast enema; Normal anatomy, anatomic variants as well as expected post-surgical appearances of the colon; Review typical contrast enema findings in different colonic pathologies including but not limited to Hirschsprung's disease, microcolon, meconium ileus, functional immaturity of the left colon, colonic stricture secondary to necrotizing enterocolitis, and colonic atresia; Review therapeutic utility of contrast enema in meconium ileus and colonic volvulus; Review air reduction enema in ileocolic intussusception.

PDEE-39 MRS Signatures Of Inborn Metabolic Errors In Children With Normal Or Near-normal Appearing Brains

Participants
Matt Whitehead, MD, Washington, Dist. of Columbia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. 1H MRS detects neurometabolic disturbances directly in normal appearing brains early in disease and in milder IEM phenotypes2. MRS often outperforms blood and CSF analyses3. Creatine deficiency syndromes, galactosemia, urea cycle, mitochondrial, and long-chain fatty acid oxidation disorders can manifest specific spectroscopic signatures and normal brain MR imaging4. Consider MRS in pediatric patients with unexplained seizures, altered mentation, stupor, developmental delay/intellectual disability, movement disorders, weakness, and/or hypoglycemia notwithstanding the appearance of the brain MR

TABLE OF CONTENTS/OUTLINE

1. Introduction/Background2. Technical considerations/recommendations3. Case examples: creatine deficiency, galactosemia, urea cycle, mitochondrial, and long-chain fatty acid oxidation disorders4. Take-home points

PDEE-4 Pediatric Facial Trauma: What The Surgeon Needs To Know.

Awards
Identified for RadioGraphics

Participants
Naoya Shatani, MD, Vancouver, British Columbia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Pediatric facial fractures follow patterns similar to those in adults, however the relative incidence of fracture patterns and associated complications change as skeletal development progresses from infant to adolescent.2. The concept of facial buttresses, well-described in adult literature, also applies to the pediatric population, providing an approach to description of injury patterns involving different facial subunits.3. When a facial fracture is clinically suspected, low dose CT from the forehead to chin, with 3D rendering, should be performed early, to provide the surgeon with optimal information for treatment planning.4. Surgeons make decisions based on aesthetics and function. It is crucial to identify and describe facial fractures according to clinically relevant facial subunit injuries. Associated features that the surgeon must be aware of are extent of displacement and alignment, and involvement of adjacent structures including the brain and dura, orbital contents, dentition, and neurovascular structures.

TABLE OF CONTENTS/OUTLINE

1. Description of relevant facial anatomy, using three dimensional illustrations, and patterns of facial fractures using concept of subunits and buttresses.2. Unique aspects of facial fractures in children and important radiologic "pearls".3. What the surgeon

wants to know for each pattern of injury: orbital, zygomaticomaxillary complex (ZMC), nasoorbitoethmoidal (NOE), Le Fort, mandibular, nasoseptal, and dentoalveolar.

PDEE-40   When Sugar Looks Like Salt: Pitfalls That Could Lead To The Incorrect Diagnosis Of Child Abuse

Participants
Nadia Solomon, MD, New Haven, Connecticut (*Presenter*) Nothing to Disclose

TEACHING POINTS

Identifying victims of child abuse is vital to protect them, yet false accusations are also damaging. We aim to provide a review of imaging findings that may suggest the incorrect diagnosis of child abuse and how to distinguish these from true cases. 1. Introduction to child abuse emphasizing importance of accurate identification 2. Clinical and imaging approaches, including best practices for imaging 3. Various processes potentially mistaken for child abuse, including presentation, pathophysiology, and imaging features to aid in differentiation

TABLE OF CONTENTS/OUTLINE

1. Common non-accidental trauma, with mechanisms and imaging findings 2. Clinical and imaging approaches for investigating child abuse 3. Processes potentially mistaken for child abuse on imaging and distinguishing features a. Accidental injury b. Congenital/developmental variants (e.g., Wormian bones) c. Birth trauma (e.g., molding) d. Infections, postinfectious conditions (e.g., syphilis) e. Primary bone diseases (e.g., bone cysts) f. Vitamin deficiencies, toxins g. Connective tissue disorders, skeletal dysplasias (e.g., Ehlers Danlos) h. Metabolic disorders (e.g., homocystinuria) i. Hematologic diseases, coagulation disorders (e.g., hemophilia) j. Hypoxic and ischemic disorders k. Other neurological conditions (e.g., hydrocephalus) l. Other genetic disorders (e.g., Prader-Willi) 4. Review of confusing imaging findings and differential diagnoses 5. Update on research/best practices for imaging suspected abuse cases

PDEE-41   Utility Of Various Measurements In Diagnosis And Management Of Lower Extremity Alignment Disorders In Pediatric Patients.

Participants
Jignesh N. Shah, MD, Germantown, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review etiopathogenesis and imaging features of various lower extremity alignment disorders in pediatric population 2. To review utility of measurements in diagnosis and management

TABLE OF CONTENTS/OUTLINE

Enumerate alignment disorders of lower extremities in pediatric patients; Discuss embryological basis and etiopathogenesis; Imaging features of alignment disorders involving lower extremities in pediatric patients including but not limited to developmental dysplasia of hip, coxa vara, coxa valga, femoral anteversion, tibial torsion, genu varum, blount disease, genu valgum, leg length discrepancy, club foot, congenital vertical talus, rocker-bottom foot, metatarsus adductus, skewfoot, flatfoot, calcaneovalgus, pes cavus, hallux valgus, cerebral palsy; Utility of various measurements such as hip alpha angle, acetabular index, reimers migration percentage index, femoral neck-shaft angle, angle of femoral anteversion, angle of tibial torsion, metaphyseal-diaphyseal angle of Drennan, lateral talocalcaneal angle, meary's angle, calcaneal inclination angle etc. to diagnose and guide management of above mentioned entities

PDEE-42   Congenital Hand Anomalies: What Does The Radiologist Need To Know?

Awards
Certificate of Merit

Participants
Ankita Chauhan, MD,MBBS, Memphis, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Background Information Congenital hand anomalies are often isolated phenomena but can be associated with other congenital anomalies and maybe the only external manifestation of a syndrome. Knowledge of radiographic features is the mainstay to characterize the hand anomalies and guide treatment for better functional prognosis. Objectives / Teaching Points 1. To become familiar with the classification of congenital hand anomalies and the syndromes associated with them. 2. To acquire a basic understanding of the embryological and genetic basis of congenital hand anomalies. 3. To review the salient imaging features of the congenital hand anomalies and treatment options.

TABLE OF CONTENTS/OUTLINE

-Embryologic and genetic basis of hand development -Classification of congenital hand anomalies -Typical imaging features of hand anomalies (including but not limited to synostoses, clinodactyly, camptodactyly, syndactylies, delta phalanx, Kirner's deformity, symphalangism, constriction band syndromes, arthrogryposis multiplex congenita) -Syndromes associated with hand anomalies (such as Holt-Oram syndrome, Thrombocytopenia Absent Radius (TAR) syndrome, VACTRL, Fanconi anemia, Apert syndrome, Poland syndrome -Treatment options -Summary

PDEE-43   The Importance Of Nuchal Access In Cranial Ultrasound: What Are We Missing?

Participants
Natalia Lima, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of this exhibit are:1. To review the main indications of cranial ultrasound in neonates;2. To show the importance and the technique of the nuchal access in the routine neonatal cranial ultrasound;3. To show based on cases from our pediatric radiology group important structures that must be evaluated by this nuchal access;4. To review based on cases from our pediatric radiology group the main congenital and acquired abnormalities of the neonatal posterior fossa only detected by the nuchal access and not identified by a routine cranial ultrasound through the anterior fontanelle.

PDEE-44   Fetal MRI At 3T: Principles To Optimize Success

Awards
Identified for RadioGraphics
Cum Laude

Participants
Fedel Machado, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

The MRI technologist plays a crucial role in patient preparation and success of examHigher SNR can be leveraged to optimize sequences and improve spatial and temporal resolution. Individual sequences play different roles in fetal MRI: showcase of frequently used sequences in clinical examplesFetal MRI at 3 T is safe: review of evidenceAdvantages and disadvantages of 3T vs 1.5 T

PDEE-45   Pediatric COVID-19 Infection From Head To Toe

Participants
Christine Nwoke, MS, Cordova, Georgia (*Presenter*) Nothing to Disclose

TEACHING POINTS

Children infected with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) may present with acute respiratory symptoms, acute systemic symptoms, or a post infectious inflammatory syndrome known as Multisystem Inflammatory Syndrome in Children (MIS-C). Symptoms of acute COVID-19 infection and MIS-C in children are often nonspecific and overlap with common pediatric pathologies such as acute appendicitis. While routine imaging is usually not indicated in pediatric COVID-19 infection, imaging can facilitate care in severe and complex cases as well as exclude alternative diagnoses. The purpose of this exhibit is to review imaging features, clinical presentation, and clinical follow up of 582 patients that presented to our institution with laboratory evidence of COVID-19 and 47 patients with clinical diagnosis of MIS-C. Cases will be reviewed in context of our current understanding of pediatric COVID-19 infection based on a literature review.

PDEE-46   MRI In Neonates: Practical Approach To Improve Image Quality And Diagnostic Yield

Awards
Certificate of Merit

Participants
Limin Xu, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

-To review principles of image optimization for neonatal MRI -To learn appropriate patient preparation and strategies to enable non-sedated MRI -To understand safety considerations -To demonstrate examples of common indications -To showcase emerging technologies that improve MR image quality and access in sick newborns

PDEE-47   A Pictorial Review Of Neurosonographic Vascular Anatomy As Depicted With Microflow Imaging

Participants
Shawn Lyo, MD, Brooklyn, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

Neurosonography is an indispensable imaging examination in the evaluation of the infant brain. Grayscale sonography allows assessment of the parenchyma and extra-axial spaces and Doppler-based imaging may evaluate the intracranial vasculature. Microflow imaging (MFI) is one of multiple recently developed Doppler sonographic techniques which utilize advanced background tissue suppression algorithms to allow non-contrast visualization of low-flow microscopic vessels which were not well visualized previously. In this pictorial review, we demonstrate the intracranial microvascular anatomy which is frequently visualized with MFI with correlation to conventional and MR angiography.

TABLE OF CONTENTS/OUTLINE

I. Neonatal neurosonography a. Grayscale b. Doppler i. Color Doppler, spectral Doppler, Power doppler ii. Advanced Doppler techniques such as MFI c. Comparison of overlayed grayscale and Doppler techniques II. Neurosonographic examination a. Standard views via anterior fontanelle i. Coronal ii. Sagittal III. Vascular anatomy a. Arteries i. Anterior circulation 1. Intracranial segments of the internal cerebral artery 2. Anterior cerebral artery 3. Middle cerebral artery 4. Lenticulostriate and thalamostriate arteries ii. Posterior circulation 1. Basilar Artery b. Veins i. Superficial venous system including sinus and cortical veins ii. Deep venous system c. Additional i. Choroid plexus/arachnoid granulations IV. Conclusion

PDEE-49   Pediatric Renal Cysts: Is It Really That Simple?

Participants
Marcelo Takahashi, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Pediatric renal cysts differential diagnosis and associated syndromes.- Key imaging features that must be evaluated in cases of pediatric renal cysts.- Imaging rationale and technique tips/recommendations

TABLE OF CONTENTS/OUTLINE

1- Introduction:Epidemiology of renal cysts in childrenNormal renal development.2- Imaging Rationale in pediatric renal cyst evaluation:Pre-natal US and MRIUSCTMRVCUG.3 - Urinary tract abnormality related cysts:Multicystic Dysplastic KidneyCystic Dysplasia4 - Genetic disorders associated with cysts:Autosomal dominant polycystic diseaseAutosomal recessive polycystic diseaseOthers (Von Hipel-Lindau, Tuberous sclerosis, Hajdu-Chenye).5 - OthersCystic partially differentiated nephroblastomaCystic nephromaAbscess6 - Pitfalls:Focal calyceal dilationNormal neonatal pyramids7 - Take Home Message

PDEE-5   Skeletal Dysplasia Families: A Comprehensive Review

Participants
Atsuhiko Handa, MD, Iowa City, Iowa (*Presenter*) Nothing to Disclose

TEACHING POINTS

Skeletal dysplasias encompass a heterogeneous group of over 400 disorders. They are individually rare, but collectively common with an approximate incidence of 1/5000; thus, radiologists occasionally encounter skeletal dysplasias in daily practice. Most skeletal dysplasias have their characteristic pattern of skeletal changes, and the diagnosis rests on pattern recognition. A group of skeletal dysplasias that share a distinctive radiological pattern can be grouped into a "skeletal dysplasia family" that generally shares a common pathogenesis. Since major skeletal dysplasia families are limited in number, the radiologists can become readily familiar with their diagnostic patterns. The purpose of this exhibit is to 1) demonstrate the radiological characteristics of major skeletal dysplasia families and 2) review their clinical and genetic features that help radiologists to participate in multidisciplinary care. After completion of this presentation, the learners will have an overall picture of the entire world of skeletal dysplasias.

TABLE OF CONTENTS/OUTLINE

- Introduction - Approach to skeletal dysplasias - FGFR3 (achondroplasia) family - COMP family - Type II collagenopathies - Dysostosis multiplex family (mucopolysaccharidoses and mucolipidoses) - TRPV4 (metatropic dysplasia) family - Skeletal ribosomopathies (eg. Schwachman Diamond) - DTDST (diastrophic dysplasia) family - Filaminopathies - Punctata group - Skeletal ciliopathies - Osteogenesis imperfecta group - Osteopetrosis group

PDEE-50   Pediatric Macrocephaly: A Systematic Approach And Review Of Etiologies And Neuroimaging Characteristics

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Jennifer Huang, MD, Nashville, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Macrocephaly, defined as head circumference > 2 standard deviations above the mean.• Distinguishing which of the four components of the cranium is increased (cerebrospinal fluid, blood, brain parenchyma, calvarium), patient age, and symptoms are key.• Benign enlargement of subarachnoid spaces (benign macrocephaly) is the most commonly imaged entity. However, there are also many pathologic etiologies (see below).• Multiple imaging modalities are complementary in the evaluation of macrocephaly.

TABLE OF CONTENTS/OUTLINE

• In-depth review of differentiating clinical and imaging features of various causes of macrocephaly, organized by each of 4 involved compartmentsso Cerebrospinal fluid spaces§ Benign enlargement of subarachnoid spaces (BESS)§ Hydrocephalus§ Hydranencephaly§ Choroid plexus neoplasmso Blood§ Hemorrhage (e.g., subdural)§ Arteriovenous malformation (e.g., Vein of Galen)o Brain parenchyma§ Anatomic megalencephaly (e.g., PTEN, PIK3/AKT/mTOR mutations)§ Metabolic megalencephaly• Glutaric aciduria type 1• Leukodystrophy (Alexander disease, Canavan disease, megalencephalic leukoencephalopathy)• Lysosomal storage disorders (e.g., mucolipidosis)§ Intracranial mass (e.g., cyst, tumor, abscess)§ Neurocutaneous disorders§ Cerebral gigantismo Calvarium§ Skeletal dysplasia (e.g., achondroplasia)§ Thalassemia major

PDEE-51   A Systematic Approach And Neuroimaging Review Of Pediatric Cerebellar Ataxia

Participants
Jennifer Huang, MD, Nashville, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Structural abnormalities and diseases causing cerebellar ataxia in children are relatively common and warrant further evaluation with imaging.• The often-nonspecific clinical presentation can present challenges in definitive diagnosis, however a combination of neuroimaging modalities and genetic testing are useful adjuncts.• A systematic approach of pediatric cerebellar ataxias categorized by imaging finding will be proposed.• Overlapping findings may be seen between categories of disease listed below.

TABLE OF CONTENTS/OUTLINE

• Detailed review of clinical and imaging features of selected causes of pediatric cerebellar ataxia, categorized into groups by salient imaging finding (additional entities may be included in final presentation)o Cerebellar mass§ Medulloblastoma§ Pilocytic astrocytoma§ Ependymoma§ Lhermitte-Duclos disease (dysplastic cerebellar gangliocytoma)o Cerebellar atrophy§ Spinocerebellar ataxia§ Friedreich's ataxia§ Ataxia-telangiectasia§ Vanishing white matter diseaseo Cerebellar malformation/underdevelopment§ Dandy-Walker syndrome§ Molar Tooth Malformation§ Rhombencephalosynapsiso Abnormal cerebellar enhancement§ Cerebellitis§ Herpesviruso Abnormal cerebellar signal§ Cerebellitis§ Paraneoplastic degeneration§ Metabolic disorders (e.g., mitochondrial, neuronal ceroid lipofuscinosis, GM2 gangliosidosis, phospholipase A2 associated neurodegeneration (PLAN))§ Hemorrhage§ Multiple sclerosis§ Infarct

PDEE-52 **Gadolinium In Pediatric Magnetic Resonance: Indications, Risks And Alternatives**

Participants
Ana Paiva Cavalcante, PhD, MD, Sao Paulo, Brazil (*Presenter*) Research Advisor, Bayer AG

TEACHING POINTS

There is great concern on Gadolinium use in children. Some strategies can be used to reduce the use of GBCA in the pediatric group.

TABLE OF CONTENTS/OUTLINE

The macrocyclic gadolinium-based contrast agents (GBCA) were recently approved for use in children under 2 years of age. These contrast agents demonstrated improved lesion detection and delineation, and were well-tolerated for use in children. However, recent observations of gadolinium (GD) tissue retention have raised additional concerns about the use of GBCA in the pediatric population. Although studies to date have not shown clinical consequences of GD tissue retention, the jury is still out on whether such consequences may arise during the lifetime of children submitted to multiple doses of GBCA. We reviewed the literature on the risks of adverse events and GD tissue retention in the pediatric population and highlighted several clinical indications in which the benefits of enhanced MRI and PET-MR outweigh potential risks. We outlined alternative strategies to reduce the use of GBCA in the pediatric group including unenhanced MRI protocols, use of Contrast Enhanced Ultrasound (CEUS), and the recent applications of liquid biopsy in pediatric tumors. Finally, we discussed the use of reduced dose of a 1.0 M GBCA, the recent applications of Deep Learning for synthetic enhanced MRI, as well as possible indications for alternative MRI contrast agents such as superparamagnetic iron-oxide nanoparticles (SPIONs).

PDEE-53 **A Radiology Resident's Guide To Imaging The Sick Neonate: A Head-to-toe Primer**

Participants
Jennifer Lindsey, MD, Nashville, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Acutely ill neonates often require imaging for common and uncommon critical diagnoses and identification of complications of therapeutic intervention. Bedside modalities (e.g., ultrasound, portable radiography, and increasingly, portable CT and MRI) are of vital importance. Effective communication with the clinical team is also essential.This educational exhibit aims to prepare radiology trainees to:1. Identify key clinical and imaging findings on head-to-toe imaging of the sick neonate.2. Understand best practices in communication, clinical intervention, and follow-up imaging.

TABLE OF CONTENTS/OUTLINE

1. Craniala. Ischemic injury (e.g., HIE, neonatal stroke, mimics),b. Hemorrhage (e.g., germinal matrix hemorrhage, subgaleal hematoma)c. Infectiond. Hydrocephalus2. Chesta. Neonatal lung diseasesb. Congenital diaphragmatic herniac. Complications of critical care (e.g., barotrauma)d. Support device complications (e.g., hepatic abscess/TPNoma, thrombosis)3. Abdominopelvica. Necrotizing enterocolitis and complications i. Radiography vs. USb. Malrotation with midgut volvulus i. Fluoroscopy vs. USc. Renal vein thrombosisd. Biliary atresia4. MSK/Spinala. Post-LP hematoma5. Non-cardiac causes of cardiac failurea. Pathologic shunts (e.g., hepatic, vein of Galen malformation)b. Congenital hemangioma

PDEE-54 **Precocious Puberty: What Radiologist Needs To Know**

Participants
Diego Guerrero Gomez SR, MD, Bogota, Colombia (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Precocious puberty (PP) is the name given to the pubertal development more than 2-2.5 standard deviations earlier than population norms (less than 8 years in girls and 9 years in boys). - Reminding the endocrinological Hypothalamus-pituitary-gonadal (HPG) axis, could be understood the main PP etiologies. - Main central (Brain) causes of PP include tumoral etiologies such as hypothalamic hamartoma, optic pathway or hypothalamic glioma, and germinomas, and non-tumoral causes like traumatic brain injury, and toxoplasmosis sequalae.- Peripheral PP could be attributed to pathology located in adrenal gland (adrenal neoplasm or congenital adrenal hyperplasia), ovaries (simple cyst, Juvenile granulosa cell tumor), testes (Juvenile granulosa cell tumor) or from Syndromic origin (McCune-Albright Syndrome).- According to the physical exam and lab-tests should be made the radiological approach as described in the proposed algorithm.

PDEE-55   Acute Imaging Manifestations Of Meckel's Diverticulum In Children

Participants
Guillermo Alfonso, DO, Tucson, Arizona (*Presenter*) Nothing to Disclose

TEACHING POINTS

Meckel diverticulum (MD) is a congenital intestinal diverticulum due to degeneration of the umbilical end of the omphalomesenteric duct in relation to the distal ileum. Although most cases are asymptomatic, some children could present with acute abdominal pain due to complications arising from MD. The clinical presentation is similar to acute appendicitis with ultrasound being the initial imaging modality of choice. Ultra-fast MRI can offer a quick and accurate alternative to established imaging modalities including contrast enhanced CT and radionuclear imaging. We propose to present an non enhanced ultrafast MRI protocol that perform robustly in the setting of both acute appendicitis and acute complications of MD

TABLE OF CONTENTS/OUTLINE

1. Anatomy and Embryology of omphalomesenteric duct2. Clinical presentation of MD3. Ultrafast MRI protocol4. Case presentations: Incidental MD, Acute Meckel Diverticulitis, Perforation, bowel obstruciton, Internal hernia5. Differential Diagnosis with illustrative examples.

PDEE-56   Imaging Of Pediatric Neuro Emergencies: Paradigm Shift

Participants
Neetika Gupta, MBBS,MD, Ottawa, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

• To illustrate the diverse etiology of acute neurological emergencies in pediatric patients. • To discuss the role of various imaging modalities and interventions in the evaluation of acute pediatric neuro emergencies.• To highlight the role of Rapid MRI in pediatric neuro emergencies, reducing the scan duration and needs for anesthesia. • To emphasize the diagnostic and prognostic role of neuroimaging in the evaluation of pediatric neuro emergencies.

TABLE OF CONTENTS/OUTLINE

• Identify the frequent traumatic and nontraumatic acute neurological emergencies in the pediatric population.• Review the key imaging findings of common pediatric neuro emergencies and their life-threatening complications.• Describe the specific role of various imaging modalities and neuro interventions in the emergency management of acute neurological emergencies of childhood. • Recognise the common imaging pitfalls in the evaluation of pediatric neuro emergencies and tips & tricks to avoid them.• Emphasize the role of Rapid MRI in pediatric neuro emergencies, reviewing the Rapid MRI protocols (vs Conventional protocol) and its clinical case-based application.• At last, compare the strengths and limitations of Rapid MRI in acute pediatric neuro emergencies.

PDEE-57   Imaging Of Non-neoplastic Mediastinal Masses In Children

Participants
Hiral Banker, MD, Memphis, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Non-neoplastic mediastinal masses are uncommon in children. These lesions can be related to congenital conditions, trauma, infection, post-surgical complications, benign enlargement of mediastinal structures, etc. The objective of this presentation is to describe various non-neoplastic pathologies seen in the pediatric age group which can present or mimic a mediastinal mass. To describe and illustrate their appearance on various imaging modalities and describe the differentiating radiological features. 3-D reformations often help in the diagnosis. Early and accurate diagnosis is helpful in reducing patient morbidity or mortality, especially in life-threatening conditions. Correct diagnosis of these entities can also help in reducing unnecessary interventions.

TABLE OF CONTENTS/OUTLINE

• Overview of mediastinal anatomy. • Describe various non-neoplastic entities that can present as mediastinal mass in children. • Describe and elucidate imaging algorithm for workup of possible mediastinal mass in children. • Describe the radiological appearance with a 3-D reformation of nonneoplastic mediastinal masses and other mimickers in children with an emphasis on life-threatening conditions e.g., aortic aneurysm.

PDEE-58   The Pathology And Radiology Of Connective Tissue Disease (CTD)-associated Lung Disease In Children And Young Adults

Participants
Andrew Schapiro, MD, Cincinnati, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Lung disease can occur in association with connective tissue disease (CTD) in children and young adults, with certain lung disease patterns tending to occur in association with certain CTDs2) The primary role of the radiologist is to identify the pattern of lung disease and note any change over time in the setting of known CTD, and to suggest the possibility of CTD in the setting of diffuse lung disease without known etiology3) The typical pathology and radiology findings of lung diseases in children and young adults with the following CTDs will be reviewed: Sjogren syndrome, systemic sclerosis and mixed connective tissue disease (MCTD), polymyositis (PM) and dermatomyositis (DM), systemic lupus erythematosus (SLE), and systemic juvenile idiopathic arthritis (sJIA)

TABLE OF CONTENTS/OUTLINE

1) Overview of CTD-associated lung disease, including the role of the radiologist2) Sjogren syndrome-lymphoid interstitial pneumonia (LIP) (emphasized)-nonspecific interstitial pneumonia (NSIP)3) Systemic sclerosis and MCTD-NSIP4) PM and DM-

organizing pneumonia (OP) (emphasized)-NSIP5) SLE-diffuse alveolar damage-hemorrhage-serositis-rarely NSIP6) sJIA-endogenous lipoid pneumonia (ELP)/pulmonary alveolar proteinosis (PAP) spectrum7) Summary of characteristic features of each condition

PDEE-59   Orbital Lesions In Pediatrics- A Radiologist'S Primer

Participants
Hiral Banker, MD, Memphis, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Orbit is comprised of many structures including the optic nerve, globe, muscles, and retro-orbital fat. A wide range of pathologies can be seen affecting the orbit. The spectrum of orbital lesions in children differs from that of adults. Certain tumors such as rhabdomyosarcoma and vascular anomalies are more common in pediatrics and have characteristic imaging appearances. Recognition of key features of various pathologies helps make the correct diagnosis and facilitates appropriate management.

TABLE OF CONTENTS/OUTLINE

• Overview of US, CT & MRI anatomy of orbit. • Describe clinical presentation and imaging appearance of various orbital lesions on different modalities such as USG, CT scan & MRI. • Explain key radiological differentiating features of pediatric orbital lesions including congenital conditions, infection, neoplasm, trauma, and vascular anomalies. • Review uncommon orbital lesions with case illustration, e.g. orbital toxocariasis.

PDEE-6   Soft Tissue Masses In The Young Infant And Neonate: When Is Sonography Not Enough?

Participants
Alex El-Ali, MD, Pittsburgh, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Given that infantile hemangioma is the most common tumor of infancy, the primary role of the radiologist is differentiating infantile hemangioma from other masses which may have an overlapping clinical presentation- Role of ultrasound is to maintain high specificity for the diagnosis infantile hemangioma- Ultrasound diagnosis of infantile hemangioma may still necessitate additional imaging if specific patterns of involvement are recognized- Clinical context serves as the bedrock of appropriate diagnosis and management

TABLE OF CONTENTS/OUTLINE

- Clinical presentation of soft tissue masses in young Infant and neonate- Sonography of soft tissue masses in in young Infant and neonate- Specific ultrasound imaging features of infantile hemangioma- Ultrasound imaging features that are inconsistent with infantile hemangioma ('Red Flags')- Location/pattern approach to infantile hemangiomas requiring additional imaging- Location specific differential considerations for vascular masses in young infants and neonates- Role of MRI and tissue sampling in neonatal soft tissue masses

PDEE-60   Don't Be Out Of The Loop: Ultrassonographic Approach Of Gastrointestinal Pediatric Emergency

Participants
Eduardo Chiovatto, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

After this presentation you will be able to identify the ultrasound anatomy of the intestinal loops in children and understand what the normal anatomy of an intestinal loop is like. In addition, the main childhood's pathologies of the intestinal loops will be presented and illustrated each of them on ultrasound. Finally, we present the challenges and pitfalls that the doctor may find when making this assessment.

TABLE OF CONTENTS/OUTLINE

Historical context of ultrasound Ultrasound anatomy Appropriate techniqueGastroesophageal reflux: Normal esophageal; Hiss angle measurement; extension of the intrathoracic and intra abdominal esophagus and esophageal caliber Hypertrophic pyloric stenosis: Normal pylorus; Pylorus thickness and length Pylorospasm Inflammatory bowel disease: Crohn's disease; Ulcerative colitis; Findings of acute inflammatory disease; chronic inflammatory disease and contrast evaluation Intussusception: ileoileal; simple and complicated ileocecale; small intestinal invagination and hydrostatic reductionNecrotizing enterocolitis: image findings and the method limitations Colitis: infectious; inflammatory: immunosuppressed and not immunosuppressed Appendicitis: Normal appendix; Classical appendicitis; Perforated appendicitis and Abscess Difficulties and Pitfalls in those exams.

PDEE-61   Ultrafast MRI For Acute Pelvic Pain In Girls: Lessons Learned

Participants
Guillermo Alfonso, DO, Tucson, Arizona (*Presenter*) Nothing to Disclose

TEACHING POINTS

Acute lower abdominal/pelvic pain is one of the common presentations to the pediatric emergency department, especially in adolescent girls. Differentiating acute gynecologic pathologies from GI conditions including acute appendicitis is often clinically challenging. Imaging plays a key role in diagnosis and ultrasound is often the initial imaging modality of choice. An Ultra-fast, un-enhanced MRI can offer a quick, safe and reliable alternative in evaluation of both lower abdominal and pelvic conditions. We will discuss the ultra-fast MRI protocol along with imaging findings of both common and uncommon pelvic conditions.

TABLE OF CONTENTS/OUTLINE

1. Clinical conditions associated with acute lower abdominal pain2. Describe an ultra-fast un-enhanced MRI protocol3. Case Presentation: Adnexal/ovarian torsion, ovarian cyst, ruptured follicles, hemorrhage into an ovarian cyst, tubal pathologies, ovarian neoplasms, pelvic inflammatory disease, hematocolpos, and ectopic pregnancy4. Differential diagnosis: Acute appendicitis, obstructive uropathy, enteritis and musculoskeletal conditions5. Pearls and pitfalls in pelvic imaging

PDEE-62   Babies Aren't Mini-Me: Lung Ultrasound In Newborn Intensive Care Unit

Participants
Sasha Gordon, BS, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Neonates receive 1-4 chest x-rays during hospitalization. Replacing chest x-ray (CXR) with lung ultrasound (LUS) reduces radiation exposure. 2. Neonatal anatomy and pathophysiology differ from adults which affects LUS interpretation.3. B-lines on LUS are commonly seen in preterm neonates with respiratory distress syndrome, yet can be normal in neonates with transient retention of fetal lung fluid.4. Neonates non-calcified ribs do not produce an acoustic shadow on LUS so pleural lines appear continuous and can be mistaken for pleural effusion, pneumothorax or subcutaneous emphysema.5. A prominent neonatal thymus mimics lung consolidation or a mass.6. High-frequency oscillatory ventilation used in neonates blunts lung sliding, which resembles pneumothorax.

TABLE OF CONTENTS/OUTLINE

LUS technique considerations: Probe selection, machine settings, scan technique, and high frequency oscillatory ventilation can impact interpretation.Neonatal vs. adult differences: Neonates have normal LUS features including B-lines, non-calcified ribs, and prominent thymus not seen in adults.Unique neonatal lung pathology: Neonates have specific lung diseases such as respiratory distress syndrome, transient tachypnea of the newborn, meconium aspiration, congenital diaphragmatic hernia, and congenital pulmonary lesions.Is LUS better? LUS is safer, less costly and more sensitive than CXR, but does have limitations.

PDEE-64   **The Many Faces Of Eosinophil-associated Diseases From Head To Toe**

Participants
H. Nursun Ozcan, MD, Ankara, Turkey (*Presenter*) Nothing to Disclose

TEACHING POINTS

Eosinophil-associated diseases (EADs) are a wide spectrum of disorders characterized by an increase in circulating or tissue eosinophils. This condition can affect several organ systems which includes; heart, lungs, liver, spleen, gastrointestinal system and central nervous system. In patients with eosinophilia and unexplained clinical findings of different organs, eosinophil associated diseases should be kept in mind. Diagnosis is often challenging and needs a combination of clinical and imaging findings along with laboratory findings. Imaging findings are crucial not only for diagnosis, but also for identifying the extent of the disease and determining the probable biopsy site. There is a lack of comprehensive review about eosinophil associated diseases that cover various systems in radiology literature. In this exhibit; we review the imaging features of various eosinophilic disorders of heart, lungs, liver, spleen, gastrointestinal system and central nervous system both in pediatric and adult patients.

TABLE OF CONTENTS/OUTLINE

1. General information and diagnostic criteria of EADs. 2. The role of radiology in the diagnosis of visceral involvement. 3. Imaging patterns of cardiopulmonary, gastrointestinal and central nervous system involvement of EADs with different radiologic modalities and follow up images. 4. Differential diagnosis of EADs and review of literature.

PDEE-65   **Tips For Imaging Pediatric Stroke: From Cradle To School**

Participants
Stephanie Nagano, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is: 1- To briefly describe pediatric risk factors, etiology and anatomical findings that can lead to stroke in chilhood and its difference from adults. 2- To describe imaging findings of acute and chronic stroke in pediatric patients and its peculiarities, as well as what is important to be reported. 3- To describe a diagnostic algorithm and the importance of each imaging method.

TABLE OF CONTENTS/OUTLINE

1- Neonatal stroke: incidence, imaging findings and anatomical peculiarities. 2- Pediatric stroke etiology, imaging findings and risk factors. 3- Imaging patterns of acute and chronic stroke. 4- Diagnostic algorithm to pediatric stroke and imaging methods. 5- Brief description of treatment and its particularity.

PDEE-66   **Imaging Features And Complications Of Paediatric Osteomyelitis: A Pictorial Assay**

Participants
Ankit Arora, MBBS, Jodhpur, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Understand the pathogenesis of hematogenous osteomyelitis in children and relevant anatomy.2. Review the radiographic, CT and MRI imaging features of osteomyelitis.3. Acquaintance of the immediate and late complications of osteomyelitis and recognise them on imaging.

TABLE OF CONTENTS/OUTLINE

• Definition and Pathophysiology• Anatomical Considerationso Blood supply of metaphysis in childhoodo Metaphyseal equivalents• Role of Imaging and Imaging approach• Imaging features:o Radiographo Ultrasoundo MRIo CT• Complications of paediatric osteomyelitis: Early and late• Cases• ConclusionBackground:The dynamic nature of the microvasculature of the epimetaphyseal region in pediatric population makes it imperative for the radiologist to study the normal physiology and subsequent course of hematogenous osteomyelitis in diagnosing its crippling compliations. Being a fairly common entity, knowledge and thereby early diagnosis with clinicoradiological correlation will aid in preventing complications. Early complications include septic arthritis, cellulitis, myositis and deep venous thrombosis in the affected limb. Delayed complications include avascular necrosis, growth arrest, fracture and chronic osteomyelitis with sinus tract formation. With this exhibit we try to illustrate the imaging findings of osteomyelitis with special emphasis on its complications.

PDEE-67   **Approach To Pediatric Renal Masses: It's Not Always Wilms!**

Participants
Vasundhara Smriti, MD, Mumbai, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Describe various renal masses in paediatric population• Provide an imaging approach to diagnose paediatric renal masses • Depict the typical & atypical imaging features of Wilms tumors• Recognise the most common non-Wilms primary renal neoplasm & its imaging features.• Describe the benign renal masses that mimic Wilms • Discuss secondary involvement of kidney by malignant tumours

TABLE OF CONTENTS/OUTLINE

• Classification of pediatric renal masses• Pathophysiology & clinical presentation of Wilms tumor • Typical & atypical imaging features of Wilms tumor • Discuss what the surgeon wants to know • Pathophysiology & clinical presentation of the common non-Wilms tumors • Highlight points to differentiate Wilms from non-Wilms tumors & the resultant impact on clinical management • Flowchart of approach to pediatric renal masses

PDEE-68   Role Of Child Life Services In Pediatric Radiology

Participants
Gloria Mendez, MS, Orlando, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

Overview of child life services in Pediatric Radiology. Different interventions to improve cost savings and reduce radiation exposure. Reducing trauma in the medical setting. Simple methods to reduce the need for sedation.

TABLE OF CONTENTS/OUTLINE

Introduction. The fundamentals of Child Life and how a Child Life Specialist is an integral part of the multidisciplinary team within the Radiology department. We will discuss the value and benefits that a Child Life Specialist has to offer to pediatric radiology imaging and how this can improve patient and family satisfaction within a hospital or an imaging center. We will also discuss the different interventions used to help increase pediatric cooperation, reduce sedation rates, and help provide higher quality images. Simple tools and resources will be shared on how an imaging center or hospital can start implementing simple and effective ways to help improve a pediatric patient's cooperation during imaging. Using different methods, together with radiology staff, to obtain successful studies within each modality of a radiology department. This presentation will focus on the value and benefits of having a Child Life Specialist and how this member of the interdisciplinary team can be a cost savings tool. Cost saving measures can include less staff needed for each procedure to help hold down patients, reduce the time a procedure room in occupied, and reduce additional medications needed such as sedatives. Conclusion.

PDEE-69   Not So Acute: Imaging Of Thoracic Manifestations Of Sickle Cell Disease In Children

Participants
Dominique Gardner, Charleston, South Carolina (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Review the pathophysiology of sickle cell disease and associated disorders.2. Discuss the clinical presentations and management of acute and chronic sickle cell manifestations within the chest in pediatric patients.3. Showcase imaging findings of sickle cell disease chest manifestations and complications in pediatric patients via radiographs, US, CT, and MRI and provide guidance on how to differentiate between similar entities.

TABLE OF CONTENTS/OUTLINE

1. Lungsa. Infarct/acute chest syndromeb. Pneumonia (including COVID-19 viral pneumonia)c. Fibrosis/interstitial lung disease2. Cardiovasculara. Cardiomyopathyb. Increased cardiac extracellular volume (ECV)/fibrosisc. Thrombosis/pulmonary embolismd. Pulmonary hypertension3. Bones/marrowa. Bone infarct/osteonecrosisb. Osteomyelitisc. Anemia/extramedullary hematopoiesisd. Iron deposition

PDEE-7   Primary Osseous Tumors Of The Pediatric Spine: Tips For Diagnosis

Awards
Certificate of Merit

Participants
Emilio Inarejos Clemente, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Describe the use of conventional techniques (radiography and CT) and multiparametric MRI for diagnosis and follow-up in children with primary spinal tumors.2. Describe the most common benign and malignant primary osseous spinal tumors in children.3. Discuss the most common imaging findings of primary osseous spinal tumors in children and compare with corresponding surgical and gross pathology findings.4. Interpret multiparametric MR imaging in patients with malignant unresectable tumors (Ewing sarcoma and osteosarcoma).

TABLE OF CONTENTS/OUTLINE

1. Background.2. Clinical findings and demographics of benign and malignant primary spinal tumors in children.3. Benign tumors: Hemangioma, osteochondroma, osteoblastoma, osteoid osteoma, unicameral bone cyst, aneurysmal bone cyst. Malignant tumors: Ewing sarcoma, osteosarcoma, chondrosarcoma, hemangioendothelioma, Langerhans cell histiocytosis.4. Conventional and advanced imaging techniques in the study of benign and malignant primary spinal tumors, emphasizing on the role of multiparametric MRI and PET-MR for diagnosis and follow-up (diffusion-weighted imaging, perfusion, dynamic contrast studies, 3D printing models).5. Radiography, CT, PET-CT, PET-MR and advanced MRI findings of benign and malignant primary spinal tumors, with illustrative examples with clinical, surgical and histopathological correlation.6. Illustrative examples of functional MRI and nuclear medicine in treatment response assessment.7. Imaging follow-up after surgery.8. Summary.

PDEE-70   How To Optimize Neuroimaging In Children With Less Sedation, Less CT And Faster MRI Protocols: Experience In A Quarternery Academic Children's Center

Participants
Aylin Tekes-Brady, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Sedation can be used to support children hold still during MRI, however negative impact of anesthesia in brain development poses concerns. 2. CT can be an alternative to MRI with sedation, given its fast image acquisition, with the caveats of radiation exposure and poor parenchymal resolution. 3. Indication specific fast MRI protocols may mitigate use of CT and sedation. 4. Age specific developmental stages can be helpful to avoid sedation: neonatal brain MRI can be performed during natural sleep. 5. Fast MRI is not a quick peek for all neuroimaging indications. 6. Reduced gradient time can be achieved by utilizing limited sequences for specific indications OR reducing spatial resolution of sequences in return for temporal resolution. 6. Child life specialists can help ease anxiety and concerns of children and families, therefore eliminate use of sedation/anesthesia.

TABLE OF CONTENTS/OUTLINE

1. define clinical indications for fast brain MRI and fast spine MRI: T2 bright lesions are best for fast MRI such as hydrocephalus and shunt evaluation, arachnoid cyst, subdural effusion/hygroma, headache, follow-up head trauma, syrinx evaluation to name a few 2. define sequences and parameters for indication specific fast brain spine MRI protocols; fast brain MRI, modified fast trauma brain MRI, fast spine MRI. 3. Indications not suitable for fast MRI: developmental delay, seizure, tumor initial diagnosis and enhancing tumor follow-up to name a few. 4. define neonatal brain MRI protocol with natural sleep.

PDEE-71   Beyond The Usual: Use Of Ultrasound For The Diagnosis Of Less Common Small Bowel Obstructions In Children

Participants
Desi Schiess, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Key features of bowel obstructions on ultrasound include free fluid, differential dilation of bowel loops, bowel wall thickening, and lead points 2. Especially in younger children, consider congenital etiologies in addition to midgut volvulus such as segmental volvulus associated congenital cysts and small bowel atresias 3. When identified sonographically, patients can be triaged directly to surgical intervention especially when danger signs such as bowel hypoperfusion are identified

TABLE OF CONTENTS/OUTLINE

a. Introduction: Epidemiology b. Ultrasound a. Pros and cons compared to radiographs, CT, MRI, and fluoroscopy b. Ultrasound technique c. Identifying and interpreting the imaging findings a. Normal sonographic appearance of bowel b. Illustrative cases on ultrasound with correlation to other modalities, including XR, CT, and fluoroscopy with surgical and pathologic correlation i. Examples of classic and subtle cases of less common bowel obstructions including: 1. Omphalomesenteric duct spectrum (Meckel's, cyst, and fibrous remnant) with associated segmental volvulus or perforation with obstruction 2. Duplication & mesenteric cysts 3. Congenital mesenteric band 4. Small bowel atresias 5. Foreign bodies, including toys and bezoars 6. Intussusceptions with pathologic lead points d. "Don't miss" sonographic findings a. Signs of bowel wall ischemia b. Pneumoperitoneum c. Midgut volvulus e. Conclusion: Teaching points reemphasized

PDEE-72   Soft Tissue Calcifications And Ossifications In The Pediatric Population: A Pattern-based Imaging Approach With A Review Of Common Etiologies

Participants
Eugen Lungu, MD,MSc, Montreal, Quebec (*Presenter*) Nothing to Disclose

TEACHING POINTS

Soft tissue densities due to calcifications or ossifications in children are less common than in adults. Their causes are more commonly due to systemic, congenital or hereditary conditions as opposed to degenerative and age-related conditions in adults. - Pathologies presenting with calcifications or ossifications in children involve mainly the cutaneous and subcutaneous soft tissues, as opposed to perivascular and periarticular locations in adults. - Imaging by radiographs, US, CT or MRI may help diagnosis; however, it may have a greater role in evaluating disease progression and treatment planning.

TABLE OF CONTENTS/OUTLINE

- Comparison of epidemiology and etiology of soft tissue calcifications and ossifications in children vs adults- Overview of the calcinosis cutis and osteoma cutis patterns at imaging- Pathophysiology, epidemiology, clinical presentation, treatment and imaging findings: Calcinosis cutis: dermatomyositis, juvenile systemic sclerosis, interferonopathies, Ehlers-Danlos syndrome, chronic kidney failure, Albright hereditary dystrophy, calcinosis cutis universalis, tumoral calcinosis, subepidermal calcified nodules; Osteoma cutis: isolated skin osteoma, plate-like osteomatosis cutis, fibrodysplasia ossificans progressiva, progressive osseous heteroplasia, benign milliary osteoma cutis.- Imaging caveats of soft tissue densities in children

PDEE-75   Imaging Of Complications After Palliative Procedures For Congenital Heart Disease

Awards
Identified for RadioGraphics

Participants
Harold Goerne, MD, Guadalajara, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review the complications of palliative procedures performed for congenital heart disease (CHD) 2. To discuss the role of different imaging modalities in assessment of these complications 3. To illustrate the imaging features of these complications

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Role of imaging modalities- CT, MRI, echocardiography, cardiac catheterization 3. Complications based on type of palliative procedures A. Increasing pulmonary artery flow: Blalock-Taussig shunt- Stenosis, occlusion ,thrombosis, pseudoaneurysm. Bidirectional Glenn shunt- Stenosis / occlusion, thrombosis, pseudoaneurysm, infection. Shunt infection / dehiscence. Fontan-Ventricular failure, systemic venous hypertension B. Decreasing pulmonary artery flow Pulmonary banding- Failure, obstruction. Norwood procedure complications- Pulmonary hypertension, systemic or pulmonary vein obstruction C. D-TGA atrial switch: Baffle stenosis, obstruction. Baffle leak. Systemic ventricular D. Aortic palliation: Recoarctation Pseudoaneurysms Dissection Stent fracture Infection 4. Conclusion

PDEE-76   Not Just Nodes And Bones: Langerhans Cell Histiocytosis In Children. From X-ray To PET-MRI

Participants
Mary Arevalo Molina, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Describe pathophysiology and current classification of Langerhans Cell Histiocytosis.- Recognize common radiological findings of LCH in X-ray, CT, and MR with a histological and immuno-histochemical confirmed.- Increase the knowledge about extra-osseous affectations of LCH and their differential diagnosis.- Provide an illustrative tutorial highlighting the utility of 18F-FDG PET to detect the spectrum of manifestations and its role for early diagnosis.- Introduce the promising PET/MR role in the assessment of LCH. Advantages and disadvantages.

TABLE OF CONTENTS/OUTLINE

1. Introduction2. Objectives3. A brief update of the newer Histiocytosis classification. Advances in pathophysiology4. Review of the current literature on Imaging methods for diagnosis, response assessment and follow-up in pediatric patients.a. Recognize the characteristic x-ray, CT, and MRI imaging findings of LCH.b. Describe the role of 18F-FDG PET-CT in the early diagnosis. Pictorial review.c. It is PET-MR time? Discuss the value in the evaluation of active lesion. Compare with PET-CT: Advantages and drawbacks.5. Not Just nodes and bones: Recognizing extra-osseous affections and their differential diagnoses.6. Summary7. References

PDEE-77   Pediatric Skeletal Deformities Analyzed By 3d Stereoradiography: Three-dimensional Analysis And Low Dose Radiation

Participants
Pedro Arruda, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The spine and lower limbs disorders in the pediatric population have a complex three-dimensional (3D) nature. A deformity seen in the coronal plane may often be accompanied by deformities in the sagittal and axial planes. Understanding the global view of the skeletal system in an orthostatic position can aid therapeutic planning. A standard radiographic study (projection in a plane) has important limitations in axial measurements, which can be overcome by computerized tomography (CT). However, CT delivers a higher radiation dose, and is not a weight-bearing study, bringing incorrect data. Stereoradiography with 3D capabilities is a low-dose, weight-bearing equipment, which takes full-body, frontal and lateral images of the skeletal system in a standing position. It provides 3D images of the spine, pelvis, and lower limbs in all spatial planes, improving visualization of the pediatric deformities. The equipment exposes much less radiation than traditional imaging technologies. When necessary frequent medical imaging, it can reduce even more the radiation exposure (MicroDose), which corresponds to 20 to 45 times less radiation than an X-ray exam.

TABLE OF CONTENTS/OUTLINE

1. Basic principles of the 3D Stereoradiography 2. Spine deformities a. Spinopelvic measurements b. 3D scoliosis and kyphosis analysis 3. Lower limbs deformities a. Lower limbs length discrepancy b. Coronal and sagittal alignment deformities c. Torsional deformities 4. Pre and postoperative analysis 5. Clinical application and compensatory mechanisms

PDEE-78   Basis, Diagnosis And Treatment Of Craniosynostosis: What The Radiologists Needs To Know

Participants
Satoru Takahashi, MD, PhD, Suita, Japan (*Presenter*) Research Grant, Siemens AG;Research Grant, LPixel Inc

TEACHING POINTS

Craniosynostoses are the premature fusion of one or more cranial sutures and cause various deformity of the skull by affected sutures. As craniosynostoses might be syndromic and related to intracranial abnormality, knowledge of the basis and treatment is essential for appropriate management. The purpose of this exhibit are;1. To review normal development and anatomy of the skull2. To show different types of craniosynostoses and their characteristics 3. To demonstrate the imaging techniques for diagnosis, preoperative assessment, and post-treatment follow-up4. To summarize surgical approaches: indication, technique, complication and outcomes

TABLE OF CONTENTS/OUTLINE

1. Embryology & Anatomy2. Classification of craniosynostosis-primary vs. secondary-nonsyndromic vs. syndromic-monosutural vs. multisutural-related cranial deformity, genetic and clinical abnormality3. Types of surgery-application and techniques-sutureectomy, cranial spring surgery, fronto-orbital advancement, cranial vault reconstruction4. Imaging -ultrasound, Xray, low-dose CT, MRI-application and combination of modalities5. Imaging key findings- sutures, deformity- venous anomaly, dilatation of emissary veins-increased intracranial pressure- cerebellar herniation, ventriculomegaly- surgical complication

PDEE-79   Congenital Intrahepatic Portosystemic Shunts With Anorectal Malformation And Cardiac Anomaly

Participants
Armaandeep Aulakh, MBBS, Mumbai, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

Introduction Congenital portosystemic venous shunts (CPSS) are rare vascular anomalies that occur secondary to abnormal involution of fetal vitelline and umbilical veins. Splanchnic blood directly into systemic circulation bypassing the first pass metabolism of liver. Depending on the site of anastomosis they can be - extrahepatic or intrahepatic. CPSS may be isolated or in

combination with multiple congenital anomalies like cardiac defects, biliary atresia, polysplenia syndrome, anorectal malformations and renal agenesis etc. Untreated CPSS may lead to hepatic encephalopathy, pulmonary hypertension and liver nodules. Hence, early diagnosis with accurate delineation of the anatomy of shunts has clinical and therapeutic implications. Teaching points After going through the presentation, the reader will be able to Understand the embryological basis of development of CPSS. Identify and differentiate various types of congenital extrahepatic and intrahepatic portosystemic shunts. Understand the findings in a rare case with multisystem involvement. Understand planning for therapeutic endovascular interventions or surgery

TABLE OF CONTENTS/OUTLINE

Table of Contents Overview of relevant anatomy and embryological basis of development of congenital portosystemic shunts Imaging the hepatic vasculature- Ultrasound/ CECT abdomen Classsification of CPSS- a. Intrahepatic b. Extrahepatic Case discussion Points to note while planning endovascular intervention or shunt surgery

PDEE-8   US Of The Spine In Neonates And Infants: A Practical Guide Of Normal Findings, Normal Variants And Pathologic Conditions

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Emilio Inarejos Clemente, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

1.Discuss the US technique, transducers and positions for evaluation of the spine in neonates.2.Describe the US appearance of the most common normal variants in neonates and children.3.Correlate the US appearance of the most common congenital and pathological entities in the spine with prenatal and postnatal MRI and the added value of color Doppler US.

TABLE OF CONTENTS/OUTLINE

1.Sonographic technique and anatomic positions.2.Normal anatomy of the spine on US with tips for anatomic references.3.Normal variants in children: Transient dilatation of the ependymal canal, filar cyst, ventriculus terminalis, prominent epidural fat, prominent filum terminale, "pseudomass" due to positional nerve root clumping, pseudosinus tract, dysmorphic coccyx.4. Checklist of anatomic structures to be assessed in the examination: spinal cord, conus medullaris, ependymal canal, pulsatility of nerve roots and filum terminale, thecal sac, intraspinal masses, sinus.5. Sonographic appearance with prenatal and postnatal MRI correlation in the following conditions:- Congenital: lipomyelocele, lipomyelomeningocele, intraspinal lipoma, tethered cord, sinus tract.- Infectious: meningitis, subdural abscess.6. Clinical indications for spinal US:- Low risk: typical sacral dimple, mild hypertrichosis, capillary malformation, hemangioma, nevus.- Intermediate risk: Atypical sacral dimple, deviation of the gluteal cleft, severe hypertrichosis.- High risk: dermal sinus, subcutaneous lipoma, and cutaneous appendage.7. Conclusion

PDEE-80   Dual Energy Abdomen CT In Pediatric Clinical Practice: A Jack Of All Trades

Participants
Woo Rim Seo, MD, Hwaseong, Korea, Republic Of (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Describe the principles of dual energy CT (DECT)- Describe the advantages of DECT by various post-processing techniques and the potential of reducing radiation dose of abdominal DECT in pediatric patients- Recognize the application of abdominal DECT in pediatric clinical practice which increases the confidence in diagnosis: experience from a single center

TABLE OF CONTENTS/OUTLINE

1. Dual energy CT (DECT)1) The principles2) The advantages of abdominal DECT: post-processing techniques and radiation dose- Water map/ Iodine map/ Virtual monochromatic images2. Application of abdominal DECT in pediatric clinical practice 1) Tumor/Oncology- Extragonadal mixed germ cell tumor- Primary lymphoma of liver- Leukemia 2) Bowel disorder- Inflammation: Crohn's disease, gangrenous appendicitis with appendicolith, diverticulitis- Ischemia: Ischemic enteritis in Henoich-Schonlein purpura 3) Trauma- Post traumatic ischemia and perforation of bowel- Renal laceration and urinary leakage 4) Metal artifact reduction- Recognize ingested foreign body and bowel complication 5) Stone evaluation- Ureteric stone evaluation using material specific urolithiasis application 6) Genitourinary - Emergency: Testis torsion, ovarian torsion, ruptured hemorrhagic ovarian cyst- Acute pyelonephritis 7) Biliary system- Acute cholecystitis

PDEE-81-HC Susceptibility Weighted Imaging (SWI): Beyond The Bleed

Participants
muhamad serhal, Beirut, Lebanon (*Presenter*) Nothing to Disclose

TEACHING POINTS

Susceptibility weighted imaging (SWI) is traditionally used to detect intracranial hemorrhage with enhanced sensitivity to microbleeds. This exhibit highlights the added value of SWI in a variety of clinical conditions encountered in childhood that may go unrecognized. SWI can reveal perfusion changes not appreciated on routine imaging and help guide the correct diagnosis. SWI is a fundamental sequence that must be part of routine brain MRI protocol.

TABLE OF CONTENTS/OUTLINE

SWI is a 3D high resolution gradient echo sequence that offers increased sensitivity to magnetic susceptibility. It is generally used to detect intracranial hemorrhage and mineralization. However, SWI lends tremendous diagnostic value to neuroimaging evaluation in a variety of pediatric pathologies. Acute arterial ischemic stroke: SWI can reveal the location of intraarterial thrombus and delineate the ischemic penumbra by demonstrating prominent veins in areas of impaired perfusion. Migraine: the neurovascular pathophysiology of migraine can result in increased or decreased venous conspicuity throughout the affected cerebral hemisphere on SWI as a result of vasoconstriction or vasodilatation. Status epilepticus: altered oxygenation can be detected by SWI as diminished cortical veins during the ictal phase or accentuated veins in the post-ictal period paralleling perfusion changes. Vascular malformations: SWI can detect and monitor high flow vascular malformations with arteriovenous shunting by demonstrating increased signal in arterialized veins.

PDEE-82-CS Causes And Variations Of The Sonographic (US) Whirlpool Sign Of The Intestine In Neonates

Participants
Alan Daneman, MD, Toronto, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

In neonates, the US whirlpool sign may be seen with volvulus due to midgut malrotation or with segmental volvulus of the intestine unrelated to midgut malrotation. In neonates with symptoms of acute abdomen or intestinal obstruction, a conscious search of the entire abdomen and pelvis with US for a whirlpool sign is essential, especially in the absence of other US signs of malrotation. Segmental volvulus most commonly effects a short segment of the small intestine, rarely a long segment and rarely the colon. Segmental volvulus may occur antenatally (when it may be associated with an intestinal atresia) or postnatally (when it may be secondary to previous intra-abdominal adhesions or inflammation). A whirlpool sign may also be seen with Type 3B atresia of the small intestine when the distal apple-peel anomaly may appear as a whirlpool on US. A pseudo-whirlpool sign may be seen in neonates with obstruction due to kinking of the intestine due to adhesions. Recognizing the whirlpool sign on preoperative US facilitates an extremely rapid diagnosis and obviates the necessity for contrast examinations of the gastrointestinal tract.

TABLE OF CONTENTS/OUTLINE

1 Introduction Background of midgut malrotation and segmental volvulus as well as Type 3B intestinal atresia. 2 Purpose To illustrate the value of sonography in documenting the presence of a whirlpool sign in neonates with acute abdomen or intestinal obstruction. 3 Discussion Illustrations of various whirlpool signs on US and importance of meticulous US technique.

PDEE-9   Diagnostic Value Of High Resolution US, Color Doppler US And Superb Microvascular Imaging (SMI) In The Evaluation Of The Sick Neonate.

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Emilio Inarejos Clemente, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Describe the current applications of bedside US in the sick neonate.2. Discuss the US technique (technical aspects, transducers) for the evaluation of the sick neonate.2. Describe the added value of Doppler US and Superb Microvascular Imaging (SMI) for the evaluation of necrotizing enterocolitis.3. Recognize US appearance of common acute pathologies in the sick neonate with radiographic and fluoroscopic correlation.

TABLE OF CONTENTS/OUTLINE

1. Current indications and applications of bedside ultrasound in neonates.2. Technical details of the sonographic procedure: High Resolution US, Color Doppler US and SMI.3. Tips to obtain optimal images.4. Use of high resolution US in the evaluation of:- Pneumothorax, distress respiratory syndrome- Necrotizing enterocolitis: severity grading with clinical and radiographic correlation- Complications of necrotizing enterocolitis: detection of pneumoperitoneum, fluid collections and portal venous gas- Malrotation with midgut volvulus: typical sonographic signs- Meconium peritonitis- Incarcerated inguinal hernia- Check placement of lines and tubes5. The use of Color Doppler US and SMI in the evaluation of:- Necrotizing enterocolitis- Malrotation with midgut volvulus- Incarcerated hernia6. Clinical management of the most frequent entities described in this exhibit.7. Conclusion.

Printed on: 06/28/22

Abstract Archives of the RSNA, 2021

Sub-Events

RIEE-1   O-RADS: Case Based Learning

Awards
Identified for RadioGraphics
Magna Cum Laude

Participants
Phyllis Glanc, MD, Toronto, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

O-RADS for ultrasound is a lexicon combined with a risk stratification and management system which can be applied to lesions involving the ovary and adnexa. This is the only risk stratification system which is paired with a management system allowing for consistent care in women with adnexal lesions.The use of a lexicon aims to improve the quality of communication between interpreting radiologists and referring clinicians.The consistent use of O-RADS is intended to decrease number of interventions for ovarian and adnexal lesions which are destined to resolve or remain stable whilst increasing appropriate referrals to a gynecologic oncologist for those with high risk of malignancy. Appropriate referral to a gynecologic oncologist has been demonstrated to decrease morbidity and improve survival in women with high grade ovarian malignancy.The use of an experiential case approach, based on O-RADS ,following a simple algorithm will familiarize users with the practical aspects of the system, enable avoidance of pitfalls and emphasize key knowledge points. This practical exercise will help the imager to make the best use of the system in daily practice.

TABLE OF CONTENTS/OUTLINE

1, Introduction to the ORADS for US Risk Stratification and Management System.2. Case Examples Beginner Level.3. Case Examples Intermediate Level.4. Case Examples Expert Level.5. Summary

RIEE-10   Amniotic Fluid Volume Assessment In Pregnancy

Awards
Identified for RadioGraphics

Participants
Rubal Penna, DO, Seattle, Washington (*Presenter*) Nothing to Disclose

TEACHING POINTS

Amniotic Fluid (AF) disturbances are associated with fetal, placental and maternal conditions.AIUM & SMFM: DVP preferred for oligohydramniosOligohydramnios: Bimodal distribution of gestational age at time of diagnosis has significant implications for etiologySpecial considerations for AF assessment in multigestation versus singleton pregnanciesRole of interventions

TABLE OF CONTENTS/OUTLINE

IntroductionAmniotic Fluid physiology and circulation pathwaysMethods (AFI, DVP, subjective) and recommendations Why & when to performOligohydramniosDiagnosis & incidenceEtiology & casesCommonPreterm premature rupture of membranes (PPROM)Fetal growth restrictionLess commonGU AnomaliesBilateral renal agenesisBilateral multicystic dysplastic kidneysBilateral UPJ obstructionLower urinary tract obstruction (e.g. Posterior urethral valves)Acquired renal cystic dysplasiaComplicationsPulmonary hypoplasiaPotter's sequencePolyhydramniosDiagnosis & incidenceEtiology & casesCommonIdiopathicMaternal diabetesMacrosomiaLess commonRelated to swallowingGI anomaliesCNS anomaliesExtrinsic compression from chest massesRelated to movementMSK anomaliesRelated to circulationHigh cardiac output states (anemia, vascular masses, hydrops)ComplicationsPlacental abruptionPPROMCord prolapsePreterm laborRole of interventions Amnioreduction, amnioinfusion and more

RIEE-11   Translabial Ultrasound Technique - A Case Based Review

Participants
Kathryn McGillen, MD, Hershey, Pennsylvania (*Presenter*) Speaker, MRI Online

TEACHING POINTS

Translabial ultrasound is a useful adjunct to evaluate anatomy that may be challenging by other modalities.Best use is to answer specific clinical questions.Extra training of sonographer and radiologists may be necessary for some applications, such as urethral imaging or pelvic floor abnormalities.

TABLE OF CONTENTS/OUTLINE

Review common uses and techniques for translabial ultrasound scanning.Review anatomy.Review classic cases.Review challenging

cases.

RIEE-12   Front And 'Centa: The Latest On MRI Imaging Of Placenta Accreta Spectrum Disorders

Awards
Certificate of Merit

Participants
Preethi Raghu, MD, San Francisco, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Understand the background, pathophysiology, and imaging appearance of placenta accreta spectrum disorders (PASD).2. Correlate image-rich ultrasound examples with MRI features, implications for management and surgical planning, and pathology findings.3. Identify imaging pitfalls on ultrasound and MRI.4. Discuss image-based prediction of degree of myometrial invasion.5. Review latest guidelines regarding PASD imaging, including MRI lexicon and protocols.

TABLE OF CONTENTS/OUTLINE

Overview:1. Incidence, risk factors, and complications of PASD2. Unusual PASD: PASD without previa, myomectomy, IVF3. Pathophysiology and updates in pathologic grading4. Multidisciplinary approach - our institutional model5. Role for IR and UAEImage examples:1. Myoadherent (accreta) and myoinvasive (increta, percreta)2. Posterior and lateral invasive placentae better seen on MRI3. Anterior invasive placenta better seen on ultrasound4. Cervical protrusion of placenta previaImaging pitfalls/mimics:1. Volume averaging2. Engorged myometrium3. Decompressed bladder4. Uterine sacculation5. Uterine contractionImage-based prediction of degree of myometrial invasion:1. Placental bulge2. Uterine serosal vascularity, intraplacental vascularity3. Diffusion weighted imaging for problem-solvingReview of latest guidelines on imaging PASD:1. FIGO 2019:a. Latest FIGO grading scheme and lexicon2. SAR/ESUR Joint Consensus Statement 2020:a. Consensus MRI lexicon and imaging featuresb. MRI protocols at 1.5T versus 3T

RIEE-13   O-RADS MRI: Lexicon Terminology, Risk Stratification, And Management

Participants
Jane Shin, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

This exhibit aims to increase understanding and acceptance of Ovarian-Adnexal Reporting and Data System Magnetic Resonance Imaging (O-RADS MRI). Although O-RADS Ultrasound is more widely known, O-RADS MRI is a newer topic that may be unfamiliar to some. There will be discussion on the ACR O-RADS MRI lexicon terms that were agreed on by the ACR O-RADS committee with the illustration of MRI findings in each. Participants will have a more confident understanding of ACR risk stratification, classification, and recommended management of various ovarian and adnexal masses on MRI. Pitfalls related to the O-RADS MRI lexicon will also be discussed.

TABLE OF CONTENTS/OUTLINE

1- ACR O-RADS MRI terminology/definitions: Physiologic, lesions (non-physiological), size, shape/contour, signal intensity, lesion components, enhancement, general and extra-ovarian findings2- Description of the O-RADS categories with the illustration of MRI findings in each and potential pitfalls3- Risk stratification and recommended management for each category4- MRI imaging protocol and patient preparation

RIEE-14   Cancer In Pregnancy: Imaging Of Common And Uncommon Pregnancy-related Cancers; Ethical And Safety Considerations And Recommended Imaging Protocols

Participants
Margaret Adejolu, FRCR,MRCP, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Radiological appearances of common pregnancy related cancers 2. Choice of imaging modality , preferred timing and dose consideration 3. Mimics of cancer in pregnancy

TABLE OF CONTENTS/OUTLINE

1. Epidemiology of cancer in pregnancy 2. Ethical Considerations in imaging 3. Safety consideration in imaging pregnant woman a. Imaging involving Ionizing radiation b. Imaging modalities not involving ionizing radiation c. Use of Contrast agents in imaging d. Moderate sedation and Image guided procedures 4. Optimal MRI protocols in oncological imaging of the pregnant patient 5. Imaging appearances of specific cancers a. Breast b. Melanoma c. Lymphoma d. Cervical e. Ovarian f. Gastrointestinal 6. Mimics of cancer in Pregnancy a. Ovarian Torsion b. Fibroid c. Dermoid d. Decidualization in the ectopic endometrial stroma of an endometrioma e. Decidualization in endometrium and cervixf. Lactating adenoma and other pregnancy related changes in breast

RIEE-15   High-resolution Diffusion-weighted Imaging By Multiplexed Sensitivity Encoding (MUSE) For Cancer Staging In Gynecology And Genitourinary

Participants
Takashi Ota, MD,PhD, Suita, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Major teaching points of this exhibit are: 1. To describe high-resolution diffusion-weighted (DW) imaging by using multiplexed sensitivity encoding (MUSE) by comparing high-resolution DW imaging by using field-of-view optimized and constrained undistorted single-shot (FOCUS). 2. To describe advantages and disadvantages of MUSE and FOCUS. 3. To review some clinical images obtained by using MUSE for cancer staging in gynecology and genitourinary. 4. To discuss how radiologists can use MUSE in the clinical practice.

TABLE OF CONTENTS/OUTLINE

A. What is MUSE? How is it different from FOCUS and conventional DW imaging? B. Advantages and disadvantages of MUSE and

FOCUS B-1. Advantages: high-resolution imaging, reduce distortion, full field-of-view (FOV) of MUSE, etc. B-2. Disadvantages: reduced FOV of FOCUS, increase noise, etc. C. Application of MUSE to gynecologic and genitourinary cancer imaging C-1. Gynecologic cancers: endometrial cancer, cervical cancer, ovarian cancer, etc. C-2. Genitourinary cancers: prostate cancer, bladder cancer, kidney cancer, etc. D. Discuss about usefulness of MUSE in the clinical practice

RIEE-16   Sonography Of Pelvic Inflammatory Disease

Participants
Samuel C. Johnson, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

TEACHING POINTS 1. Acute Pelvic inflammatory disease (PID) results in a spectrum of severity involving the fallopian tube, from acute salpingitis to pyosalpinx and tubo-ovarian abscess (TOA). 2. Early and accurate sonographic identification of the extent of infection aids successful implementation of the appropriate treatment regimen including ultrasound guided drainage. 3. Residual or chronic PID, including actinomycotic infections, may present a diagnostic dilemma, indistinguishable from malignancy.

TABLE OF CONTENTS/OUTLINE

TABLE OF CONTENTS I. IntroductionII. Salpingitis a. Normal fallopian tube b. Acute salpingitis c. Chronic salpingitisIII. PyosalpinxIV. Tubo-ovarian abscess a. Acute b. Chronic/organized c. ActinomycosisV. Peritonitis a. Adhesions b. Peritoneal inclusion cyst VI. Abscess Drainage a. Approach i. Transvaginal ii. Transabdominalb. Technique i. Catheter placement ii. Aspiration & lavageVII. HydrosalpinxVIII. Differential Diagnosis a. Endometriosis b. Hemorrhagic ovarian cyst c. Ovarian cystic teratoma d. Ovarian malignancy e. Ectopic pregnancy f. Appendicitis g. Diverticulitis

RIEE-17   Role Of MR Imaging For Fertility And Reproductive Function Preserving Treatments In Patients With Gynecologic Tumors

Participants
Mayumi Takeuchi, MD, PhD, Tokushima, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. The development of conservative or minimally invasive treatments that preserve fertility and reproductive function, or reduce the post-operative side effects such as lymphedema and dysuria contributes to the quality of life of the patients of reproductive age affected by gynecologic tumors. 2. The role of MRI has increased in the accurate evaluation of diseases required to make appropriate diagnostic and treatment decisions, and more detailed MRI interpretation is needed to determine the indications for fertility-preserving treatments. 3. Appropriate use of advanced MR sequences (reduced FOV DWI, computed DWI, susceptibility-weighted sequence, 3D-T2WI, 3D-DCE MRI, and MR spectroscopy) for the accurate tumor size measurement and localization, the evaluation of minute tumor invasion or local extension, and the estimation of tumor grade and histological subtypes is important.

TABLE OF CONTENTS/OUTLINE

Oocyte retrieval procedure /cryopreservationCervical cancer-Conization /Radical trachelectomy-Ovarian transposition before radiation-Less invasive surgery (Nerve-sparing radical hysterectomy, omitting lymphadenectomy)Endometrial cancer-Hormone therapyMyometrial tumor-Minimal invasive treatments (Myomectomy, UAE, MRgFUS, hormone therapy) for leiomyoma-Tumorectomy for low-grade ESSOvarian tumor-Fertility-preserving options for borderline and malignant tumors

RIEE-18   Cancer In Pregnancy

Awards
Identified for RadioGraphics

Participants
Liina Poder, MD, Mill Valley, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Balance maternal benefit and fetal risk2. Optimize imaging and treatment in a multidisciplinary team3. Use contrast materials when benefit outweighs risk4. Involve, inform, and counsel patients about risks of imaging and consent5. Learn how to image more common malignancies in pregnancy

TABLE OF CONTENTS/OUTLINE

Cancer in pregnancy is challenging. Though rare (~1:1000 pregnancies) the incidence is rising from postponed childbearing. Cancer related symptoms can be disguised by gestational physiologic changes. Imaging, management, and treatment require a carefully choreographed multidisciplinary team. The risk-benefit of every imaging modality, the strategies to balance the safety of mother and fetus, and the support of the patient and family at every step are mandatory. Because they lack ionizing radiation, US and MRI are usually chosen, but certain conditions require other modalities. We aim to provide a clear review of the imaging triage, safety considerations, and case-based disease specific imaging of cancer in pregnancy.1. Epidemiology2. Effects of Ionizing Radiation, Teratogenesis & Carcinogenesis3. Radiologist's Role in Multidisciplinary Team Decision Making4. Patient Prognosis, Counseling, and Informed Consent5. Imaging Modalities - Risks and Benefits6. Contrast agents (CT, MR, NM, US), Risks (maternal & fetal), & Breastfeeding7. Fertility sparing and imaging findings (ovum retrieval, surgical options, etc.)8. Case based review - (Breast, Lymphoma, Cervix, Leukemia, Ovary, Other)

RIEE-19   Recent Progress In Endometriosis: What Radiologists Should Know

Awards
Certificate of Merit

Participants
Yumiko Oishi Tanaka, MD, Tokyo, Japan (*Presenter*) Research Grant, F. Hoffmann-La Roche Ltd;

TEACHING POINTS

1. To review the imaging findings of classical ovarian endometriotic cysts, deeply infiltrating endometriosis (DIE). 2. To describe the

points for differential diagnosis of endometriotic cysts and DIE with technical consideration of MR. 3. To discuss the conservative therapy for endometriosis and those outcome evaluated by MR. 4. To discuss the imaging findings of complications of the endometriosis, including infection, rupture, malignant transformation, and deciduosis during pregnancy.

TABLE OF CONTENTS/OUTLINE

Fundamentals of pelvic endometriosis (Definition -Pathogenesis -Epidemiology -Symptoms -Treatment) - Classic imaging findings of endometriotic cysts of the ovaries and its variation (Shading, T2-dark spot sign, Adhesion) - Deeply Infiltrating Endometriosis (DIE) and Focal Adenomyosis located in the Outer Myometrium (FAOM) or extrinsic adenomyosis (Definition, Relationship between DIE and FAOM) - Staging systems (Revised ASRM staging, ENZIAN classification) - Treatment option and outcome diagnosing with MR (Gonadotropin-Releasing Hormone antagonist and agonist, Progesterone, Oral contraceptives)- Complications (Infection, Rupture) - Neoplasms arising from endometriosis (Incidence, Risk factors, Histopathological types of the tumors and their imaging findings) - Mimickers of malignant tumors arising from endometriosis (Polypoid endometriosis, Deciduosis)

RIEE-2   Didn't See It Well? Endovaginal Gel!

Participants
Marcela Lauar, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

It is known that regular transvaginal sonography has limitations in evaluating cervical and vaginal disorders. Gel sonovaginography has shown an improvement in visualization, resolution and assessment of local lesions and structures, because of the partial distension and standoff of vaginal walls caused by the introduced gel. It also forms an acoustic window between the surrounding structures and the transducer, which provides better assessment of the vaginal walls, fornices, cervix, pouch of Douglas, rectovaginal septum, anterior rectal wall, paravaginal and parametrial tissues and bladder.This method can be performed as an extension of regular transvaginal sonography, not causing extra harm to the patient.To demonstrate vaginal lesions that had limited evaluation in transvaginal/translabial ultrasound, and could be better identified and characterized by the use of vaginal gel. To didactically review some cases in which the use of vaginal gel was essential for diagnosis and evaluation of the findings, in order to help radiologists remember this tool, and how it can be helpful.

TABLE OF CONTENTS/OUTLINE

Evaluation of a series of transvaginal ultrasounds that required endovaginal gel for proper diagnosis, including some common pathologies in this location - like endometriosis, endocervical polyp, recto-vaginal fistula, vaginal and periurethral cysts, among others -, as well as 3-D reconstructions when adequate, and correlation with other imaging methods, based on our service's digital archive.

RIEE-20   Getting The Fetal Right Ventricle Right!

Participants
Bhargavi Sovani, MBBS, Mumbai, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

Fetal echocardiography holds an exceptional place in detecting fetal cardiac anomalies and thus predicting syndromic associations. Both the ventricles are equal in size in a normal fetus. Chamber discrepancy is often the first whistleblower for cardiac anomalies. The right ventricle has specific features that aid in its identification.Z scores help indicate the pathological ventricle in case of chamber discrepancy. The status of the right ventricle mirrors the milieu of the fetus and reflects systemic cardiovascular derangements if any. This exhibit focuses on identification of right ventricular anomalies, altered physiology, associated abnormalities and underlying conditions, based on abnormal right ventricle size.

TABLE OF CONTENTS/OUTLINE

1.Normal right ventricle on fetal echocardiography2.Physiological causes of ventricular size discrepancy3. Pathological causes of ventricular size discrepancy4.Case series of various causes of small right ventricle: PAIVS(pulmonary atresia intact ventricular septum) ,TAVSDPA(tricuspid atresia ventricular septal defect with pulmonary atresia), TAVSD with MAPCA(multiple aorto pulmonary collateral arteries) /CAT(common arterial trunk)5.Case series of various causes of large right ventricle: Hypoxia, Vein of Galen malformation, absent Ductus Venosus, premature closure of Ductus Arteriosus , AVSD(arteriovenous septal defect)+ DORV(Double outlet right ventricle), myopathies, Non compaction cardiomyopathy, right ventricular aneurysm

RIEE-21   Hysterosalpingography And Endometriosis: Beyond The Tube Patency

Participants
Danielle Teles Leal, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Approximately 10 percent of reproductive-age women globally have endometriosis, and it has been reported up to 50 percent of women with infertility. The hysterosalpingography (HSG) is the most common first-line diagnostic test used for infertility investigation. The purpose of this presentation is to demonstrate that signs of endometriosis can be and should be suspected in hysterosalpingography, beyond the tubal patency, correlating these findings with other imaging methods (ultrasound and magnetic resonance imaging), based on our service's digital archive.

TABLE OF CONTENTS/OUTLINE

Evaluation of endometriosis' signs in hysterosalpingography, comparing these findings with other imaging methods.Illustrational cases of endometriosis, including pelvic adhesions, forced uterine reflection, and uterine tube changes tube (e.g contour irregularities, hematosalpinx, medialization and diverticulas).

RIEE-22   Do Not Lose Your Nerve! What Every Radiologist Should Know About Endometriosis-associated Neuropathy.

Awards
Certificate of Merit

Participants
Danielle Teles Leal, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Endometriosis is a common gynecological disease, which affects women of reproductive age. This disease is frequently associated with chronic pain however, the mechanisms for this symptom are not yet well defined. It is believed that this pain can be nociceptive, inflammatory, neuropathic or a combination of these.Nerve involvement by endometriosis is rare and often overlooked in imaging exams, but the early diagnosis and treatment is essential to avoids chronic sensorimotor neuropathy.Recent studies also shows that presence of pathological DTI findings of the sacral nerve roots correlates with the type of pain, adhesions, and deep endometriosis, providing a better understanding of pain.The purpose of this presentation is to review the anatomy of pelvic nerves and show neural involvement cases in endometriosis.

TABLE OF CONTENTS/OUTLINE

Present a brief review of the anatomy of the nerves of the pelvis.Demonstrate the imaging findings of the pelvic nerve's involvement in endometriosis, directly and indirectly, thought the resonance magnetic imaging, lumbosacral tractography 3D reconstructions and DTI values changes (Fractional Anisotropy).

RIEE-23   Endometrial Neoplasms In MRI: A Practical Guide For The Radiologist

Participants
Luciana Piccolo, MD, Campo Grande, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Describe magnetic resonance imaging findings in endometrial tumors. Demonstrate the applicability of magnetic resonance imaging in endometrial cancer, and its limitations. Detail the different stages of endometrial cancer and discuss the use of diffusion-weighted and dynamic contrast-enhanced magnetic resonance imaging for endometrial cancer staging. Describe potential imaging pitfalls and propose strategies to avoid them. Propose a structured reporting for local staging purposes.

TABLE OF CONTENTS/OUTLINE

Endometrial cancer contributes substantially to female mortality and morbidity around the world. Guidelines recognize that magnetic resonance imaging is the best method for an evaluation which is essential in determining the correct approach for treatment. The depth of myometrial invasion is considered the most important morphological prognosis factor. Therefore, a good quality exam together with an appropriate technique, is fundamental. Recognizing pitfalls can be challenging and we therefore propose strategies to confront these diagnostic challenges. Practical tips, potential pitfalls, discussions about imaging findings, and a structured report are also considered in this work with the aim of contributing to the day-to-day practice of radiologists, improving information quality, and objectivity in relating the findings.

RIEE-24   Multi-imaging Evaluation Of The Most Common Surgical "Blind-spots" On Endometriosis

Participants
Thiago Pereira Fernandes da Silva, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

To Review the fundamental concepts of endometriosis on imaging through a systemic revision of pelvic imaging anatomy in correlation with the most common MRI and US findings.To highlight the fundamental anatomic structures and imaging findings relevant to the preoperative stage of the disease. To illustrate US and MRI findings of peculiar "blind-spots" endometriotic lesions. To correlate US and MRI features with intraoperative laparoscopy findings of pelvic and extra-pelvic endometriosis, with a focus on the potential "blind-spots" in the surgical approach.

TABLE OF CONTENTS/OUTLINE

- Revisit Background Concepts on Endometriosis.- Anatomy of the Pelvis- Imaging Endometriosis: basic patterns.- MRI vs US in endometriosis- Flowchart: "the blind spots" - Series of cases and teaching points related to each "blind-spot", mostly illutrated with MRI and US. Teaching points will be highlighted

RIEE-25   The Many Faces Of Endometriosis: A Systematic Compartment Based MRI Approach

Participants
Surabhi Kaushik, MD, New Delhi, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

•Enlist the various anatomic locations and morphologic types of endometriosis in female pelvis.•Describe the MR imaging appearances of pelvic endometriosis.•Provide a compartment based approach and structured imaging reporting template.

TABLE OF CONTENTS/OUTLINE

•Morphological types and subtypes of Endometriosis :-ØSuperfcial endometriotic implantsØDeep infltrative endometriosisØOvarian endometriomas•Compartment based approach :-Ø The anterior compartment -anatomic spaces and structures posterior to the pubic symphysis and anterior to the anterior wall of the uterus and vagina.Ø The middle compartment- midline structures including the uterus, vagina, uterine ligaments, fallopian tubes, and ovaries.Ø The posterior compartment - structures and spaces posterior to the posterior wall of the uterus and vagina.•MR Imaging Protocol (Sequences and rationale) :-Ø T2WI echo-planar fast spin echo sequences without fat suppression.Ø T1WI with and without fat suppression (Fat-suppressed T1-weighted 3D gradient-echo LAVA sequence).Ø Difusion-weighted imaging (DWI)Ø Subtraction sequences post-contrast T1WI with fat suppressionØ Susceptibility weighted imaging•MR Imaging appearances of Endometriosis•Structured reporting template :- A comprehensive endometriosis-specific report which improves presurgical mapping of lesions.

RIEE-26   ACR O-RADS MRI Lexicon - Made Simple!

Awards
Certificate of Merit

Participants
Michelle Zhang, MD, Montreal, Quebec (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Describe and understand the 7 categories of the O-RADS MRI lexicon.2. Describe ovarian/adnexal lesions in a standardized fashion using the O-RADS MRI lexicon.

TABLE OF CONTENTS/OUTLINE

1. Backgrounda. Why utilize the O-RADS MRI lexicon?b. Overview of the 7 categories2. Category #1: Major categoriesa. Physiological: (i) Follicles (ii) Corpus luteumb. Lesion: (i) Cystic lesion (ii) Solid component (iii) Solid lesion3. Category #2: Size4. Category #3: Shape or contour of the solid lesion/solid tissue a. Smoothb. Irregular5. Category #4: Signal intensitya. Homogeneityb. T1 signal intensityc. T2 signal intensityd. B-value/DWI6. Category #5: Lesion components a. Cystic (i) Simple fluid (ii) Non-simple fluid (iii) Fluid/fluid level (iv) Shadingb. Solid (i) Solid tissue - Papillary projection - Mural nodule - Irregular septation/wall -Larger solid component(ii) Other (solid appearing material but not considered truly solid tissue) - Smooth septations - Blood clot, debris, fibrin strands - Fat, hair, calcification, Rokitansky nodule7. Category #6: Enhancement a. Time intensity curves (i) Low risk (ii) Intermediate risk (iii) High riskb. Visual analysis (i) </= myometrium (ii) > myometrium8. Category #7: General and extra-ovarian findingsa. Peritoneal fluidb. Fallopian tubesc. Peritoneal inclusion cystd. Ovarian torsione. Peritoneal thickening/nodules9. Summary10. Multiple choice questions concentrating on the main learning points with reference back to the previous information slides

RIEE-28   Role Of MRI In Endometrial Cancer: An Update

Participants
Cibele Luna, Miami, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To describe the current role of MRI in the management of endometrial cancer (EC) 2. To display the MRI appearance of EC according to the various FIGO stages 3. To revise the MRI appearance of recurrent and metastatic EC.

TABLE OF CONTENTS/OUTLINE

1. Overview of EC: Current statistics and magnitude of the problem, Current histopathologic and molecular classification, Overview of current management of EC 2. Role of MRI in EC: Role of imaging according to National Comprehensive Cancer Network guidelines, MRI in the initial workup of EC (Selection of patients for fertility-sparing therapy), MRI in the follow-up and surveillance of EC, MRI in recurrent and metastatic EC. 3. MRI Technique and optimization of protocol 4. Normal uterine zonal anatomy on MRI 5. General MRI appearance of EC on T2 weighted, diffusion weighted and dynamic contrast-enhanced images 6. Initial workup of EC: FIGO staging* Early-stage disease, Advanced-stage disease, Comparison with Union for International Cancer Control TNM staging. 7. MRI in recurrent and metastatic EC** Pelvis, Peritoneum, Lymph nodes, Liver, Other abdominal organs, Musculoskeletal and soft tissue, Central nervous system. *For each stage, a representative illustration and MRI images will be provided.**Representative images for each site of recurrence will be provided.

RIEE-29   Acute Abdominal Pain In Women Can Surprises You: Spectrum Of Gynecologic Emergencies

Participants
Cecilia Ruiz de Castaneda, Toledo, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is: 1. To describe gynecologic anatomy and review the visceral spaces of the female pelvis. 2. To review and illustrate the computed tomography (CT) imaging features of acute gynecologic diseases. 3. To analyze the differential diagnosis and provide diagnostic keys to identify pitfalls.

TABLE OF CONTENTS/OUTLINE

Gynecologic emergencies in premenopausal women are commonly presented to the emergency department with non-specific abdominal pain. For this reason, it can be challenging to differentiate gynecologic pathology from urologic and gastrointestinal diseases. When the suspicion of gynecologic disease is high, the first-line imaging test usually obtained is pelvic ultrasound. However, if the initial diagnosis is very broad or there is no suspicion of gynecologic pathology, CT may be the initial imaging study for acute abdominal pain. A high level of suspicion and knowledge of the CT imaging features of gynecologic diseases are essential for prompt diagnosis. We propose a radiological approach based on the recognition of computed tomography imaging patterns.

RIEE-3   Ultrasound Of The Pelvic Floor: Don't Be Afraid Anymore!

Awards
Certificate of Merit

Participants
Marcela Lauar, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Pelvic floor dysfunctions can have a significant impact in woman's life quality, especially after the fifth decade. Physical examination has limits evaluating pelvic floor, since it can underestimate the involvement of compartments. - Although 3-D and 4-D translabial ultrasound are relatively new methods, their high accuracy in the evaluation of pelvic floor dysfunction has provided an ascending role in clinical evaluation and providing pre operative information.- The purpose of this presentation is to review the normal anatomy in pelvic floor translabial ultrasound, as well as the most common pathologies and their image findings.

TABLE OF CONTENTS/OUTLINE

- Case-based didactic review of how the most common findings in pelvic dysfunction manifest in pelvic ultrasound, including stress urinary incontinence, pelvic organs prolapses, slings evalutation, among others - based on our service's digital archive.- Correlation with 3D reconstructions, magnetic resonance image (MRI) are also established when appropriate.- Take-home messages- References

Endometrial Cancer From Diagnosis To Cure: A Multidisciplinary And Multimodality Review

Participants
Marta Flory, MD, Davis, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

Learning Objectives: 1.Understand the approach to diagnosis and management of endometrial cancer, including risk factors, high risk histopathologic features, and the role of imaging. 2.Effectively identify endometrial cancer on US, including high grade features, as well as on MR and other imaging modalities, and be familiar with the FIGO staging and imaging correlates. 3.Understand the pathways of spread of endometrial cancer, and be able to alert surgeons to imaging features that impact management such as >50% myometrial invasion and disease outside of the uterus (such as locoregional invasion, distant metastases, and peritoneal disease). 4.Incorporate a focused GYN ONC search onto your basic search pattern that addresses the most frequent areas of recurrence and metastases. 5.Be familiar with the current standard & cutting edge surgical and medical oncology treatment strategies, as well as the role of radiation therapy in the treatment of endometrial cancer.

TABLE OF CONTENTS/OUTLINE

1.Diagnosis: a-Clinical features of endometrial cancer b-Risk Factors c-Histopathology d-Pelvic US 2.Imaging: a-Endometrial cancer on US, MRI, & PET/CT, with multimodality review of FIGO stages b-Review pathways of lymphatic spread of endometrial cancer c-Common sites of metastases & recurrence 3.Treatment: a-Surgical Treatment: TLH, Sentinel Lymph Node resection b-Medical Oncology Treatment: Chemotherapy, Immunotherapy c-Radiation Therapy: Pelvic Radiation, Vaginal Cylinder & Cervical Brachytherapy, & Interstitial Brachytherapy

RIEE-31 O-RADS MRI Risk Stratification System: Pearls And Pitfalls

Awards
Cum Laude

Participants
Stephanie Nougaret, MD, Montpellier, France (*Presenter*) Nothing to Disclose

TEACHING POINTS

To understand the components of the O-RADS MRI risk scoreTo accurately recognize solid tissue and solid components not considered solid tissue To correctly analyze diffusion weighed imaging and time intensity curves in order to accurately assign an O-RADS MRI risk score

TABLE OF CONTENTS/OUTLINE

1. Briefly review the components of O-RADS MRI risk score2. Pearls and Pitfallsa. Technical aspectsi. Pre-contrast1. T2 weighted sequences with thin slices <3mm2. Acquire T2 weighted and DWI series in a similar planeii. Setting up appropriate post-contrast scans for time intensity curve analysis1. 3mm slice thickness2. 15 second time resolution3. Acquire one set of images prior to contrast injection to allow for subtractionb. Differentiating solid tissue from other solid components not considered solid tissue i. Fat, clot, debrisii. Normal ovarian parenchymaiii. Rokitansky protuberanceiv. Endosalpingial foldsv. Tubal fimbriaevi. Thickened/smooth wall or septac. Differentiate simple vs non simple fluidd. Analyzing DWI accuratelyi. T2 black out effectii. T2 shine through effectiii. Pitfalls related to restricted DWIe. Analyze time intensity curves accurately when the solid tissue isi. Small in sizeii. Weakly enhancingiii. Adjacent or within high signal fluid

RIEE-32 O-RADS US + O-RADS MRI: Understanding Their Complementary Roles

Participants
Marisa Martin, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Ultrasound is often the first-line imaging modality for adnexal mass characterization given its relatively high sensitivity for malignancy, however specificity is imperfect-Up to 30% of adnexal masses remain sonographically indeterminate-Patients managed with only US have a risk of inappropriate treatment that could be mitigated by using a higher specificity modality such as MRI, but not all patients need MRI. Examples include:1. MRI may downscore lesions from US when dark T2/dark DWI pattern is present or fat is clearly demonstrable2. MRI may upscore lesions when small soft tissue elements are not visible at US within large cysts-Key differences between O-RADS US and O-RADS MRI1. O-RADS US provides management recommendations; O-RADS MRI does not2. Vascularity is determined by color scores on O-RADS US; O-RADS MRI assesses lesion enhancement using perfusion characteristics3. The same O-RADS scores have different positive predictive values for malignancy-O-RADS US 5 lesions have a 50% or greater positive predictive value for malignancy, compared with ~90% for O-RADS MRI 5-Ultrasound is a primary test and MRI is a confirmatory test for adnexal mass characterization, so sensitivity/specificity vary accordingly

TABLE OF CONTENTS/OUTLINE

-Brief review of the history and applications of the O-RADS systems-Review the key differences between the O-RAD US and O-RADS MRI systems-Review the complementary roles of O-RADS US and O-RADS MRI through multimodality imaging examples-Summary of key concepts

RIEE-33 Atypical, But Not Critical: Differentiating Uterine Sarcomas From Atypical Myomas

Awards
Cum Laude

Participants
Fernanda Pegoraro I, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Leiomyomas are the most common neoplasm found in the uterus, with a prevalence reaching 70-80% among women aged 50 years and older. Conversely, gynecological sarcomas are rare and highly aggressive tumors that require prompt radical resection, with leiomyosarcoma being the most commom histological type. Typical fibroids are easily identified on MRI, as they have characteristic

features. However, there are several leiomyoma variants, such as cellular and atypical leiomyomas and so they can demontrate atypical images appearance that may be difficult to differentiate from leiomyosarcomas. In pre-menopausal patients, the preservation of the uterus is prioritized with conservative therapies. In such cases, mini-invasive surgery may lead to tumor fragmentation, and sometimes to spillage in the case of malignancy. Therefore, it is extremely important to differentiate between benign leiomyomas and leiomyosarcomas before the therapeutic decision.

TABLE OF CONTENTS/OUTLINE

This study aims to familiarize radiologists with the algorithm proposed by "Cendus Abdel Wahab, MD et al", which will be applied to a several cases being illustrated as a quiz. We hope to highlight the useful radiological signs for the differentiation between atypical leiomyomas from uterine sarcomas. The criteria considered in this study are hight T2 and diffusion-weighted imaging signal and low apparent diffusion coeficiente (ADC) as predictors of malignant sarcomas.

RIEE-34   Where The Fluid Stops: Adhesions And Peritoneal Pockets

Participants
Stephannie Santana, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Abdominal adhesions are formations of fibrous tissue that develop between structures in response to tissue damage. Prior abdominal surgery, peritonitis, pelvic inflammatory diseases, endometriosis, and radiotherapy to the abdominal area all are factors known to induce intraabdominal adhesions.• Intraabdominal adhesions are a common cause for chronic abdominal pain, bowel obstruction, especially of the small bowel in up to 75%, mechanical ileus in adult patients, infertility and difficult in subsequent surgery, causing increased morbidity and mortality.• The findings obtained in laparoscopic surgery are the most accurate way to determine the adhesions, although surgery itself is widely regarded to be leading cause of adhesions. Thus a non-invasive technique could be of significant benefit.• Ultrasonography and cine-magnetic resonance imaging is used as an important tool in determine adhesions, however imaging methods are not always reproducible.• Thus some secondary peritoneal changes seen in conventional imaging methods could be better explored.

TABLE OF CONTENTS/OUTLINE

• This study proposes indirect radiological signs that suggest the presence of adhesions, such as peritoneal pockets, loculated peritoneal fluid, peritoneal failure, recto-uterine pouch (POD) adhesions and atypical uterus positioning, correlating these signs with surgical findings, aiming to corroborate with pre-existing kwonledge.

RIEE-35   Staging Of Uterine Malignancies: What Radiologists Need To Know

Participants
Cristina Gomez Varela, MD, Pontevedra, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

We review the epidemiology of uterine cancer, the FIGO staging system and the role of imaging in the staging of uterine malignancies.

TABLE OF CONTENTS/OUTLINE

Background. Imaging modalities. Dissemination patterns: lymphatic spread, intraperitoneal seeding and hematogenous dissemination. FIGO staging of uterine malignancies: endometrial cancer, uterine sarcoma and cervical cancer. Conclusions.

RIEE-36   Peering Into The Pelvis With 3D Uterine Ultrasound - What You Need To Know!

Participants
Colin Rowell, MD, Fruit Cove, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

Ultrasound is the first-line screening and diagnostic imaging tool to evaluate the uterus. It is helpful to evaluate pelvic anatomy and to diagnose pelvic problems such as pelvic pain, bleeding, and suspected benign or malignant pathologies. After reviewing this case-based exhibit, the learner will be able to: - Describe pelvic ultrasound techniques with particular attention on 3D sonography. - Recognize the normal uterine and endometrial appearance on 3D ultrasound. - Diagnose uterine and endometrial pathology with some case-based cross-sectional correlation. - Determine whether additional imaging with pelvic MR may be warranted.

TABLE OF CONTENTS/OUTLINE

I. Objectives II. BackgroundIII. 3D Ultrasound of the UterusA. Ultrasound technique, tips, and pitfallsB. Uterus i. Normal anatomy 1. Endometrium 2. Congenital variants a. Arcuate vs. Septate uterus b. Bicornuate uterus c. Uterus didelphys ii. Problem Solving and Pathology with 3D Ultrasound 1. Normal vs. malpositioned intrauterine device 2. Endometrial polyps 3. Uterine Leiomyomas a. FIGO Staging (FIGO 0-8) and Submucosal FibroidsIV. Conclusions

RIEE-37   Malignancies In Pregnancy: Imaging Considerations And Management

Awards
Certificate of Merit

Participants
Lekui Xiao, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. For many women, it is during pregnancy that the ovaries are first imaged. It is imperative that clinicians and imaging specialists understand the characteristic findings and follow-up for incidentally detected ovarian lesions in pregnancy. Early diagnosis, although complicated by pregnancy, is key in optimizing evaluation and treatment. 2. Cervical cancer incidence peaks during childbearing years and is clinically managed through Pap screening. This malignancy is usually managed well before imaging is needed. However, staging of invasive cancer requires cross-sectional imaging. 3. Uterine, vulvar, and vaginal malignancies are rare in pregnancy.

However, they are best diagnosed through clinical exam, pelvic ultrasound, and subsequent MRI for staging. 4. Diagnosis of non-gynecological malignancies relies more on ionizing radiation through modalities such as computed tomography or mammography. 5. When weighing the pros and cons of contrast use and radiation, the benefit to the mother in making an early and accurate diagnosis often outweighs the theoretical risk to the fetus.

TABLE OF CONTENTS/OUTLINE

1. Introduction2. Incidental ovarian masses detected on prenatal ultrasound a. Benign versus malignant b. Management 3. Cervical cancer a. Imaging considerations b. Management4. Other less common gynecologic malignancies a. Uterine malignancies b. Vaginal & vulvar malignancies5. Imaging of non-gynecologic malignancies in pregnancy a. Safety b. Radiation considerations6. Teaching Points

RIEE-38   MRI Features Of Ovarian Lesions: How Far Can We Go In Predicting Histology?

Participants
Natália Cavalcante, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Indeterminate adnexal masses are commonly referred to MRI for further diagnostic work-up after initial ultrasound evaluation. Although imaging features can often be non-specific, correlation with clinical and epidemiologic features can aid in the diagnostic approach. In MRI, T2 morphology plays an essential role in narrowing the differential diagnosis of these lesions. The adequate characterization of features that are suspicious for high-grade malignancy can help determine treatment options and improve outcomes, especially when preservation of fertility is desirable. The purpose of our exhibit is: 1. To illustrate morphologic T2 features of low grade, borderline and malignant adnexal lesions; 2. To review the main differential diagnosis of adnexal masses based on simplified workflows; 3. To present cases with histologic confirmation.

TABLE OF CONTENTS/OUTLINE

Introduction of optimal pelvic MRI protocols; Overview of the most common types of neoplastic ovarian masses; Proposed flowcharts to guide the differential diagnosis of ovarian lesions;Presentation of cases of low grade, borderline, and malignant adnexal lesions, with emphasis on the T2 morphology.

RIEE-39   The 2021 Update On MRI For Endometrial Cancer: What The Radiologist Needs To Know

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Ekta Maheshwari, MD, Pittsburgh, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

Endometrial cancer is the most common gynecologic malignancy in industrialized countries, where its incidence is increasing. Globally, it remains the sixth most common cancer in women. Contemporary evidence based data and expert opinions recommend MRI for endometrial cancer in non surgical candidates, patients with suspected cervical involvement, those desiring fertility sparing or other conservative management, and in patients with recurrence being considered for pelvic exenteration. MRI provides critical information on tumor size, depth of invasion and lymph node status. This case-based review reflects a multidisciplinary international collaboration and will summarize updated information concerning the role of MRI for endometrial cancer staging, treatment planning and follow up, including information regarding dedicated MRI protocols, tips for MRI reporting and strategies for image quality optimization. Emerging MRI techniques will also be discussed.

TABLE OF CONTENTS/OUTLINE

1. How MRI improves patient management for early stage, fertility sparing, advanced disease, follow-up and recurrence assessment. 2. Dedicated MRI protocols, including patient preparation, role of functional MRI sequences & tips for MRI reporting. 3. FIGO stage-specific MRI findings and tips for assessing challenging cases. 4. Case-based review of MRI for initial treatment planning, response assessment & post therapy follow up. 5. Future directions, including new DWI methodologies, fast MR techniques & PET/MRI for endometrial cancer imaging.

RIEE-4   Mimickers Of Gynecologic Tumors

Participants
Tsukasa Saida, MD, Tsukuba, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Various organs exist around the female reproductive organs, and tumors arising from these organs can be mistaken for gynecologic tumors. In this exhibition, we introduce various tumors in various organs other than the female reproductive organs that need to be differentiated from gynecologic tumors, and explain the diagnostic points in a quiz format. The teaching points of this exhibit are: 1. Tumors of the rectum, appendix, bladder, ureter, abdominal wall, and nerves can be mistaken for gynecological tumors, and it is important to closely observe the continuity between the tumor and surrounding organs. 2. Various types of tumors, such as gastrointestinal stromal tumors, myxoma, schwannomas, desmoid, sarcomas, and epithelial tumors other than in gynecologic organs, need to be distinguished from gynecologic tumors and we indicate their typical imaging findings.

TABLE OF CONTENTS/OUTLINE

A. Quiz imagesB. Explanation of interpretations of quiz images with reference to additional imagesC. Overview of the disease, including imaging findings

RIEE-40   Myometrial Scar Ectopic Pregnancy - A Review

Awards
Certificate of Merit

Participants
Lucien Rizzo, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Myometrial scar ectopic pregnancies are associated with a high morbidity rate.2. Specific findings on pelvic ultrasound should raise concern for a myometrial scar ectopic pregnancy.3. Adjunct imaging can be beneficial in confirming the diagnosis of myometrial scar ectopic pregnancy.4. As there are no standardized guidelines regarding the therapeutic management of myometrial scar ectopic pregnancy the radiologist is likely to be consulted for diagnostic and/or therapeutic dilemmas.5. Uterine artery embolization by the interventional radiologist can be incorporated into the surgical management of myometrial scar ectopic pregnancy.

TABLE OF CONTENTS/OUTLINE

I. IntroductionII. Spectrum of Ultrasound Findings in Myometrial Scar Ectopic Pregnancy [Imaging pearls. Indications and recommendations for adjunct imaging.]III. Therapeutic and Management Options [Including uterine artery embolization.]IV. Multimodality Case ReviewV. Test Your Knowledge

RIEE-41   3D Pelvic Ultrasound: Plane And Simple

Participants
Iris Chen, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

Ultrasound (US) is the mainstay of pelvic imaging given its broad availability, real-time imaging, cost-effectiveness, and lack of radiation. Three-dimensional (3D) US for the female pelvis has revolutionized the evaluation of pelvic anatomy and pathology with multiplanar assessment. Current applications for 3D US not only include evaluation of common pathologies, but also can be utilized in the workup of infertility and as imaging guidance for procedures. Limitations of 3D US include quality dependence on two-dimensional image resolution, artifact recognition in 3D reconstructions, and learning curve associated with 3D US manipulation by the examiner. As 3D US becomes more widespread in clinical practice, it is important to understand how to optimize 3D US for both the user and interpreter to improve diagnostic evaluation.

TABLE OF CONTENTS/OUTLINE

The exhibit will introduce normal pelvic anatomy as visualized on 3D US with both user- and interpreter- techniques to optimize 3D US of the pelvis to best evaluate its common pathologies. We will include a comprehensive overview of entities in which 3D ultrasound plays a key role in making the diagnosis. These include congenital uterine anomalies, endometrial polyps, fibroids, intrauterine devices, hydrosalpinx, pelvic floor and mesh evaluation, and pregnancy. Learning is reinforced through an interactive case review with quiz.

RIEE-42   Recurrent Tumors Of The Uterine Cervix And Corpus: Multimodality Imaging Review And Implications For Clinical Management

Participants
Ekta Maheshwari, MD, Pittsburgh, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

Recurrent tumors of the uterine cervix and corpus are challenging clinical scenarios for which radiologic imaging is essential for salvage therapy planning and follow-up. Therapeutic strategies for local pelvic recurrences include surgical exenteration and radiotherapy. While potentially curative, these therapies are not without risk and necessitate precise delineation of tumor extent. Patients presenting with extensive pelvic recurrence or with distant disease are typically triaged to systemic therapy, for which imaging is equally vital to evaluate tumor extent and subsequent response to therapy. This case-based review reflects a multidisciplinary international collaboration and will summarize the role of imaging for recurrent tumor detection and delineation, treatment planning and post-therapy follow up.

TABLE OF CONTENTS/OUTLINE

1. Summary of key surgical, radiation oncology and medical oncology strategies for recurrent disease.2. Case-based review illustrating the role of imaging (CT, PET/CT, MRI, PET/MRI) for detection, treatment selection and treatment planning of recurrent cancers of the uterine cervix and corpus (i.e. endometrial & mesenchymal neoplasms).3. Illustrative case-based review of uterine cervix/corpus recurrence cases, including treatment strategy and rationale with examples of post-therapy follow up.4. Guidelines for radiologic reporting.

RIEE-43   MR Imaging Review Of Gynaecological Malignancies In Pregnancy

Participants
Alexandra Renn, MBBS, London, United Kingdom (*Presenter*) Nothing to Disclose

TEACHING POINTS

o Understand the incidence, presentation and management of gynaecological malignancies in the pregnant patient.o Demonstrate the imaging characteristics of gynaecological malignancies in the pregnant patient.o Recommendations to avoid potential pitfalls when faced with challenging clinical dilemmas.

TABLE OF CONTENTS/OUTLINE

Epidemiology of Gynaecological Malignancies in the pregnant patient.• Pathophysiology (with focus on hormonal changes/immune suppression)• Clinical presentation and its limitations (including challenges regarding tumor markers (specifically CA-125))Pictorial demonstration of specific gynaecological cancers in the pregnant patient, including learning points for each (please see PDF upload):• Cervical (to include comparison with the non-pregnant patient to emphasize limitations of accurate staging)• Ovarian (including borderline ovarian tumors)• Endometrial• Vaginal and Vulval.'Tumor Mimics' in the pregnant patient, with a discussion regarding methods to minimise misdiagnosis.Imaging recommendations (focus upon MRI but with a general discussion regarding ultrasound and CT)• Strategies for image optimisation• Potential imaging pitfalls.Ethical issues in the investigation and management:• Subsequent challenges in imaging• Surgery• Chemotherapy/radiotherapy• Risk to foetus/motherConclusion

RIEE-44　　**Placenta Accreta Spectrum: The Role Of MRI**

Awards
Identified for RadioGraphics

Participants
Joanna Ohlendorf, MD, Nashville, Tennessee (*Presenter*) Nothing to Disclose

TEACHING POINTS

Placenta accreta spectrum (PAS) disorders are increasing in prevalence and can be a major cause of maternal morbidity and mortality, especially if not detected prior to delivery. The management of PAS requires a multidisciplinary approach, which includes imaging evaluation to tailor the treatment plan. Ultrasound is the screening imaging modality of choice, however, MRI is a valuable adjunct for assessing the depth of placental invasion and extent of uterine and extra-uterine involvement. We aim to review the role of prenatal and postpartum MRI in PAS, focusing on MRI findings, management implications, and pathologic correlation. We will do this via a case-based approach, emphasizing the standardized imaging protocol and reporting system described in the PAS joint consensus statement by SAR and ESUR. Accurate, standardized reporting of the imaging features of PAS by the radiologist will help guide the appropriate management of this increasingly common disease.

TABLE OF CONTENTS/OUTLINE

A. Review of normal MRI placental findings during pregnancy.B. Review of standardized MRI techniques and sequences.C. Review the MRI findings and reporting lexicon of PAS.D. Case based review of PAS MRI emphasizing the imaging findings, depth of invasion, topography of invasion, and extra-uterine extension. Examples during pregnancy with implications on delivery planning, as well as postpartum monitoring in the setting of conservative management will be included. Operative and pathology report correlation will be provided.

RIEE-45　　**Urinary Tract Endometriosis: Imaging Features, Complications And Preoperative Evaluation**

Participants
Ruggeri Guimaraes, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

1 - To review usual and unusual location and imaging features of urinary tract endometriosis and its complications. 2 - To provide a set of the main radiological features helpful in the management of urinary tract endometriosis towards the most correct therapeutic approach. 3 - To illustrate cases of urinary complications resulting from surgical treatment of endometriosis.

TABLE OF CONTENTS/OUTLINE

1 - Diagnostic tools, including transvaginal ultrasound and magnetic resonance imaging, as well as the correlation and comparison between them. 2 - Imaging protocols. 3 - Usual and unusual location, imaging features, and urologic complications. 4 - Current conservative and surgical management. 5 - Role of imaging in surgical planning, relevant report information and advantages of a structured report. 6 - Urinary complications resulting from surgical treatment of endometriosis.

RIEE-46　　**From Head To Toe: Acute Presentations Of The Pregnant And Postpartum Patient**

Participants
Sarah Moorman, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Both physiologic and mechanical risk factors predispose pregnant and postpartum patients to complications and injuries2. There are certain "can't miss" pathologies that radiologists must recognize to prevent complications to the mother and/or fetus3. Other common and uncommon processes can also occur during pregnancy and may present with acute symptoms

TABLE OF CONTENTS/OUTLINE

1. Review risk factors that may predispose pregnant/postpartum patients to certain complications2. Review multi-organ system pathology and complications in pregnant and postpartum patients:a. Neuroradiology: dural venous sinus thrombosis, hemorrhagic infarct, stroke, posterior reversible encephalopathy syndrome, reversible cerebral vasoconstriction syndromeb. Cardiothoracic: pulmonary embolus, aortic dissectionc. Musculoskeletal: pelvis stress fractures, transient osteoporosis of the hip, muscular and ligamentous injury/tearsd. Abdominopelvic: appendicitis, ectopic pregnancy, placenta percreta, degenerating fibroid, pyelonephritis, obstructing calculus, deep venous thrombosis3. Summary of key findings/features by organ system

RIEE-47　　**Growing Pains: Multi-modality Pre-natal Imaging Of Fetal Tumors With Post-natal Correlation**

Participants
Murat Oztek, MD, Seattle, Washington (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Review of pre-natal detection and evaluation of fetal benign and malignant tumors based on anatomical location- Review of imaging appearance, with post-natal correlation- Review of potential complications, such as hydrops, and airway obstruction-Discuss management techniques including in utero intervention and alternative modes of delivery such as ex utero intrapartum treatment (EXIT)- Role of the radiologist in the multi-disciplinary team

TABLE OF CONTENTS/OUTLINE

1. Fetal tumors, both benign and malignant, will be reviewed head to toe, based on anatomical location.-Intracranial: Glioma, craniopharyngioma, teratoma, lipoma, and choroid plexus papilloma-Neck: Teratoma, lymphangioma, and angiomas-Cardiac: Rhabdomyoma (including tuberous sclerosis association) and fibroma-Soft tissue: Infantile fibrosarcoma, rhabdomyosarcoma, and PNET-Abdominal: Hemangioendothelioma, mesenchymal hamartoma, hepatoblastoma, mesoblastic nephroma, Wilms, and neuroblastoma-Pelvis: Sacrococcygeal teratoma,ovarian cystic mass2. Imaging techniques: ultrasound, including use of 3D imaging, MRI, imaging for in utero intervention, and delivery planning3. Potential complications4. Role of the radiologist in management of pregnancy and delivery planning5. Post-natal imaging correlation and role of the radiologist in management6. Flow chart outlining

imaging approach, emphasizing role of the radiologist

RIEE-48   Don't Stress-Do Your Best: Case-based Review Of Common (And Some Uncommon) Fetal Genetic Anomalies

Participants
Hassan Aboughalia, MBBCh, Seattle, Washington (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Case-based presentation of commonly encountered fetal genetic syndromes. 2. Case-based presentation of several less commonly encountered fetal genetic syndromes.3. Review of the clinical and imaging approach with suggested timelines for follow up and re-imaging to clarify findings, and the role of the radiologist in the management team. 4. Algorithmic approach to distinguishing features and differential diagnosis.

TABLE OF CONTENTS/OUTLINE

1. Commonly encountered syndromes (Trisomy 21, 18, 13, 9).2. Less commonly encountered syndromes (Turner, chromosomal transpositions and translations, Beckwith Weidemann, caudal regression, Meckel-Gruber, Joubert syndrome, Pentalogy of Cantrell, VACTERL, Holt-Oram, and prune belly syndrome).3. Imaging appearance on US, 3D US, and MRI, and associated pathology photos.4.Review the clinical approach from the time of US diagnosis and the need for further imaging when indicated/appropriate.5. Describe the role of the radiologist in management of such pregnancies. 6. Provide an algorithmic approach based on the pattern of anomalies, to arrive at a differential diagnosis or a specific diagnosis.

RIEE-49   Comprehensive Multi-modality Imaging Review Of Uterine Leiomyomas And Associated Complications

Participants
Bahar Mansoori, MD, Seattle, Washington (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Review the classification of leiomyomas by location and histopathology 2) Overview the common and uncommon imaging findings of leiomyomas on plain film, US, CT, MRI, and PET-CT 3) Multi-modality imaging review of potential complicationsAlgorithmic approach to differential diagnosis and mimics 4) Overview the role of imaging and image-guided interventions in the management

TABLE OF CONTENTS/OUTLINE

Classification of leiomyomas by location (FIGO classification)Classification of leiomyomas by histopathology, review of multi-modality imaging, and clinical significance of subtypesHistopathologically typical leiomyomaNon-degeneratedDegenerated (Fatty, carneous, cystic, hyaline, myxoid)Histopathologically variant leiomyoma (Mitotically active,cellular, STUMP tumor,atypical)Imaging of atypical growth pattern and clinical relevanceDisseminated peritoneal leiomyomatosis,Benign metastasizing leiomyoma,Intravenous leiomyoma,Parasitic leiomyoma,Broad ligament leiomyomaMulti-modality imaging review of potential associated complicationsHemorrhage,Torsion,Prolapse,Infarction,Mass effect on adjacent organs,Metastatic,Malignant degenerationAlgorithmic approach to differential diagnosis and pitfallsReview of treatment optionsPre-surgical planningPlanning for uterine artery embolizationReview of available interventions and associated complicationsHIFU (high-intensity focused ultrasound) treatmentIndications and techniques for MR-guided HIFU and US-guided HIFU

RIEE-5   Cesarean Scar Ectopic Pregnancy: Intrauterine But Not Ok!

Awards
Certificate of Merit

Participants
Michelle Debbink, MD, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Early first trimester is the best time to diagnose a cesarean scar ectopic pregnancy (CSEP); 2) Accurate diagnosis requires a high index of suspicion, complete patient history, imaging the entire uterus, and recognition of imaging findings; 3) Key imaging findings for CSEP include low implantation, cross over sign, and decreased residual myometrial thickness; 4) Differential diagnoses include low-lying but normal gestational sac, abortion in progress, or cervical ectopic; 5) Missed or late diagnosis of CSEP can lead to hemorrhage, uterine rupture, or severe placenta accreta spectrum (PAS) disorder; 6) Early recognition of CSEP is critical for appropriate medical or surgical management to reduce maternal morbidity and preserve fertility

TABLE OF CONTENTS/OUTLINE

CSEP overview: Incidence increasing in parallel with cesarean rates; frequently missed diagnosis; intrauterine location does not always imply normal; Key sonographic issues: Wide field of view, sac location, cross over sign, cardiac activity. Key findings to guide management: Residual myometrial thickness, exogenous vs endogenous growth; Management options: guided by growth type; include: laparoscopic/hysteroscopic resection; suction D&C; transcervical balloon compression; high frequency ultrasound; or medical management (e.g., methotrexate); Consequences of CSEP (worsened by late diagnosis or management): Hemorrhage, uterine rupture (early and late), gravid hysterectomy, severe PAS necessitating preterm birth and hysterectomy, maternal death.

RIEE-50   Benign, Malignant Or In Between? From Fibroids To Leiomyosarcomas. A Cased-based Review Of The Spectrum Of Uterine Smooth Muscle Tumors

Participants
Wendy Tu, MD, Edmonton, Alberta (*Presenter*) Nothing to Disclose

TEACHING POINTS

As the management of uterine leiomyoma has evolved, so too has the role of cross-sectional imaging in fibroid assessment before and after treatment. MRI in particular is highly accurate in characterizing fibroid distribution, prompting efforts to systematize description of fibroid sub-locations within the uterus in a manner that is actionable by gynecologists. Though many fibroids have characteristic imaging features, even benign fibroids may exhibit a range of atypical appearances related to degeneration. Moreover, challenges remain in non-invasively deciphering benign fibroids from those along an atypical histologic spectrum ranging

from cellular leiomyoma to leiomyosarcoma, a distinction with potentially immense clinical significance.

TABLE OF CONTENTS/OUTLINE

This exhibits aims to: Discuss the histology and multimodality imaging findings of typical, degenerated, histologically atypical and malignant uterine smooth muscle tumors. Discuss imaging and clinical findings which may help differentiate malignant from benign smooth muscle tumors (diffusion, enhancement, washout), as well as use of radiomics and spectroscopy. Describe the use of standardized reporting for uterine fibroids using FIGO classification. Highlight the role of imaging in preoperative assessment, including 3D printing in pre-treatment planning. Discuss the current role of uterine fibroid embolization and post-operative imaging monitoring, specifically the parameters for response assessment.

RIEE-51   CT-virtual Hysterosalpingography Normal And Pathologic Findings With Correlation With Other Diagnostic Modalities And Surgery

Participants
Patricia M. Carrascosa, MD, Buenos Aires City, Argentina (*Presenter*) Speakers Bureau, General Electric Company

TEACHING POINTS

CT virtual hysterosalpingography provides accurate and complete evaluation of the female reproductive system. • To be familiar with the normal anatomy and pathologic disorders on CT virtual hysterosalpingography studies. • To illustrate the typical imaging findings of different pathologies on CT virtual hysterosalpingography exams. • To correlate the CT virtual hysterosalpingography findings with other imaging modalities (US, MRI, X-ray HSG), hysteroscopy and surgery. • To be noticed of the advantages and limitations of the procedure.

TABLE OF CONTENTS/OUTLINE

• Description of the CT virtual hysterosalpingography procedure. Patient preparation. • CT scanner requirements. Description of CT image acquisition protocol. • The importance of the contrast injection protocol. • Image analyses, post-processing tools and image interpretation. Role of the endoluminal virtual views. • Spectrum of normal and pathologic fallopian tubes findings. • Correlation with other imaging modalities, such as US, MRI and X-ray HSG o Normal anatomy o Cervical stenosis o Uterine cavity and cervical canal synechiae o Uterine polyps o Uterine wall pathology (Myomas; adenomyosis) o Uterine malformations o Tubal pathology • Correlation with hysteroscopy and surgery o Uterine polyps and submucous myomas o Uterine cavity and cervical canal synechiae o Hydrosalpinx • Summary

RIEE-52   Uterine Leiomyoma A Resident Guide To Classify Typical And Not So Typical Fibroids

Participants
Mary Arevalo Molina, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To review leiomyoma appearance and classification system (FIGO).- To understand the different degeneration types and most common associated pathologies.- Provide an illustrative tutorial highlighting the utility of MRI to detect unusual uterine leiomyomas.- Understand the advantages of MRI as an important diagnostic test in uterine leiomyomas affection.

TABLE OF CONTENTS/OUTLINE

1. Introduction2. Indications3. Technique4. FIGO Classification5. Pictorial review common and unusual uterine leiomyomas6. Take home points7. References

RIEE-53   From Adhesions To Septa: Imaging Findings In Infertility And Impact On Management

Participants
Akshya Gupta, MD, Pittsford, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. There are a variety of underlying conditions that can impact fertility in women. Having an understanding of the associated imaging findings of ovarian, tubal, and uterine pathology is essential for the practicing radiologist.2. There are specific imaging findings that can impact the likelihood of success of assistive reproductive technology. These findings should be highlighted in the radiology report.

TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Overview of imaging techniques for the evaluation of the female reproductive tract including ultrasonography, sonohysterography, hysterosalpingography, and magnetic resonance imaging 3. Review of the typical clinical and imaging paradigm in the workup of infertility 4. Review of pathologies that can impact the management of infertility including: a. Endometrial polyp b. Endometrial adhesions c. Uterine fibroids d. Adenomyosis e. Endometriosis f. Hydrosalpinx/Tubal Occlusion g. Mullerian Anomalies 5. Briefly review potential complications of reproductive therapy including ovarian hyperstimulation 6. -Highlight future directions in imaging of infertility, such as imaging of uterine transplantation

RIEE-54   Practical Approach To Typical And Atypical Fibroids: A Primer For Radiologists.

Participants
Brenda Hernandes dos Santos Teixeira, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

1 - To improve the understanding of typical and atypical fibroids and their histological features. 2 - To review FIGO classification system of fibroids, emphasizing the relevant imaging characteristics that must be present in the report. 3 - Point out the advantages of the structured reporting of Magnetic Resonance Imaging (MRI) pelvis for &7;broids and its importance to clinical and surgical practice. 4 - To illustrate the main imaging methods to assess fibroids, such as Ultrasound (US) and MRI, and to highlight the importance of appropriate image acquisition protocols in MRI. 5 - To show the typical and atypical imaging characteristics of fibroids and how to differentiate them on MRI.

RIEE-55 Revisiting Endometrial Cancer: Review And Update

Participants
Joao Pedro Costa, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Briefly review the main histological subtypes of endometrial cancer and its implications on prognosis and managementDescribe the MRI protocol and diagnostic value of each sequence for tumor stagingRecognize the classic appearance of endometrial cancer on MRIPropose a systematic MRI evaluation to understand the landmarks in the FIGO staging classificationDiscuss the role of MRI to aid the decision of lymphadenectomy, fertility sparing surgery, lymph node sentinel approach and FDG PET/CT staging.

RIEE-56 Step By Step Evaluation Of The Risk Stratification In Benign Pathology According To The O-RADS Us Consensus. What Every Resident Should Know.

Participants
Estefania Gallego Diaz, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

The Ovarian-Adnexal Reporting and Data System US risk stratification and management system is designed to provide concrete interpretations, to decrease ambiguity in US reports, and to provide a management recommendation for each risk category.To explain the importance of O-RADS US and unify concepts used here. To Review benign categories, specifying precisely what should and should not be seen in benign pathologies and how to approach the possibility of malignant pathology.To present in a didactic way with diagrams and clinical cases the most relevant findings of the most frequent O-RADS US categories. (1to 3) To Simplify the evaluation of the ovary for residents. What every resident should know to accurately rule out benign pathology.

RIEE-57 Malignancy In Pregnancy: Multimodality Imaging And Treatment

Participants
Silvana C. Faria, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

Cancer is the second most common cause of death in women of reproductive age. Cancer can be seen in 0.1% to 0.2% of pregnant women, affecting 1 in 1000 pregnancies. However, since women are delaying childbearing to the third and fourth decade of life, we are seeing an increase in cancer cases in pregnant women. The most commonly diagnosed malignancies during pregnancy include cervical cancer, breast, lymphoma, leukemia, melanoma, thyroid, colon and ovarian cancer. The imaging issues in pregnant women with cancer may be challenging. There are important considerations for the radiologist in the diagnosis and staging of malignancy during pregnancy. The diagnosis of cancer in pregnancy may be delayed due to mistaken attribution of symptoms to the pregnancy itself. Additionally, the effects of pregnancy on tumor biology and the potential deleterious effects of oncologic treatment in the fetus will be discussed. Imaging plays an important role in the diagnosis, staging, management and monitoring of treatment response of malignancy during pregnancy. Our aim is to review imaging features of malignancy in pregnant women with examples from US, CT, MRI and PET/CT images.

RIEE-58 Placenta Accreta Spectrum Imaging: Cardinal Signs, Pitfalls And Advances In Predicting Severe Invasive Disease

Participants
Inessa Goldman, MD, Bronx, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

To outline the cardinal imaging signs with best sensitivity and specificity to make diagnosis of placenta accreta spectrum disorder (PAS) on US and MRI.Illustrate common pitfalls encountered in imaging of PAS on US and MRI.Emphasize placental bulging sign (PBS) as the best sign that correlates with presence of severe PAS (s-PAS) (i.e. placenta increta and percreta).

1.List various imaging signs on US used to diagnose PAS.2. Cardinal imaging signs on US that show highest accuracy in predicting PAS and their pitfalls:a. Loss of clear zoneb.Myometrial thinningc. Abnormal lacunaed. Placental bulge sign - highest accuracy in predicting s-PAS. 3.Signs used to diagnose PAS on MRI with emphasis on cardinal features, such as a.heterogenous placenta; b.dark intraplacental bands c. PBS.d. abnormal subplacental vascularity. 4. Pitfalls on MRI including hemorrhage or thrombosed vessels; fibroids; contractions. 5. PBS has highest accuracy in predicting S-PAS both on US and MRI. 6. Briefly discuss high interobserver variability and its implications.

RIEE-59   Placenta Accreta: When Placenta Is Out Of Place

Participants
Carlos Riquelme, MD, Providencia, Chile (*Presenter*) Nothing to Disclose

TEACHING POINTS

1.On MRI, the normal placenta appears homogeneous with intermediate signal intensity on T2-weighted image, including clear distinction from the underlying myometrium.2. Previous cesarean section and placenta previa are the two major risk factors for placenta accreta. 3.The MRI sequences for the diagnosis of placenta accreta includes: a.T2-SSFSE: information about anatomic detail, position, attachment and depth of placental invasion b.Balanced steady state gradient echo sequence or Fast Imaging Employing Steady state Acquision: anatomical assessment, vascularity and evaluation of adjacent structures. c.T1-weighted sequence: evaluation of hemorrhage d.Diffusion-weighted image: myometrial invasion3.- The most sensitive and specific MRI signs to evaluate invasive placentation are: a. Uterine bulging: includes placenta with lumpy contour and rounded edges b. Heterogeneous placental signal c. T2 dark intraplacental bands d. Focal gap in myometrium e. Bladder tenting.

TABLE OF CONTENTS/OUTLINE

1.Introduction2.Normal Placenation3.Placenta Accreta: a.Classification b.MR imaging protocols c.Normal MR imaging appeerence of placenta d.Imaging in placenta accreta vera e.Imaging in placenta incretaf.Imaging in placenta percreta4. Pearls and pitfalls5. Summary

RIEE-6   The Confounding Ultrasound Diagnosis Of Ectopic Pregnancy: Lessons Learned From Peer Learning

Awards
Certificate of Merit

Participants
Jung Yun, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Understand importance of accurate US diagnosis of ectopic pregnancy (EP) when medical therapy will be used, to avoid inadvertent treatment of a desired intrauterine pregnancy (IUP) 2. Differentiate tubal EP from a corpus luteum (CL) by echogenicity relative to ovarian parenchyma, push technique and claw sign 3. Distinguish interstitial EP from eccentrically located IUP (angular) 4. Use trophoblastic flow in abnormal intrauterine locations to help identify intrauterine EP in Cesarean scar or cervix 5. Recognize that hemoperitoneum without visualized EP may be due to EP or hemorrhagic cyst 6. Distinguishing an abortion in progress from a pregnancy of unknown location (PUL) may not always be possible and requires clinical follow-up

TABLE OF CONTENTS/OUTLINE

(I) Definitions with examples (A) PUL = "normal pelvic US" (B) Definitive tubal EP: yolk sac or embryo (1) Extrauterine tubal EP (2) Interstitial EP (C) Likely tubal EP (1) Tubal ring/bagel (2) Hematosalpinx/blob (D) Intrauterine EP (1) Cesarean scar (2) Cervical (E) Hemoperitoneum: amount, location (II) Diagnostic dilemmas (A) Tubal EP vs CL (1) Grayscale appearance (2) Color Doppler (3) Maneuvers (B) Normal IUP vs Intrauterine EP (1) Interstitial EP vs "angular" IUP (2) Cesarean scar or cervical EP vs abortion in progress (3) Tips (a) Coronal reformat (b) Trophoblastic flow (c) Gestational sac shape (d) Presence of embryonic cardiac activity (C) Hemoperitoneum (1) Ruptured EP vs hemorrhagic cyst (2) Heterotopic pregnancy (III) Other (A) Mullerian duct anomaly (B) Fibroids (C) Mirror image

RIEE-60   Mullerian Duct Anomalies: The Diagnosis Is In The Eye Of The Beholder.

Participants
Ana Villamizar, MD, Bogota, Colombia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Discuss the clinical relevance of Müllerian duct anomalies and the main classification used for its assessment (AFS and ESHRE)2. Recognize the performance of both classifications as a tool of particular value when imaging uterine anomalies.3. To evaluate the MRI findings in normal and abnormal uterus and anomalies associated.4. Illustrate classic examples of the different uterine variations.1. To teach about the Müllerian duct anomalies and the syndromes associated, how to describe and classify them through the review of our own cases.

TABLE OF CONTENTS/OUTLINE

1. Definition of normal embryology of the Mu¨llerian duct2. Description of the American and European classification of the Mu¨llerian duct anomalies3. Discussion of associated anomalies and syndromes with examples from our own cases.4. Conclusions

RIEE-61   Pitfalls Of Pregnancy: An Organ-system Review Of Non-obstetric Complications And Emergencies In The Pregnant Patient

Awards
Identified for RadioGraphics

Participants
Gayatri Joshi, MD, Atlanta, Georgia (*Presenter*) Nothing to Disclose

TEACHING POINTS

Assessment of the emergent pregnant patient can be challenging due to nonspecific presenting symptoms, altered anatomy,

physiologic aberrations in physical exam & laboratory findings, and magnified risk of poor outcome for clinically significant missed diagnoses.After completion of this exhibit, learners should: 1. Be familiar with the spectrum of non-obstetric complications and emergencies during pregnancy, with an understanding of differential considerations by organ system. 2. Differentiate between non-obstetric emergencies based on multimodal imaging & clinical features. 3. Proficiently facilitate optimized imaging workup for the pregnant patient based on clinically suspected diagnosis & ACR appropriateness guidelines.

TABLE OF CONTENTS/OUTLINE

This exhibit will: 1. Review non-obstetric complications and emergencies of pregnancy by organ system. 2. Illustrate multimodal imaging findings and clinical features of each entity. 3. Discuss diagnostic pitfalls & methods for improving diagnostic accuracy in the setting of physiologically altered anatomy and physical exam during pregnancy. 4. Review ACR appropriateness criteria in the work-up of pregnant patients. 5. Briefly discuss management considerations, as applicable to the radiologist, to aid in appropriate direction of patient care.

RIEE-62-HC Uterine Niche; The Spectrum Of Findings On MRI

Participants
Roisin MacDermott, MBBCh,MRCS, Dublin 4, Ireland (*Presenter*) Nothing to Disclose

TEACHING POINTS

The number of caesarean sections preformed annually is increasing worldwide, leading to the growing recognition of the long term sequelae of this procedure. One such pathology which is of increasing interest is that of a uterine niche (diverticulum or isthmocele), defined as an indentation of the myometrium of at least 2mm in depth at the site of a CS scar. It is associated with a number of obstetric and gynaecological consequences including ectopic pregnancy, malplacentation and abnormal uterine bleeding. MRI is gaining popularity as an adjunct modality to US for the assessment of uterine niche and its secondary associations.The purpose of this exhibit is; 1)To summarise the prevalence and risk factors for development of Uterine Niche.2)To highlight the associated Gynaecological and Obstetric sequelae.3)To demonstrate the MR appearances of the uterine niche, from diagnosis to post operative appearances.4)To review management based on imaging findings

TABLE OF CONTENTS/OUTLINE

Introduction.Prevalence and Risk factors.Obstetric associations.Gynaecological associations. Management. MR Imaging appearances-Diagnosis,Complications,Post operative appearances.Take home points.

RIEE-63-HC Role Of Ultrasound In Partial Androgen Insensitivity Syndrome

Participants
Samvid Kotia JR, MBBS, Mumbai, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1.Ultrasound plays a major role in diagnosing various types of DSD (Disorders of Sex Development) by detecting the presence or absence of ovaries, testes, or ovotestis; as it presents as a socio-endocrinological emergency before sex is assigned to a neonate 2. The presence or absence of Mullerian structures helps in further sub-categorization. 3.Ultrasound and FNAC helps in the early detection of malignant changes in the gonads.

TABLE OF CONTENTS/OUTLINE

1.Introduction-DSDs are disorders of sexual development with discordance between genotype, phenotype (external genital organs), and internal reproductive organs. PAIS is an XY type of DSD with defective androgen receptors. 2. Pathology- PAIS manifests as an X-linked recessive condition. Despite normal testosterone production, the active form of DHT is not detected due to defective androgen receptor formation leading to under-masculinized/ambiguous genitalia in the fetus. 3.Diagnosis-It is based on biochemical, karyotyping, and imaging correlation. On USG, there is absence of Mullerian structures (uterus, fallopian tubes), absence of ovaries with the presence of well-formed testes in the inguinal canal or the labia. The prostate and seminal vesicles are also absent. The distal 1/3rd of the vagina is present. Breast ultrasound helps in the detection of gynecomastia. Due to stimulation from LH; Leydig cell/Sertoli cells hyperplasia occurs which presents as a focal hypoechoic lesion near the rete testes. 4.Role of ultrasound in the diagnosis of malignancy

RIEE-7 Beyond Television Screens: An Update Of 3-d Ultrasound In The Evaluation Of The Female Pelvis

Participants
Marcela Lauar, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

3-Dimensional ultrasound has been gaining an ascending role in clinical evaluation, as it provides images in planes previously unavailable in 2-D ultrasound, allowing their users to not be limited by conventional planes.It has shown great potential in the evaluation of gynecological patients, providing a coronal view of the uterus, outlining its external contour and cavity. It is also a valuable tool in urogynecological translabial evaluation, since it clearly illustrates the relationship of the vagina, urethra, rectum, muscular pelvic floor, and even synthetic materials (slings), when present. As it provides accurate and in a cost effective setting, clinicians can have important benefits in improving their skills and adding 3-D ultrasound in their gynecological routine.

TABLE OF CONTENTS/OUTLINE

Clinical and epidemiological aspects.A pictorial review of gynecological pathologies better evaluated with ultrasound 3-D reconstructions, and the technique used to obtain them, based on our service's digital archive of a range of different conditions (from the common ones to the rarest), correlated with 2-d ultrasound images, hysterosalpingography and magnetic resonance imaging (MRI), including adenomyosis, Mullerian anomalies, deep pelvic endometriosis, intrauterine dispositive dislocation, endometrial polyps, pelvic floor disorders, among others. Take-home messages.References.

RIEE-8 OBs SOS!

Participants
Marcela Lauar, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The main complaints by women in childbearing age in the emergency department are pelvic pain and vaginal bleeding. Combined with clinical evaluation, physical examination and laboratorial tests, imagingfindings can help lead to an assertive medical management. Among various radiology exams, sonography consists on the main imaging method to evaluate pelvic pathologies, such as vasa previa, placental abruption, placenta previa, ovarian torsion, pseudoaneurysm, retained products of conception, appendicitis, invasive mole, among others.

TABLE OF CONTENTS/OUTLINE

A pictorial review of cases of emergency findings of woman in childbearing age based on our service's digital archive, in order to assist radiologists to recognize the various pathologies in the diagnosis of obstetric and gynecologic emergencies through the imaging findings, associated with the patients' clinical information.

RIEE-9   **Gynecologic Oncology Tumor Board: How The Radiologist Adds Value**

Participants
Hannah Recht, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. The radiologist plays a key role at gynecology oncology tumor board.2. Advanced imaging provides additional information beyond the clinical examination, traditionally used for staging in gynecologic oncology.3. Disease specific imaging findings guide diagnosis and management in gynecologic oncology patients.

TABLE OF CONTENTS/OUTLINE

1. Introduction: Key role of the radiologist during gynecologic oncology tumor board discussions.2. Female pelvic anatomy and key surgical anatomic landmarks3. Ovarian cancera. Preoperative risk stratification of adnexal masses - US, MRI, and DE CTb. Staging: Assessment of disease extent and sites predisposing to suboptimal cytoreduction or necessitating neoadjuvant therapyc. Evaluation of tumor response; recommendation of biopsy site in recurrent diseased. Recurrence and extension of relapse4. Cervical cancera. Staging: MRI to assess extent of disease to determine hysterectomy vs. radiation treatment (RT); assessment for trachelectomy and fertility sparing; PET/CT for nodal and distant metastasesb. Evaluation of tumor response; follow up vs. salvage therapyc. Relapse and exenteration5. Endometrial cancera. Staging: Preoperative extent of diseasei. Myometrial invasion, nodal involvement, assessment for RTb. Recurrence: Assessment of size of vaginal cuff recurrence6. Special considerationsa. Vaginal and vulvar cancer stagingb. Uterine sarcomac. Primary tumor of unclear etiologyd. Pregnancy

Printed on: 06/28/22

NPMEE-10 Management To Achieve Zero Non-action For SUFs

Participants
Tomoyuki Noguchi, MD, PhD, Fukuoka City, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

There are some serious cases in which the attending physician who ordered an imaging test such as CT or MRI did not check the radiological report thoroughly and left the patient without proper and timely practice, with serious consequences. The main reason for this malpractice is that the attending physician who requested the imaging examination is unaware of incidental and significant findings outside his/her area of interest. This incidental and significant finding was called "Significant Unexpected Findings (SUFs)" by the Royal College of Radiologists. Patients are the victims of untreated SUFs, and the mission of medical staffs is to take steps to save them by eliminating untreated SUFs. The purpose of this educational presentation is to introduce the measures for SUFs in the radiological reports at our institution and to publicize that we can achieve zero non-action on SUFs.

TABLE OF CONTENTS/OUTLINE

1. Frequency of SUF malpractice, 2. Pathology of SUF malpractice, 3. Responsibility for SUF malpractice, 4. Read acknowledgement system, 5. SUF alert system, and 6. Our fail-safe system for SUFERR (SUF Errors in Radiological Reports).

NPMEE-11 Digital Flashcards: A Silent Revolution in Medical Education

Awards
Certificate of Merit

Participants
Julie Adhya, DO, Pittsburgh, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

As technology advances, so too should the methods of education within medicine. Digital flashcards provide an effective and practical method of studying with proven long-term retention if properly utilized. Digitizing information allows for a lightweight, yet robust database with automated scheduling and universal accessibility.

TABLE OF CONTENTS/OUTLINE

1. Compare conventional versus digital flashcards.2. Provide a brief overview on how to make and use digital flashcards.3. Discuss the benefits and positive impact of digital flashcards on medical education for students and residents.

NPMEE-12 As COVID-19 Continues, What CT Intern Technicians Need To Know?

Participants
Hui Hao, Xi'an, China (*Presenter*) Nothing to Disclose

TEACHING POINTS

What CT intern technicians need to know in the COVID-19 epidemic;What new technologies can help us in the COVID-19 epidemic;Focus on the innovation of teaching mode for intern CT technicians.

TABLE OF CONTENTS/OUTLINE

What CT intern technicians need to know Identify three areas: contaminated, semi-contaminated, and clean areas; and two channels: staff and patient channels. Understand infection control principles: wear personal protective equipment and keep distance when possible. Clarify disinfection plans: floor and air in scanning room; machine surface; air, surface and contact items in operation room What can technology help Non-contact positioning: remote bed height adjustment, AI-assisted patient positioning High-resolution or dual-energy chest CT for more accurate diagnosis AI technology for rapid lesion detection and diagnosis Focus on the innovation of teaching mode for intern CT technicians Emphasize professional knowledge, be skillful and flexible in application Enhance standards and procedure training for handling public health emergencies Strengthen the standardized teaching and assessment of protection, infection control and disinfection Combine practice with drills to motivate students

NPMEE-13 Valuable In-Person Feedback Between Radiology Faculty And Trainees

Awards
Certificate of Merit

Participants
Charmi Vijapura, MD, Cincinnati, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Review benefits of radiology faculty and trainee in-person feedback2. Discuss key components of effective two-way communication and in-person feedback3. Identify barriers and biases seen when providing in-person feedback4. Recommend possible interventions to improve faculty and trainee in-person feedback

TABLE OF CONTENTS/OUTLINE

• Background• Feedback methods• Components of effective feedback• Timeline during rotations• Feedback settings• Evaluation settings• Biases and special considerations• Barriers to communication• Interventiono Pre-intervention faculty assessmento Annual workshopo Educational lecture by in-house or external experto Role-play scenarios

NPMEE-14   RadDiscord, The Big Bang: A COVID-19 Era Digital Educational Platform

Participants
Grace Zhu, MD, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. RadDiscord is a novel, pandemic-era, open-access digital educational platform available to the global radiology community. 2. RadDiscord has an impact on clinical radiology through transforming the education of radiology residents around the world and improving access to knowledge to radiologists.3. After reviewing this exhibit, the reader will understand the community's origins, growth trajectory, distribution of members, member recruitment process, and future directions.

TABLE OF CONTENTS/OUTLINE

1. Introduction to RadDiscorda. Community's Origin2. RadDiscord's growth trajectory since inception on 10/10/20213. RadDiscord's distribution of membersa. Institutions representedb. Countries represented4. RadDiscord usage patterns by members (residents, fellows, faculty)5. RadDiscord's approach to educationa. Group study sessionsb. Faculty-led case based reviewsc. Faculty-led didacticsd. Live, interactive question and answer between faculty and traineese. Member created educational content6. Future directions7. How to get involved

NPMEE-15   Essential Ingredients For Building A High Performing Team

Awards
Identified for RadioGraphics

Participants
Jonathan Kruskal, PhD, MBChB, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

To deliver top quality imaging care to all patients, a well structured and effectively functioning cohesive team of caregivers is required. Team structure should be diverse and intentionally inclusive, and led by an inclusive, adaptive and participating leader. For the team to function effectively, members must be aware of personal implicit biases, should be culturally sensitive and humble, and must function as ally's and upstanders. Additionally, open bidirectional communication must exist, along with effective decision making processes, and wellbeing and safety must be prioritized. All roles and expectations are clearly defined, the vision and mission is well enunciated, and processes exist to manage conflicts when these arise. Team members are held accountable in a learning and improvement environment.

TABLE OF CONTENTS/OUTLINE

Building blocks of a high performing teamHoe the pandemic has impacted each of the required components, The inclusive, adaptive, participatory, servant meta-leader, Implicit biases and stereotyping, Cultural awareness, sensitivity and humility, Micro-aggressions - examples and interventional response toolkit, Equality, equity and deconstructing systemic barriers, Wellness and professional fulfillment

NPMEE-16   Practical Applications Of Behavioral Economics Theories To Drive Radiology Based Population Health

Participants
Dayna Levin, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

Behavioral economics and asymmetric paternalism can be utilized to improve the practice of radiology.Common decision heuristics can be leveraged to design interventions to support population health.Within radiology, designing incentives to nudge patients toward high value screening studies can improve population health.Behavioral based incentives including social comparison and choice architecture can be utilized to change ordering physician and radiologist practice.

TABLE OF CONTENTS/OUTLINE

Define behavioral economics and understand its utility in modularizing patient and physician behaviors.Describe various decision errors that can be leveraged to optimize incentive design to change behaviors such as framing, status quo bias, loss aversion, overweighting small probabilities and present bias preferences.Discuss how interventions can be designed within radiology practices to nudge patients and ordering physicians toward appropriate utilization of high value imaging and decrease utilization of low value imaging.Choice architecture and defaultsOpt-in for low value imaging Pre schedule annual screening testsIncentives Rewarding adherence with clinical decision supportIncent usage of templated reporting with evidence based imaging follow-up.Social comparisonDashboard tracking of performance data Provide comparative data for clinical decision support ordering compliance

NPMEE-17   Alternative Payment Models: Overview, Remaining Questions, And Unmet Needs For Radiology Six Years Into The Medicare Access And Children's Health Insurance Program Reauthorization Act

Participants
Kayla Berigan, MD, Burlington, Vermont (*Presenter*) Nothing to Disclose

TEACHING POINTS

? Under the Medicare Access and CHIP Reauthorization Act (MACRA), value-based care legislation passed in 2015, providers may choose to participate in the Merit-Based Incentive Payment System (MIPS) or Alternative Payment Models (APMs).? APMs offer added financial incentive for quality and cost-effectiveness, and CMS is encouraging the transition to APMs as the next step in value-based care's evolution.? While quality metrics for Radiology exist under MIPS, the measurement of quality in Radiology under APMs and the resultant impact on reimbursement are less clear. ? The Vermont All Payer ACO, a first-of-its-kind APM developed in partnership with CMS, places Medicare, Medicaid, and commercial payers under one payment structure. Quality metrics under this and other APMs are pertinent mainly to Primary Care providers, and the development of metrics that demonstrate Radiology's impact on quality remains an unmet need.? Physician-Focused Payment Models (PFPMs), a subtype of APM, were thought to offer a promising pathway for specialist participation in APMs, but none of the proposed models have been approved by CMS. Thus far, there have been no proposed PFPMs for Radiology.

TABLE OF CONTENTS/OUTLINE

I. Evolution of Value-Based Care II. Structure of MACRA and the QPP III. Structure of APMs IV. Vermont All Payer ACO: structure & metricsV. Relevance of APMs for Radiologists B. Physician-Focused Payment Models (PFPMs): a proposed pathway to APMs for specialists? C. Remaining questions and unmet needs

NPMEE-18 A Grassroots Approach To Forming A Diversity, Equity, And Inclusion Committee In An Academic Radiology Department: Early Successes And Lessons Learned

Awards
Identified for RadioGraphics

Participants
Sarah Averill, MD, Iowa City, Iowa (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Differences in institutional culture, population characteristics, and available resources require adaptive approaches to foster successful diversity, equity, and inclusion (DEI) initiatives.2. Collaborative and shared decision-making leadership models allow for intradepartmental communities to form organically and can create pathways for effective "bottom up" organizational change. 3. Voluntary participation as compared to mandatory participation can be an effective strategy for team building and for cultivating diversity champions in radiology departments with multiple different working groups.

TABLE OF CONTENTS/OUTLINE

1) Learn about the formation and function of a DEI committee representing multiple working groups within an academic radiology department.2) Discuss collaborative leadership and committee management models, such as shared decision-making and self-determination theory, to facilitate change through intrinsic motivation and cultivation of diversity champions.3) Present committee initiatives such as development of a DEI-informed technologist recruitment plan and department-wide professional development series.4) Discuss strategies for using institutional resources and national DEI networks to develop educational programming.5) Present literature-based discussion of the issue of mandatory versus voluntary participation in anti-racism and implicit bias trainings.6) Review pitfalls, lessons learned, and next steps for education, department staff engagement, trainee recruitment.

NPMEE-19 Assessing The Impact Of Radiology Integration During Gross Anatomy Curriculum On Diversity In Medical Student Perceptions And Interest

Participants
Annelise Silva, MEd, Beavercreek, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Comprehensive surveys can lead to holistic assessment of how institutions are meeting radiology curricular benchmarks and identify areas for opportunity; specifically in support of students from underrepresented groups in medicine-Earlier radiology integration into curriculum can impact general student perception of radiology and as a career option-At institutions with/without integrated radiology curriculum in gross anatomy, first-year students responded that radiology education was "inadequate/very inadequate" & "much more teaching is needed"

TABLE OF CONTENTS/OUTLINE

Background Despite 2014 recommendations made by the American College of Radiology (ACR), there remains no standard radiology instruction in US medical school curriculum. Recent prioritization of gender & racial diversity opens opportunities to examine student attitudes toward radiology in gross anatomy instruction as it relates to promoting more engagement in the field. Thus, this study seeks to assess gender and degree of radiology integration into gross anatomy curriculum as mediators of student attitude toward radiologyMethods Following education research committee & IRB approvals, 170 first year medical students from two US allopathic medical schools invited in retrospective self-reported survey on general attitudes toward radiology and its integration into gross anatomy curriculumResults Data for the survey was collected and extracted from Google Forms software & inputted into Microsoft Excel, followed by SPSS for final statistical analysis

NPMEE-20 Putting The "Culture" Back Into Just Culture: Engaging Radiology Departments In The Journey To Safer Care

Participants
Sarah Bastawrous, DO, Seattle, Washington (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Define the just culture model and its role in radiology 2. Discuss importance of systems errors using real-life radiology department scenarios 3. Explore critical steps in the creation of a just culture model, to include peer learning 4. Discuss foundations of success for maintaining just culture that can improve communication and decision making skills

TABLE OF CONTENTS/OUTLINE

1. Overview of origins of just culture across industries and impact on healthcare/medical errors 2. Individual versus organizational accountability and responsibility to systems improvement 3. Team training with real-life examples of error in radiology departments

4. Human behaviors and human reactions to error a. Define and provide examples of behaviors b. At risk behavior 5. Radiology leadership responsibilities: a. Education of learners b. Patient centered care c. Peer learning d. Prioritization of environments of learning, transparency and valuee. Basic faculty patient safety competencies 6. Second victim: a. Definition of second victim b. How to support the second victim 7. Maintenance of just culture in radiology a. Safety as department goal b. Encourage reporting c. Front line staff and solutions d. Establish process and policy 8. Conclusion

NPMEE-21 "How Do You Do In Clinic?" -- A Quick And Easy Guide On How To Calculate A Radiologist's Workload And Clinical Productivity

Participants
Timothy Waits, MD, Lexington, Kentucky (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Almost all radiologists want to know how they perform in clinic but not everyone knows how to calculate their clinical productivity.2. Radiologist's clinical productivity can be easily calculated with work Relative Value Units (wRVU) based on the CPT codes of common radiology exams/procedures and compared to the benchmarks.3. Knowledge of clinical productivity measurement and management can provide insights for radiologist's value and workload to benefit both radiology practice and individual radiologists.

TABLE OF CONTENTS/OUTLINE

1. wRVU: definition, utilization, and limitsA. Define the Relative Value Unit (RVU) and differentiate the three typesB. Explain how wRVU is limited by CPT codeC. Describe utilization of wRVU by administrators and radiologist for compensation and workload.2. Lists of CPT codes and wRVUs of major exams and procedures for radiology subspecialties (body, breast, Chest/Thoracic, MSK, Neuroradiology, Nuclear medicine, Pediatrics, and Interventional radiology).3. Discuss how to evaluate clinical productivity with wRVU and benchmarks.4. Using a case-based format, apply the above information to calculate daily wRVUs to monitor productivity and workload to meet the goals.

NPMEE-22 Resonant And Diverse Teams For Patient Centered Care

Participants
Mary Rachel Nute, BS, Davie, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

· Teamwork is a component of the patient centered care curriculum. Effective teams deliver clinical care, however are also critical in reorganizing departments to adapt to modern conditions and support staff wellness· Explain teams vs working groups· Describe team resonance and strategies for building emotional intelligence (EI) of groups· Understand the origins of Agile Leadership. Describe the central tenets, agile teams vs. conventional teams, and how to apply in medicine· Describe the benefits of diversity and inclusivity in teams, and strategies for an inclusive team culture

TABLE OF CONTENTS/OUTLINE

Teamwork is key to an agile organization's response to changing care environmentsImpact on quality and safetyDemands of multidisciplinary careRedesign to refocus on patientsRSNA Patient Centered Care CurriculumDifferentiate working groups from teams. InterdependenceAccountabilityLeadershipWork productBarriers to teamwork in academic departmentsMission complexityMentalityOrganizational structureEI and team resonanceEmotional intelligence builds trust, identity and efficacyStrategies for building EI of groups. Creating norms around emotional awarenessAgile Leadership and TeamsOrigin and evolutionConventional Teams vs Agile TeamsCentral Tenets of Agile TeamsConditions favorable for Agile TeamsTeam Diversity and InclusivityBenefits of team diversityUnderstand equity vs. equalityIndividual engagement to pursue equity and inclusivityDiversity strategies overlap with Agile Leadership and Just Culture

NPMEE-23 Snowball Sampling On Social Media: Advantages And Methodology Of Using Twitter As A Survey Distribution Tool In Radiology

Participants
Andrea Harris, BA, Silver Spring, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

Snowball sampling is a statistical strategy to gather data in difficult to access populations such as alternative social groups, exclusive membership, and groups with health disparities. Aligning this technique with social media channels, such as Twitter, provide a cost-effective alternative to traditional survey distribution methods. This exhibit will provide a step-by-step explanation of the snowball sampling method, including: IRB approval, selection of initial respondents, key messaging points, troubleshooting steps, and collection of results. Review of current medical literature on traditional survey response vs. social media-based snowball sampling will provide context for the value of this method. We also present a case study on clinician ordering preferences for CT in COVID-19 management.

TABLE OF CONTENTS/OUTLINE

Introduction to snowball sampling and respondent-driving samplingMethods for survey recruitment on social media, including selection of initial respondentsDemographics of Twitter users and respondents, including specialty and geographyRespondent results from case study on ordering of CT for COVID-19 managementBenefits and limitations of Twitter as a social media platform for snowball samplingComparison to alternative methods of survey distributionSummary and conclusions

NPMEE-24 Webinars For Continuous Medical Education During COVID-19: A Cross-sectional Survey Of Attendees' Perspectives

Participants
Kiran Hilal SR, MBBS, Karachi, Pakistan (*Presenter*) Nothing to Disclose

TEACHING POINTS

To assessed the accessibility, adaptability, and convenience of the medical profession through virtual learning.how effective was

virtual learning during the COVID-19 pandemic among medical professionals in Pakistan.To assess the major drawbacks of virtual learning and there solutions.Local survey to a new era of virtual learning how we can make it better.

TABLE OF CONTENTS/OUTLINE

Total 12 webinar-based CME sessions were conducted from the period between June to December 2020. The attendees of the online webinars consisted of radiologist/non-radiologist physician /radiology technicians. At the end of webinar feedback survey responses were recorded through online polling.The purpose of gathering feedback from the participants of CME activities was to gain insights on the acceptance for conducting such activities online, and how likely they are willing to participate in these activities in future.questions were designed in such a way to gather responses on non-traditional aspects affecting the life of medical professionals during the COVID 19 pandemic and how online education has gained popularity and feasibility in their new routine practices

NPMEE-25   An Interactive Web-based Radiology Career Awareness Program Design For School ; Undergraduate Career Labs.

Participants
ANANYA SINGH, Land OLakes, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

The exhibit:1. Systematically explains, design of proposed interactive web-based tool for promoting radiology awareness in school/college career lab programs and its fusion with existing tools2. Provides valuable take-away points for radiology professionals in various roles; parents, educators, students, health policy/practice professionals & leaders

TABLE OF CONTENTS/OUTLINE

1. Introduction of existing tools to determine career cluster focus in school & college career labs & limitations.2. Proposed introductory healthcare & radiology modules & fun-quiz at elementary /middle school level:a. Module 2a: Great American teach-in programs: Proposed web-based tool to enhance parental participation from radiology profession b. Module 2b: Introduction to radiology career hybrids with other profession & fun-quiz: Career fusion with Army, community health, business, global health3. Raising awareness in high school/college:a. Module-specific design for understanding common diseases, radiology & global healthcare. b. Resolving new career conflicts in high school: dedicated module-based interactive education of hybrid radiology career fusions: biostatistics, government & policy, community service, Mathematics, genetics/molecular biology, law, business c. Introduction to clinical radiology, radiology physics, workflow, technologist education, research, policy/practice d. Module integration with career labs & certification: Likerts psychometric scale, pre & post test performance on 5 point scale, didactic quiz

NPMEE-26   A Virtual Reality: Developing A Mock Virtual Interview Program For Residency Applicants

Participants
Jesse Conyers, MD, Atlanta, Georgia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Interviews are a key component of the residency application process. 2. Practice virtual interviews can help applicants prepare for the unique social and technical challenges for residency interviews. 3. Implementing an international, free mock interview system can increase residency applicants' confidence with video conference interviewing and help applicants develop connections in radiology.

TABLE OF CONTENTS/OUTLINE

BackgroundDesign and implementation:Recruiting volunteer interviewersScheduling interview time slots based on interviewer availabilityDeveloping an online scheduling system and booking pageLinking online appointments to video conference softwareApplicant sign-up processCommunicationFeedback using pre and post-interview surveysConclusion

NPMEE-27   Communication Tools Returning Our Focus To Patient Centered Care: Principles, Blind-spots, Structured Communication And Checklists

Participants
Mary Rachel Nute, BS, Davie, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

· Discuss the importance of communication. Recognize it as a component of the RSNA patient centered care curriculum, as well as a leading source of error leading to medical harm· Understand our strengths and weaknesses communicating as radiologists· Develop proficiency in two commonly used tools for structured communication (SBAR and AIDET)· Consider the use of checklists in medicine, and identify opportunities for use in Radiology

TABLE OF CONTENTS/OUTLINE

· Effective and evolved communication is a central tenet of Patient Centered Care, however cultural and institutional obstacles exist· Conveyance vs. Convergence as arenas of communication· Our stakeholders and the value communication adds to our practice· Ineffective communication is the leading cause of medical error? Four types of communication failures Examples of litigation, legislation and regulations born from radiology communication failures· Seven principles for effective communication· Two standardized tools for structured communication to know? AIDET is widely used for all types of patient encounters and favored by hospital administrators? SBAR, adapted from workflow on nuclear submarines, organizes critical time-sensitive situational communication· Checklists are innovative tools to bring an individual or group to common focus? Combats human tendency to drift from best practices, promoting efficiency and safety? Five characteristics of a good checklist? Example checklists for use in your practice and a group exercise for trainee or professional development

NPMEE-28   Elements Of Style For Radiologists - Grammar, Syntax, And Style Tips For A Well-written Radiology Report

Participants
Hailey Choi, MD, San Francisco, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

By viewing this educational exhibit, the reader will be able to: Recognize the importance of effective writing in producing radiology reports, in the era of increasing health care transparencySuccessfully communicate salient points for a radiology report in simple English languageAvoid common mistakes in grammar and syntax

TABLE OF CONTENTS/OUTLINE

BackgroundIncreasing attention on radiology reports with recent drive for information un-blocking (21st Century Cures Act) A well-written, error-free radiology report provides vital information for patients and providers, increases radiologist's credibility, and showcases his/her expertiseGrammar and syntaxSubject-verb agreementDouble negativesModifying gerunds ("improved diminishing")Split infinitivesStyle and compositionUse active voice: put topic as the subject and action as the verbKeep to one tensePut statements in positive formClarityAim for precisionWord choiceBrevity: write short information-rich sentencesEmphasize what is importantErrors to avoidRun-on sentenceWordiness and inflation (constitutes, represents, exists, serves, facilitates)JargonDangling modifier"T" (tea) party (unclear ineffective pronouns, this, that, these, those, there)AbbreviationsConclusions in the findings or repetition of findings in the impressionCase examples

NPMEE-29   Incorporating Diagnostic Imaging Into Undergraduate Medical Education: A Guide For Educators.

Awards
Cum Laude

Participants
Francisco Garrido Cisterna, MD, Santiago, Chile (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Integration is the organization of teaching matter to interrelate or unify subjects frequently taught in separate academic courses or departments. 2. There are several strategies for integrating radiology into undergraduate curricula, from isolated courses to transdisciplinary programs. 3. The incorporation of radiology in the undergraduate allows to show its role as a member of the interprofessional health team. 4. The learning objectives to be developed in undergraduate medical training include the indication of imaging studies according to the clinical scenario and the recognition of typical patterns of frequent diseases.

TABLE OF CONTENTS/OUTLINE

1. Introduction 1.1. Current status 1.2. Why radiology is important in undergraduate medical education?2. Integration strategies in the curriculum 2.1. Harden's steps on the integration ladder 2.2. Curriculum integration in radiology3. What to teach? 3.1. Learning objectives and the local and national needs assessments 3.2. Radiology in the international outcome frameworks for undergraduate medical education 3.3. Recommendations from leading scientific societies in radiology4. How to teach? 4.1. Traditional methodologies 4.2. Using technology: mobile apps and simulated workstations5. How to assess?6. Summary

NPMEE-3   The Radiology Patient Experience: Key Concepts And Strategies To Maximize Success

Awards
Certificate of Merit

Participants
Miltiadis Tembelis, Mineola, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. The patient experience has become an increasingly recognized and important component of quality measures.2. It is important to understand and appreciate what patients may experience during their time in the radiology department and interventional radiology suite.3. Embracing key concepts involving the patient experience can help radiologists build stronger relationships with patients, provide excellent care, and be committed to maximizing patient centered care, patient engagement, and patient satisfaction.4. Effective communication, interest in the patient's agenda, empathy, and patient involvement in care are central to the patient experience and are often included on questionnaires to patients regarding their experience.

TABLE OF CONTENTS/OUTLINE

-Define "the patient experience"-Describe how this relates to diagnostic and interventional radiology-Share how the patient experience is evaluated-Highlight key concepts regarding the patient experience and holistic care from the available medical literature, specific to diagnostic and interventional radiology-Suggest strategies for and directions of future discussions, engagements, and innovations in the patient experience

NPMEE-30   Ergonomics In The Radiology Workplace

Participants
Anand Rajan, MD, Columbus, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Occupational repetitive stress injuries are very common and can be debilitating for a Radiologist. Most radiologists spend more than 8 hours per day at the computer and are at increased risk for repetitive stress injuries.2. Repetitive stress injuries are occupational overuse syndromes that result from repetitive motions and sustained awkward movements. These include carpal tunnel syndrome, ulnar neuritis, upper extremity tenosynovitis, gluteal tendinitis, neck and back pain.3. Optimizing your radiology workstation will reduce the risk of repetitive stress injuries.4. Radiology workplace ergonomics continues to be an area of interest for Radiologists. Familiarity with the latest literature and recommendations can improve your practice.

TABLE OF CONTENTS/OUTLINE

1. Background - Review current literature regarding prevalence of musculoskeletal injuries affecting Radiologists.2. Review the most common occupational repetitive stress injuries affecting radiologists.3. Recommendations for Desk and Seating - How to make adjustments for optimal comfort at the workstation. Includes basic tutorial on how to adjust an ergonomic chair (knobology).4. Recommendations for Monitor Displays - Setup options for efficiency, neck comfort, and reduce eye strain.5. Recommendations for Office Equipment - Examples of commonly available office equipment that you are using now and how to use them ergonomically.6.

Recommendations on when to take breaks, standing, and looking away from the monitor.7. Summary of Recommendations8. References

NPMEE-32   Why Has AI Not Replaced Radiologists?

Participants
Anurima Patra, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

TEACHING POINTS

Using case study examples from our AI program, we will drive the following teaching points•AI is at the peak of inflated expectations•Major barriers for clinical grade AI include lack of large datasets, quality gaps in public datasets and the 'black-box' nature of AI methods•Imaging AI has to follow the paradigm "first, do no harm". Bias elimination is critical to avoid perpetuation of existing disparities and inspire trust in stakeholders•Domain expertise of radiologists is essential to define use cases, data curation and annotation, interpretation of results and lifecycle management of AI models•Although imaging AI has strong business potential, a cascade of payment reforms are needed for commercially viable AI solutions

TABLE OF CONTENTS/OUTLINE

•Hype around imaging AI: Doomsday predictions from AI experts•Impact of ImageNet on computer vision research•Complexity of imaging vs tasks in ImageNet•AI development pipeline?Case study: AI for automated volumetric pancreas segmentation on CT•Barriers for clinical grade AI?Lack of annotated datasets•Case study: Novel approaches for creating annotated datasets?Quality gaps in imaging datasets on the Cancer Imaging Archive (TCIA) •Case study: Pancreas cancer imaging datasets on TCIA ?Trust & Transparency: Foundations for imaging AI?Unique risks of bias in imaging AI•Measures to mitigate unintended consequences•Business of imaging AI? Patents, mergers & acquisitions, investments? Challenges of current payment models? Blueprint of reforms to promote imaging AI on a commercial scale

NPMEE-33   From Peer Review To Peer Learning: Lessons Learned From Successful Implementation

Participants
James H. Birkholz, MD, Lebanon, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Provide examples of obstacles encountered during the creation of a Peer to Peer Learning process (P2PL) at our institution. 2) Discuss specific solutions utilized in the successful creation of our P2PL, including existing PACS options, cloud based PACS case anonymisation and survey creation, virtual meetings. 3) Discussion of our current P2PL process flow, including the case dissemination and group review.

TABLE OF CONTENTS/OUTLINE

1) Obstacles Encountered During Creation of a P2P Process 2) Case Collection & Anonymisation 3) Survey Creation & Case Dissemination 4) Case Review & Discussion 5) Departmental & Divisional Support (Continuing Medical Education credit & Funding)

NPMEE-34   Community-Based Participatory Research (CBPR): A Practical Guide For Radiologists

Awards
Identified for RadioGraphics

Participants
Arissa Milton, BS, Madison, Wisconsin (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Traditional research approaches have neither engaged the interests of communities nor addressed health disparities adequately.- CBPR:o Collaborative process that recognizes unique strengths and equitably involves all partners in the research process.o Begins with a research topic important to the communityo Combines civic engagement with expertise from scientists and the community to catalyze social and policy change to improve health.

TABLE OF CONTENTS/OUTLINE

1. Rationale for CBPR approacha. Gaps in current researchb. History of abuse and mistrust of researchersc. Decreased rate of knowledge translation between research activities and community adoption of evidence-based practices2. CBPR Guidea. Basicsi. Definitionii. Principlesiii. Exemplarsb. Establish a Partnershipi. Find community collaboratorsii. Build and maintain relationshipsiii. Utilize strengths and resourcesc. Identify a Questioni. PICO formatii. Based on importance/relevance to the communityd. Execute Research with Collaboratorse. Translate Resultsi. Collaborative nature creates a more holistic and authentic framework for translationii. Advocate for social change benefiting the communityiii. Inform evidence-based interventions3. Applications for Radiologya. Cancer Screeningb. Barriers to Imaging Technologiesc. Engagement and Recruitment of Participants

NPMEE-35   Establishing An Institutional Women In Radiology Group: A Toolkit From The American Association For Women In Radiology

Awards
Certificate of Merit

Participants
Sarah Kamel, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

Despite increasing representation in medical schools and surgical specialties, recruitment of women into radiology has been stagnant. Furthermore, women in academic radiology are less likely to be promoted to full professorship or leadership roles. A robust support system from women in radiology groups has been shown to produce numerous benefits: develop mentorship, guide career trajectory, improve camaraderie and increase awareness of gender-specific issues, to name a few. The aim of this presentation is to describe a pathway to establishing a women in radiology group at the institution level with the goal of promoting the advancement of women in radiology. Teaching points: 1) Women in radiology groups are necessary to foster mentorship, promote

leadership, recruitment, and advancement of women in radiology.2) Anyone at any stage of their career can accomplish creation of a women in radiology group using the framework and tools provided here. 3) Formally structured groups with departmental support are strongly encouraged to maintain the success, outreach, and longevity of the group.

TABLE OF CONTENTS/OUTLINE

1) Evidence in support of women in radiology groups and the potential benefits. 2) Pathway to establishing a women in radiology group: a) determine level of collaboration desired. b) initial planning and member recruitment. c) determining group goals and structure. d) acquiring institutional support. e) barriers to implementation. 3) Recommended resources for a women in radiology group. 4) Data regarding experiences of others.

NPMEE-36   A Review Of Diversity In Radiology

Participants
Jerome Watts JR, Silver Spring, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

A lack of diversity exists in the field of Radiology. Ongoing studies are addressing this disparity in a variety of ways.

TABLE OF CONTENTS/OUTLINE

We reviewed the lack of diversity in radiology in the United States and how future studies and initiatives can begin to address this gap. We used a review of the literature targeting articles addressing five themes: 1) recruitment, 2) exposure 3) policy and regulation, 4) levels of diversity, and 5) trainee and faculty perception of diversity. We found that this lack of diversity is multifactorial, including biases within policies and committees at medical institutions, a lack of role models and early exposure to radiology, and missed opportunities to secure the interest of underrepresented in medicine (URM) in radiology. We summarized recommendations from eight studies that obtained the insight of specific populations, such as medical students, women, and URM faculty on matters of diversity as well as factors that influence their specialty choice via surveys. However, not many studies surveyed URM trainees on these matters. To address this gap, future studies may want to use surveys in collaboration with medical institutions with diverse pools of students, such as historically black colleges/universities, to inquire about their perspectives and use this to improve recruitment and retention of said students.

NPMEE-37   Technological Tools In Neuroradiology Online Education. How To Engage Medical Students For Online Neuroradiology Classes?

Participants
Juliana Duarte, Porto Alegre, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

-The improvement action offered aims to present practical elements for the use of resources from the virtual learning environment in neuroradiology made available by the University to teachers.-Use of free technological tools aims at greater interaction with students.

TABLE OF CONTENTS/OUTLINE

The teaching material with links to videos explaining all the tools was available since beginning of training. Hyperlinks in presentation files are great resources. The training structure included the presentation of the features of the Academic Moodle, other web conferencing rooms such as Teams, Elos and GMeet and technological tools based on the practical experience of the teacher responsible for the training. The shared technological tools included: Padlet, Kahoot, Mentimeter, Screencastify, Mural, Google Drive, WhatsApp, Telegram and Plickers. Moodle resources are the functionalities that the teacher can make available to the student. The main ones are: Archive; Book; Page; Folder; Label; URL. Moodle activities are the functionalities that promote interaction and interactivity with the student through the delivery and performance of activities. The main ones are: Daily; Choice; Forum; Glossary; Evaluation Laboratory; Research; Quiz; Assignment; and web conferencing rooms. It is possible to chain them together, that is, to perform a task the student must complete another one beforehand. In this way the student follows a path in his learning process. Final remarks.

NPMEE-38   Lessons Learned: What I Learned In Training That I Wish I Had Paid Attention To.

Participants
Krishna Mundada, MBBS,MBBS, mumbai, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

This exhibit categorizes and highlights the errors I wish I should have paid attention to in my training and possible solutions to these errors.Online portals for reports collection resulted in radiology reports being scrutinized by patients and relatives. This poses a challenge when radiologists are cross-questioned in a setting involving incomplete patient knowledge. This exhibit introduces steps to face such dilemmas and highlights the relevant soft skills.Updating one's skills and knowledge using an understanding of relevant research, to be more up-to-date is important in the current pandemic.A spectrum of disorders associated with the infection have emerged. It is important to have knowledge of both statistically and insignificant associations, for knowing etiology and mitigating diagnostic dilemmas.COVID-19 has overburdened many specialties, including radiology. This exhibit discusses ways to alleviate workplace frustration and promote radiology wellness.

TABLE OF CONTENTS/OUTLINE

Evidence Based PracticeSystem Based PracticePractice Based LearningLearning Conceptual Evidence Pyramids and its approachApplications of Evidence Based Practice during COVID 19Patient Centric RadiologyPatient communicationEducation of Patient and FamilyManagement of Patient AnxietyAssuring patients of interdepartmental communicationErrors in Radio-DiagnosisTypes of ErrorsCause of ErrorsPotential solutions to errors.Radiologist BurnoutBurnout during residencyCauses of BurnoutWays to mitigate burnout

NPMEE-39   Real-time Streaming Virtual Reality Video Feeds For Socially Distanced Radiology Education

Participants

Peter J. Haar, MD, PhD, Richmond, Virginia (*Presenter*) Nothing to Disclose

TEACHING POINTS

Real-time streaming VR video feeds present panoramic, stereoscopic visual and auditory information that is experienced with a head-mounted display to provide a vivid and immersive first-person learning experience, as the instruction is taking place. The teaching points of this exhibit include the following: first, to provide an overview of VR and streaming video feeds; second, to describe methods of creating remote streaming VR learning experiences; and third, to explore potential benefits of real-time VR feeds compared to traditional methods of instruction.

TABLE OF CONTENTS/OUTLINE

1) Overview of the vivid, three-dimensional simulated environment of VR. 2) Description of the advantages and limitations of first-person perspective real-time VR video feeds. 3) Equipment and resources necessary to develop real-time VR training experiences. 4) Designing the experience, room and camera set-up, and technical issues. 5) Potential benefits of streaming VR feeds in radiology education. 6) Early feedback from residents on the effectiveness of real-time streaming VR educational experiences.

NPMEE-4   Are You Ready!! Finance Basics For Trainees For Their First Job

Awards
Certificate of Merit

Participants
Achint K. Singh, MD, San Antonio, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Physicians get extensive training in their respective medical field but there is no training in the finances - To learn basics of finances related to debt management, budgeting and investing- To learn the core principles of investing

TABLE OF CONTENTS/OUTLINE

This presentation will be organized in the following mannerA) Debt ManagementB) BudgetingC) Investing- Basics of investing- Retirement accounts- Taxable accounts

NPMEE-41   Programming Knowledge For The Radiology Resident: A Tool To Improve The Workflow

Participants
Henrique Lino, MD, Sau Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

Radiology and computers are intrinsically related. The recognition of basic patterns of programming logic may help to develop scripts and simple software to help on regular tasks. Script languages as AutoHotkey can prototype custom applications helping to develop structured reports, macros, and text expansion.

TABLE OF CONTENTS/OUTLINE

Introduction: Computers are now an intrinsic tool for the radiologist. Understand programming help to improve its use, save time and organize the workflow. Objectives: (1) to review the use of programming in radiology. (2) to review sample codes in AutoHotkey to help with radiology workflow and structured reports. Methods: We provide same samples and comment our codes to work as reference for radiology residents. Discussion: The base syntax of programming languages is easy to learn and with some hours the resident may develop applications to save larger amounts of time. Dictionary of useful terms in programming: basic terms to understand reference texts. Conclusion: An organized and efficient workflow as well time saving features are always a benefit for the resident.

NPMEE-42   Equity Diversity And Inclusion In Canadian Radiology

Awards
Certificate of Merit

Participants
Kiana Lebel, Montreal, Quebec (*Presenter*) Nothing to Disclose

TEACHING POINTS

Diversity in medicine is associated with numerous benefits for the health care system and patients Women are underrepresented in Canadian Radiology There is no data regarding ethnic diversity or indigenous representation in Canadian Radiology Actionable strategies exists to promote and increase diversity in Canadian Radiology Leadership commitment is required to increase diversity in Canadian Radiology, with the ultimate goal of improving patient care

TABLE OF CONTENTS/OUTLINE

1.Value of diversity in medicine and Radiology Demonstrated benefits of diversity in medicine and industry, including innovation, empathy and improved patient outcomes 2. Gender diversity in Canadian Radiology Gender disparity is decreasing in medicine but persistent in Canadian RadiologyPaucity of women in Canadian Radiology leadership Paucity of women in Canadian Radiology academia Gender pay gap in Canadian radiology3. Ethnic diversity in Canadian Radiology2015 Canadian Truth and Reconciliation Commission report called for increased indigenous healthcare workers However, there is currently no data on ethnic diversity or indigenous representation in Canadian Radiology 4. Strategies to improve diversity in Canadian Radiology: National/International level Institutional levelDepartmental/Practice levelIndividual level

NPMEE-43   Clinical Oncology Module For The ESTRO Core Curriculum

Participants
Yannick Eller, MD, Bern, Switzerland (*Presenter*) Nothing to Disclose

TEACHING POINTS

B: Clinical oncologists are physicians with the competencies to manage cancer patients through the entire disease pathway combining the competencies of radiation and medical oncologists. The 4th edition of the European Society for Radiotherapy and Oncology Core Curriculum for Radiation Oncology/Radiotherapy has received wide support by the clinical oncology community. The aim was to develop a clinical oncology module that could be combined with the ESTRO curriculum to enable clinical oncology trainees to follow a single curriculum.M: A range of stakeholders including National Society representatives, an oncologist from a low- middleincome country, and a recently appointed specialist, developed and commented on iterations of the curriculum. Further modifications were made by the ESTRO Education Council.

TABLE OF CONTENTS/OUTLINE

R: The module is based on the CanMEDS 2015 framework and identifies 20 enabling competencies in the Medical Expert role that are required in addition to the ESTRO curriculum for the training of clinical oncologists. Recommendations are made for the levels of Entrustable Professional Activities (EPAs) to be attained by the end of training.D: The Clinical Oncology module, when combined with the ESTRO curriculum, covers the entire cancer pathway rather than being modality specific. It is hoped it will aid in the development of comparable standards of training in clinical oncology across Europe and may also have utility in low- and middleincome countries as well as providing a single curriculum for trainees.

NPMEE-44 Entrepreneurship 101: A Primer To Start-up's And New Ventures

Participants
Aman Saini, DO, Phoenix, Arizona (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Radiologists and interventional radiologists are increasingly becoming involved in new ventures and start-up's.2. Knowledge of the basics of establishing a team, patent licensing, business plan, seed round and Series A funding is essential for a successful start-up.3. Creating an effective pitch deck is essential to securing funding and mentorship early on.4. Everything begins and ends with the patent; what a great patent should include.

TABLE OF CONTENTS/OUTLINE

Business plan 1. Executive summary2. Company and business model—vision, mission, structure. 3. Market conditions-industry analysis, definition of target market, trends, competitive analysis (SWOT)4. Product/service explanation—current problem, proposed product/solution, competitive advantage, intellectual property. 5. Management and operations roles—well rounded team, diverse backgrounds, strengths, and experience. Good mentorship. 6. Marketing and sales—marketing, sales strategy, growth, distribution7. Financial plan with costs (fixed and variable), funding, revenue projections8. Funding: seed/angel investing, accelerator, SBA loan, crowdfunding, venture capital 9. Legal structure—sole proprietorship, partnership, LLC, corporation Pitch Deck: Selling your idea and company to potential investors.

NPMEE-45 Beyond Black And White: Launching A Multitiered Equity, Diversity, And Inclusion Initiative At A Large Academic Radiology Department

Participants
Ramesh S. Iyer, MD, Sammamish, Washington (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Disparities and inequities in healthcare are pervasive.2. A multi-pronged departmental approach is necessary to address gaps in equity and diversity in radiology.3. Coordinating lectures by subject experts is integral to such an initiative, but is only one component.4. Harmonizing with broader institutional efforts is beneficial.5. Regularly "spotlighting" non-physician personnel at faculty meetings may foster a culture of inclusivity and flatten hierarchies.6. Outreach programs at local schools may generate interest in science and technology and foster mentorship opportunities between radiologists and young people in the community.

TABLE OF CONTENTS/OUTLINE

1. Review our departmental experience in creating an EDI committee comprised of four subcommittees focused on education, recruitment, recognition, and building a pipeline.2. Describe efforts to establish an educational curriculum for physicians and staff that includes both invited speakers and online EDI modules.3. Convey our experience with recruiting underrepresented minority students, trainees, faculty, and staff to our department.4. List strategies for ensuring a less biased candidate selection and interview process for recruitment efforts.5. Describe how structured mentoring initiatives can improve faculty retention including EDI faculty.6. Share methods of highlighting EDI efforts of radiology team members.7. Highlight community outreach efforts that introduce young people to radiology and foster interest in science and technology.

NPMEE-5 Injury Prevention: Ergonomic Considerations For Mammography Technologists

Participants
Dana Smetherman, MD, MPH, New Orleans, Louisiana (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Widespread adoption of digital mammography has resulted in changes in workload and job activities of mammography technologists, including shorter appointments and higher exam volumes.2. As a result, mammography technologists may spend more of their work day engaged in repetitive movements of patient positioning and image acquisition, with less variability in work activities than in the past.3. This evolution could put mammography technologists at risk for repetitive stress and other overuse injuries.4. Department leadership partnered with physical therapy to conduct an ergonomic assessment of the breast imaging department.5. Short and long term measures were implemented to improve technologist body mechanics and work environment.

TABLE OF CONTENTS/OUTLINE

I. Review of job dutiesII. Assessment of physical environmentIII. Risk factor identification (OSHA W-1 Basic Screening Tool)IV. RULA Employee Worksheet Assessment Tool scoreV. Mammographic positioningA. PostureB. Height discrepancy between technologist and patientVI. Placement of other devicesA. Wall paddle storage unitsB. PrintersC. TelephonesD. Computer monitorsE. WorkstationsVII. Other considerationsA. Anti-fatigue floor mats B. Non-adjustable workstation heightsC. Overmount push buttons for exposure without foot pedalsVIII. Review of mitigation measures to reduce potential for musculoskeletal injury

NPMEE-6　Delivering Informed And Inclusive Imaging Care To Transgender Patients

Awards
Identified for RadioGraphics
Magna Cum Laude

Participants
Crysta Iv Kyrazis, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Transgender persons experience a high prevalence of adverse health outcomes, with 28% postponing necessary medical care due to fears of discrimination.2. Educating healthcare providers about terminology and disparities faced by transgender people has been shown to improve patient experience and comfort with seeking care.3. Radiologists are important providers of healthcare and should be aware of these issues, as well as relevant imaging features.

TABLE OF CONTENTS/OUTLINE

1. Introduction a. Terminology b. Appropriate use of language: Correct use of names and pronouns, avoiding gendered assumptions, defining offensive or intrusive language2. Barriers to healthcare among transgender individuals a. Stigmatization and discrimination b. Access to healthcare and insurance c. Changes to screening protocols in primary care3. Improving inclusivity in a radiology department (as supported by the ACR) a. Etiquette b. Provider education (e.g., Respectful imaging acquisition, trauma informed approach to care) c. Environment (e.g., "Women's" imaging, all-gender restrooms and dressing rooms, gowns) d. Electronic medical record: Gendered language in documentation e. Institutional4. Imaging review of gender affirming surgeries, particularly genital reconstruction a. Pre-operative surgical planning b. Post-operative appearance and complications5. Conclusion

NPMEE-7　Transition From Peer Review To Peer Learning: Lessons Learned.

Participants
Sirus Saeedipour, DO, Olathe, Kansas (*Presenter*) Nothing to Disclose

TEACHING POINTS

One of the most common causes of radiology misses is an error in perceptionPeer learning embraces errors as opportunities to increase engagement and educationChallenges are expected when transitioning from traditional peer review to peer learning, which present as opportunities for improvement

TABLE OF CONTENTS/OUTLINE

MOTIVATIONLimitations of Peer ReviewHistorically, a system to meet hospital and regulatory requirementsInconsistent selection of cases with inherent problems (e.g., low inter-reader reliability, skewed miss rates due to disease prevalence, etc)Environment of defensiveness and feelings of being "singled out"Benefits of Peer LearningFocus on the group, not the individualHelps identify system issuesLearning for all (e.g., inclusion of residents during conference)No scoring systemCases selected based on value-add that will improve diagnostic accuracySatisfies hospital licensure and reg. requirementsTRANSITIONING TO PEER LEARNINGProcessEach division accumulates cases in rolling 1-4 month periodsIdeal learning opportunities selected by section QI liaison who:Reviews submitted case with reporting radiologist; Selects cases for peer learning conferencePeer Learning Conference LayoutLearning OpportunitiesBiasClassificationsPerceptionInterpretationTechnical FactorsReportingCommunicatingRadiologist RecommendationsGreat Calls ChallengesLegal considerationsChallenges with case miningAccountability by each sectionLessons learned with example cases and classification

NPMEE-8　Equality, Equity, Disparity: Why Radiology Community Should Care?

Participants
Kheng L. Lim, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is to expose the radiology community to the research done in the social sciences highlighting the consequences of extreme disparity and the reasons we should care. We will take a closer look through the lens of social science literature and present research-based evidence. This exhibit will explore the issue of extreme inequality and disparity and how these factors affect our health and wellbeing.

TABLE OF CONTENTS/OUTLINE

Explain the concept of equality and equity. Explore the social determinants of health. One of the five domains is access to quality healthcare. Present the reasons why we should promote equity. Review the literature showing correlation of violent crime and poverty, and correlation of increased risky behavior with perceived inequality. Illustrate the "sense of fairness" through the lens of primate research. Present facts of unequal rise in the household incomes of lower class, middle class, and upper class over the past five decades in the USA. Explain the Gini coefficient as a measure of inequality in a distribution. Show the linear correlation of income inequality and index of health and social problems among developed countries. Compare age-adjusted mortality in poor versus rich zip codes in the USA. Present the "Great Gatsby curve" which counters the ideals of the American dream. Reveal the unconscious biases we may subject ourselves to as we climb the rungs of the social ladder.

NPMEE-9　How We Got Here: A Review Of Anti-Black Discrimination And Inequities In Radiology

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Julia Goldberg, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is to: 1. Review a timeline of systemic anti-Black discrimination in medicine, focusing on biased practices in diagnostic radiology during its inception in the early 1900s. 2. Recognize pioneering Black radiologists who advanced scholarship,

patient care, and diversity within medicine and radiology. 3. Acknowledge where we are as a field today with regards to workforce diversity and racial healthcare disparities. 4. Identify opportunities for anti-racism work within the field of radiology today.

TABLE OF CONTENTS/OUTLINE

1. Background of institutional racism within the field of medicine in the late 19th to early 20th centuries. 2. Early radiology organizations' involvement with structural discrimination. 3. Pioneering Black radiologists and their work to advance the field of radiology. 4. Effects of discrimination on radiology-delivered patient care and healthcare disparities. 5. Current challenges and opportunities to address racial bias within radiology.

Sub-Events

CHEE-1   Multimodality Imaging Of Pathologic Conditions Involving Extrapleural And Paravertebral Compartments

Participants
Daniel Rodriguez-Vargas, MD, Huelva, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

Recognition of each mediastinal compartment and its contents is important since facilitates differential diagnosis on imaging examinations and avoids misdiagnosis of normal structures as pathologic conditions. Furthermore, recognition of the extrapleural space, which is often overlooked on cross-sectional imaging, may also avoid inadequate management of certain entities that might appear herein. After viewing this presentation, participants will be able to recognize boundaries between prevascular, visceral, paravertebral and extrapleural compartments and their normal contents, following the latest ITMIG classification and identify post-traumatic, neoplastic and miscellaneous conditions in extrapleural and paravertebral spaces.

TABLE OF CONTENTS/OUTLINE

1.CT images and anatomic diagrams of mediastinal and extrapleural spaces and their contents (diagrams remain original design from the authors) 2.*Review of pathologic conditions 2.1. Extrapleural hematoma 2.2. Ewing and Ewing-like sarcomas 2.3. Neurogenic tumors 2.3.1. NST: schwannoma, neurofibroma, plexiform neurofibroma and MPNST 2.3.2. Neurogenic neoplasms of the autonomic ganglia 2.4. Extranodal lymphoma 2.5. Solitary fibrous tumor 2.6. Extramedullary hematopoiesis. *Each condition exposed is accompanied by at least one radiologic case and explanatory diagrams whose design remains original work from the authors, noting the most important epidemiologic and radiologic features within a table entitled "red flags" 3. Conclusion 4. Acknowledgement

CHEE-10   AEF And/or CPFE? That Is The Question

Participants
Carlos Suevos, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

• To clarify the multiple synonyms the entity Airspace Enlargement with Fibrosis (AEF) has been given lately in order to differentiate it from the Combined Pulmonary Fibrosis and Emphysema (CPFE) syndrome• To learn the pathophysiology underlying AEF and CPFE, so as to understand their radiological translation in Chest Computed Tomography scans• To recognize, when possible, the distinctive radiological characteristics among AEF and CPFE in order to ensure a correct treatment and detect complications in follow-up in the latter

TABLE OF CONTENTS/OUTLINE

1. Nomenclature: confusing terminology. 2. Pathology. 3. CT Findings. 4. Differential Diagnoses. 5. Conclusion

CHEE-102   Dynamic Chest X-ray Using A Flat-panel Detector System: An Update

Participants
Takuya Hino, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Dynamic X-ray (DXR) with a flat-panel detector has unique features such as high temporal resolution, simple examination in standing position. DXR can provide sequential images and can help to represent or identify continuous change of lung and thorax. Previous studies have reported that DXR has the efficacy in visualizing the temporal change of translucency of lung fields. This technique is also applied to pulmonary ventilation and circulation. Recently, dynamic motion of thorax, diaphragm and lung visualized by DXR are also drawing attention. This exhibition shows the update of DXR with the latest findings, including lung field planimetry, pulmonary circulation, and motion analysis.

TABLE OF CONTENTS/OUTLINE

1. Dynamic diaphragm motion by DXR2. Ventilation map by DXR3. Perfusion map by DXR4. Projected lung area (PLA) and its temporal change by DXR5. Vector field dynamic X-ray (VF-DXR) in bilateral lung field

CHEE-104   Posterior Mediastinum Diagnostic Approach

Participants
Valentina Escandar, MD, Santiago, Chile (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Review Mediastinal Compartments Division and posterior mediastinal relevant anatomy.2. Recognize important features and signs in Chest X-Ray that indicates we are dealing with a posterior mediastinal mass.3. Approach to the posterior mediastinal lesions based on their anatomic origin.4. Identify the main imaging features of posterior mediastinal lesions and relationship with neighboring structures that can provide a definite diagnostic information.

TABLE OF CONTENTS/OUTLINE

1. Introduction. a. International Thymic Malignancy Interest Group (ITMIG) classification. 2. Important features and signs in Chest X-Rays for localizing posterior mediastinal lesions. 3. Schematic classification of the posterior mediastinal lesions according to their anatomic origin.4. Main imaging features and helpful diagnostic clues for common and uncommon posterior mediastinal masses.5. Conclusions.

CHEE-105   A Thoracic Radiologist's Guide To Identification And Management Of Mammary Findings On Chest Ct

Participants
Toma Omofoye, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

To understand: 1. The appearance of characterizable benign and malignant mammary findings on Chest CT 2. Chest CT appearances and evolution of the post-treatment breast 3. Categorize management recommendations for thoracic radiologists encountering CT breast abnormalities.

TABLE OF CONTENTS/OUTLINE

Based on cases at a tertiary oncologic referral center, a review of CT findings with multimodality correlation (mammography/ultrasound/MRI/pathology). Including: • Benign appearances (cystic disease, oil cysts, macro vs microcalcification, fibroadenomas) • Malignant appearances (primary breast cancer, invasive ductal, metastases, etc) • Post cosmetic augmentation (breast implants/expanders variants) - normal/abnormal evolution (ruptures, anaplastic lymphoma, silicone granulomatosis) • Post breast cancer surgery (resection variations) • Autologous tissue flap variants evolution/complications (e.g. fat necrosis, recurrence) • Other procedures (localization devices, breast management options, direct silicone injections, etc) • Inflammatory breast cancer and mimics (infection, radiation, fibromatosis) • Age related breast density, HRT, systemic disease. • Indeterminate findings • Specific best recommendations for further imaging/management • Reporting tips to improve breast imaging correlation • Role of the thoracic radiologist

CHEE-107   High Attenuation Pulmonary Opacities And Calcifications: A Case-based Review

Participants
Murilo Peixoto, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

There are a number of clinical scenarios that can lead to the appearance of high-attenuation pulmonary opacities and calcifications, most of which associated with the deposition of calcium, such as in infectious and non-infectious granulomatous conditions; or other high attenuation substances from medical treatment or occupational and recreational exposure like amiodarone, iron, mercury, barium and talc.Though there are distinctive clinical informations that can help differentiate these conditions, the patient's past medical data and history of exposure to substances are not always readily available. The aim of this exhibit is to explore the conditions that can present with high-attenuation pulmonary opacities and calcifications on chest computed tomography with emphasis on their distinctive imaging features through a case-based review.

TABLE OF CONTENTS/OUTLINE

1. Series of cases illustrating conditions that feature high-attenuation pulmonary opacities and calcifications on chest CT.2. Discussion of their distinctive characteristics, which can be helpful to differentiate these conditions when clinical information is not available, and provide a rationale for proposing possible differential diagnoses.3. Take-home messages.4. References.

CHEE-108   Here We Go Again: Anatomic And Pathologic Causes Of Recurrent Pulmonary Infections

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Michael Harowicz, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Review the potential etiologies and pathophysiology of recurrent pneumonia2) Identify the imaging characteristics of these anatomic variants, congenital and pathologic disorders3) Discuss radiologic features that affect prognosis and determine optimal management

TABLE OF CONTENTS/OUTLINE

Tracheobronchial anatomic variants tracheal diverticulum and diverticulosis, cardiac bronchus,Congenital disorders: scimitar syndrome, proximal interruption of pulmonary artery, intralobar and extralobar sequestrationEsophageal disorders: achalasia, scleroderma-associated esophageal dysmotilityImmunodeficiency: Good syndrome, common variable immunodeficiency, cystic fibrosisOthers: atypical mycobacterial infection, right middle lobe syndromeClinical considerations: clinical algorithm for determining the appropriate treatment based on patient presentation, microbiology, and imaging findings; imaging findings that are associated with morbidity/mortality

CHEE-109   Portable Chest Radiology: Pearls And Pitfalls

Participants
Max American, MD, Fairfield, California (*Presenter*) Nothing to Disclose

1. Describe different pitfalls and misses in portable chest radiology.2. Discuss multiple categories of different pathology entities in the chest.3. Demonstrate various cases and examples of portable chest radiographs.4. Develop plans, strategies and patterns to avoid pitfalls and misses.

TABLE OF CONTENTS/OUTLINE

Introduction- Portable chest radiology- Pitfalls and missesCategories and Cases- Lines, tubes and devices: Examples- Airways, lungs and pleura: Examples- Heart and mediastinum: Examples- Bones, soft tissues and upper abdomen: Examples- Other entities: ExamplesPlan- Strategies to avoid pitfalls and misses- Proposed Patterns

CHEE-11   Role Of Radiology In Addressing The Challenge Of Lung Cancer After Lung Transplantation.

Participants
Francis Delaney, MD, Dublin, Ireland (*Presenter*) Nothing to Disclose

TEACHING POINTS

• Primary lung cancer is an increasingly recognised complication of lung transplant and may become an important survival-limiting factor with growing use of extended-criteria donors and improved management of other complications. • Radiologists have a key role to play in tackling this issue at multiple stages in the transplantation pathway. • Pulmonary nodules are commonly identified in lung transplant patients, have a spectrum of etiologies which varies depending on time since transplant and cannot be managed according to standard clinical guidelines. • Pre-transplant recipient CT detects suspicious lung nodules. Chest CT also forms part of the donor assessment for smokers in some centres and similarly identifies suspicious lung lesions as well as structural lung disease that increases the risk of developing cancer in the allograft. • Criteria for lung cancer screening in high-risk patients have recently been expanded. Based on the risk of lung cancer after transplant, evidence from single studies and extrapolation of findings from lung cancer screening trials, the role of regular follow-up chest CT after lung transplant is now under consideration and has been adopted in some institutions with a focus on single lung transplant recipients and cases with a donor smoking history.

TABLE OF CONTENTS/OUTLINE

1. Current Trends in Lung Transplantation 2. Pulmonary Nodules in Transplant Patients - Etiology and Management 3. Primary Lung Cancer after Lung Transplant 4. Pre-transplant Assessment 5. Post-transplant Screening - What is the Evidence?

CHEE-110   Seeing Through Ground - Glass Opacities: A Survival Guide For General Radiologists.

Participants
David Castanedo SR, MD, Santander, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review the main imaging features of the wide range of diseases that radiologically present with Ground - Glass Opacities. 2. To provide a diagnostic approach of Ground - Glass Opacities in different clinical scenarios.3. To focus on the diagnostic pearls that enable a correct diagnosis. 4. To study other patterns in which Ground- Glass Opacities appear: crazy - paving and mosaic patterns.

TABLE OF CONTENTS/OUTLINE

1. Definition and Etiology of Ground - Glass Opacities (GGO). 2. Classification of GGO. 3. Diffuse GGO and acute dyspnea. 3.1. Cardiogenic pulmonary edema. 3.2. Permeability pulmonary edema with diffuse alveolar damage. 3.3. Alveolar hemorrhage. 4. Diffuse GGO and chronic dyspnea. 4.1. Non-specific interstitial pneumonia (NINE). 4.2. Desquamative interstitial pneumonia. 4.3. Lymphocytic interstitial pneumonia. 4.4. Radiation pneumonitis. 5. Diffuse GGO in immunocompromised patients. 5.1. Pneumocystis pneumonia. 5.2. Viral pneumonias. 6. Centrolobulillar GGO. 6.1. Aspiration. 6.2. Hypersensitivity pneumonitis. 6.3. Respiratory bronchiolitis. 7. Crazy paving pattern. 8. Mosaic pattern. 9. Conclusion. 10. References.

CHEE-111   A Pictorial Roadmap Of Thoracic Manifestations Of Tuberculous And Non-tuberculous Mycobacterial Infection

Participants
Alberto Paternain, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

- To describe the typical and less common imaging manifestations of pulmonary tuberculosis (TB). - To illustrate the different radiologic patterns of non-tuberculous mycobacteria (NTM) lung infection.

TABLE OF CONTENTS/OUTLINE

- Tuberculous and non-tuberculous mycobacteria. Classification.A. Pulmonary tuberculosis: prevalence, transmission, infection and disease.- Radiological manifestations of pulmonary tuberculosis: primary tuberculosis (mediastinal lymphadenopathy), pulmonary consolidations, pleural effusion. - Radiological manifestations of post-primary tuberculosis: cavitation, endobronchial spread.- Tuberculosis in the immunocompromised patients: miliary tuberculosis.- Uncommon findings of thoracic tuberculosis: chronic empyema, bronchiolithiasis, Rasmussen aneurysm, aspergilloma, pericarditis.- Latent and inactive tuberculosis: Ghon focus and Ranke complex, cicatrization atelectasis, traction bronchiectasis, apical pleural thickening, peribronchial fibrosis. B. Non-tuberculous mycobacteria: species and characteristics.- Cavitary form (classic form): Middle-aged men, smokers. - Bronchiectatic form (non-classic form): white and elderly women. Cylindrical bronchiectasis in the middle lobe or lingula, with centrilobular nodules in a "tree in bud" pattern(bronchiectatic-nodular form)- Immunocompromised patients: disseminated disease: lymphadenopathy and small opacities and pulmonary nodules.- Nodular form.- Patient with deglutition problems.- Hypersensitivity form.

CHEE-112   Attention Mechanism And Weakly Supervised Learning Solve Complicated Problems: Principles And Application To IIP Classification

Participants
Nonoko Takeuchi, RT,MS, Toyoake, Japan (*Presenter*) Nothing to Disclose

In order to develop deep learning model for medical images, it is necessary to provide correct label to the input images. However, it is sometimes difficult even for experts to correctly label unclear disease such as interstitial lung disease. Therefore, weakly supervised learning is a method to solve this problem. In addition, it is known that the attention mechanism, which has received much focus in recent years, can dramatically improve the accuracy. The purpose of this exhibit is to show the principle of the weakly supervised learning method using the attention mechanism and an example of its application to the classification of idiopathic interstitial pneumonias (IIP).The major teaching points of this exhibit are:1. It's very important and difficult for medical AI to prepare the accurate labels.2. Weakly supervised learning solves the issue.3. Attention mechanism boost up the classification performance.4. Attention based weakly supervised learning classify IIP pattern with high accuracy.

TABLE OF CONTENTS/OUTLINE

1. Data issue for medical AI development2. Principle of weakly supervised learning: Multiple instance learning3. Attention based multiple instance learning4. Application for classification of IIP patterns in CT images

CHEE-113 Airway And Parenchymal Respiratory Papillomatosis With Malignant Transformation

Participants
Meng Hao, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Respiratory papillomatosis is caused by infection with HPV and often manifests as nodular lesions most commonly in the laryngeal and subglottic region, but can extend into the lower respiratory tract and lung parenchyma. 2. Although rare, there is a risk for malignant transformation into squamous cell carcinoma. 3. Findings associated with malignant transformation such as increased size of pulmonary nodule/mass or development of cystic features.

TABLE OF CONTENTS/OUTLINE

Respiratory papillomatosis is an infection caused by the human papillomavirus and most frequently localized to the laryngeal and subglottic region. However, in approximately 5%, and fewer than 1% of respiratory papillomatosis involve the trachea and pulmonary parenchyma. Among those with pulmonary parenchymal involvement, the risk for malignant transformation is cited to be 2-3%. This exhibit will present cases and review imaging findings of respiratory papillomatosis involving the trachea and pulmonary parenchyma. We will also present the CT and FDG PET/CT imaging findings of patients with biopsy proven malignant transformation to squamous cell carcinoma. We will provide bronchoscopy and pathology imaging correlates. While malignant transformation of respiratory papillomatosis is a rare entity, it is important to recognize these imaging features to prompt early biopsy and treatment planning.

CHEE-116 How To Interpret Esophageal Cancer MR For Practical Use In Oncologic Decision Making

Participants
Rohee Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To discuss the issues and role of the radiologist in oncologic decision making for esophageal cancer 2. To recognize the optimal MRI protocol indicated for tumor staging of esophageal cancer 3. To illustrate imaging features of esophageal cancer on dynamic contrast-enhanced MR in each stage

TABLE OF CONTENTS/OUTLINE

I. Introduction A. Epidemiology of esophageal cancer B. Diagnosis - pros and cons of different imaging modalities and advantage of MR for evaluation of esophageal cancer C. Treatment D. The role of the radiologist in the oncologic multidisciplinary teamII. MRI scanning protocol A. T2-weighted image B. Diffusion-weighted image C. Dynamic contrast-enhanced T1-weighted imageIII. Structure of esophagus - normal anatomyIV. Esophageal cancer staging using MR: correlation with endoscopic findings A. T1 B. T2 C. T3 D. T4V. Esophageal MR for evaluation of treatment responseVI. Summary

CHEE-117 Deep Learning Reconstruction In Chest CT - Issues Considered From The Dose Reduction And Image Quality In Clinical Cases -

Participants
Hiroshi Moriya, MD, Fukushima, Japan (*Presenter*) Advisor, NantWorks LLCResearch Grant, Canon Medical Systems Corporation

TEACHING POINTS

1. Various noise reduction processing technologies2. Deep learning reconstruction (DLR)3. Lung CT images using AiCE lung (Techniques tuned for lung images)4. Mediastinal CT image using AiCE body and body-sharp (Techniques tuned for abdominal images)5. Radiation dose and image quality on chest CT6. Relationship between radiation dose and image quality reduction effect using DLR

TABLE OF CONTENTS/OUTLINE

Noise reduction technology for X-ray CT such as MBIR and DLR is evolving. This technology is used for low-dose imaging such as lung cancer CT screening. The DLR includes training with low quality datasets and tunes how to generate high quality images from low quality images while maintaining signal and spatial resolution. As a result, under the current imaging conditions of 1 mSv to 2 mSv for lung cancer screening, good noise reduction was obtained with the technology tuned for lung CT and abdominal CT. However, the noise reduction effect was not sufficiently obtained with ultra-low dose CT (0.1 mSv to 0.2 mSv), and processing that increased noise was also observed. In some cases, abdominal DLR was better than lung DLR. To optimize the noise reduction process, it is necessary to tune the training data to include the ultra-low dose CT datasets.

CHEE-118 Test Yourself!: A Case-based Quiz On Interstitial Lung Disease

Participants
Ana Gandara, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

- Identify through a series of image-based cases the different interstitial lung diseases.- Emphasize the accurate description of each morphologic pattern.- Recognize the different clinical features that help categorize each entity. - This exhibit will help residents and radiologist reinforce the radiological and clinical characteristics of the interstitial lung diseases, keeping in mind that interdisciplinary consensus remains the gold standard for the diagnosis.

TABLE OF CONTENTS/OUTLINE

The cases will be presented in a quiz format with 4 answer options. The list of cases includes but is not limited to:- Idiopathic interstitial pneumonias-- Usual interstitial pneumonia -- Nonspecific interstitial pneumonia-- Cryptogenic organizing pneumonia-- Respiratory bronchiolitis - interstitial lung disease-- Desquamative interstitial pneumonia-- Lymphoid interstitial pneumonia-- Acute interstitial pneumonia- Combined pulmonary fibrosis and emphysema- Anti-Jo-1 antibody positive interstitial lung disease- Lymphangitis carcinomatosis- Langerhans cell histiocytosis

CHEE-119   Putting The Pieces Together: A Clinical-based Imaging Approach For The Diagnostic Challenge Of HIV-associated Opportunistic Pneumonias

Participants
Maria G. Gracia Munoz, MD, Tlalpan, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

The diagnosis of pulmonary infections is an everyday challenge for the radiologist; in immunocompromised patients, the difficulty is increased by the wide variety of possible etiologies. By integrating the imaging findings with the clinical and laboratory information available, we increase the certainty of our diagnoses and we can better guide the referring physicians in the complex management of these patients. The teaching points of this exhibit are: to describe the epidemiology of HIV infection and the morbidity and mortality of opportunistic pneumonias in immunocompromised patients, to identify an appropriate imaging approach for opportunistic pneumonias by adjusting the ACR Appropriatness Criteria and by implementing strategies for CT radiation dose optimization, to ilustrate the high-resolution CT patterns associated with opportunistic pneumonias, outlining the importance of clinicalinformation and CD4-cell count and to describe the treatment and prevention strategies of HIV-associated opportunisticpneumonias.

TABLE OF CONTENTS/OUTLINE

Facts about HIV infection and opportunistic pneumoniasRecomendations and CT protocols for chest imaging in immunocompromised patientsHigh resolution CT findings in opportunistic pneumoniasTreatmentPrevention

CHEE-12   "Forgotten Third Circulation": Rediscovering The Thoracic Lymphatic System

Participants
Manoel Felipe Cavalcanti, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Review the anatomy, embryology, and physiology of the thoracic lymphatic system.- Discuss about the current view of lymphangiogenesis, the identification of new lymphatic markers and its role in diseases like lung cancer and metastasis.- Demonstrate the main imaging techniques available for the evaluation of the lymphatic system.- Describe through illustrative cases common and uncommon lymphatic diseases in the chest.

TABLE OF CONTENTS/OUTLINE

1- Introduction.2 - Anatomy and physiology of the lymphatic system.3 - Imaging techniques and protocols for the study of the thoracic lymphatic system.4 - Imaging review of thoracic lymphatic diseases and diseases with a lymphatic distribution: lymphocele, lymphangioma, lymphangioleiomyomatosis, sarcoidosis, Kaposi sarcoma, pulmonary lymphoma, among others.

CHEE-120   The Traumatic And Non-traumatic Tracheal Disease

Participants
Ana Villamizar, MD, Bogota, Colombia (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To provide the radiologist the knowledge with the knowledge tools to recognize the normal anatomy and to help to create a mental map of the non-traumatic and traumatic pathologies that affect the trachea.2. Propose a classification that facilitates the recognition of non-traumatic pathologies involving the trachea3. To describe the abnormal CT findings of the different traumatic and non-traumatic pathologies. 4. Expose main scenarios with a checklist, to provide an easy form of evaluating the trachea.

TABLE OF CONTENTS/OUTLINE

1. Anatomy of the trachea2. Main Tracheal Traumatic Injuries. 3. Classification of the Tracheal Disease. 4. Practical approach to dealing with tracheal disorders; checklist5. Conclusions

CHEE-121   Looking For A Sign?: A Case-based Quiz Of Classic Signs And Patterns Of Lung Infections

Participants
Gustavo Alonzo Correa I, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

To describe the imaging appearance of classic signs and patterns of pulmonary infections.To explain the pathophysiologic basis of classic signs and patterns of pulmonary infections.To discuss the differential diagnosis of classic signs and patterns of pulmonary infections.

TABLE OF CONTENTS/OUTLINE

IntroductionConsolidation and air bronchogramFeeding vessel signHalo signReverse halo signAir crescent signFinger in glove signSplit pleura signAir fluid levelMiliary patternTree in bud patternCrazy paving patternLobar pneumoniaBronchopneumoniaInterstitial

CHEE-122-HC   Nonaortic Mediastinal Emergencies: What The Radiologist Needs To Know

Participants
Mikel Jauregui Garcia, Galdacano, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

CT is the modality of choice for evaluation of mediastinal emergencies. In esophageal emergencies, like intramural dissection or complete perforation (Boerhaave syndrome), a CT with both intravenous contrast and oral contrast will help us to make the correct diagnosis. When we see an abscess on deep neck spaces which spreads to retropharyngeal space, we should extend our study to the chest in order to rule out mediastinitis. Patients with COVID-19 pneumonia seems to have more prevalence of pneumomediastinum when undergoing invasive mechanical ventilation.

TABLE OF CONTENTS/OUTLINE

The group of nonaortic mediastinal emergencies includes a variety of entities that will be, many of the times, life-threatening. These pathologies, as they are not very common, and clinically may be nonspecific, are often not easy to diagnose. There will be different pathophysiologic etiologies, as internal trauma, infection, malignancy or conditions secondary to invasive procedures. We review the different esophageal injuries we can find, as esophageal dissection, perforation or fistulas between the esophagus and the respiratory tract. Acute mediastinitis, remembering its different foci and routes of dissemination, is another important pathology. It seems that COVID-19 infection has impact on mediastinum too, leading to some conditions as pneumomediastinum or bronchopleural fistulas. The correct and timely diagnosis of all these entities will be crucial for an accurate and optimal management of them.

CHEE-123-HC   Mechanism Of AIs In COVID-19 CAD And Techniques To Improve AI Performance

Participants
Masahiro Oda, PhD, Nagoya, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purposes of our exhibit are:1. To learn how AIs in COVID-19 CAD system understand and diagnose chest CT images2. To learn lung diseases that COVID-19 AI commonly misdiagnoses3. To learn how to improve recognition performance of COVID-19 AI

TABLE OF CONTENTS/OUTLINE

COVID-19 CAD- Demand of COVID-19 CAD for chest CT images- Its mechanismAIs used in COVID-19 CAD- Segmentation AI: segment lung normal, ground-glass opacity, consolidation, pleural effusion regions from CT images- Diagnosis AI: classify CT images into diagnosis resultLung diseases that AI misdiagnoses as COVID-19 cases- Organized pneumonia, bacterial pneumonia, lung cancer- Why they are misdiagnosedTechniques to improve AI recognition performance- CT image preprocessing: multiple window level/center image and multiple resolution image generations to capture shadows in lung, lung anatomical structure-aware data augmentation- AI models: lung local and global spatial feature extraction model by dense pooling and dilated convolution, aggregation of estimation results by multiple AI models to improve accuracy- Learning method of AIs: unsupervised learning that reduces manual annotation cost for AI training- Postprocessing: geometrical feature-based false positive reductionContribution of COVID-19 CAD to radiologist- Provide rapid diagnosis result- Quantitative analysis of lung condition- Reduce misdiagnosis

CHEE-124   The Radiographic Findings Of NTM Lung Disease

Participants
John Baek, Daegu, Korea, Republic Of (*Presenter*) Nothing to Disclose

TEACHING POINTS

To present the epidemiology and clinical presentation of nontuberculous mycobacterial (NTM) pulmonary infections in endemic areas. To illustrate different imaging presentation of pulmonary NTM in patients with or without comorbidities and other conditions. To discuss the clinical and imaging clues that can help narrow down the differential diagnosis

TABLE OF CONTENTS/OUTLINE

Epidemiology and pathophysiology of NTM lung disease The classical pattern of NTM lung disease: fibrocavitary and nodular bronchiectatic forms Radiographic findings of NTM lung disease in the patients with or without comorbid disease, such as chronic obstructive pulmonary disease, prior tuberculosis, idiopathic interstitial pneumonia, and bronchiectasis. Several nodules or masses in asymptomatic patients A solitary nodule or mass in asymptomatic patients Hot tub lung Rare radiologic findings: disseminated and endobronchial NTM Summary

CHEE-13   Imaging Of Vascular Complications After Lung Transplantation

Participants
Arzu Canan, MD, Dallas, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

Although vascular complications are rare after lung transplantation, they are associated with high mortality and morbidity.Differentiation of expected post-surgical appearance of vasculature from vascular complications is essential for early diagnosis and management of complications.Knowledge of expected post-surgical changes on imaging is also pivotal for avoiding unnecessary interventions and treatments.

TABLE OF CONTENTS/OUTLINE

1. Indications for lung transplant. 2. Surgical technique. 3. Expected post-surgical appearance of vasculature on CT. a. CT protocols (chest CT, chest CTA and gated chest/cardiac CTA). 4. Post-transplant complications. a. Stenosis of anastomosis site; Types, mechanisms and imaging findings on CT. i. Pulmonary artery stenosis ii. Pulmonary vein stenosis. b. Pulmonary embolism. 5. Other imaging modalities for diagnosis; invasive angiography, magnetic resonance angiography. 6. Treatment. 7. References. 8. Conclusion

CHEE-14   No Signs of Stopping: Remembering All The Chest CT Signs, With Radiopathologic Correlation

Participants
Fumiko Yagi, MD, Shinjuku-ku, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

(1) Understanding lung anatomy that radiologists need to know for chest CT imaging.(2) Understanding the CT imaging findings, differential diagnoses, and correlations between CT and pathology for each characteristic CT sign.

TABLE OF CONTENTS/OUTLINE

I. IntroductionII. AnatomyIII. Parenchymal signs-Halo sign-Reversed halo sign (atoll sign)-Air crescent sign-Meniscus sign-Mosaic attenuation pattern-Three-density pattern (headcheese sign)-Crazy-paving appearance-Galaxy sign-Comet tail sign-Popcorn calcification-Melting ice cube signIV. Airway signs-Air bronchogram sign-Signet ring sign, string of pearls sign, tram line sign-Tree-in-bud sign-Gloved finger sign-Frown sign-Saber-sheath tracheaV. Vascular signs-CT angiogram sign-Feeding vessel sign-Polo mint sign-Scimitar signVI. Pleural signs- Split pleura sign

CHEE-15   Common Blind Spots Of Chest Radiography And How To Avoid Them

Participants
Cato Chan, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

Common "blind spots" on chest radiographs include the apices, retrocardiac space, osseous pathology, subdiagphramatic space, hilar pathology, faint airspace opacities, expiratory radiographs. Examples of such and basic strategies to mitigate these pitfalls are reviewed in this exhibit.

TABLE OF CONTENTS/OUTLINE

1. Introduction (Prevalence, Indications) 2. Causes of misses on Chest Radiographs (Scanning, Recognition, Decision-making, Technical limitation) 3. List of common chest radiograph "blind spots" 4. Example cases and potential strategies a. Rib and Retrocardiac Opacities (Bone Suppression, Angulation, Dual Energy Radiographs) b. Apical Opacities (Window and level, Lordotic View) c. Apical Lucencies (Positioning) d. Rib fractures (Sharpening) e. Lytic Bone lesions f. Subdiagphramatic Opacities (Correlation with prior Abdomen imaging) g. Hilar opacities (Correlation with prior Cardiac imaging) h. Faint airspace opacities (Computer aided detection) i. Expiratory Radiograph 5. Technical limitations of Chest Radiography 6. Discussion 7. Conclusion

CHEE-16   Chest CT Imaging: From Classical CT Signs To Up-To-Date CT Features

Participants
Masahiro Yanagawa, MD, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The morphological diagnosis using CT images is very useful and important for diagnosing pulmonary diseases. Especially, high resolution CT is indispensable for diagnoses. High-spatial-resolution (HSR) CT is a recently developed device which may provide more detailed information for lung anatomy and disease states by clearly delineating CT findings. This education exhibit focuses on classical CT signs of conventional CT and novel features of HSR CT. It is much appreciated if our information would be useful in your clinical and research setting.

TABLE OF CONTENTS/OUTLINE

1. The definition and clinical significance of classical CT signs and patterns for differential diagnoses: air crescent sign, angiogram sign, beaded septum sign, comet tail sign, crazy-paving appearance, feeding vessel sign, galaxy sign, gloved finger sign, halo sign, mosaic attenuation pattern, pitfall sign, reversed halo sign, signet ring sign, split pleura sign, and tree-in-bud pattern. 2. About high-spatial-resolution (HSR) CT: 1) equipment performance, 2) image quality, and 3) usefulness and future directions in thoracic imaging. 3. Diagnostic performance of HSR CT for lung cancer in clinical cases: 1) prediction for the invasiveness of lung adenocarcinoma, and 2) impact on clinical staging of lung cancer (T descriptor).

CHEE-17   Dynamic Digital Radiography Of The Thorax: What The Radiologist Needs To Know

Participants
Nicolas Gillingham, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To describe the principles and image acquisition technique of dynamic digital radiography (DDR)2. To illustrate advantages and potential pitfalls for interpreting DDR radiographs by presenting clinical images3. To demonstrate various thoracic applications and case studies of DDR radiography, including real-time cines of rapid-acquisition dynamic imaging.

TABLE OF CONTENTS/OUTLINE

1. Principles and image acquisition techniquea. Acquisition techniqueb. Patient positioning and respiratory instructionsc. Radiation dose compared to standard x-ray and CT2. Advantages and potential pitfalls for interpreting DDR radiographsa. Ability to visualize the motion of the entire diaphragm throughout the respiratory cycleb. Patient compliance with breathing instructionsc. Effective review and reporting of exams containing static and dynamic image series3. Thoracic DDR applicationsa. Characteristics of lung function observed with dynamic imaging:i. Lung inflationii. Synchronicity of diaphragmatic motioniii. Visualization of relative diaphragm excursioniv. Assessment of intercostal musclesv. Chest wall motionvi. Abdominal wall motionb. Dynamic (cine) imaging of obstructive lung diseasec. Dynamic (cine) imaging of restrictive lung diseased. Dynamic (cine) imaging of neuromuscular disease

CHEE-18   Stepwise Diagnostic Algorithm Of High Attenuated Pulmonary Abnormalities On CT

Awards
Certificate of Merit

Participants
Taiki Fukuda, MD, Tokyo, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

To demonstrate a proposed stepwise diagnostic approach to high attenuated pulmonary lesions. To learn 8 categories of high attenuated pulmonary abnormalities. To acknowledge their pathologic backgrounds.

TABLE OF CONTENTS/OUTLINE

1) Mechanism of high attenuated pulmonary abnormalities on CT When calcification is not detected by CT? : partial volume effect, aeration etc. 2) Five-step diagnostic algorithm STEP 1: Are they associated with metallic artifacts? If STEP 1 is no, go to STEP 2. STEP 2: Are they linear, consolidation, ground glass opacity or others? If STEP 2 is others, go to STEP 3. STEP 3: Are they associated with soft tissue or not? If STEP 3 is yes, go to STEP 4. STEP 4: Are they solitary or multiple? If Step 3 is no, go to STEP 5. STEP 5: Are they located in peripheral or non-peripheral area of the lung? 3) Representative cases of 8 categories With metallic artifact: seed migration, cement migration, barium aspiration, metal foreign body. Linear pattern: pulmonary alveolar microlithiasis, staple line, diffuse pulmonary ossification, etc. Consolidation pattern: amiodarone, lipiodol embolism, etc. GGO pattern: metastatic calcification. Solitary nodule: lung cancer, hamartoma. Multiple nodules: metastasis, pneumocytoma, hyalinizing granuloma, etc. Peripheral: thoracolithiasis, talc pleurodesis. Non-peripheral: broncholithiasis, mucoid impaction. 4) Conclusion Our proposed algorithm will help to determine whether the lesion needs to start prompt treatment.

CHEE-19   Scratching The Surface: Exploring Cutaneous And Subcutaneous Lesions Of The Chest

Participants
William Stutzman, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Cutaneous and subcutaneous lesions of the chest contain valuable information for developing primary diagnoses, or for providing evidence for syndromes.2. A wide variety of superficial soft tissue lesions are common in clinical practice which include benign and malignant tumors, tumor-like conditions, infectious and inflammatory lesions, and trauma as well as treatment related processes.3. The expanding availability of radiologic imaging with CT, F18 FDG PET/CT, and ultrasound helps narrow down the differential diagnosis.4. The differential diagnosis may be limited further by considering the age of the patient, anatomic location of the lesion, salient imaging features, and clinical manifestation.

TABLE OF CONTENTS/OUTLINE

1. Review normal chest wall anatomy.2. Classification of a variety of superficial pathology of the chest wall.3. Characteristic radiographic findings and useful teaching points.a. Malignant tumor: Primary and metastatic.b. Benign tumor.c. Tumor-like conditions: Keloid, tumoral calcinosis, silicone injection.d. Infectious.e. Inflammatory.f. Traumatic.g. Treatment related: surgery, radiation therapy.h. Recognize cutaneous and subcutaneous lesions that can be seen in various syndromes.

CHEE-2   Benign And Malignant Complications Following Esophagectomy

Participants
Jeanne Kochkodan-Self, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Both benign and malignant complications may occur following esophagectomy. 2. Knowledge of the common sites of benign complications, such as ischemic ulcers or strictures, as well as the common sites of cancer recurrence can help radiologists make the correct diagnosis. 3. Knowledge of the normal post-operative appearance of a gastric conduit will help radiologists recognize complications when they occur.

TABLE OF CONTENTS/OUTLINE

1. Surgical approaches to esophagectomy 2. Benign complications a. Anastomotic dehiscence b. Ischemic ulcer and perforation c. Stricture d. Para-conduit hernia 3. Malignant complications a. Anastomotic recurrence b. Mediastinal recurrence c. Tracheo-esophageal fistula

CHEE-20   Lung Stereotactic Body Radiation Therapy (SBRT)

Participants
Sebastian M. Gill, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) To review the concept of SBRT, the differences with conventional radiotherapy, and its indications in lung cancer. 2) To recognize the early and late CT imaging findings after SBRT. 3) To identify the signs of suspected local recurrence after SBRT on CT. 4) To know the possible complications of SBRT.

TABLE OF CONTENTS/OUTLINE

1) Introduction. General aspects of radiotherapy. 2) Overview and general aspects of SBRT. 3) Indications and other possible uses of SBRT. 4) Differences between conventional radiotherapy and SBRT. Examples. 5) Imaging findings after pulmonary SBRT. 6) Early CT findings. Examples. 7) Late CT finding. Examples. 8) Signs of suspected local recurrence on CT. 9) Difficulties in the early detection of local recurrence. 10) Local recurrence. Examples. 11) Assessment of the response to treatment after SBRT. Role of complementary PET-CT. Future: Radiomics? 12) Summary of the possible complications after SBRT treatment. 13) Key points 14) References.

CHEE-21   Three-dimensional Image Of Intralobular Structure By Ultra-high-resolution CT

Participants
Hiroshi Moriya, MD, Fukushima, Japan (*Presenter*) Advisor, NantWorks LLCResearch Grant, Canon Medical Systems Corporation

TEACHING POINTS

Ultra-high-resolution CT (UHRCT) is a CT that achieves high spatial resolution by reducing the detector size to 1/4. In the previous studies, the bronchial visualization ability of UHRCT with SHR mode (matrix: 1024, 0.25 mm thickness) was superior compared with conventional HRCT. In the depiction of lung field structure, bronchi with an inner diameter of 0.4 mm are delineated. Contrast enhancement and deep learning reconstruction method (DLR) enhances the contrast effect of peripheral blood vessels and improves visualization. By improving the resolution of these existing structures, it has become possible to display the intralobular structure in three dimensions.

TABLE OF CONTENTS/OUTLINE

This presentation will show the following four points.1. Depiction of intralobular structure by UHRCT2. Improvement of blood vessel visualization ability by DLR3. How to create a 3D image in the lung lobule4. Three-dimensional display of the structure and lesions in the lobules of typical diseases

CHEE-22   Chest Ultrasound For The Screening And Diagnosis Of Pulmonary Lymphatic Diseases In Children

Participants
Karen Ramirez Suarez, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Pulmonary lymphatic anomalies encompass several conditions such as pulmonary lymphangiectasia, plastic bronchitis, idiopathic chylothorax, among other conditions. - Dynamic contrast MR lymphangiography (DCMRL) has demonstrated a common pathway of abnormal lymphatic flow into the mediastinum, lung parenchyma, pleural surfaces, and bronchial submucosa (pulmonary lymphatic perfusion syndrome). - While DCMRL is an accurate technique to evaluate lymphatic perfusion in children; it is an invasive and costly procedure and its access may be limited because it requires expertise. - Chest ultrasound shows features that correlate with DCMRL findings and it appears to be a promising noninvasive tool to screen for pulmonary lymphatic diseases in children. - Chest ultrasound findings of pleural irregularity, subpleural cystic-appearing structures accompanied by complex pleural effusions and/or underlying pulmonary edema suggest the diagnosis of pulmonary lymphatic disorders. - Ultrasound findings can then be used to decide patients that will required DCMRL for definitive diagnosis and potential interventions.

TABLE OF CONTENTS/OUTLINE

1. Indications and imaging correlation of US and DCMRL findings. 1.1 Normal findings in Chest US and DCMRL 1.2 Suggestive findings of pulmonary lymphangiectasia. - Chest US findings: Pleural irregularity, Subpleural cystic spaces, Pleural effusion, B lines - DCMRL findings: Lung lymphatic perfusion, Pleural enhancement, Pleural effusions with Gadolinium leakage, Pulmonary edema (T2-W images).

CHEE-23   Pulmonary And Disseminated Blastomycosis. Common And Uncommon Imaging Manifestations

Participants
Ana Villanueva, BMedSc, Toronto, Ontario (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review the wide spectrum of radiological manifestations of pulmonary and disseminated blastomycosis 2. To review entities that mimic blastomycosis and learn how to narrow differential diagnosis based on combination of epidemiologic, clinical and radiologic findings

TABLE OF CONTENTS/OUTLINE

North American blastomycosis caused by Blastomyces dermatitidis is an uncommon, but potentially lethal invasive fungal disease, endemic in Canada and the upper Midwest of the United States. Clinically, blastomycosis can be difficult to recognize even in the endemic areas. It is often initially misdiagnosed as community acquired pneumonia, malignant tumor or tuberculosis resulting in treatment delays and unnecessary surgery (Fig.1). Consolidation and masses, with or without cavitation are the most common findings. Uncommon findings include miliary disease, cysts and pleural effusions. Extrapulmonary sites of dissemination include skin, bones, genitourinary system and CNS. Bone involvement has been reported in up to 25% of extrathoracic cases (Fig.2). Only seven cases of thyroid involvement have been published (Fig.3). Blastomycosis may respond to antifungal therapy, however rarely, pulmonary involvement may progress rapidly to respiratory failure, requiring ventilation (Fig.4).

CHEE-24   Incidental Breast Findings At Chest CT: What The Radiologist Needs To Know

Awards
Certificate of Merit
Identified for RadioGraphics

Participants
Justin Stowell, MD, Jacksonville, Florida (*Presenter*) Nothing to Disclose

TEACHING POINTS

Incidental breast findings occur in 0.1% of CT exams and are often overlooked or incompletely characterized. Not all require breast imaging evaluation. Fleischner Society Glossary for Thoracic Imaging define a mass as "any pulmonary, pleural, or mediastinal lesion greater than 3 cm" while the BI-RADS Lexicon define it as a 3D, space-occupying lesion of any size. Nodule is not a BI-RADS descriptor. Suspicious CT features of malignancy include irregular shape, spiculation, and rim enhancement as well as new skin/trabecular thickening or axillary lymphadenopathy. Unilateral axillary/subpectoral lymphadenopathy requires correlation with vaccination history before initiating a diagnostic evaluation.Posttreatment changes may evolve for years following intervention. Suspicious findings include new masses in the operative bed, increasing distortion, skin/trabecular thickening, and size of fluid collections following a period of stability.

TABLE OF CONTENTS/OUTLINE

Background, Incidence, Application of BIRADS Lexicon (nodule vs mass)Parenchymal/Axilla a. Masses/cysts, Distortion/Asymmetries, Calcification (malignant Ca++ too small for CT resolution, coarse Ca++ benign) b. Breast density reporting c. Hormone effects d. Axillary lymph node measurement/evaluation especially in era of COVID vaccination Postop a. Augmentation (implants, autologous fat transfer, free silicone) b. Lumpectomy c. Mastectomy techniques i. Reduction mammoplasty ii. Skin-sparing, Radical iii. Flaps:

DIEP, TRAM, latissimus d. Complications

CHEE-25   Radiological-pathological Correlation In Nonspecific Interstitial Pneumonia: State-of-the-art Images By Ultra-high-resolution Computed Tomography

Participants
Tae Iwasawa, MD,PhD, Yokohama, Japan (*Presenter*) Support, Canon Medical Systems CorporationSupport, Ziosoft Inc.Speaker, FUJIFILM Holdings CorporationSpeaker, Boehringer Ingelheim GmbH

TEACHING POINTS

Nonspecific interstitial pneumonia (NSIP) is one of the common radiological and histological patterns in interstitial lung diseases (ILD). NSIP is frequently seen in collagen disease-related ILD, interstitial pneumonias with autoimmune features (IPAF), and in smokers after treatment of desquamative interstitial pneumonia. NSIP has heterogeneous characteristics in terms of disease behavior and prognosis, and some patients still experience disease progression despite therapy. In conventional high-resolution computed tomography (HRCT) with 512 × 512 matrix size, ground-glass opacity overlapped reticulation along the broncho-vascular bundles is a common radiological pattern. On the other hand, ultra-high-resolution computed tomography (U-HRCT) with 1024 × 1024 matrix size, 0.25-mm slice thickness, and a deep learning reconstruction algorithm for the lung can clearly visualize intralobular reticular opacities. In U-HRCT, we can easily understand the "temporal and spatial homogeneity," which is a characteristic histological NSIP finding. In this presentation, we will show the state-of-the-art U-HRCT images of NSIP in a variety of diseases compared with histological specimens.

TABLE OF CONTENTS/OUTLINE

What is NSIP? What is U-HRCT? (Fig.1) The characteristic CT findings of NSIP (Fig.2). Comparison between NSIP and usual interstitial pneumonia in U-HRCT (Fig.3). NSIP in systemic sclerosis. NSIP in rheumatoid arthritis (Fig.4). NSIP in smokers (Fig.5)

CHEE-26   Multidisciplinary Approach To Chronic Thromboembolic Pulmonary Hypertension (CTEPH), Surgical Technique, And Complications

Awards
Identified for RadioGraphics
Cum Laude

Participants
Lewis Hahn, MD, San Diego, California (*Presenter*) Nothing to Disclose

TEACHING POINTS

Chronic thromboembolic pulmonary hypertension (CTEPH) is defined as mean pulmonary artery pressure > 25 mm Hg, pulmonary capillary wedge pressure < 15 mm Hg, and presence of chronic thromboembolic disease after 3 months of anticoagulation. Imaging features of CTEPH include peripheral thrombus, intraluminal webs, bands, and small caliber/occluded pulmonary arteries. Enlargement of the right heart and main pulmonary artery is seen due to pulmonary hypertension. CTEPH diagnosis and treatment strategy should ideally be made through a multidisciplinary discussion between cardiac surgeons, pulmonologists, cardiologists, and radiologists. Treatments for CTEPH include pulmonary thrombolectomy (PTE), balloon pulmonary angioplasty (BPA), and medical therapy. PTE is the only curative therapy for CTEPH. PTE is performed via arteriotomy followed by dissection of the pulmonary arteries between the intima and media. BPA is performed similarly to coronary balloon angioplasty with visualization of disease on catheter angiogram followed by angioplasty. Complications of PTE and BPA include reperfusion edema, hemorrhage, pulmonary artery injury, rethrombosis/pulmonary embolism, and pericardial effusion/hemopericardium.

TABLE OF CONTENTS/OUTLINE

CTEPH pathophysiology and imaging features; Multidisciplinary approach to CTEPH; PTE indications and technique; Normal post-operative imaging following PTE; Complications of PTE; BPA indications and technique; Normal post-operative imaging following BPA; Complications of BPA

CHEE-27   Ultra-low-dose Lung CT For COVID-19 Viral Pneumonia Using Deep Learning Reconstruction.

Participants
Seiko Kobayashi, RT, Hakodate, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

CT images play a pivotal role in not only screening for COVID-19 viral pneumonia findings, but also assessing severity and related complications. However, in some cases, we may avoid taking follow-up inspection or applying to young patients worrying about radiation dose. We developed an appropriate scan protocol for balancing diagnostic accuracy and exposure dose reduction so that we scan take the inspection as necessary.

TABLE OF CONTENTS/OUTLINE

We applied an ultra-low-current CT protocol for assessing COVID-19 viral pneumonia. Thin-slice CT images were reconstructed using deep learning algorithm optimized for lung diagnosis, and data acquisition was performed by ultra-low-current scanning (40mA). Compared to the conventional method (auto exposure control SD=10 at 5mm thickness, hybrid iterative reconstruction (IR)), diagnostic ability is sufficient to detect lung ground-glass opacity findings. Depending on physique, the exposure dose was reduced by up to 83% (4.85mSv?0.8mSv). Additionally, in the noise characterization (Noise-Power-Spectrum), our new protocol is equal to or better than the conventional ones. The ultra-low-current scanning and deep learning reconstruction (DLR) is clinically available and promising for reducing exposure dose and providing important image findings for establishing therapeutic strategy in patients with COVID-19 infection.

CHEE-28   Imaging Of Immunotherapy In NSCLC

Awards
Cum Laude
Identified for RadioGraphics

Participants
Girish S. Shroff, MD, Houston, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

Familiarize radiologists with: 1. The principles and indications of immunotherapy in NSCLC 2. The imaging manifestations of typical and atypical response patterns to therapy and unique complications of therapy

TABLE OF CONTENTS/OUTLINE

Based on extensive imaging experience from a leading cancer center:Introduction•Background on immunotherapy•Simplified principles of immune checkpoint inhibitor therapyImmunotherapy in NSCLC•Indications•Biomarkers (PD-L1, tumor mutational burden) Response assessment & atypical response patterns compared to conventional chemotherapy•Response criteria (immunotherapy versus conventional chemotherapy)•Pseudoprogression•HyperprogressionImaging Complications of Therapy•Immune related adverse events with focus on those that can be misinterpreted as metastatic or progressive disease and those that can have clinical implications (hypophysitis, neurological, thyroiditis, pneumonitis, sarcoid-like reaction, cardiac, colitis, hepatitis, cholangitis, pancreatitis, adrenalitis)•Clinical treatment implications of imaging

CHEE-29   Complications In Lung Transplant Recipients: What The Radiologists Need To Know

Participants
Masaki Katsura, MD, PhD, Tokyo, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

(1) Overview the currently available procedures of lung transplantation. (2) Discuss the physiologic changes following lung transplantation. (3) Describe the common and uncommon complications according to the time elapsed from lung transplantation. (4) Recognize radiological manifestations of posttransplant complications on follow-up imaging.

TABLE OF CONTENTS/OUTLINE

(1) Overview of lung transplantation procedures; single lung transplantation, bilateral lung transplantation, cadaveric lobar transplants, transplantation of lobes from living donors, heart-lung transplantation. (2) Physiologic changes following lung transplantation; airway hyperreactivity, impaired cough reflex and mucociliary clearance, oropharyngeal and gastroesophageal dysfunction, respiratory muscle dysfunction, changes in pulmonary function test results. (3) Primary graft dysfunction; ischemia-reperfusion injury. (4) Surgical complications; bronchial anastomotic, vascular anastomotic, and pleural complications. (5) Immunological complications; acute allograft rejection, bronchiolitis obliterans syndrome, restrictive allograft syndrome. (6) Infectious complications; bacterial, fungal, mycobacterial, viral, and parasitic infections. (7) Malignancy after lung transplantation; posttransplant lymphoproliferative disorder, native lung malignancy in single lung transplant patients. (8) Other complications; drug-induced complications, pulmonary embolism and infarction, recurrence of primary disease.

CHEE-3   Benign Lymphatic Abnormalities In The Thorax

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Thomas Shum, PhD, Rockville, Maryland (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Understand normal pulmonary lymphatic drainage and how drainage is impacted in disease states. 2. List imaging manifestations of impaired thoracic lymphatic drainage. 3. Describe the imaging and treatment of thoracic duct injury.

TABLE OF CONTENTS/OUTLINE

1. Normal lymphatic pathways in the lung and mediastinum 2. Pulmonary lymphatics a. Reversal of lymphatic flow b. Pulmonary lymphangiectasia c. Intrapulmonary lymph node engorgement 3. Chylous pleural effusion 4. Mediastinal lymphatic malformations 5. Thoracic duct injury

CHEE-31   Neuroendocrine Lung Tumors: Classification, Clinical And Imaging Findings With Pathologic Correlation

Participants
Carlos Senra, MD, Barcelos, Portugal (*Presenter*) Nothing to Disclose

TEACHING POINTS

Regarding lung neuroendocrine tumors (Lu-NENs), we aim to:- Review the classification of Lu-NENs;- Explore the differences of clinical and nuclear medicine behavior between low- to intermediate-grade tumors and high-grade carcinomas.- Review the main imaging findings of Lu-NENs with pathologic correlation.

TABLE OF CONTENTS/OUTLINE

Lu-NENs are a heterogeneous family of neoplasms classified in 4 distinct histologic subtypes (i.e., typical carcinoid, atypical carcinoid, small cell lung carcinoma and large cell neuroendocrine lung carcinoma). Diffuse idiopathic pulmonary neuroendocrine cell hyperplasia is a preinvasive lesion associated with carcinoids. Classification of Lu-NENs is based on mitotic count, necrosis and cytologic features. Although not part of the classification criteria, Ki-67 proliferative index is an essential prognostic parameter. Lu-NENs are characterized by wide clinical behavior spectrum, including low-grade tumors with 98% 5-year survival to high-grade carcinomas with less than 20% 5-year survival. Pathology is the gold-standard test for the diagnosis of Lu-NENs. Nonetheless, key imaging/morphologic features and avidity for FDG and somatostatin analogues (i.e., DOTA-peptides) in PET examination may be used to support the diagnosis.

Neuro-pulmonary Disorders

Participants
Furkan Ufuk, MD, Denizli, Turkey (*Presenter*) Nothing to Disclose

TEACHING POINTS

? To review diseases that may affect both the lung and central nervous system (CNS) simultaneously or at different times. ? To review the imaging findings of neuro-pulmonary disorders.

TABLE OF CONTENTS/OUTLINE

Infectious diseases: Although many conditions can affect both the lungs and the CNS, tuberculosis, fungal infections (especially mucormycosis), parasitic diseases (e.g., cyst hydatid), and viral diseases (varicella-zoster) are common. Inflammatory conditions: Systemic inflammatory diseases may involve both the CNS and the lungs. The most common of these diseases can be sarcoidosis, systemic lupus erythematosus, and Behçet's disease. Vascular disorders: Vasculitis and thromboembolic events can affect both the lungs and the CNS. Vascular anomalies can be found in both lung and CNS in Hereditary Hemorrhagic Telangiectasia (Osler-Weber-Rendu disease). Tumoral disorders: Primary tumors can metastasize to both the lungs and the CNS. Primary lung malignancies can metastasize to the CNS, and rarely CNS neoplasms can metastasize to the lungs. In addition, the lungs can be affected by neurocutaneous syndromes such as neurofibromatosis or tuberous sclerosis.

CHEE-33 **Don't Judge A Book By Its Cover - Uncommon Pulmonary Nodules And Mimickers Of Primary Lung Cancer**

Participants
Anitha Kini, MD, DMRD, Bangalore, India (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To present the differential diagnosis of pulmonary nodules other than primary lung cancer, including both solid and subsolid lesions, with histopathological correlation2. To discuss the imaging features of these lesions with emphasis on findings that may help to differentiate them from primary lung cancer

TABLE OF CONTENTS/OUTLINE

Pulmonary nodules are commonly found on CT of the chest. Most of these nodules are deemed indeterminate and will require surveillance or further management, including biopsy, to exclude lung cancer. The goal of this educational exhibit is to discuss the differential diagnoses of pulmonary nodules other than lung cancer, with emphasis on CT findings that may help in the differential and to discuss the best management strategies for final diagnosis, notably the role of follow up, fine needle aspiration and core needle biopsy. Awareness of these conditions with an understanding of their pathologic background, careful attention to the clinical information, imaging findings and correct management steps will help achieve a correct diagnoses.

CHEE-34 **Biomarkers In Pneumonia: It's Time For Radiologists To Close The Gap**

Participants
Julia Asmar, MD, Kansas City, Missouri (*Presenter*) Nothing to Disclose

TEACHING POINTS

Explain relevance of biomarkers in evaluating pulmonary infection and their impact on diagnosis/prognosisHighlight the incorporation of biomarker data in the formulation of an appropriate imaging differential diagnosis

TABLE OF CONTENTS/OUTLINE

Biomarkers are measurable molecules that predict the presence of disease, indicate its severity, and guide duration of therapy. Procalcitonin (PCT), R-Reactive Protein (CRP), erythrocyte sedimentation rate (ESR), and ß-D-glucan (Fungitell®) are universally available biomarkers of pulmonary infection. PCT secretion is upregulated in bacterial but not in viral infections, and elevated PCT in the appropriate imaging context often indicates bacterial pneumonia. A normal PCT helps support the diagnosis of viral infection (e.g. influenza and COVID-19) in affected patients with pulmonary opacities. Elevation of ß-D-glucan, a component of fungal cell walls (e.g. Aspergillus, Histoplasma), helps distinguish certain fungal infections from bacterial/viral pneumonia, and enables timely diagnosis of angioinvasive aspergillosis. Certain biomarkers (e.g. Ferritin, CRP, PCT) help predict disease severity in COVID-19 before clinical deterioration.Radiologists can mine the electronic medical record for biomarker data to support specific diagnoses in suspected pulmonary infection or non-specific airspace disease. Moreover, when imaging findings are suggestive, radiologists may recommend determination of specific biomarkers to enable timely definitive diagnosis and treatment.

CHEE-36 **The Many Faces Of Pulmonary Aspiration: Aspiration Pneumonia, Aspiration Pneumonitis, Diffuse Aspiration Bronchiolitis And Microaspiration. (mechanisms And Imaging Clues With Pathologic Correlation)**

Participants
Tomas C. Franquet, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

Review and discuss characteristic clinical, imaging, and pathological findings that can aid the radiologist in prioritizing the differential considerations when faced with aspiration disordersUnderstanding their specific imaging features is crucial for making an accurate and early diagnosis, which impacts management.

TABLE OF CONTENTS/OUTLINE

Aspiration is often the result of impaired swallowing, which allows oral or gastric contents, or both, to enter the lung.The diagnosis of pulmonary aspiration depends on a characteristic clinical history, risk factors, and compatible findings on chest radiography. We provide an overview of aspiration-related pulmonary disorders, focusing particularly on those entities not widely appreciated and on recent advances in our understanding of aspiration-related pulmonary syndromes, which can be broadly grouped into those predominantly affecting the airways or the lung parenchyma. Understanding their specific imaging features is crucial for making an accurate and early diagnosis, which impacts management.

CHEE-37   Peripheral Pulmonary Artery Imaging Using Ultra-high Resolution CT - A New Method Of Evaluating Vascularity In The Lung Field -

Participants
Hiroshi Moriya, MD, Fukushima, Japan (*Presenter*) Advisor, NantWorks LLCResearch Grant, Canon Medical Systems Corporation

TEACHING POINTS

1. Pulmonary artery visualization with 3DCTA2. Enhancement of contrast medium of small blood vessels by ultra-high resolution CT (UHRCT)3. Depiction of intralobular blood vessels4. How to display the vascularity of peripheral blood vessels in the lung field5. Pulmonary artery thromboembolism case presentation

TABLE OF CONTENTS/OUTLINE

1. UHRCT improves the visualization of small pulmonary arteries compared to conventional 3DCTA.2. In UHRCT, the reliability of CT values of small structures is improved by reducing the partial volume effect due to the miniaturization of voxels. In particular, the contrast effect of small vessels with a diameter of 1 mm or less is enhanced. In addition, deep learning reconstruction reduces lung noise and sharpens vascular contours.3. Intralobular blood vessels are visualized, and blood vessels around lung cancer and subpleural blood vessels are depicted using UHRCT.4. How to display the vascularity of peripheral blood vessels in the lung field. Contrast effect of small vessels are displayed by subtraction between UHRCT and conventional CT. MIP images display the distribution of contrast medium in the lung field.5.Pulmonary artery thromboembolism (PE) case presentation. The outline of the contrast-enhanced blood vessel and CE defect are clearly visualized. The PE area is visualized as a blood vessel miniaturization and avascular area. Peripheral pulmonary artery imaging may be used to evaluate blood flow in the lung field.

CHEE-39   The Female Thorax - A Case Based Review Of Thoracic Pathology In The Female Patient

Awards
Certificate of Merit
Identified for RadioGraphics

Participants
Katerina Konstantinoff, MD, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is to:1. Illustrate the importance of sex differences when formulating differential diagnoses for thoracic imaging findings.2. Provide a case based review of imaging features of a selection of thoracic pathology that is unique to or predominantly affects females.

TABLE OF CONTENTS/OUTLINE

1. Tracheobronchial-Pulmonary: Lymphangioleiomyomatosis, Thoracic endometriosis, Meigs' syndrome, Ovarian hyperstimulation, Idiopathic laryngotracheal stenosis2. Cardiovascular: Spontaneous coronary artery dissection, Vasculitis, Takotsubo cardiomyopathy, Turner syndrome3. Autoimmune diseases: Scleroderma, Rheumatoid arthritis, mixed connective tissue disease, Sjogren's.4. Neoplasms: Benign: Benign metastasizing leiomyoma. Malignant: Breast cancer, metastases (Ovarian, Choriocarcinoma, Uterine leiomyosarcoma)5. Pregnancy Related: Amniotic fluid embolism, Eclampsia, Peripartum cardiomyopathy6. Chest wall: Gigantomastia, Elastofibroma dorsiSummary: Certain diseases are unique to or disproportionately affect the female sex and may manifest as important findings across cardiothoracic imaging studies of various modalities. These entities range from benign to malignant, and from primary diseases affecting thoracic organs, to localized manifestations of systemic disease. Awareness of these pathologies with female preponderance is important when formulating a robust differential diagnosis in order to avoid diagnostic pitfalls and help guide patient management.

CHEE-4   Proposal Of Optimal Contrast Method For Pulmonary Artery/vein Separation Imaging: How To Accomplish Faster 3d Image Construction, Reduced Contrast Agent Dose, And Improved Image Quality

Participants
Kazuaki Hoyama, Kagoshima, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

3D images of the pulmonary vasculature in preoperative CT assessments for video-assisted thoracic surgery are excellent means to show positional relationships of tumors and blood vessels and provide useful surgery support information. However, false recognition of artery/vein or poor depiction of the vasculature can occur during automatic pulmonary arteriovenous extraction depending on the imaging method and conditions used.This study aimed to propose the use of the Split Bolus Tracking (SBT) method to accomplish faster 3D image construction, reduced contrast agent dose, and improved image quality as a result of improved accuracy of automatic extraction.In the SBT group, the contrast agent could be reduced by 75% on average, and the mean difference in the CT value between pulmonary arteries and veins (220 HU) was significantly higher (p < 0.01). As a result, falsely recognized blood vessels were decreased, visual evaluation was improved, and 3D construction time was reduced by 42 min (p < 0.01).

TABLE OF CONTENTS/OUTLINE

A.Advantages of the SBT method in pulmonary artery/vein separation imagingB.Faster 3D construction of the pulmonary vasculature using a workstationC.Percentage of contrast agent dose reductionD.Difference in the CT value between pulmonary arteries and veinsE.Improved visual evaluationF.Schematic diagram of the SBT method

CHEE-40   Beyond Idiopathic In Pulmonary Fibrosis: Genetics, Immunology And More

Awards
Certificate of Merit

Participants
Rosita M. Shah, MD, Villanova, Pennsylvania (*Presenter*) Nothing to Disclose

1.Beyond supporting an IPF diagnosis, imaging findings of pulmonary fibrosis are relevant as a guide for biopsy in indeterminate for UIP or alternate diagnosis patterns, surveillance in at risk patients including familial pulmonary fibrosis, and anti-fibrogenic therapeutic options. 2.Genomic abnormalities including shortened telomere length(TERT), abnormal mucin (MUC5B) and surfactant production (SFPTC) are associated with increased risk of developing IPF and other interstitial lung disease with accelerated course. 3.MUC5B is associated with dominant UIP pattern in hypersensitivity pneumonitis and rheumatoid arthritis. 4.Evolving fibrosis patterns at imaging may be associated with chronic granulomatous inflammation syndromes and COVID-19. 5.Dominant cystic pattern in young patients with IPF may be associated with genetic surfactant deficiency.

TABLE OF CONTENTS/OUTLINE

1.Established and newly recognized risk factors/associations in pulmonary fibrosis •Genomic variants •Immune mediated inflammation •Post-infectious/inflammatory fibrosis including COVID-19 •Non-sarcoid chronic granulomatous inflammation 2. Lung injury versus repair •Pathophysiology of fibrosis •Therapeutic considerations 3.Imaging in diagnosis, surveillance and therapeutic decision making in pulmonary fibrosis 4.Clinical syndromes beyond idiopathic pulmonary fibrosis •Familial pulmonary fibrosis •Hermansky-Pudlak •Anti-synthetase •Surfactant C deficiency •IgG4 •Granulomatous lymphocytic interstitial lung disease

CHEE-41   Organizing Your Approach To Lung Injury

Awards
Identified for RadioGraphics
Magna Cum Laude

Participants
Travis Henry, MD, Durham, North Carolina (*Presenter*) Nothing to Disclose

TEACHING POINTS

-Non-traumatic lung injury can be caused by a variety of insults. Regardless of cause, the most common pathologic response to injury is usually organizing pneumonia (OP) and/or diffuse alveolar damage (DAD).-Identifying the cause of lung injury on imaging is usually not possible. It is imperative that the imager recognize the findings of lung injury and understand the temporal changes that occur with different the phases of lung injury so that the clinical team can investigate the cause.-OP is a common and usually milder form of lung injury that typically presents weeks to months after an insult. The significance of OP on biopsy is variable - it may be the cause of a patient's symptoms or a minor component of another disease-DAD is a severe form of injury from damage to the epithelium and/or endothelium. DAD has three phases with distinct (but often overlapping) imaging: acute/exudative; proliferative/organizing; chronic/fibrotic.-Acute respiratory distress syndrome (ARDS) is a clinical diagnosis based on the level of hypoxemia and presence of lung injury on imaging. DAD is the histologic correlate of ARDS, however patients with DAD may not have ARDS, and patients with ARDS may not have DAD on pathology.

TABLE OF CONTENTS/OUTLINE

A. IntroductionB. Common forms of lung injury (OP, DAD)C. Imaging timeline of lung injury (days-acute; weeks-organizing; months-fibrotic)D. Differential diagnosis clinical aspects (ARDS; Cryptogenic OP)E. Clues to differentiate lung injury from mimics on imaging

CHEE-42   Mesothelioma Imaging: Current Practice And Future Directions

Participants
Chad D. Strange, MD, Seabrook, Texas (*Presenter*) Nothing to Disclose

TEACHING POINTS

To understand: - Combined imaging and surgery are necessary for complete staging. -Unique features of current staging in mesothelioma with focus on resectable vs. unresectable disease. -Unique modifications of RECIST 1.1 criteria to assess response after therapy. -3D volumetric techniques provide new opportunities for mesothelioma imaging.

TABLE OF CONTENTS/OUTLINE

Based on the clinic-radiological experience of a tertiary oncological referral center. Introduction: -Impact of pathological variations on imaging -Unique growth pattern impact on evaluation Staging mesothelioma: -Multimodality CT, MRI, PET/CT, and Surgery staging -Current mesothelioma staging and limitations with examples -Discuss criteria for unresectability with example cases -Surgical/oncological implications of staging Response Assessment: -Modified RECIST 1.1 -Discuss how uniquely modified for mesothelioma with example cases Future Directions: -Volumetric analysis of mesothelioma

CHEE-43   PET/CT Assessment Of Esophageal Cancer

Participants
Staci Gagne, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

The incidence of esophageal cancer in the United States has grown more rapidly than any other solid tumors over the past several decades. Despite being one of the ten most frequent cancers in the world, it continues to carry a poor prognosis with a less than 15% 5-year survival rate. To further understand this disease, this exhibit aims to 1) characterize the unique difficulties in diagnosing and treating esophageal cancer, 2) present the current diagnosis and staging guidelines, 3) expand on the role of the radiologist and how PET/CT has evolved within the diagnosis and management of esophageal cancer, and 4) discuss current and investigative treatment strategies to include surgery, chemotherapy and radiation.

TABLE OF CONTENTS/OUTLINE

1. Epidemiology and anatomy of esophageal cancer: presentation, esophageal anatomy, types of esophageal cancer, and the effects these have on staging and prognosis2. Current diagnosis and staging guidelines of esophageal cancer: invasive and noninvasive tests used3. PET/CT and the assessment of esophageal cancer how its role has evolved and how it is used now; its role in multidisciplinary conference, and its pitfalls4. Current and investigative areas of treatment and management algorithms: surgery, chemotherapy, and radiation often in combination and imaging

CHEE-44   Emerging Phenotypes Of Chronic Lung Allograft Dysfunction (CLAD) In Long-term Lung Transplant Survivors

Participants
Staci Gagne, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

TEACHING POINTS

Lung transplantation has come a long way in the past several decades and yet still trails behind other solid organ transplants in terms of survival. One of the main complications affecting long-term survival is the development of chronic lung allograft dysfunction (CLAD). Therefore, identifying CLAD in a lung transplant is vital to the prognosis of the patient and provides a crucial role for the radiologist. The purpose of this exhibit is to 1) learn what CLAD is and what it means for the patient and their lung transplant, 2) review imaging findings of the emerging phenotypes of CLAD and correlative pulmonary functions and pathology, 3) understand the clinical implications of these phenotypes, and 4) discuss the current and investigative areas of management and treatment. Presented cases are from the experiences at a tertiary academic center with the largest lung transplantation program in the region. The exhibit is designed to provide a practical guide in diagnosis and management of CLAD which is relevant to an ever-growing number of patients.

TABLE OF CONTENTS/OUTLINE

1. Current definition of CLAD Definition, epidemiology, and clinical implication2. Risk factors of CLAD: recurrent infection, rejection, gastroesophageal reflux, etc.3. Emerging phenotypes of CLAD Bronchiolitis obliterans syndrome (BOS) and Restrictive allograft syndrome (RAS) - clinical presentations, course, and prognosis with correlative pathologic findings4. Management of CLAD: Current recommendations and future directions with emphasis on a role of radiologists

CHEE-45   Two Thin Layers Of Trouble. A Journey Through Pleural Neoplasms.

Awards
Certificate of Merit

Participants
Alvaro Bartolome Solanas, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

Pleural tumours are a small but significant kind of chest neoplasms. The basic imaging techniques are CXR and CT scan. MRI can play an important role helping on the characterization of some pleural tumours. In any case the imaging characterisation of the different pleural neoplasms is a difficult task because of the big overlap between imaging characteristics. Usually the final diagnosis is obtained through biopsy where the US could play a major role.This pictorial review intends to bring some light to this matter by:-Reviewing basic pleural anatomy and general imaging features of pleural neoplasms-Describing a comprehensive classification and an approach to pleural neoplasms-Illustrating key clinical and imaging features of the different pleural neoplasms-Illustrating some tumor-like pleural lesions that simulate pleural neoplasms

TABLE OF CONTENTS/OUTLINE

Introduction:Anatomy and basic histologyImaging generalities of pleural tumoursGeneral classification of pleural neoplasmsPictorial review with key clinical and imaging features of the different pleural neoplasms:- Primary neoplasms:Mesothelial (Malignant mesothelioma), Mesenchymal (Solitary fibrous tumour, lipoma, liposarcoma, synovial sarcoma...), Lymphoproliferative (Primary pleural lymphoma)- Secondary neoplasms:Metastatic implants, Pleural invasion- Tumor-like lesions

CHEE-46   Sternum - A Small Big Bone

Participants
Vivien Bonadio, MD, Bebedouro, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is: 1. To review anatomy of sternum. 2. To approach anatomical variations. 3. To discuss mechanic and traumatic pathologies and expected image patterns. 4. To overview different image finding of spondyloarthropathy, infectious diseases, tumors and post-operative conditions.

TABLE OF CONTENTS/OUTLINE

1. Review bone, ligamentous and joint anatomy of sternum and what can be evaluated on image exams in a multimodality approach. 2. To approach sternal anatomical variations and image aspects, such as: disproportion of its components, sternal foramina, xiphoid shape variations, pectus carinatum and pectus excavatum. 3. Mechanic/traumatic pathologies and image findings, particularly arthritis, mechanical overload, acute and healed fracture. 4. Expected image findings on spondyloarthropathy, emphasizing SAPHO syndrome. 5. Infectious diseases that can affect the sternum, focusing on septic arthritis and also addressing other rarer infections, such as sporotrichosis. 6. Sternum tumors, such as enchondroma and chondrosarcoma. 7. Post-operative conditions of the sternum, such as pseudoarthrosis and sternal prostheses.

CHEE-47   Hypersensitivity Pneumonitis: An Update Based On The New American Thoracic Society Guideline

Participants
Pegah Khoshpouri, MD, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

TEACHING POINTS

Familiarize radiologists with new ATS guideline for diagnosis of hypersensitivity pneumonitis (HP).Review radiological terms and features that help radiologist in diagnosis of HP.Understand the chest HRCT scan features that help categorize scans into the typical HP, compatible with HP, and Indeterminate for HP.Provide an algorithmic approach for diagnosis of HP with emphasis on the role of radiologists.

TABLE OF CONTENTS/OUTLINE

Review of the natural history and epidemiology of HP.Review of the pathogenesis of HP with radiological correlation.Recommended

chest HRCT protocol parameters in the diagnosis of HP.Review and update on radiological terms for heterogeneous lung attenuation.Chest HRCT scan features of the nonfibrotic HP pattern (Typical HP, Compatible with HP, and Indeterminate for HP): A pictorial review.Chest HRCT scan features of the fibrotic HP pattern (Typical HP, Compatible with HP, and Indeterminate for HP): A pictorial review.Review of the histopathological criteria for the diagnosis of HP.Algorithmic approach for evaluation of HP.

CHEE-48   Pulmonary Hypertension: Updated Clinical Classification And CT Pulmonary Angiography Evaluation

Awards
Certificate of Merit

Participants
Farah Tamizuddin, MD, New York, New York (*Presenter*) Nothing to Disclose

TEACHING POINTS

Pulmonary hypertension (PH) is a chronic progressive disease classified into five groups, each with similar clinical presentations and therapies. Recent 2019 updates address pulmonary capillary hemangiomatosis (PCH), pulmonary veno-occlusive disease (PVOD), and lymphangioleiomyomatosis (LAM), given better understanding of their pathophysiology. Computed tomography pulmonary angiography (CTPA) is key in PH evaluation and can aid in early diagnosis, increasing chances of survival and symptom improvement. Therefore, the objectives are to a) review the updated 2019 PH classification with pertinent pathology correlation and b) discuss the role of imaging and review helpful findings for PH diagnosis on CTPA.

TABLE OF CONTENTS/OUTLINE

1. PH definition (hemodynamic parameters, clinical presentation). 2. Updated 2019 PH classification [group 1, pulmonary arterial hypertension (PAH); group 2, left heart disease; group 3, lung disease and/or hypoxia; group 4, pulmonary artery obstruction; group 5, unclear/multifactorial]. 3. Role of imaging in early PH diagnosis (V/Q scan, CTPA, Fleischner 2021 position paper). 4. Key CTPA features of PH: A. Signs of PH. B. Group 1, imaging features of idiopathic PAH, venous/capillary causes (PVOD/ PCH), cirrhosis/ portal hypertension, intracardiac shunts. C. Group 2, imaging features of heart and valvular causes. D. Group 3, CT indicators of obstructive/restrictive PH, LAM. E. Group 4, identifying CTEPH (webs, vascular strictures, dual energy CTPA iodine defects).

CHEE-49   Spectrum Of Hepatopulmonary Diseases: From Imaging Features To Clinical Management

Participants
Pegah Khoshpouri, MD, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

TEACHING POINTS

Familiarize radiologists with the intrathoracic manifestations of hepatic diseases.Educating different hepatic and intraabdominal manifestation of pulmonary and cardiac diseases.Comprehensive review of imaging features, clinical manifestations, and management of diseases affecting both lungs and liver.

TABLE OF CONTENTS/OUTLINE

Review of the hepatopulmonary axis anatomy and potential communications.Review of the portosystemic shunt pathways.Pulmonary manifestation of portal hypertension: 1. Hepatopulmonary syndrome 2. Portopulmonary hypertension 3. Portopulmonary fistula/shunt 4. Portosystemic (non-pulmonary) fistula/shunt 5. Hepatic hydronephrosisDiseases with Hepatic and Pulmonary manifestations: 1. Cystic fibrosis 2. Alfa-1 antitrypsin deficiency 3. Hereditary hemorrhagic telangiectasia 4. Drug toxicities 5. Autoimmune diseasesCardiopulmonary manifestations of hepatic carcinoid disease.Hepatic manifestations of pulmonary hypertension and right heart strain.

CHEE-5   Interstitial Lung Abnormality (ILA) And Lung Cancer

Awards
Certificate of Merit
Identified for RadioGraphics

Participants
Akinori Hata, MD, Suita, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Interstitial lung abnormalities (ILA) are defined as incidental CT findings of non-dependent abnormalities affecting more than 5% of any lung zone, including ground-glass or reticular abnormalities, lung distortion, traction bronchiectasis/ honeycombing, and non-emphysematous cysts. ILA is often progressive and associated with reduced exercise capacity, decline in lung function, and increased mortality. The clinical importance of ILA is increasingly recognized. In addition, ILA often coexists with lung cancer. The purpose of this exhibit is 1) To learn the findings of ILA; 2) To know the evidence of poor prognosis in lung cancer patients with ILA; and 3) To understand the clinical importance of ILA in management for lung cancer patients.

TABLE OF CONTENTS/OUTLINE

1. Typical findings and subtypes: non-subpleural, subpleural non-fibrotic, and subpleural fibrotic2. Imaging pitfalls: aspiration, osteophyte-related fibrosis, centrilobular nodularity, pleuroparenchymal fibroelastosis-like lesion, dependent abnormality 3. Clinical pitfalls: co-existing ILA and lung cancer and its implication in diagnosis and treatment 4. Prognostic implications: Association with survival in early and advanced stage lung cancer. 5. Recommended management in lung cancer patients with ILA.

CHEE-50   Beyond The Usual And Emerging Interstitial Lung Diseases: What Radiologists Need To Know

Participants
Pegah Khoshpouri, MD, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

TEACHING POINTS

Familiarize radiologists with less reported and emerging interstitial lung diseases (ILD).Educating clinical correlations of less known ILDs.Teaching expected imaging findings in less known ILDs.Review of treatment options and management of emerging and less

known ILDs.

CHEE-51   Do You Really Know Lung-RADS®v1.1?: The Screening And Management Card Game

Participants
Lucas Farias, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is: 1) To play with cards imaging characteristics related to Lung-RADS® v1.1. 2) To review Lung-RADS® v1.1 assessment categories and updates. 3) To correlate important findings with the with histopathological diagnosis. 4) To discuss image findings according to Lung-RADS® v1.1 in order to enhance radiologists' skills. 5) To highlight their characteristics in order to familiarize the multidisciplinary medical society for thoracic radiology with these conditions, preventing unfavorable patient outcome.

CHEE-52   The Battle Of Our Era, A Constant Fight; A Pictorial Review Of The Radiologic Techniques And Imaging Features Of Coronavirus Disease 2019

Participants
Nancy Margarita Gutierrez Castaneda, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

TEACHING POINTS

To describe the general characteristics of COVID 19.To review the pathophysiology, transmission, clinical features and diagnosis of COVID 19.To know the clinical utility and imaging features of the modalities most commonly used in diagnosis and evaluation of coronavirus disease 2019.To describe the CO RADS description.To examine thromboembolic and extrathoracic imaging features in COVID 19. To know the pulmonary and systemic complications of COVID 19.To discuss the appropriate treatment and follow up of the COVID 19

CHEE-54   Mediastinal Teratoma: From Basic To Advanced

Participants
SANGGYUN KIM, MD, Gwangju, Korea, Republic Of (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Identify the diagnostic strategy in approaching the patients with mediastinal teratoma 2. Describe the multimodality imaging findings of mediastinal teratoma 3. Discuss the unusual clinical and radiologic manifestations of mediastinal teratoma

CHEE-55   Fat Containing Lesions Of The Chest: A Pictorial Review With Computed Tomography And Magnetic Resonance Imaging Findings

Participants
Tugce Agirlar Trabzonlu, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

TEACHING POINTS

Fat-containing chest lesions may be encountered on many cardiothoracic examinations on daily workflow. When a fat containing cardiothoracic lesion is identified, its anatomic origin and characteristic imaging appearance often allow a definitive radiologic diagnosis, and often preclude further invasive diagnostic procedures. Although chest CT allows easy identification of the macroscopic fat, several MR imaging techniques can provide further information to identify microscopic fat, which can be helpful in characterization of some entities such as thymic hyperplasia or arrhythmogenic right ventricular dysplasia. This exhibit will review fat containing chest lesions based on their anatomic locations with describing the role of the computed tomography (CT) and magnetic resonance imaging (MRI) in their diagnosis.

liposarcoma, lipomatous hypertrophy of the interatrial septum, arrhythmogenic right ventricular dysplasia)- Pulmonary parenchymal and endobronchial lesions (Hamartoma, lipoid pneumonia, lipoma)-Pleural and Chest Wall Lesions (Lipoma, hibernoma, extrapleural fat, liposarcoma, lipomatosis, elastofibromatodorsi, fat necrosis)-Diaphragmatic hernia (Morgagni hernia, Bochdalek hernia, hiatal hernia, juxtacaval fat)

CHEE-56   Do You Know Many Diseases Share The Same CT Findings With COVID-19 Pneumonia?: Diseases Spectrum, Pathologic Background And Differential Diagnosis

Participants
Takeshi Johkoh, MD, PhD, Amagasaki, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

1.To know the diseases sharing the same CT findings with COVID-19 pneumonia (COVID-19P) . 2. To understand pathological causes. 3. To acknowledge key CT findings for the differentiation

TABLE OF CONTENTS/OUTLINE

1. Diseases which share the same CT findings: A. Moderate COVID-19P; cellular NSIP , COP,EP, Drug Related Pneumonia (DRP) , desquamative Interstitial Pneumonia (DIP) , early anti MD-5 antibody positive dermatomyositis pneumonia (AMD5P), and moderate H1N1 influenza pneumonia(H1N1P). B. Severe COVID-19P; acute interstitial pneumonia , advanced AMD5P, severe DRP, and severe H1N1P .2. Pathological Causes. A. Moderate COVID-19P and differential diseases shares either cellular infiltration, alveolar filling or, intraluminal organization. B. Severe COVID-19P and differential diseases share OP with supervening fibrosis and/or organizing diffuse alveolar damage. Note; all diseases have immunologic reaction. 3. Differentiation Points. A. Moderate COVID-19P: Moderate COVID-19 P; round ground-glass opacity (GGO). COP/EP/moderate DRP; relatively large amount of consolidation. DIP; emphysema in GGO. early AMD5P: rapidly progressing. B. Severe COVID-19P: Almost impossible, however, they share the same treatment such as ECMO, strong immune suppressive therapy , etc. With this exhibit, unnecessary repeated PCR , long isolation, and inappropriate therapy will be able to be reduced.

CHEE-57   Estimating Respiratory Volume By Measuring Thoracic Volume - Analysis Performed Using Respiratory Dynamics CT Data -

Participants
Hiroshi Moriya, MD, Fukushima, Japan (*Presenter*) Advisor, NantWorks LLCResearch Grant, Canon Medical Systems Corporation

TEACHING POINTS

Pulmonary function test requires a deep breath of the subject, so there is a high risk of droplets and aerosol diffusion. Therefore, we investigated a method for measuring respiratory function from the movement of the subject's body surface.1. Respiratory CT method2. Examining the correlation between lung volume and trunk volume from respiratory function CT data3. Estimate lung volume only from body surface measurements

TABLE OF CONTENTS/OUTLINE

Fifty patients who underwent four-dimensional respiratory dynamics CT (5-second respiratory cycle image) for preoperative diagnosis of lung resection.1. Measurement of lung volume: Extract the air region in the body and calculate the lung volume at each respiratory phase.2. Measurement of trunk volume: The trunk of the imaging range is extracted from the four-dimensional respiratory dynamics CT image, and the volume of the entire trunk in each respiratory phase is calculated.3. Comparison of volume fluctuations due to respiration Correlation and reliability evaluation of fluctuations in lung volume and trunk volume due to respiratory phase.4. Comparison of volume fluctuation and measured value of respiratory function test. In the case of chest breathing, the respiratory volume and the volume fluctuation of the thorax are almost the same. In the case of abdominal breathing, it is necessary to include the abdomen in the measurement.

CHEE-58   Role Of Imaging In Lung Transplantation: A Primer For Radiologists

Participants
Kaustav Bera, MBBS, Cleveland, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. To review the history, indications and surgical techniques for lung transplantation.2. To discuss the role of various imaging modalities for patient selection and assessing the post-transplant complications of lung transplantation.3. To understand the spectrum of post-transplant imaging findings using a case-based format.

TABLE OF CONTENTS/OUTLINE

Introduction and history of lung transplantation. Indications and contraindications for lung transplantationTypes of lung transplants and surgical techniques for transplantationImaging modalities and their role for proper patient selection. Classification of post lung transplantation complications(with sample cases)a. Based on anatomy/etiologyi. Pulmonary parenchymal complications(reimplanatation response, rejection- hyperacute and acute rejection, infection, Posttransplantation Lymphoproliferative Disorder, Chronic lung allograft dysfunction (CLAD)recurrence of primary disease). ii. Pleural complications(Pneumothorax, air leak, hemothorax, pleural effusions, empyema). iii. Infections(Bacterial, viral and fungal). iv. Vascular complications (Vascular anastomotic stenosis). v. Airway complications(bronchial dehiscence and stricture). vi. Mechanical and other complications (donor-recipient mismatch, pulmonary torsion).b. Base on time of occurrencei. Immediate (<24 h).ii. Early (>24 h-1 week). iii. Intermediate (8 days-2 months).iv. Primary late (2-4 months).v. Secondary late (>4 months).

CHEE-59   "What Goes Around Comes Round" To The Lungs - A Pictorial Review Of The Different Radiological Presentations Of Pulmonary Metastases.

Participants
Camila Franco, BMedSc, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

TEACHING POINTS

I. Discuss the role of imaging in the initial assessment and follow-up of patients with suspected pulmonary metastases.II. Review

the most common tomographic patterns of pulmonary metastases and understand the main pathways of tumor spread to the lungs.III. Recognize atypical manifestations and complications of pulmonary metastases and their differential diagnosis.IV. Identify post-treatment changes and what is important to report.

TABLE OF CONTENTS/OUTLINE

1. The role of different imaging techniques in evaluating pulmonary metastases:a. Radiographyb. Computed tomography (CT)c. PET/CT2. Pathophysiology of tumor spread to the lungsa. Hematogenous spreadb. Tumor embolic. Lymphatic spreadd. Aerogenous metastasese. Pleural seeding and "drop metastases"3. Different (common and uncommon) presentations of lung metastases in specific casesa. Calcified metastasisb. Cavitated metastasisc. Hemorrhagic metastasisd. Spontaneous pneumothoraxe. Miliary metastasisf. Cannonball metastasisg. Pleural carcinomatosis and "drop metastases"4. Post-treatment changesa. Surgeryb. Radiotherapy modalitiesc. Ablation techniques

CHEE-6   When To Call On-call: 15 Must Know Portable Cxr Cases And Mimics

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Leah Strickland, MD, Durham, North Carolina (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Understand the technical challenges of portable radiography 2. Discuss common artifacts and mimics that lead to portable chest radiograph misinterpretations 3. Review must know portable chest x ray cases

TABLE OF CONTENTS/OUTLINE

Portable Radiograph Technique - 1. Comparison with standard PA chest radiographs 2. Technical and quality challenges 3. Patient factors (phase of respiration, patient rotation); Lines that don't end where they should - 1. Cases: Chest tubes, left paramediastinal cath tips, IAPBs, ECMO; Not the textbook pneumonia - 1. Cases: Lower lobe collapse, torsion, cavitary pneumonia, abscess 2. Mimics: overlying soft tissue, layering pleural effusion, atelectasis, aspiration, technical factors; Where is that air? - 1. Cases: Pneumothorax (floating fat pad sign, deep sulcus sign), pleural effusion, hydropneumothorax, pneumomediastinum (Naclerio V sign of esophageal rupture) 2. Mimics: Pneumothorax (skinfold artifact, severe bullous emphysema), Pleural effusion (asymmetric overlying soft tissue, patient rotation), Pneumomediastinum (mach effect, pneumopericardium, major fissure with lordotic positioning, medial pneumothorax, inflated IABP); The mediastinum is too wide - 1. Cases: Hematoma, pericardial effusion 2. Mimics: Mediastinal widening (soft tissue, technical factors); There's something on the edge of the film - 1. Cases: cupola sign (pneumoperitoneum), shoulder dislocation 2. Mimics: Free air (stomach gas)

CHEE-60   Beyond Pulmonary Embolism Diagnosis: Advanced Clinical Applications Of Dual-energy Lung CT

Awards
Certificate of Merit

Participants
Daisuke Yamada, MD, Tokyo, Japan (*Presenter*) Nothing to Disclose

TEACHING POINTS

Dual-energy lung CT has been used for diagnosing pulmonary thromboembolism (PTE); however, the applications are actually diverse. The teaching point of this exhibit is to demonstrate the imaging findings of dual-energy CT in lung diseases in addition to PTE.

TABLE OF CONTENTS/OUTLINE

1. To demonstrate the principle of dual-energy CT. 2. To demonstrate pseudo lesions that can be mimics 3. To demonstrate the imaging findings of dual-energy CT for lung diseases in addition to PTE. Cases include : Pseudo lesion •Misalignment of scan timing for contrast-enhanced •Beam hardening artifact •Respiratory motion artifact •Metal artifact Abnormalities of bronchial/lung parenchyma •Bronchial atresia •Congenital pulmonary airway malformation (CPAM) •Emphysema •Acute Exacerbation in Interstitial Lung Disease •Combined pulmonary fibrosis and emphysema (CPFE) Abnormalities of pulmonary blood vessels •Pulmonary tumor thrombotic microangiopathy (PTTM) •Chronic thromboembolic pulmonary hypertension (CTEPH) •Hepatopulmonary syndrome •Coronavirus disease 2019 (COVID-19) •Varicella Zoster virus (VZV) vasculitis •Intravascular lymphoma •Major thoracic vascular invasion of lung cancer •Pulmonary vein stenosis after catheter ablation

CHEE-61   Pleural Effusion: What Every Radiologist Should Know

Participants
Llúria Cornellas Escayola, Barcelona, Spain (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:- To review pleural effusion's main features regarding its etiology, epidemiology, clinical aspects and management.- To depict the main findings in various imaging modalities and their clinical implications.- To update key concepts in the role of imaging-guided interventional procedures in pleural effusion's management.

TABLE OF CONTENTS/OUTLINE

1. Pleural effusion: definition, etiology and clinical aspects.2. Imaging findings in pleural effusion: a pictorial review - Chest x-ray - Ultrasound - Computed tomography - Magnetic resonance imaging3. Imaging-guided interventional procedures in pleural effusion: - Thoracentesis - Pleural biopsy - Pleural drainage

CHEE-62   Interpreting Portable Chest X-rays: Pears And Pitfalls

Participants
Stacey V. Weisman, MD, Port Washington, New York (*Presenter*) Nothing to Disclose

1. Portable chest x-rays are common, but often difficult to interpret, due to limitations such as magnification, overlying hardware, supine position of the patient, and often very ill patients with complex health conditions and many multiple x-ray abnormalities. 2. A systematic approach is key to accurate interpretation. 3. Special attention should be made to certain blind spots on the image, where abnormalities are often overlooked. 4. For post-operative x-rays, understanding potential complications, and therefore knowing what to look for, is key. 5. It is important to recognize how the imaging appearance of both normal and abnormal x-ray findings may differ between the supine and upright position.

TABLE OF CONTENTS/OUTLINE
