Achieving the elevation of thyroid stimulating hormone (TSH) prior to ablative treatment of differentiated thyroid cancer (DTC), must be caused either by suspending replacement therapy with maintenance with Liothyronine (LT3) or by administering parenteral human recombinant TSH (rhTSH). It is known that hypothyroidism leads to a decrease in the glomerular filtration rate (GFR), so we wanted to compare its impact according to the protocol used.*Methods and Materials We carried out a retrospective study of 192 patients (W: 151, M: 41, Mean age: 45 years) since 2014, with a histological diagnosis of DTC referred to the Nuclear Medicine Service of the Hospital Universitario Son Espases for radioiodine ablation of remnant thyroid tissue. 49 patients with the rhTSH protocol (Group A) and 143 with the TL3 protocol (Group B) were selected with three different regimens of substitution treatment (B1:45comp [43], B2:30comp [50], B3:20comp [50]). The GFR was calculated with the MDRD-4 formula prior to therapy (FG?), on the day of treatment (GFR?) and at 6 months (GFR??) with dosimetric recording during their hospitalization.*Results The decrease in the FG? is 2% in Group A and 19.2% in Group B. The variation of the GF?/FG? was less than 1mL/min/1.73m2 in Group A while Group B presented a decrease close to 3mL/min/1.73m2, being the subgroup B1 the one that presented the greatest decrease (6mL/min/1.73m2). The lowest GFR showed an elimination of less than 50% at 48 hours, which for some cases and depending on the dose, imply exceeding the recommended limits. Radiopharmaceutical was slightly higher in Group A.*Conclusions The faster elimination in Group A seems to depend only on the absence of deterioration of the GFR. Low GFR should be avoided, administering rhTSH in patients with borderline rate and reducing the dose in patients with a low baseline GFR.*Clinical Relevance/Application The functional impact of this research will allow establishing an individualized and more efficient protocol for each of these patients.

RESULTS

The decrease in the FG? is 2% in Group A and 19.2% in Group B. The variation of the GF?/FG? was less than 1mL/min/1.73m2 in Group A while Group B presented a decrease close to 3mL/min/1.73m2, being the subgroup B1 the one that presented the greatest decrease (6mL/min/1.73m2). The lowest GFR showed an elimination of less than 50% at 48 hours, which for some cases and depending on the dose, imply exceeding the recommended limits. Radiopharmaceutical was slightly higher in Group A.

CLINICAL RELEVANCE/APPLICATION

The functional impact of this research will allow establishing an individualized and more efficient protocol for each of these patients.

PD02-A1   Ultralow Dose Computed Tomography For The Evaluation Of Pediatric Pectus Excavatum: Evaluation Of Radiation Dose, Image Quality And Diagnostic Performance.

Participants
Sebastian Gallo-Bernal, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To compare the radiation dose, image quality, and diagnostic performance of a new ultralow (UL) dose protocol versus standard thoracic CT for the evaluation of pediatric patients with pectus excavatum*Methods and Materials In this IRB approved and HIPPA compliant retrospective study, we searched electronic health records (EHR) to identify all pediatric patients who underwent a CT (standard or UL) as part of the standard of care evaluation of pectus excavatum between 2010-20. The UL protocol consisted of a low voltage (70-90 kV) and low current (50 mAs) setting with iterative construction. An equal number of standard and UL CT scans were included. EHR imaging and clinical follow up were reviewed for at least 1 year after CT to evaluate for potentially missed thoracic pathology. Size-specific dose estimates and effective radiation doses were calculated following AAPM guides. Signal to noise and contrast to noise ratios were calculated. Subjective image quality was assessed by 2 expert radiologists using a 5 point Likert scale. Variables were compared using parametric and non-parametric tests in R v.4.0.5*Results 208 pectus excavatum thoracic CTs [104 UL (age 14.14±2.15); 104 standard (age 14.84±2.7)] corresponding to 174 patients were included for analysis. The UL group had statistically significant reductions (p<0.001) in effective radiation dose (0.144 vs 1.075 mSv) and SSDE (0.504 vs. 3.434 mGy) compared with the standard protocol. Objective (SNR (23.7 vs 34.9) and CNR (21.6 vs 38.4)) and subjective measures of image quality (bone (4.0 vs 4.6), lung (3 vs 4.4) and soft tissue (2.2 vs 3.8)) were also significantly different (p<0.001). No differences were seen in the pulmonary nodules' number and size (1.36 ± 0.56 vs 1.54 ± 0.88 nodules per scan; nodule size 4.5±0.96 vs 4.4±1.5 mm). Clinical and imaging follow up (clinical follow up 19.83 ± 12.4 mos; imaging follow up 11.17±8.85 mos) of all 104 patients undergoing UL CT demonstrated no evidence of symptomatic thoracic pathology besides pectus. 46/104 of UL CT patients underwent a follow up thoracic CT within 36 mos; 6 patients had pulmonary nodules. A single 2 mm pulmonary nodule was seen on follow up CT not visible on the UL CT performed 6 months prior: all other nodules on the follow up CT were present on the original UL CT and unchanged in size (10 nodules; diameter 4.5 mm)*Conclusions Ultralow dose thoracic CT is a viable option for imaging pediatric patients with pectus excavatum, with effective radiation dose comparable to chest radiographs and mild increase in image noise that did not significantly reduce detection of thoracic pathology including small pulmonary nodules.*Clinical Relevance/Application UL pediatric thoracic CT can be adopted in routine clinical practice for specific indications including pectus excavatum

RESULTS

208 pectus excavatum thoracic CTs [104 UL (age 14.14±2.15); 104 standard (age 14.84±2.7)] corresponding to 174 patients were included for analysis. The UL group had statistically significant reductions (p<0.001) in effective radiation dose (0.144 vs 1.075 mSv) and SSDE (0.504 vs. 3.434 mGy) compared with the standard protocol. Objective (SNR (23.7 vs 34.9) and CNR (21.6 vs 38.4)) and subjective measures of image quality (bone (4.0 vs 4.6), lung (3 vs 4.4) and soft tissue (2.2 vs 3.8)) were also significantly different (p<0.001). No differences were seen in the pulmonary nodules' number and size (1.36 ± 0.56 vs 1.54 ± 0.88 nodules per scan; nodule size 4.5±0.96 vs 4.4±1.5 mm). Clinical and imaging follow up (clinical follow up 19.83 ± 12.4 mos; imaging follow up 11.17±8.85 mos) of all 104 patients undergoing UL CT demonstrated no evidence of symptomatic thoracic pathology besides pectus. 46/104 of UL CT patients underwent a follow up thoracic CT within 36 mos; 6 patients had pulmonary nodules. A single 2 mm pulmonary nodule was seen on follow up CT not visible on the UL CT performed 6 months prior: all other nodules on the follow up CT were present on the original UL CT and unchanged in size (10 nodules; diameter 4.5 mm)

CLINICAL RELEVANCE/APPLICATION

UL pediatric thoracic CT can be adopted in routine clinical practice for specific indications including pectus excavatum

PD02-A2   Developmental Dysplasia Of The Hip: A Plain Film Deep Learning Approach

Participants
Marcelo Takahashi, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

To develop an artificial intelligence algorithm capable of automatically classifying pediatric frontal hip plain films as either well positioned or rotated, measure the acetabular index, identify the location of femoral head ossification center and generate an overlay of the Hilgenreiner and line and Perkins.*Methods and Materials This is an ongoing IRB approved research. Two hundred and fity hip plain films of children between 0 and 36 months of age (mean 28 months), 181 female and 119 male, were retrieved from PACS. The images were manually annotated (masks of the iliac bones, femoral head ossification centers, obturator foramina and coordinates for the lateral and medial borders of the acetabular roofs) by two radiologists. Two hundred labelled images were utilized for training an AI algorithm based on the popular U-net architecture and the remaining 50 labelled images were utilized for testing. Algorithm's output was set as both an overlay image with calculated acetabular index as well as a rotation index (based on the ratio of iliac bones areas and obturator foramina areas).*Results One exam was excluded from test set due to poor quality. Iliac

bone, obturator foramen and femoral head segmentation was considered adequate for 47/49 test exams.Automated acetabular index had a good correlation with manually calculated acetabular index, with a Spearmans correlation of 0.707.*Conclusions Although this AI model is still in a very initial stage, it has already demonstrated the capacity of not only identifying missaligned pediatric hip plain films (by comparing the area of the iliac bones and obturator foramina) but also the capacity of automatically plotting the main radiologic lines and calculating the acetabular index.*Clinical Relevance/Application With further research and a larger dataset as to improve generalization our algorithm could be used as a helpfull tool for the evaluation of hip dysplasia in locations were radiologic and/or orthopedi image consultation is not feasible

RESULTS

One exam was excluded from test set due to poor quality. Iliac bone, obturator foramen and femoral head segmentation was considered adequate for 47/49 test exams.Automated acetabular index had a good correlation with manually calculated acetabular index, with a Spearmans correlation of 0.707.

CLINICAL RELEVANCE/APPLICATION

With further research and a larger dataset as to improve generalization our algorithm could be used as a helpfull tool for the evaluation of hip dysplasia in locations were radiologic and/or orthopedi image consultation is not feasible

PD02-A3   Imaging The Pediatric Mandible

Participants
Jacob McCallum, DO, Grand Rapids, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is to:Review common and uncommon conditions affecting the mandible in pediatrics

TABLE OF CONTENTS/OUTLINE

Conditions that affect the mandible in infancy. For example Caffey disease and child abuseConditions that affect the mandible in older children and young adults. Benign odontogenic lesions: bacterial osteomyelitis/periapical abscess, dentigerous cyst, ameloblastoma.Malignant odontogenic: ameloblastic carcinomaBenign non-odontogenic: fibrous dysplasia, cherubism, juvenile ossifying fibroma, central giant cell granuloma, chronic nonbacterial osteomyelitisMalignant non-odontogenic: Ewing sarcoma, neuroblastoma, leukemia/lymphomaConditions that affect the temporomandibular joint. For example juvenile idiopathic arthritis, non-inflammatory disk disease, idiopathic condylar resorption, unilateral condylar hyperplasia .

PD02-A4   Skeletal Dysplasia Families: A Comprehensive Review

Awards
Identified for RadioGraphics

Participants
Atsuhiko Handa, MD, Iowa City, Iowa (*Presenter*) Nothing to Disclose

TEACHING POINTS

Skeletal dysplasias encompass a heterogeneous group of over 400 disorders. They are individually rare, but collectively common with an approximate incidence of 1/5000; thus, radiologists occasionally encounter skeletal dysplasias in daily practice. Most skeletal dysplasias have their characteristic pattern of skeletal changes, and the diagnosis rests on pattern recognition. A group of skeletal dysplasias that share a distinctive radiological pattern can be grouped into a "skeletal dysplasia family" that generally shares a common pathogenesis. Since major skeletal dysplasia families are limited in number, the radiologists can become readily familiar with their diagnostic patterns. The purpose of this exhibit is to 1) demonstrate the radiological characteristics of major skeletal dysplasia families and 2) review their clinical and genetic features that help radiologists to participate in multidisciplinary care. After completion of this presentation, the learners will have an overall picture of the entire world of skeletal dysplasias.

TABLE OF CONTENTS/OUTLINE

- Introduction - Approach to skeletal dysplasias - FGFR3 (achondroplasia) family - COMP family - Type II collagenopathies - Dysostosis multiplex family (mucopolysaccharidoses and mucolipidoses) - TRPV4 (metatropic dysplasia) family - Skeletal ribosomopathies (eg. Schwachman Diamond) - DTDST (diastrophic dysplasia) family - Filaminopathies - Punctata group - Skeletal ciliopathies - Osteogenesis imperfecta group - Osteopetrosis group

IN04-A1 **Visual Transformers Do Not Outperform Convolutional Neural Networks For Disease Detection In Chest Radiographs**

Participants
Zachary Murphy, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Recently, visual transformer (VT) architectures have shown better classification performance than convolutional neural networks (CNN) on general image datasets like ImageNet. However, it is unclear how well these VT models perform in medical imaging tasks, such as disease detection in chest radiographs (CXRs).In this work, we performed extensive tuning of CNN and VT models on publicly available CXR datasets for detection of 14 diseases and compared their performance on internal and external datasets.*Methods and Materials We compared DenseNet121 CNN and Facebook's Data-efficient Image Transformers (DeiT) VT architectures, both pre-trained on ImageNet. We chose DenseNet121, as it forms the basis of CheXnet, a well-known model for detection of diseases in CXRs with benchmark comparisons to other state of the art models. The DeiT model is one of the first VTs that performs well on ImageNet without large amounts of data.We fine tuned these models on the NIH CXR14 dataset containing 112,120 CXRs annotated for 14 disease labels. Data were split into train, validation, and test subsets according to a 70/10/20% split. After hyperparameter optimization with grid search on train and validation sets, final models were trained by combining the train and validation sets. Test performance was assessed on the held-out NIH CXR14 test set and external datasets of 25,000 images each from CheXpert, PadChest, and MIMIC datasets.For each set, we calculated AUC for detection of each label and the prevalence-weighted average with confidence intervals using 1,000-sample bootstrapping. Time required for model training was also evaluated.*Results The DeiT model had a weighted AUC of 0.777 on the internal NIH CXR14 test set, while the DenseNet121 model had a higher weighted AUC of 0.789 (p<0.001). Performance on individual classes showed similar differences, with DeiT performing at or below DenseNet121 for each label (Figure 1A).Similar findings were observed on the external test sets (Figures 1B, C, & D), with DeiT weighted AUC 0.003 to 0.012 lower than DenseNet121 with non-overlapping confidence intervals.The DeiT and DenseNet 121 models took an average of 72.6 and 34.3 minutes/epoch, respectively, on a Quadro RTX 5000 GPU.*Conclusions The DeiT VT model performed marginally worse than the DenseNet121 model on internal and external test sets. Furthermore, DeiT models required >2x the amount of time to train per epoch. While VTs have shown improvements over CNNs in general imaging datasets, our results suggest that they may not yet be ready to replace CNNs in CXR disease detection.*Clinical Relevance/Application While recent advances are promising, VTs may not be ready to replace convolutional models for medical domain-specific tasks such as chest radiograph disease detection.

RESULTS

The DeiT model had a weighted AUC of 0.777 on the internal NIH CXR14 test set, while the DenseNet121 model had a higher weighted AUC of 0.789 (p<0.001). Performance on individual classes showed similar differences, with DeiT performing at or below DenseNet121 for each label (Figure 1A).Similar findings were observed on the external test sets (Figures 1B, C, & D), with DeiT weighted AUC 0.003 to 0.012 lower than DenseNet121 with non-overlapping confidence intervals.The DeiT and DenseNet 121 models took an average of 72.6 and 34.3 minutes/epoch, respectively, on a Quadro RTX 5000 GPU.

CLINICAL RELEVANCE/APPLICATION

While recent advances are promising, VTs may not be ready to replace convolutional models for medical domain-specific tasks such as chest radiograph disease detection.

GU04-B1   Prospective Validation Of The Novel Scoring System For Prostate Cancer Recurrence Detection: The Prostate Imaging For Local Recurrence Reporting, PI-RR

Participants
Martina Pecoraro, MD, Roma, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To prospectively validate a recently released scoring system (PI-RR) for the standardized interpretation and reporting of prostate cancer (PCa) local recurrence diagnosis after radical prostatectomy (RP) and radiation therapy (RT).*Methods and Materials Patients with clinical suspicion of prostate cancer recurrence (diagnosis of biochemical recurrence or PSA above nadir or according to risk grouping) were enrolled and underwent mpMRI of the prostatic bed/prostate. Two radiologists independently analyzed the images using the novel Prostate Imaging for local Recurrence Reporting (PI-RR). According to the PI-RR a cutoff = 3 and 4 was set for suspicion of recurrence. Follow-up, histopathology, when available, and nuclear medicine modalities were used as standard of reference.*Results A total of 77 patients were enrolled. Multiparametric MRI showed a sensitivity, specificity, PPV, and NPV for recurrence detection of 88.5% (95% confidence interval [CI]: 79.2-95.4), 93.5% (95% CI: 87.9-96.7), 73.9% (95% CI: 62.5-85.6), and 78.9% (95% CI: 84.3-88.2), respectively. The area under the curve (AUC) was 0.89 (95% CI: 0.86-0.95). Minimum follow-up was of 12 months.*Conclusions Detection of prostate cancer local recurrence is crucial to guide treatment decisions. PI-RR proved to be an accurate tool for recurrence detection, improving patient's management.*Clinical Relevance/Application PI-RR proved to be a valuable guide to improve the management of men with recurrent prostate cancer by achieving better diagnostic performance and personalized treatment tailored to the specific patients.

RESULTS

A total of 77 patients were enrolled. Multiparametric MRI showed a sensitivity, specificity, PPV, and NPV for recurrence detection of 88.5% (95% confidence interval [CI]: 79.2-95.4), 93.5% (95% CI: 87.9-96.7), 73.9% (95% CI: 62.5-85.6), and 78.9% (95% CI: 84.3-88.2), respectively. The area under the curve (AUC) was 0.89 (95% CI: 0.86-0.95). Minimum follow-up was of 12 months.

CLINICAL RELEVANCE/APPLICATION

PI-RR proved to be a valuable guide to improve the management of men with recurrent prostate cancer by achieving better diagnostic performance and personalized treatment tailored to the specific patients.

GU01-A3   **Application Value Of 3D Isotropic T2 Weighted Images For Assessing Vaginal Fornix Invasion Of Cervical Cancer**

Participants
Xing Meng, Dalian, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the value of curved planar reformation (CPR) on 3D isotropic (3D-ISO) T2WI imaging for assessing vaginal fornix invasion of cervical cancer.*Methods and Materials 33 cervical cancer patients with cervical cancer confirmed by pathology admitted were enrolled in this study. All patients underwent 2D sagittal T2WI and 3D-ISO T2WI scans on Ingenia 3.0T CX (Philips Healthcare, Best, the Netherlands) scanner, and CPR on 3D-ISO was performed on Philips IntelliSpace Portal workstation. Two physicians evaluated whether the uterine fornix of cervical cancer patients was involved in the 3D-ISO CPR image and T2WI sagittal image, respectively, and compared the results with the postoperative pathology to observe the accuracy of the 3D-ISO sequence curved reconstruction in the diagnosis of vaginal fornix involvement. The ?2 test was used to compare the results of the two groups.*Results Compared with T2WI, there were truer positive (4 vs. 6) and true negatives (20 vs. 22) cases in the 3D-ISO assessment of vaginal fornix invasion, and fewer false positive (6 vs. 4) and false negative (3 vs. 1) cases. The accuracy of 3D-ISO sequence and T2WI were 84.85% and 72.73%, the sensitivity was 85.71% and 57.14%, and the specificity was 84.62% and 76.92%, respectively. The accuracy, sensitivity and specificity of 3D-ISO sequence were higher than that of T2WI. There was no statistically significant difference (P > 0.05).*Conclusions CPR on 3D-ISO T2WI has considerable clinical value for diagnosis of vaginal fornix invasion of cervical cancer, which provides a reliable reference for clinical pathological staging and treatment plan, and is worthy to be promoted in clinical experiment.*Clinical Relevance/Application Compared with 2D T2WI, 3D-ISO T2WI CPR is more accurate in the assessment of vaginal fornix involvement and can help in the staging of cervical cancer, which is of great value in the accurate formulation of treatment plan.

RESULTS

Compared with T2WI, there were truer positive (4 vs. 6) and true negatives (20 vs. 22) cases in the 3D-ISO assessment of vaginal fornix invasion, and fewer false positive (6 vs. 4) and false negative (3 vs. 1) cases. The accuracy of 3D-ISO sequence and T2WI were 84.85% and 72.73%, the sensitivity was 85.71% and 57.14%, and the specificity was 84.62% and 76.92%, respectively. The accuracy, sensitivity and specificity of 3D-ISO sequence were higher than that of T2WI. There was no statistically significant difference (P > 0.05).

CLINICAL RELEVANCE/APPLICATION

Compared with 2D T2WI, 3D-ISO T2WI CPR is more accurate in the assessment of vaginal fornix involvement and can help in the staging of cervical cancer, which is of great value in the accurate formulation of treatment plan.

CH03-B3   **Impact Of A Nurse Practitioner In A Diverse Inner-city Academic Lung Cancer Screening Program**

Participants
Maximilian C. Stahl, BA, Bronx, New York (*Presenter*) Nothing to Disclose

PURPOSE

The lung cancer screening program at our inner-city academic medical center cares for an under-served, majority ethnic minority population. In April 2018, a full-time nurse practitioner (NP) joined the team to focus on patient encounters, outreach, and intensified patient and referrer communication. The purpose of this study was to determine the impact of this intervention on exam volume and patient compliance.*Methods and Materials Retrospective chart review. All patients enrolled in our screening program from June 2016 to February 2020 were included. The pre-intervention and post-intervention period were 6/1/2016-3/31/2018 and 4/1/2018-2/29/2020, respectively, dichotomized by the implementation of the NP.*Results 3947 screening exams were performed on 2097 patients (mean age 67.7y± 5.8y, 51.3% women). 22.5% were White and 30.7% were Black. 36.7% identified as Hispanic. Median smoking history was 51.2 pack-years. Mean monthly volumes increased 33.0% (75.4±19.5 vs 100.0±11.1 exams/month, p<0.001) when comparing the 22 months pre and post intervention for the overall population and for all demographics [Men: 34.0% (36.4±10.4 vs 48.9±6.5 exams/month, p<0.0005), Women: 31.0% (39.0±11.2 vs 51.1±8.2 exams/month, p<0.0001), White: 20.0% (17.9±6.6 vs 21.5±5.5, p<0.05)], Non-White: 37.0% (57.5±14.5 vs 78.6±9.7, p<0.0001), Hispanic/Latino: 45.0% (26.2±7.0 vs 38.1±7.4 , p<0.0001), Non-Hispanic/Latino: 25.0% (39.6±11.0 vs 49.5±9.1, p<0.01)]. First follow-up compliance for new patients was unaffected by the intervention, 42.0% (139/328) vs 39.0% (301/781) (p=0.23). The proportion of Lung RADS 3 and 4 exams resulting in biopsy did not significantly differ (20.0% vs. 20.2%, p=0.98).*Conclusions The introduction of a full-time NP to our diverse urban lung cancer screening program significantly improved exam volume across all demographics. Patient compliance was not affected and requires further investigation*Clinical Relevance/Application Addition of an NP to our lung cancer screening program improved volume significantly across all demographics; further innovation is needed to impact compliance.

RESULTS

3947 screening exams were performed on 2097 patients (mean age 67.7y± 5.8y, 51.3% women). 22.5% were White and 30.7% were Black. 36.7% identified as Hispanic. Median smoking history was 51.2 pack-years. Mean monthly volumes increased 33.0% (75.4±19.5 vs 100.0±11.1 exams/month, p<0.001) when comparing the 22 months pre and post intervention for the overall population and for all demographics [Men: 34.0% (36.4±10.4 vs 48.9±6.5 exams/month, p<0.0005), Women: 31.0% (39.0±11.2 vs 51.1±8.2 exams/month, p<0.0001), White: 20.0% (17.9±6.6 vs 21.5±5.5, p<0.05)], Non-White: 37.0% (57.5±14.5 vs 78.6±9.7, p<0.0001), Hispanic/Latino: 45.0% (26.2±7.0 vs 38.1±7.4 , p<0.0001), Non-Hispanic/Latino: 25.0% (39.6±11.0 vs 49.5±9.1, p<0.01)]. First follow-up compliance for new patients was unaffected by the intervention, 42.0% (139/328) vs 39.0% (301/781) (p=0.23). The proportion of Lung RADS 3 and 4 exams resulting in biopsy did not significantly differ (20.0% vs. 20.2%, p=0.98).

CLINICAL RELEVANCE/APPLICATION

Addition of an NP to our lung cancer screening program improved volume significantly across all demographics; further innovation is needed to impact compliance.

CH03-B5   **Prevalence And Predictors Of Severity Of Bronchiectasis In Participants In Low-dose CT Screening For Lung Cancer**

Participants
Qiang Cai, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Bronchiectasis is responsible for loss of lung function, significant use of health care resources, and can result in increased morbidity and mortality in people with specific cardiopulmonary diseases. This report is to assess the frequency and severity of bronchiectasis of participants in a low-dose CT (LDCT) screening program.*Methods and Materials We re-reviewed the initial LDCTs of all smokers, aged 40 to 85, enrolled in the Mount Sinai Early Lung and Cardiac Action Program (MS-ELCAP) from 2010 to 2019. The ELCAP Bronchiectasis Score (ELCAP-BrS) used four scales, the severity of bronchial dilatation, the extent of bronchial dilatation, bronchial wall thickening, and endobronchial mucoid impaction, to document bronchiectasis for each of six lung regions with the lingula regarded as a separate lobe, also to summarize by combing the right and left upper, mid, and lower lungs.*Results Re-review of LDCTs of 2191 screening participants identified bronchiectasis in 504 (23.0%) of 2191 participants, but it had not been reported on the original report for 461 (91.5% underreporting). Median ELCAP-BrS was 12 (IQR: 9-16). Overall, bronchiectasis was the lower lobe predominant with involvement increasing from 57.4% to 78.4% to 91.2% to 93.4% in the 1st, 2nd, 3rd, and 4th quartiles respectively. However, mid lung involvement increased significantly (p<0.001) from the 2nd to 4th quartile (from 46.8% to 72.8% to 97.7%) and was the most affected region in the 4th quartile. Multivariable logistic analysis showed that bronchiectasis increased with increasing age (OR=2.0 per decade;95%CI:1.7-2.4), former smokers (OR=1.34;95%:CI:1.02-1.74), self-reported COPD (OR=1.41;95%CI:1.04-1.91), and elevated diaphragm (OR=4.1;95%CI:1.6-11.0), but decreased in overweight (OR=0.6;95%CI:0.5-0.9) or obese (OR=0.5;95%CI:0.4-0.8) participants.*Conclusions The prevalence of bronchiectasis in smokers undergoing LDCT screening was high and underreported. We recommend that bronchiectasis be reported in LDCT screening programs as its potential

progression over the entire period of enrollment can be followed, thus enabling assessment of the benefits of early management of bronchiectasis.*Clinical Relevance/Application Bronchiectasis and its severity and extent are important and we recommend that reporting of bronchiectasis findings on LDCTs should be encouraged, particularly as older smokers are at increased risk.

RESULTS

Re-review of LDCTs of 2191 screening participants identified bronchiectasis in 504 (23.0%) of 2191 participants, but it had not been reported on the original report for 461 (91.5% underreporting). Median ELCAP-BrS was 12 (IQR: 9-16). Overall, bronchiectasis was the lower lobe predominant with involvement increasing from 57.4% to 78.4% to 91.2% to 93.4% in the 1st, 2nd, 3rd, and 4th quartiles respectively. However, mid lung involvement increased significantly (p<0.001) from the 2nd to 4th quartile (from 46.8% to 72.8% to 97.7%) and was the most affected region in the 4th quartile. Multivariable logistic analysis showed that bronchiectasis increased with increasing age (OR=2.0 per decade;95%CI:1.7-2.4), former smokers (OR=1.34;95%:CI:1.02-1.74), self-reported COPD (OR=1.41;95%CI:1.04-1.91), and elevated diaphragm (OR=4.1;95%CI:1.6-11.0), but decreased in overweight (OR=0.6;95%CI:0.5-0.9) or obese (OR=0.5;95%CI:0.4-0.8) participants.

CLINICAL RELEVANCE/APPLICATION

Bronchiectasis and its severity and extent are important and we recommend that reporting of bronchiectasis findings on LDCTs should be encouraged, particularly as older smokers are at increased risk.

CH03-B6   Reversed Halo Sign And Associated Features With Correlation To The Final Diagnosis

Participants
Felipe Camara, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

to correlate the reversed halo sign (RHS) and its imaging features to the final diagnosis.*Methods and Materials This is a retrospective study, performed in a tertiary hospital to characterize the associated tomographic features of the RHS and correlate them with the final diagnosis. Inclusion criterion: at least one chest CT scan performed in the 2015-2020 period with one or more RHS. All chest CT performed in that period containing "reversed halo" description in the report were retrieved through an electronic search engine. These cases were anonymized and evaluated by 2 researchers blinded to both the clinical history and the final diagnosis, who evaluated the following image characteristics: distribution, number of RHS, location, and type of halo: nodular, smooth, or thickened (consolidation margin > = 1,0 cm). Researchers blinded to the images evaluated the electronic medical records of these patients and retrieved the following clinical information: definitive diagnosis, age, sex, and comorbidities. Exclusion criteria: the absence of a defined final diagnosis, images not found in the system, and absence of RHS at the images.*Results 351 patients fulfilled the inclusion criteria, of which 65 were excluded. The mean age was 56.3 years and 90.5% (259 patients) had some type of associated comorbidity. A total of 207 patients (72.2%) had "smooth halo", 53 (18.6%) had "thick halo" and 26 (9.2%) had "nodular halo". 267 patients (93.3%) of the total had the RHS preferentially in a peripheral location and 19 (6.6%) in a central location. Pulmonary thromboembolism was the diagnosis most frequently found with 120 cases (41.9%), most of them with a "smooth halo" (81.6%) and almost all of them with a preferentially peripheral location with 99.1% of the cases. Other diagnoses found were cryptogenic organizing pneumonia (17.1%), bacterial pneumonia/septic embolism (15.7%), viral pneumonia by the new coronavirus and H1N1 (12.9%), granulomatous diseases infections (6.5%) and miscellaneous (5.9%).*Conclusions The morphological features and distribution of RHS may contribute to narrowing the differential diagnosis. Associated with the patient's clinical data, this information may help to find the final diagnosis in many cases.*Clinical Relevance/Application This is the largest sample in the literature evaluating the RHS, its imaging features, and correlating both with the final diagnosis. It is also the first study of its kind to be carried out after the COVID-19 pandemic.

RESULTS

351 patients fulfilled the inclusion criteria, of which 65 were excluded. The mean age was 56.3 years and 90.5% (259 patients) had some type of associated comorbidity. A total of 207 patients (72.2%) had "smooth halo", 53 (18.6%) had "thick halo" and 26 (9.2%) had "nodular halo". 267 patients (93.3%) of the total had the RHS preferentially in a peripheral location and 19 (6.6%) in a central location. HN05-A1 Prevalence Of Sigmoid Sinus Diverticulum And Dehiscence And Their Association With Tinnitus.

Participants
Pradeep Kiresur, MBBS,DMRD, Bangalore, India (*Presenter*) Nothing to Disclose

PURPOSE

Studies have shown the association of Sigmoid sinus diverticulum and dehiscence to be associated with tinnitus. However, there are no enough studies on prevalence of Sigmoid sinus diverticulum and dehiscence. The study is aimed to look at the prevalence of sigmoid sinus diverticulum and dehiscence and their association with tinnitus.*Methods and Materials A retrospective review of all the temporal bone imaging (Computed tomography) from January 2018 to March 2021 done in a tertiary hospital in Bengaluru was performed. Sigmoid sinus diverticulum was defined as focal out pouching of the normal semicircular sigmoid sinus groove. The dehiscence was defined as cortical bone defect with air on sinus sign. The presence and laterality of sigmoid sinus diverticulum and dehiscence were recorded. Electronic medical records were reviewed to obtain history of tinnitus and exclude other causes.*Results A total of 560 studies were reviewed. Seven patients (1.3%) had sigmoid sinus diverticulum with sigmoid sinus dehiscence(SSDD). Nine patients (1.6%)had sigmoid sinus dehiscence with no diverticulum(SSDh). Two patients (0.4%)had sigmoid sinus diverticulum but no dehiscence(SSD). Of these eighteen patients eleven (61 %) patients were symptomatic with tinnitus (SSDD -3, SSD-2, SSDh-6), 4 (22%) were asymptomatic (SSDD-2, SSDh-2) and for three patients history was not available. Of these eleven symptomatic patients seven had tinnitus on the corresponding side and two patients had bilateral tinnitus. Two patients had tinnitus not corresponding to the side of sigmoid sinus diverticulum and dehiscence. Review of available magnetic resonance venogram for the symptomatic patients showed the presence of sigmoid sinus stenosis in three cases (SSDD-2, SSDh-1).*Conclusions The prevalence of SSD and SSDh (total 3.2%) is low but when present most had symptoms of tinnitus suggesting a causal association of these lesions.*Clinical Relevance/Application Tinnitus is caused by multiple pathologies. Our study showed that Sigmoid sinus diverticulum and dehiscence has low prevalence in population but still can be the cause for tinnitus.

RESULTS

A total of 560 studies were reviewed. Seven patients (1.3%) had sigmoid sinus diverticulum with sigmoid sinus dehiscence(SSDD). Nine patients (1.6%)had sigmoid sinus dehiscence with no diverticulum(SSDh). Two patients (0.4%)had sigmoid sinus diverticulum but no dehiscence(SSD). Of these eighteen patients eleven (61 %) patients were symptomatic with tinnitus (SSDD -3, SSD-2, SSDh-6), 4 (22%) were asymptomatic (SSDD-2, SSDh-2) and for three patients history was not available. Of these eleven symptomatic patients seven had tinnitus on the corresponding side and two patients had bilateral tinnitus. Two patients had tinnitus not corresponding to the side of sigmoid sinus diverticulum and dehiscence. Review of available magnetic resonance venogram for the symptomatic patients showed the presence of sigmoid sinus stenosis in three cases (SSDD-2, SSDh-1).

CLINICAL RELEVANCE/APPLICATION

Tinnitus is caused by multiple pathologies. Our study showed that Sigmoid sinus diverticulum and dehiscence has low prevalence in population but still can be the cause for tinnitus.

HN05-A2 MRI-based Assessment Of The Mylohyoid Muscle In Squamous Cell Cancer Of The Floor Of Mouth: A 7-points Score Method

Participants
Jasmina De Groodt, MD, Trieste, Italy (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to identify preoperative MR imaging characteristics of mylohyoid muscle that predispose the outcome of surgical intervention toward an insecure (positive or close) surgical margin in squamous cell carcinoma of the floor of mouth.*Methods and Materials Between March 2010 and March 2021, 80 consecutive patients with diagnosis of squamous cell carcinoma of the floor of mouth underwent surgical intervention at our institution. Among these, 55 with preoperative MR imaging and postoperative pathologic reports after surgery were included. Two neuroradiologists evaluated retrospectively the preoperative MR imaging scans to predict the tumor spread through the mylohyoid muscle using a 7-point scale: 1, distance between tumor and mylohyoid = 5 mm; 2, distance < 5 mm but no contact; 3, tumor in contact with mylohyoid; 4, bulging of mylohyoid; 5, thinned and/or irregular mylohyoid; 6, full-thickness signal alteration; 7, signal alteration trough mylohyoid in submandibular space.*Results A score of >4 could predict an insecure margin with same sensitivity in both neuroradiologists assessment (90,91%, C.I. 0.57±0.99) and with specificity respectively of 56,82% (C.I. 0.41±0.71) and 59,09% (C.I. 0.49±0.73). The interobserver agreement of MR imaging scores was excellent in specificity (Chi-squared 0.095, P=0.7584) with a high negative predictive value (96%, C.I. 0.77±0.99).*Conclusions The pre-surgery MR imaging scoring system for the mylohyoid muscle is a promising predictor of the surgical margin in floor of mouth squamous cell carcinoma.*Clinical Relevance/Application Preoperative MRI score-based assessment of mylohyoid muscle's infiltration could guide surgeon in predicting surgical invasiveness and complexity as well as in reconstruction planning.

RESULTS

A score of >4 could predict an insecure margin with same sensitivity in both neuroradiologists assessment (90,91%, C.I. 0.57±0.99) and with specificity respectively of 56,82% (C.I. 0.41±0.71) and 59,09% (C.I. 0.49±0.73). The interobserver agreement of MR imaging scores was excellent in specificity (Chi-squared 0.095, P=0.7584) with a high negative predictive value (96%, C.I. 0.77±0.99).

CLINICAL RELEVANCE/APPLICATION

Preoperative MRI score-based assessment of mylohyoid muscle's infiltration could guide surgeon in predicting surgical invasiveness and complexity as well as in reconstruction planning.

MS01-A2   **Computational Modeling Using Automated DL-based Quantitative CT Visualization Of Traumatic Hemothorax And Point-of-care Clinical Parameters Predicts Hemorrhage Related Outcomes.**

Participants
Bryan Nixon, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

We develop and test a computational model for prediction of exsanguination-related complications from traumatic hemothorax (massive transfusion (MT) and in-hospital mortality (IHM)) incorporating automated voxelwise deep learning (DL)-based quantitative visualization (QV) combined with relevant clinical variables available at point of care. Model performance is compared to QV measurements (HTXvol-auto) alone, and subjective consensus grading (HTX-subj: small, moderate, large) by an expert trauma and chest radiologist. HTXvol-auto with the best performing algorithm (FAN U-Net) are validated against manual ground truth (HTXvol-manual), and results are compared to U-Net and 3D U-Net as baseline.*Methods and Materials The study included manually-labeled admission chest computed tomography (CT) images from 77 adult patients with traumatic hemothorax (HTX) between 2016-2018 from one trauma center. DL results including Dice similarity coefficients (DSCs) from 4-fold cross-validation were compared for 3D U-Net, U-Net, and FAN U-Net (a multiscale feature extraction model with scale invariant attention mechanism). FAN U-Net HTXvol-auto was incorporated into a random forest (RF) multivariable model including age, injury mechanism (blunt or penetrating), HR, SBP, and lactate. Performance of the RF model, HTXvol-auto alone, and HTX-subj was evaluated for the composite outcome (MT + IHM).*Results Mean DSCs for 3D U-Net, U-Net, and FAN U-Net were 0.37±0.14, 0.60±0.13, and 0.61±0.14, respectively. HTXvol-auto had excellent agreement (ICC=0.76) and correlation (Pearson r=0.91) to HTXvol-manual, with -0.6 mL mean under-measurement bias. The RF model, HTXvol-auto alone, and HTX-subj had area under receiver operating characteristic (auROC) of 0.94, 0.71, and 0.76, respectively. Using peak Mathews correlation coefficient, optimal predictive HTXvol-auto threshold was 318 mL.*Conclusions The RF model incorporating HTXvol-auto and clinical variables available at the point of care showed improved accuracy over automated volumes and subjective grading alone for predicting hemorrhage-related outcomes.*Clinical Relevance/Application HTX is often described subjectively. We demonstrate the value of a multivariable model using objective, interpretable QV and clinical data for personalized hemorrhage-related outcome prediction.

RESULTS

Mean DSCs for 3D U-Net, U-Net, and FAN U-Net were 0.37±0.14, 0.60±0.13, and 0.61±0.14, respectively. HTXvol-auto had excellent agreement (ICC=0.76) and correlation (Pearson r=0.91) to HTXvol-manual, with -0.6 mL mean under-measurement bias. The RF model, HTXvol-auto alone, and HTX-subj had area under receiver operating characteristic (auROC) of 0.94, 0.71, and 0.76, respectively. Using peak Mathews correlation coefficient, optimal predictive HTXvol-auto threshold was 318 mL.

CLINICAL RELEVANCE/APPLICATION

HTX is often described subjectively. We demonstrate the value of a multivariable model using objective, interpretable QV and clinical data for personalized hemorrhage-related outcome prediction.

MS01-A3   **Radiologic Manifestations Of Turner Syndrome**

Participants
Eric Crotty, MD, Cincinnati, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

1) Turner Syndrome (TS) is the most common sex chromosome disorder in females and is caused by the loss of part or all of an X chromosome. Multiple genotypes and phenotypes exist with varying extent of multisystem involvement.2) Radiologists may encounter TS patients in a variety of settings and from varied referral sources. Knowledge of the multisystemic involvement and the diverse appearance on different modalities can result in earlier diagnosis and help improve outcomes by directing patients to appropriate resources.3) Systems affected include cardiovascular, musculoskeletal, genitourinary, immune, and auditory systems.

TABLE OF CONTENTS/OUTLINE

MS01-B1 Resident-Attending Discrepancy Rates For Two Consecutive Versus Nonconsecutive Weeks Of Overnight Shifts

Participants
Ryan Rigsby, MD, Loma Linda, California (*Presenter*) Nothing to Disclose

PURPOSE

In 2017, the ACGME revised its night float policy by permitting residents to train more than 6 consecutive shifts. At our institution, two senior radiology residents dictate urgent/emergent studies from 9pm-8am. They are assigned 6 shifts in a row with 14 shifts in a 4-week block. Residents voiced personal preferences, however, to work either 7 or 14 shifts in a row. This was permitted on a voluntary basis for resident convenience. Those choosing 7 shifts typically had a mix of day shifts and days off between their first and second 7-night blocks. We retrospectively analyzed resident-attending discrepancy rates comparing those choosing 14 consecutive nights vs. split 7-night shifts (nonconsecutive) hypothesizing increased second-week discrepancy rates for the consecutive group.*Methods and Materials In 2020, 24 consecutive weeks were analyzed. Database searches used departmentally standardized terms for discrepancies, which were counted if significant enough to warrant attending contact of the care team. Studies were counted as positive or negative for discrepancy. Cross-sectional (CS; i.e., MR and CT), radiograph plus occasional fluoroscopy (XR), ultrasound (US), and overall discrepancy rates were calculated. Paired and unpaired t tests were performed with significance considered p less than 0.05. IRB waiver was obtained.*Results Eighteen residents (8 R4s, 10 R3s) were on rotation with 6 rotating twice. For the 24 sets of two-weeks covered, 8 were nonconsecutive and 16 were consecutive. All residents were compliant with ACGME duty hours. Total studies were 27,906 with 35% CS (including 5% MR), 55% XR, 10% US. Pediatric cases comprised 20%. For week 1, nonconsecutive vs. consecutive discrepancy rates were 2.2 vs. 1.4% CS, 0.1 vs. 0.2% XR, 0.2 vs. 0.2% US, 0.9 vs. 0.6% overall. For week 2, nonconsecutive vs. consecutive discrepancy rates were 2.0 vs. 1.9% CS, 0.3 vs. 0.2% XR, 1.1 vs. 0.7% US, 1.0 vs. 0.9% overall. There was no significant difference in the overall rates for week 1 vs. 2 within the nonconsecutive group (p=0.64), within the consecutive group (p=0.19), or between the groups for week 1 (p=0.32) or week 2 (p=0.60).*Conclusions Overnight discrepancy rates were not significantly different for residents working 14 consecutive vs. nonconsecutive shifts and were = 1.0% overall, similar to rates in the literature.*Clinical Relevance/Application Fatigue and its potential impact on patient care are important topics of medical training. Progressive autonomy is needed to produce competent, independent radiologists, but trainee autonomy must not compromise high quality patient care. This single-institution pilot study shows that residents who chose 14 consecutive overnight shifts performed similarly to those who worked nonconsecutive shifts.

RESULTS

Eighteen residents (8 R4s, 10 R3s) were on rotation with 6 rotating twice. For the 24 sets of two-weeks covered, 8 were nonconsecutive and 16 were consecutive. All residents were compliant with ACGME duty hours. Total studies were 27,906 with 35% CS (including 5% MR), 55% XR, 10% US. Pediatric cases comprised 20%. For week 1, nonconsecutive vs. consecutive discrepancy rates were 2.2 vs. 1.4% CS, 0.1 vs. 0.2% XR, 0.2 vs. 0.2% US, 0.9 vs. 0.6% overall. For week 2, nonconsecutive vs. consecutive discrepancy rates were 2.0 vs. 1.9% CS, 0.3 vs. 0.2% XR, 1.1 vs. 0.7% US, 1.0 vs. 0.9% overall. There was no significant difference in the overall rates for week 1 vs. 2 within the nonconsecutive group (p=0.64), within the consecutive group (p=0.19), or between the groups for week 1 (p=0.32) or week 2 (p=0.60).

CLINICAL RELEVANCE/APPLICATION

Fatigue and its potential impact on patient care are important topics of medical training. Progressive autonomy is needed to produce competent, independent radiologists, but trainee autonomy must not compromise high quality patient care. This single-institution pilot study shows that residents who chose 14 consecutive overnight shifts performed similarly to those who worked nonconsecutive shifts.

MS01-B2 Traumatic Abdominal Wall Hernias In The Pediatric Population

Participants
Grant VanNess, BS, Westfield, Indiana (*Presenter*) Nothing to Disclose

PURPOSE

Pediatric traumatic abdominal wall hernias (TAWH) are rare but potentially devastating injuries, classically considered to be caused by handlebar injuries from bicycle accidents. However, our anecdotal experience suggests pediatric TAWH are far more likely following road traffic accidents and have a high association with other significant intra-abdominal injuries. Therefore, the purpose of this study was to determine the incidence, mechanisms of injury, associated injuries, and outcomes of TAWH in the pediatric population.*Methods and Materials This retrospective observational study used data from two large urban level 1 trauma centers. Institutional trauma registries were queried from January 1, 2008 to December 31, 2020 for patients under 18 years old diagnosed with traumatic abdominal wall hernias, excluding those without initial abdominopelvic CT imaging. Finalized CT reports and images were reviewed to confirm the presence of a TAWH and document any associated secondary injuries. The medical record was used to extract pertinent physical findings, interventions performed, and outcomes.*Results A total of 14 patients met inclusion criteria with an incidence of 6.4 cases/100,000 patients-year, a mean age of 11.5 (range 7-17), 8 males (57.1%), and mean Injury

Severity Score (ISS) of 17.9 (range 1-48, with 57.1% with ISS &gt 15). The most common mechanism of injury was motor vehicle collision (N=8, 57.1%) followed by bicycle accident (N=3, 21.4%). The mean hospital stay was 11.5 days with 2.8 days in the ICU. All 14 required surgery, including 11 acute primary hernia repairs and 1 delayed primary hernia repair. A total of 12 (85.7%) had associated injuries, including 8 (57.1%) with intestinal injuries, 2 (14.3%) with splenic injuries, 2 (14.3%) with kidney injuries, 3 (21.4%) with pelvic fractures, 3 (21.4%) with femur fractures, and 1 (7.1%) with a Chance fracture of the lumbar spine.*Conclusions Pediatric TAWH are more likely due to motor vehicle collisions, with a majority (85.7%) suffering other significant injuries, most frequently to the bowel (57.1%). The classic handlebar injury seen in a minority of cases was much less likely to be associated with additional injuries.*Clinical Relevance/Application Current data on pediatric TAWH is limited primarily to case reports and case series, with fewer than 100 documented. A large-scale study is needed to better characterize this rare disease entity.

RESULTS

A total of 14 patients met inclusion criteria with an incidence of 6.4 cases/100,000 patients-year, a mean age of 11.5 (range 7-17), 8 males (57.1%), and mean Injury Severity Score (ISS) of 17.9 (range 1-48, with 57.1% with ISS &gt 15). The most common mechanism of injury was motor vehicle collision (N=8, 57.1%) followed by bicycle accident (N=3, 21.4%). The mean hospital stay was 11.5 days with 2.8 days in the ICU. All 14 required surgery, including 11 acute primary hernia repairs and 1 delayed primary hernia repair. A total of 12 (85.7%) had associated injuries, including 8 (57.1%) with intestinal injuries, 2 (14.3%) with splenic injuries, 2 (14.3%) with kidney injuries, 3 (21.4%) with pelvic fractures, 3 (21.4%) with femur fractures, and 1 (7.1%) with a Chance fracture of the lumbar spine.

CLINICAL RELEVANCE/APPLICATION

Current data on pediatric TAWH is limited primarily to case reports and case series, with fewer than 100 documented. A large-scale study is needed to better characterize this rare disease entity.

NMMI01-B1   Predicting Patient Response To Y-90 Selective Internal Radiation Therapy (SIRT) Using Tumor-to-Normal Tissue (T/N) Dosimetry Ratios

Participants
Munir Ghesani, MD, New York, New York (*Presenter*) Author, Siemens AG;Speaker, Siemens AG

PURPOSE

The purpose of our work is to predict response in patients undergoing locoregional therapy to the liver with Y-90 microspheres using tumor-to-normal tissue (T/N) dosimetry ratios.*Methods and Materials 39 patients (7 femal:32 male, mean age 68.3± 7.6y), underwent PET/CT imaging after treatment with Y-90 microspheres. For attenuation correction and localization of the Y-90 microspheres, the low mA, non-diagnostic CT images from PET/CT were used. The acquisition took 15 min and the reconstruction matrix size was 200x200x75 mm and voxel size of 4.07x4.07x3.00 mm. For dosimetry calculations the local deposition method with known activity of Y-90 was used. For each patient, regions-of-interest (ROIs) for tumor(s) and whole liver were manually created; the normal tissue ROI was created automatically. mRECIST criteria on MRI done at a month post treatment and subsequently every three months after Y-90 treatment, were used to assess response.*Results For 39 patients, the mean liver, tumor, and normal tissue doses (mean ± SD) were, 55.17±26.04 Gy, 911.87±866.54 Gy and 47.79 ±20.47 Gy respectively. Among these patients, 31 (79%) showed complete response (CR) and 8 (21%) showed progression of disease (PD). For patients with CR, the mean T/N dose ratio obtained was 24.91 (range 3.09 - 80.12) and for patients with PD, the mean T/N dose ratio was significantly lower, at 6.69 (range 0.36-14.75).*Conclusions According to our results, we conclude that patients with CR have a statistically higher T/N dose ratio than those with PD. For patients with low T/N ratios, close to or less than 1.0, thorough follow-up is required, and repeated treatment may be necessary. Because, the number of PD cases was limited, partial volume effect was not considered and motion correction was not applied for lesions in superior hepatic lobes, further investigation is highly desirable.*Clinical Relevance/Application Tumor-to-normal tissue dosimetry ratios can be used for predicting response in patients undergoing locoregional therapy to the liver with 90Y microspheres.

RESULTS

For 39 patients, the mean liver, tumor, and normal tissue doses (mean ± SD) were, 55.17±26.04 Gy, 911.87±866.54 Gy and 47.79 ±20.47 Gy respectively. Among these patients, 31 (79%) showed complete response (CR) and 8 (21%) showed progression of disease (PD). For patients with CR, the mean T/N dose ratio obtained was 24.91 (range 3.09 - 80.12) and for patients with PD, the mean T/N dose ratio was significantly lower, at 6.69 (range 0.36-14.75).

CLINICAL RELEVANCE/APPLICATION

Tumor-to-normal tissue dosimetry ratios can be used for predicting response in patients undergoing locoregional therapy to the liver with 90Y microspheres.

NMMI01-B4   Tailored Gadolinium-based Nanoparticles Escorting Mesenchymal Stem Cells For Ischemic Stroke Therapy

Participants
Shiman Wu, MD, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

A gadolinium(Gd)-based nanoparticles(NPs) with protective effect was designed for escorting mesenchymal stem cells (MSCs) for ischemic stroke therapy and in vivo tracking by MRI, so as to protect MSCs from the excessive Ca2+ and reactive oxygen species (ROS) microenvironment due to ischemia.*Methods and Materials NaGdF4 nanoparticles were synthesized, coated with polydopamine (PDA) for scavenging ROS, and conjugated with alendronate sodium (ALD) for chelating the intracellular Ca2+. Ischemic stroke model was induced by middle cerebral artery occlusion (MCAO) on rats. MSCs labeled with NaGdF4@PDA@ALD NPs (NPANs-MSCs), non-labelled MSCs and the same volume of saline were stereotaxtically injected into the brain of MCAO rats. All rats were monitored over time T1 weighted imaging(T1WI) and the arterial spin labeling (ASL) sequence via MRI.*Results NaGdF4@PDA@ALD NPs (NPANs) exhibited with high r1 longitudinal relaxivity (17.16 mm-1 s-1). In NPANs-MSCs group, prominent hyperintense signal was observed in the striatum (the ischemic core) and cortex (peri-infarct region) 7, 14, 21 days after stroke. Both NPANs-MSCs and non-labelled MSCs groups showed relatively higher cerebral blood flow (rCBF) compared with the saline-control group on post-stroke day 7. Besides, compared with day 7 after stroke, NPANs-MSCs group demonstrated significantly increased reperfusion in striatum at day 14, while non-labeled MSCs group did not. On day 21 after stroke, the ischemic left brain showed similar pattern of cerebral blood flow as the contralateral right brain.*Conclusions Transplanted NPANs-MSCs were successfully migrated, showing enhanced signal intensity in ischemic stroke areas and increased blood flow. The protecting property of NPANs-MSCs could improve the therapeutic effect of MSCs towards stroke.*Clinical Relevance/Application Based on the challenge of transplanted MSCs, NPANs were specifically tailored to help MSCs overcome the oxidate stress due to ischemia. Meanwhile, Gd-based NPs could help track MSCs on T1WI in vivo, avoiding the ambiguity between iron-based-NPs-labelled cells and microbleeds on T2WI. Though Gd-based NPs might cause adverse effect due to Gd deposition, it can help us initially investigate the mechanism of the migration of MSCs and can be switched into non-Gd-based NPs for in vivo tracking for further study. In summary,

NPANs-MSCs would be a new approach to accelerate the clinical translation of stem cell therapy, and shed light on new nanomedicine designation and development.

RESULTS

NaGdF4@PDA@ALD NPs (NPANs) exhibited with high r1 longitudinal relaxivity (17.16 mm-1 s-1). In NPANs-MSCs group, prominent hyperintense signal was observed in the striatum (the ischemic core) and cortex (peri-infarct region) 7, 14, 21 days after stroke. Both NPANs-MSCs and non-labelled MSCs groups showed relatively higher cerebral blood flow (rCBF) compared with the saline-control group on post-stroke day 7. Besides, compared with day 7 after stroke, NPANs-MSCs group demonstrated significantly increased reperfusion in striatum at day 14, while non-labeled MSCs group did not. On day 21 after stroke, the ischemic left brain showed similar pattern of cerebral blood flow as the contralateral right brain.

CLINICAL RELEVANCE/APPLICATION

Based on the challenge of transplanted MSCs, NPANs were specifically tailored to help MSCs overcome the oxidate stress due to ischemia. Meanwhile, Gd-based NPs could help track MSCs on T1WI in vivo, avoiding the ambiguity between iron-based-NPs-labelled cells and microbleeds on T2WI. Though Gd-based NPs might cause adverse effect due to Gd deposition, it can help us initially investigate the mechanism of the migration of MSCs and can be switched into non-Gd-based NPs for in vivo tracking for further study. In summary, NPANs-MSCs would be a new approach to accelerate the clinical translation of stem cell therapy, and shed light on new nanomedicine designation and development.

NMMI01-B5 Advances In Nuclear Medicine Imaging For Detection Of Alzheimer Disease

Participants
Pokhraj Suthar, MBBS, Chicago, Illinois (*Presenter*) Nothing to Disclose

TEACHING POINTS

Various PET agents available for detection of Alzheimer's disease (AD), with examples.Study important signs in PET (Amyloid and FDG) imaging for diagnosis of AD.Clinical application of Amyloid PET and F-18 FDG PET imaging in Dementia.

TABLE OF CONTENTS/OUTLINE

Alzheimer disease(AD) is progressive neurodegenerative disease characterized by impairments in memory & cognitive functions accounting for 60% to 80% cases of dementia. Pathophysiology of AD includes deposition of beta-amyloid & tau tangles leading to synaptic dysfunction & death of neuronal/glial cells. Various imaging modalities used for diagnosis of AD. MRI brain demonstrate cortical atrophy in advance cases of AD. FDG PET imaging demonstrate hypometabolism. Amyloid PET imaging targets early deposition of amyloid in the gray matter. FDA approved PET agent for imaging of amyloid are F-18 Florbetapir, Florbetaben, Flutemetamol and for imaging of tau protein is F-18 Flortaucipir(Tauvid). F-18 GTP1(Genentech Tau Probe 1) is a radioligand for detecting neurofibrillary tangle tau protein in AD. Increased F-18 labelled amyloid agents uptake in gray matter & is early biomarker and can be detected in patients before appearance of clinical symptoms of AD or prior to changes evident on F-18 FDG PET. Regional distribution of tau in brain has better correlation with disease progression & it may become positive before amyloid imaging. Through this exhibit, we intend to strategically discuss important signs, artifacts & clinical applications of PET brain imaging radiopharmaceuticals in AD.

GI03-A11   Evaluation Of Her2 Expression In Gastric Cancer Using Quantitative Ct Perfusion Parameters

Participants
Zhang Min, Jinan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the feasibility of multiple CT perfusion parameters in distinguishing expression of HER2 in gastric cancer preoperatively.*Methods and Materials 68 patients confirmed of gastric cancer with gastroscopy were preoperatively examined perfusion CT (PCT) and curative gastrectomy. The enrolled patients were divided according to HER2 expression in term of positive and negative group. PCT parameters, blood-flow (BF), blood volume (BV), mean transmit time(MTT),time to peak (TTP) and permeability surface(PS)were calculated. The differences of parameters in HER2 groups were calculated with student t test. A receiver operating characteristic (ROC) analysis was applied to evaluate the diagnostic performance of meaningful PCT parameters.*Results PS and BV in HER2 negative group were 35.82±5.67 (ml/100g/min) and 4.42±1.13 (ml/100g). They were 45.32±8.40(ml/100g/min) and 5.96±1.35(ml/100g) in HER2 positive group. There were statistical differences in PS and BV between HER2 positive group and negative group. The area under the ROC curve for the diagnosis of HER2 positive gastric cancer by BV and PS was 0.843(sensitivity, 73.6%; specificity, 93.3%) and 0.819(sensitivity, 77.4%; specificity, 80.0%), with the cut-off value of 38.25 ml/100g/min and 5.01ml/100g, respectively.*Conclusions PCT can quantitatively evaluate HER2 expression in gastric cancer, a prognostic indicator related to gastric cancer.*Clinical Relevance/Application PCT quantitative parameters are potential in disguising HER2 expressions in gastric cancer.

RESULTS

PS and BV in HER2 negative group were 35.82±5.67 (ml/100g/min) and 4.42±1.13 (ml/100g). They were 45.32±8.40(ml/100g/min) and 5.96±1.35(ml/100g) in HER2 positive group. There were statistical differences in PS and BV between HER2 positive group and negative group. The area under the ROC curve for the diagnosis of HER2 positive gastric cancer by BV and PS was 0.843(sensitivity, 73.6%; specificity, 93.3%) and 0.819(sensitivity, 77.4%; specificity, 80.0%), with the cut-off value of 38.25 ml/100g/min and 5.01ml/100g, respectively.

CLINICAL RELEVANCE/APPLICATION

PCT quantitative parameters are potential in disguising HER2 expressions in gastric cancer.

GI03-A3   Artificial Intelligence-based Analysis Of Body Composition - A New Software Tool For Rapid Fully Automatic Image Segmentation

Participants
Nick Beetz, MD, Berlin, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate a new artificial intelligence (AI)-based workflow, trained to automatically detect a selected computed tomography (CT) slice at the third lumbar vertebra (L3) and automatically perform complete image segmentation for analysis of body composition, and to compare its performance to an established semi-automatic segmentation tool in regard of speed and quality of the measurements.*Methods and Materials For fully automatic analysis of body composition, a U-Net was trained using 200 axial CT images at L3 (Visage). A second U-Net was trained to identify the L3 vertebra along the sagittal direction of the image data. For semi-automatic analysis of body composition, a conventional image segmentation software (sliceOmatic v5.0, Tomovision) was used. Using both segmentation methods the tissue was differentiated into psoas muscle, skeletal muscle, visceral adipose tissue (VAT) and subcutaneous adipose tissue (SAT). The area in square centimeters (cm2) of each segmented tissue class was calculated. To evaluate both methods, DICOM slice files of 20 random CT at L3 were segmented with both methods. Semi-automatic image segmentation was performed by two radiologists and compared to the fully automatic workflow with L3 recognition. Quality of the segmentations was compared using the relative difference between the measurements.*Results Success rate of L3 recognition was 100 % for the AI-based workflow. Compared to the semi-automatic segmentation fully automatic AI-based segmentation of the different tissue areas yielded a relative difference of 0.22 % for skeletal muscle, 0.49 % for psoas muscle, 1.34 % VAT und 0.18 % SAT in the first reader, and a relative difference of 0.17 % for skeletal muscle, 0.49 % for psoas muscle, 2.61 % for VAT und 0.19 % for SAT in the second reader. AI-based segmentation was significantly faster than semi-automatic segmentation (Visage 3 ± 0 seconds versus sliceOmatic 170 ± 40 seconds, p< 0,001, for reader 1, and 152 ± 40 seconds, p< 0,001, for reader 2).*Conclusions Fully automatic AI-based, PACS-integrated analysis of body composition with L3 recognition is feasible and easily available from CT imaging. Fully automatic AI-based assessment of body composition using Visage shows almost identical measurements of body composition parameters compared to conventional semi-automatic image segmentation. The embedded solution also offers the familiar clinical tools and does not require any transfer of data. This AI-based software solution alleviates the need for external software and enables future studies to analyze body composition in large patient populations.*Clinical Relevance/Application Rapid and accurate fully automatic AI-based analysis of body composition may aid in risk stratification and improvement of patient care.

RESULTS

Success rate of L3 recognition was 100 % for the AI-based workflow. Compared to the semi-automatic segmentation fully automatic AI-based segmentation of the different tissue areas yielded a relative difference of 0.22 % for skeletal muscle, 0.49 % for psoas muscle, 1.34 % VAT und 0.18 % SAT in the first reader, and a relative difference of 0.17 % for skeletal muscle, 0.49 % for psoas muscle, 2.61 % for VAT und 0.19 % for SAT in the second reader. AI-based segmentation was significantly faster than semi-automatic segmentation (Visage 3 ± 0 seconds versus sliceOmatic 170 ± 40 seconds, p< 0,001, for reader 1, and 152 ± 40 seconds, p< 0,001, for reader 2).

CLINICAL RELEVANCE/APPLICATION

Rapid and accurate fully automatic AI-based analysis of body composition may aid in risk stratification and improvement of patient care.

GI03-A4   Abdomen Radiographs In The CT/MR Era, Update 2021: The Surprising Numbers And Implications For Training

Participants
Yang Jiang, DO, Jacksonville, Florida (*Presenter*) Nothing to Disclose

PURPOSE

Purpose: An analysis of abdomen radiograph nationwide utilization trends over the past two decades, with particular emphasis on the implications for trainees*Methods and Materials Medicare procedure volumes from 2000 through 2019 were analyzed with respect to 3 studies: single view abdomen; two view abdomen; two view abdomen plus chest filmMedicare volumes can then be extrapolated to approximate nationwide procedure utilization.*Results In 2019, 10.1 million abdomen radiographs were performed in the U.S.Over the twenty year span, the number of single view abdomen studies actually rose significantly, from 5.5 million in 2000 to 7.4 million in 2019 -- a surprising 34% increase.*Conclusions Despite the primacy of cross-sectional imaging, abdomen radiograph utilization remains remarkably durable, with over 10 million studies yearly.*Clinical Relevance/Application Abdomen radiograph interpretation will be a necessary patient care skill in radiology practices for years to come, and so instruction directed toward that skill should should remain part of our standard resident curriculum.

RESULTS

In 2019, 10.1 million abdomen radiographs were performed in the U.S.Over the twenty year span, the number of single view abdomen studies actually rose significantly, from 5.5 million in 2000 to 7.4 million in 2019 -- a surprising 34% increase.

CLINICAL RELEVANCE/APPLICATION

Abdomen radiograph interpretation will be a necessary patient care skill in radiology practices for years to come, and so instruction directed toward that skill should should remain part of our standard resident curriculum.

GI03-A5   Factors Affecting MRI Scanner Efficiency In An Academic Center

Participants
Paul Smereka, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

To investigate patient level factors affecting liver MRI exam time, with an aim to improve efficiency by allotting different scanner slot times based on patient characteristics.*Methods and Materials Scan times for all extracellular contrast enhanced Liver MRI exams performed on a 1.5T and 3T scanner in 2019 were assessed at an outpatient facility. To measure the scan times on our different scanners, we developed an open-source software tool that automatically transmits information about executed sequences to a central intranet server where the sequence data are aggregated by examinations for retrospective analysis. Here, scan time is defined as the duration between the start of the first adjustment scan to the end of last imaging sequence. Any patient symptoms and breathing issues during the exam were recorded by the technologist. Additional patient characteristics were determined using review of EMR. Welch's T-test and Pearson's Chi Square Test were used to assess continuous and categorical values. Patients with breathing issues during exam (i.e could not follow breathing instructions, difficulty with breath hold sequences) were compared to those who did not.*Results 322 total scans were performed with median scan time 19.24 minutes. Scan times were significantly increased for patients with breathing issues during exam (N=49, median=23.98 minutes) versus not (N=273, median = 18.69 minutes, p<.001). When scans were separated into groups with/without breathing issues, the group with breathing issues had a significantly higher proportion of patients for whom English was not their first language (21/49 [43%] vs 28/207 [14%] , p = 0.007), and who used a translator during the exam (14/49 [29%] vs 35/273 [13%], p=0.01) . Patients who had breathing issues were also significantly older (mean 63.11 vs 58.12, p=0.02). No other patient characteristics were significantly different: sex (p=0.29), BMI(p=0.98), hearing problem(p=0.11), vision problem (p=.30), claustrophobia (p=0.67), asthma (p=0.849, COPD (p=0.67), other lung disease(p=0.15), CHF (p=0.39), other heart disease (p=0.61), or prior MRI (p=0.62).*Conclusions The ability to follow breathing instructions and complete breath hold sequences has a significant impact on patient scan time. Older patients and those who are not native English speakers had more breathing issues during scans requiring increase in scan time. Future educational efforts will target improving scan time in these patients.*Clinical Relevance/Application Implementing clearer instructions in different languages, and allotting more time per scan for older patients and non-native English speakers my improve MRI scanner efficiency.

RESULTS

322 total scans were performed with median scan time 19.24 minutes. Scan times were significantly increased for patients with breathing issues during exam (N=49, median=23.98 minutes) versus not (N=273, median = 18.69 minutes, p<.001). When scans were separated into groups with/without breathing issues, the group with breathing issues had a significantly higher proportion of patients for whom English was not their first language (21/49 [43%] vs 28/207 [14%] , p = 0.007), and who used a translator during the exam (14/49 [29%] vs 35/273 [13%], p=0.01) . Patients who had breathing issues were also significantly older (mean 63.11 vs 58.12, p=0.02). No other patient characteristics were significantly different: sex (p=0.29), BMI(p=0.98), hearing problem(p=0.11), vision problem (p=.30), claustrophobia (p=0.67), asthma (p=0.849, COPD (p=0.67), other lung disease(p=0.15), CHF (p=0.39), other heart disease (p=0.61), or prior MRI (p=0.62).

CLINICAL RELEVANCE/APPLICATION

Implementing clearer instructions in different languages, and allotting more time per scan for older patients and non-native English

speakers my improve MRI scanner efficiency.

GI03-A6   Contrast-enhanced Endoscopic US Of Sentinel Lymph Nodes In Esophageal Cancer Following Peri-tumoral Injection

Participants
Priscilla Machado, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

In patients with early-stage esophageal cancers, lymph node (LN) positivity stratifies patients that might benefit from neoadjuvant therapy prior to resection. The US contrast agent Sonazoid (GE Healthcare, Oslo, Norway) has been shown to be a useful lymphatic tracer following peri-tumoral injection. Hence, we evaluated the performance of contrast-enhanced endoscopic US (CE-EUS) guided fine needle aspiration (FNA) following peri-tumoral inject of sentinel lymph nodes (SLNs) compared to standard EUS guided FNA for nodal staging in esophageal cancer patients.*Methods and Materials In this IRB- and FDA-approved pilot study, patients with newly-diagnosed esophageal cancer undergoing staging EUS provided informed consent to undergo CE-EUS. A Prosound F75 US system (Hitachi Medical Systems, Tokyo, Japan) with harmonic contrast software and a GF-UCT180 curvilinear endoscope (Olympus, Tokyo, Japan) was utilized. All lymph nodes identified by EUS were noted. Sonazoid (dose: 1 mL) was then administered into the submucosal plane peri-tumorally and all detected SLNs underwent FNA. Per standard-of-care, FNA was also performed on LNs considered suspicious by EUS alone. Performance of each modality was compared against cytology.*Results Twenty patients were enrolled and completed to date. No adverse events were observed following peri-tumoral injection of Sonazoid under EUS guidance. A total of 92 nodes were identified. Standard EUS identified 28 LNs as high risk with 10 amenable to biopsy. Of these 10, 4 were found to contain metastatic disease (cytological yield = 40%). CE-EUS identified a total of 38 enhancing nodes out of which 35 were amenable to biopsy. Of these 35 nodes, 17 were found to contain metastatic disease (cytological yield = 49%). Importantly, 5 patients (25% of study total) had their nodal status upgraded with the addition of CE-EUS, directly altering their course of therapy.*Conclusions Initial results suggest CE-EUS may increase FNA cytologic yield by ruling out nodes not associated with the tumor drainage pattern and also identifying SLNs with metastatic deposits that would not be biopsied under standard EUS criteria.*Clinical Relevance/Application CE-EUS with peri-tumoral injection of a microbubble agent can improve SLN identification and characterization in esophageal cancer patients by offering more reliable tumor staging for clinical decision-making.

RESULTS

Twenty patients were enrolled and completed to date. No adverse events were observed following peri-tumoral injection of Sonazoid under EUS guidance. A total of 92 nodes were identified. Standard EUS identified 28 LNs as high risk with 10 amenable to biopsy. Of these 10, 4 were found to contain metastatic disease (cytological yield = 40%). CE-EUS identified a total of 38 enhancing nodes out of which 35 were amenable to biopsy. Of these 35 nodes, 17 were found to contain metastatic disease (cytological yield = 49%). Importantly, 5 patients (25% of study total) had their nodal status upgraded with the addition of CE-EUS, directly altering their course of therapy.

CLINICAL RELEVANCE/APPLICATION

CE-EUS with peri-tumoral injection of a microbubble agent can improve SLN identification and characterization in esophageal cancer patients by offering more reliable tumor staging for clinical decision-making.

GI03-A8   End-to-end Automated Body Composition Analyses With Integrated Quality Control For Opportunistic Assessment Of Sarcopenia In CT

Participants
Maike Theis, MSc, Bonn, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To automate body composition analysis and the assessment of fatty degeneration of skeletal muscle tissue on abdominal CT-scans with focus on integrated quality control (QC) required for large-scale application in clinical routine practice.*Methods and Materials The developed pipeline consists of two main steps, each followed by a quality control step. For extraction of a single slice at the L3/L4 lumbar level, a convolutional neural network (CNN) was trained on 240 3D CT-scans using the nnU-Net framework. For 2D segmentation of visceral and subcutaneous adipose tissue and skeletal muscle (VAT, SAT, SM), a fully convolutional 2D U-Net with competitive maxout units was developed separately on 1143 CT images. Fatty-muscle fraction (FMF) was determined in a post-processing step. Automated quality control was integrated by a logistic regression model classifying the presence of L3/L4 in the 3D CT-scan and a linear regression model for individual prediction of the segmentation quality in terms of the Dice-score. Both models were based on the predictions of the respective CNN.The performance of the slice extraction part, the tissue segmentation part, and of the entire pipeline was evaluated on 364 independent CT data from two centers and compared to manual analyses.*Results Excellent results were obtained on the dual-center test set. For slice extraction, mean z-deviation was 2.46±6.20mm and for tissue segmentation Dice-scores were 0.95±0.04 (SM), 0.98±0.02 (VAT) and 0.97±0.04 (SAT). For these evaluations, 10 patients with metallic implants were manually excluded.Importantly, no data were excluded for evaluation of the end-to-end performance of the entire pipeline with integrated QC. With restrictive setting of quality control, 39 of 364 cases were flagged as possibly having limited segmentation quality, including 8 patients with severe artefacts caused by metallic implants. With QC, high agreement was achieved between manual and fully automated analyses with mean relative area-deviations of ?SM=3.3±4.1%, ?VAT=3.0±4.7%, ?SAT=2.7±4.3% and ?FMF=4.3±4.4%.*Conclusions The proposed pipeline enables large-scale assessment of body composition metrics in clinical routine without the need for any manual interaction.*Clinical Relevance/Application End-to-End automation with integrated QC allows routine application of body composition analyses, e.g. for opportunistic assessment of sarcopenia.

RESULTS

Excellent results were obtained on the dual-center test set. For slice extraction, mean z-deviation was 2.46±6.20mm and for tissue segmentation Dice-scores were 0.95±0.04 (SM), 0.98±0.02 (VAT) and 0.97±0.04 (SAT). For these evaluations, 10 patients with metallic implants were manually excluded.Importantly, no data were excluded for evaluation of the end-to-end performance of the entire pipeline with integrated QC. With restrictive setting of quality control, 39 of 364 cases were flagged as possibly having limited segmentation quality, including 8 patients with severe artefacts caused by metallic implants. With QC, high agreement was achieved between manual and fully automated analyses with mean relative area-deviations of ?SM=3.3±4.1%, ?VAT=3.0±4.7%, ?SAT=2.7±4.3% and ?FMF=4.3±4.4%.

CLINICAL RELEVANCE/APPLICATION

End-to-End automation with integrated QC allows routine application of body composition analyses, e.g. for opportunistic

assessment of sarcopenia.

CH04-B1 Pulmonary Fibrosis In Patients With COVID-19 Pneumonia Treated With Low-dose Radiotherapy. Preliminary Results

Participants
Sara Gomez Pena, Madrid, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the findings on chest computed tomography (CT) in patients who received 4-7 months before low-dose radiotherapy (LD-RT) and to assess whether they present more fibrosis compared to patients who have not received LD-RT.*Methods and Materials Two expert cardiothoracic radiologists analyzed the chest CTs realized in patients who received 100 cGy to total lungs in a single fraction in order to treat COVID-19 pneumonia, the day of the LD-RT (0), day +7 and 4-7 months later. A semi-quantitative CT score was calculated based on the extent of lobar involvement (0: 0%; 1: <5%; 2: 5-25%, 3: 26-50%; 4: 51-75%; 5: 76-100%; global score 0-25). To be able to determine the degree of fibrosis we assessed among other radiological findings: ground glass opacities (GGO), consolidations, crazy-paving pattern, interstitial thickening, subpleural lines, parenchymal bands, bronchial dilatations, adenopathy and pleural effusion. We also evaluated the distribution and predominance of the findings and determined the predominant pattern in each lobe (A: GGO, B: consolidation, C: linear opacities, D: fibrosis). We used the Kappa coefficient for the qualitative variables and the intraclass correlation coefficient (ICC) for the quantitative variables. A Wilcoxon sign rank test for paired data was used to assess the variables.*Results Of the 41 patients who received LD-RT, 13 have died. To date, of the remaining 28, 16 patients have already undergone a chest CT at 4-7 months. We aimed to carry out the rest in the coming months. Median age was 63.5 (IQR 57-76). With almost perfect agreement, the extension score improved significantly (p=0.004; p=0.001) on day 7 and at 4-7 months (p=0.003; p=0.002). At 4-7 months there were a significant decreased in consolidation (p=0.009; p=0.009), also with almost perfect agreement. There were no other significant changes in the evaluated radiological findings. Median time to undergo the last chest CT was 159 days (ranging 141.5-165.5).*Conclusions Our preliminary results show that LD-RT produces a radiological improvement of COVID-19 pneumonia and that there is no significant increase in fibrosis parameters. Randomized trials are needed to establish whether there is a higher degree of fibrosis in those patients treated with LD-RT.*Clinical Relevance/Application LT-RT could be a feasible and well-tolerated treatment, without worsening the degree of fibrosis in patients with CPVOD-19 pneumonia.

RESULTS

Of the 41 patients who received LD-RT, 13 have died. To date, of the remaining 28, 16 patients have already undergone a chest CT at 4-7 months. We aimed to carry out the rest in the coming months. Median age was 63.5 (IQR 57-76). With almost perfect agreement, the extension score improved significantly (p=0.004; p=0.001) on day 7 and at 4-7 months (p=0.003; p=0.002). At 4-7 months there were a significant decreased in consolidation (p=0.009; p=0.009), also with almost perfect agreement. There were no other significant changes in the evaluated radiological findings. Median time to undergo the last chest CT was 159 days (ranging 141.5-165.5).

CLINICAL RELEVANCE/APPLICATION

LT-RT could be a feasible and well-tolerated treatment, without worsening the degree of fibrosis in patients with CPVOD-19 pneumonia.

CH04-B2 Ct Morphological Features Of The Mediastinal Drowning Sign In Pulmonary Diffuse Lymphangiomatosis

Participants
Qi Hao, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to identify morphological characteristics of the mediastinal drowning sign (MDS) on chest CT in patients with diffuse pulmonary lymphangiomatosis (DPL) that may aid the diagnosis of this congenital lymphtic disease.*Methods and Materials We retrospectively reviewed chest CT images from 38 patients with surgery proven DPL who demonstrated the MDS. Direct lymphangiography and thorax and abdominal MSCT examination were performed in all patients. Among them, 18 cases underwent enhanced MSCT examination. Two chest radiologists analysed the morphological characteristics of the MDS and others findings of the lesion and reached decisions by consensus.*Results The mediastinal drowning sign was seen in all patients with DPL. The typical imaging features of MDS were diffuse homogeneous (32/38, 84%) or inhomogeneous (16%) water-like or mucous density (32/38, 84%) in the whole aidpose region of the mediastinum without displacement and deformation of the trachea and large vessels. MSCT lymphangiography showed extensive deposition and leakage of contrast-medium (Ultra-liquid iodized oil) distributed along the mediastinum, the bilateral pulmonary hilum and the peribronchovascular bundles, which suggests lymphangiogenesis, lymphatic dilatation and reflux. The other accompanying findings includes Obstruction of thoracic duct (100%) and right lymphatic duct (12/38, 32%), dilated bronchomediastinal trunk (6/38, 16%), bronchovascular bundle and interlobular septal thickening (35/38, 92%), diffuse inhomogeneous GGO (35/38, 92%), chylothorax or extrapleural soft tissue thickening (30/38, 79%) and abnormal lymphatic vessels in the abdomen and bone (9/38, 24%).*Conclusions Our data suggest that

morphological characteristics of the MDS on chest CT, such as the presence of diffuse homogeneous water-like or mucous density in the whole fatty tissue region of the mediastinum with deposition and leakage of lymphatic contrast-medium, no displacement and deformation of the trachea and large vessels, as well as the association with other pulmonary interstitial thickening and chylothorax, should lead radiologists to to take the diagnosis and differentiation of DPL.*Clinical Relevance/Application Diffuse pulmonary lymphangiomatosis (DPL) is a rare congenital lymphtic developmental malformation in thorax. The mediastinal drowning sign (MDS) is one of the important manifestations of DPL and has important significance for the early diagnosis with pulmonary interstitial thickening and of chylothorax. This sign has not been reported in the literature by our knowledge.

RESULTS

The mediastinal drowning sign was seen in all patients with DPL. The typical imaging features of MDS were diffuse homogeneous (32/38, 84%) or inhomogeneous (16%) water-like or mucous density (32/38, 84%) in the whole aidpose region of the mediastinum without displacement and deformation of the trachea and large vessels. MSCT lymphangiography showed extensive deposition and leakage of contrast-medium (Ultra-liquid iodized oil) distributed along the mediastinum, the bilateral pulmonary hilum and the peribronchovascular bundles, which suggests lymphangiogenesis, lymphatic dilatation and reflux. The other accompanying findings includes Obstruction of thoracic duct (100%) and right lymphatic duct (12/38, 32%), dilated bronchomediastinal trunk (6/38, 16%), bronchovascular bundle and interlobular septal thickening (35/38, 92%), diffuse inhomogeneous GGO (35/38, 92%), chylothorax or extrapleural soft tissue thickening (30/38, 79%) and abnormal lymphatic vessels in the abdomen and bone (9/38, 24%).

CLINICAL RELEVANCE/APPLICATION

Diffuse pulmonary lymphangiomatosis (DPL) is a rare congenital lymphtic developmental malformation in thorax. The mediastinal drowning sign (MDS) is one of the important manifestations of DPL and has important significance for the early diagnosis with pulmonary interstitial thickening and of chylothorax. This sign has not been reported in the literature by our knowledge.

CH04-B4 Post COVID-19 Interstitial Lung Syndrome (PCOILS): A Fibrosing Or Non-fibrosing Disease?

Participants
Diletta Cozzi, MD, Prato, Italy (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study is to describe HRTC interstitial changes occurring 6-months after the admission for COVID-19.*Methods and Materials This is a single-center interim-analysis of a larger prospective-multicenter-national trial (12 Italian referral centers for ILDs). We describe the first cases enrolled in the period September 2020 - March 2021 at our university hospital and we collect data of patients at baseline and after 6 (+/-1) months after hospital discharge.HRCT changes at 6 months involving more than 5% of the total lung volume were considered significant. Patients with significant HRCT changes will undergo BAL and/or cryobiopsy and a subsequent follow-up with HRCT and lung function evaluation at 12(+/-1) and 18 (+/-1) months. A team of dedicated-thoracic radiologists evaluated at 6-months all patients that recovered from COVID-19. Radiologists were asked to define each HRCT as negative for pleural-parenchymal alterations, alterations' extension <less than 5%, positive for alterations major than 5% (whether the alterations were predominantly fibrosing-like or non-fibrosing).*Results 142 HRCT were evaluated. In particular 71/142 (50%) had a complete remission from lung involvement. The remains 71 patients had interstitial lung changes (both fibrosing-like and non-fibrosing): 41/142 less than 5%, 30/142 more than 5%. Of these, 26/142 (18.3%) showed interstitial fibrotic changes (with UIP pattern, NSIP and/or OP pattern and indeterminate pattern with diffuse ground glass). A small minority (1.4%) presents with the typical UIP pattern observed in IPF: we can't exclude that this might be expression of a pre-existing non-recognized UIP/IPF.*Conclusions These preliminary results show that a half of patients that recovered from COVID-19 have persistent HRCT changes 6-months after the acute infection. The trial was designed to define the risk factors for development of long-term-pulmonary sequelae of COVID-19, detect possible novel biomarkers for disease progression (including BAL and histopathology assessment). The analysis confirms that after COVID-19 infection a large minority of patients (18.3%) develops interstitial lung changes mostly with NSIP-OP, indeterminate features or ground glass, possible expression of the slow-healing OP/DAD pattern observed in the acute phase.*Clinical Relevance/Application The clinical meaning of the observed HRCT changes remains unclear. These results need further evaluations, especially after the 12-month-HRCT follow up, in order to define if HRCT findings are the expression of a real fibrosing disease. We are nowadays evaluating the first HRCT after 1 year-follow up.

RESULTS

142 HRCT were evaluated. In particular 71/142 (50%) had a complete remission from lung involvement. The remains 71 patients had interstitial lung changes (both fibrosing-like and non-fibrosing): 41/142 less than 5%, 30/142 more than 5%. Of these, 26/142 (18.3%) showed interstitial fibrotic changes (with UIP pattern, NSIP and/or OP pattern and indeterminate pattern with diffuse ground glass). A small minority (1.4%) presents with the typical UIP pattern observed in IPF: we can't exclude that this might be expression of a pre-existing non-recognized UIP/IPF.

CLINICAL RELEVANCE/APPLICATION

The clinical meaning of the observed HRCT changes remains unclear. These results need further evaluations, especially after the 12-month-HRCT follow up, in order to define if HRCT findings are the expression of a real fibrosing disease. We are nowadays evaluating the first HRCT after 1 year-follow up.

VA04-B1   **Imaging Of Venous Thrombosis With Ferumoxytol Enhanced Magnetic Resonance Angiography**

Participants
Sipan Mathevosian, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

PURPOSE

Ferumoxytol is a vascular contrast agent increasingly being used as an alternative to gadolinium-based agents, especially in critically ill patients and those with renal failure. Ferumoxytol enhanced magnetic resonance angiography (FE-MRA) is useful for a broad variety of arterial and venous applications. However, existing data on the utility of FE-MRA in the detection of deep venous thrombus (DVT) is limited, especially in critically ill patients. The purpose of this study was to evaluate the utility of FE-MRA for imaging of DVT in a large cohort of patients.*Methods and Materials After IRB approval, a single-center retrospective review was performed on all patients undergoing FE-MRA. A total of 798 patients with MR Angiograms and MR Venograms of the neck, chest, abdomen, pelvis, and extremities from July 2013 to June 2020 were included in this study. Reports from these studies were reviewed for presence of DVT. In all cases, patients had a history of chronic renal failure with contraindication to Gadolinium-based contrast agents. Vascular enhancement was achieved via administration of ferumoxytol (Feraheme, AMAG pharmaceuticals - Waltham, MA) at a dose of 4 mg/kg.Examinations were performed on Siemens 1.5T and 3.0T MR scanners. All studies included multiplanar post-contrast high-resolution breath-held 3D MRA. Post processing included reconstruction of multiplanar images, MIP images and 3-D volume rendered images in OsiriX software (Pixmeo - Bernex, Switzerland) and Vitrea software (Vital Images - Minnetonka, MN).*Results Venous thrombosis was identified in 83 of 798 studies (10.4%). 40 of 83 (48.2%) of DVT positive studies had a specific indication to evaluate for venous stenosis or thrombosis. Venous thrombosis was identified in a number of vascular beds with many patients having overlapping sites, and included: central thoracic veins (n=56), IVC or iliac veins (n=25), portomesenteric veins (n=9), peripheral extremity veins (n=4), renal veins (n=2), pulmonary veins (n=1), and intracardiac thrombus that included right atrial and Fontan conduit thrombus (n=2). Average patient age was 41.2 ± 22.6 years (0.4 - 78.3). 48 patients were male and 35 were female. Average patient weight was 64.1 ± 28.4 kg (6.5 - 131.5) and average weight-based contrast dose was 8.7 ± 4.0 mL (0.9 - 17). There were no adverse reactions.*Conclusions In patients with allergy or contraindication to conventional contrast mediums, ferumoxytol enhanced MRA is promising as an efficient and effective modality for detection of venous thrombosis in a variety of vascular beds.*Clinical Relevance/Application In patients with allergy or contraindication to conventional contrast mediums, FE-MRA is a promising modality for detection of venous thrombosis in a variety of vascular beds.

RESULTS

Venous thrombosis was identified in 83 of 798 studies (10.4%). 40 of 83 (48.2%) of DVT positive studies had a specific indication to evaluate for venous stenosis or thrombosis. Venous thrombosis was identified in a number of vascular beds with many patients having overlapping sites, and included: central thoracic veins (n=56), IVC or iliac veins (n=25), portomesenteric veins (n=9), peripheral extremity veins (n=4), renal veins (n=2), pulmonary veins (n=1), and intracardiac thrombus that included right atrial and Fontan conduit thrombus (n=2). Average patient age was 41.2 ± 22.6 years (0.4 - 78.3). 48 patients were male and 35 were female. Average patient weight was 64.1 ± 28.4 kg (6.5 - 131.5) and average weight-based contrast dose was 8.7 ± 4.0 mL (0.9 - 17). There were no adverse reactions.

CLINICAL RELEVANCE/APPLICATION

In patients with allergy or contraindication to conventional contrast mediums, FE-MRA is a promising modality for detection of venous thrombosis in a variety of vascular beds.

CH04-D1   Clinical Evaluation Of An Artificial Intelligence Algorithm For The Detection Of Incidental Pulmonary Emboli On Routine Contrast Enhanced Chest CT

Participants
Yin Xi, PhD, Dallas, Texas (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate an incidental pulmonary embolism (iPE) Artificial Intelligence (AI) algorithm in patients referred for routine, contrast-enhanced CT (CECT)of the chest at two healthcare systems served by the same radiologists. We examined the performance of the algorithm, impact of different patient populations and conditions associated with misclassification.*Methods and Materials The iPE algorithm was prospectively applied to Contrast enhanced Chest CT (CECCT)exams between September 2019 and February 2020 at a safety net hospital (SNH) and academic referral hospital (ARH). Clinical reads were performed by radiologists serving both institutions. A consensus overread was performed on algorithm and/or clinical report positive exams. In addition, exams were reviewed to assess for etiologies which could contribute to misclassification.*Results The iPE algorithm analyzed 7,466 CECT exams (mean age: 59±15, 3,811 women). The algorithm had a sensitivity of 83.3%, specificity of 99.8%, and negative predictive value of 99.7%. Significant differences in age, gender, percentage of outpatients, percentage of urgent and stat cases, and prevalence of associated cancer diagnosis between the two institutions did not alter the positive rates for detection of iPE (SNH: 1.26% vs ARH: 1.77%, P=NS). Several factors contributed to misclassification, including anatomy altered by prior surgery and rim enhancement of metastatic lesions.*Conclusions The AI-algorithm had moderate sensitivity but a high specificity and negative predictive value in detecting iPE. The detection rate was similar at 2 hospitals with different patient populations and referral patterns. We also identified several sources of misclassification which could serve as targets to potentially improve the performance of the algorithm*Clinical Relevance/Application Incidental pulmonary embolism (iPE) is a finding on routine CT exams ordered for other reasons and is associated with increased mortality and morbidity. An Artificial Intelligence (AI) algorithm that detected iPE could be beneficial to radiologists. However, the variability in contrast timing, underlying pathology, and patient referral pose significant challenges to an algorithm for iPE.

RESULTS

The iPE algorithm analyzed 7,466 CECT exams (mean age: 59±15, 3,811 women). The algorithm had a sensitivity of 83.3%, specificity of 99.8%, and negative predictive value of 99.7%. Significant differences in age, gender, percentage of outpatients, percentage of urgent and stat cases, and prevalence of associated cancer diagnosis between the two institutions did not alter the positive rates for detection of iPE (SNH: 1.26% vs ARH: 1.77%, P=NS). Several factors contributed to misclassification, including anatomy altered by prior surgery and rim enhancement of metastatic lesions.

CLINICAL RELEVANCE/APPLICATION

Incidental pulmonary embolism (iPE) is a finding on routine CT exams ordered for other reasons and is associated with increased mortality and morbidity. An Artificial Intelligence (AI) algorithm that detected iPE could be beneficial to radiologists. However, the variability in contrast timing, underlying pathology, and patient referral pose significant challenges to an algorithm for iPE.

CH04-D4   Utilizing Artificial Intelligence To Determine Morphological Features Of Thoracic Aorta Via Non-contrast Chest Computed Tomography

Participants
Jinrong Yang, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

To preliminarily explore the feasibility of using artificial intelligence to automatically measure the morphological features of thoracic aorta on non-enhanced chest CT, so as to understand the anatomical morphological characteristics of thoracic aorta.*Methods and Materials Retrospectively collected 156 participants who underwent chest CT examination and had no disease affecting the morphology of aorta. In this paper, the AI based method is used as a research tool to calculate the related parameters automatically. Utilizing AI to measure the morphological features of the thoracic aorta (including diameters and areas at nine levels recommended by the AHA guidelines, volume and length at two adjacent levels, and total volume and length). The AI method proposes a framework of aortic segmentation based on deep learning network. According to the aortic segmentation results and its anatomical characteristics, a method of straightening the tubular structure of the aorta by aligning the centerline is used to reconstruct the results of the aorta, which simplifies the calculation process. And we further explore the anatomical morphological characteristics of the normal thoracic aorta stratified by sex and age.*Results It is feasible to use AI to automatically measure the morphological features of thoracic aorta, which is in good agreement with the results of manual measurement. In quantitative terms, the AI-based results achieved the mean Dice scores of 0.9511. Based on this, we conducted a comparative study on the morphology of aorta. The morphological features values of male were greater than that of female. The diameter and area of MD level had the strongest correlation with age (R=0.59). The diameter and area of MAs increased rapidly with age, and they increased by 2.05mm and 1.06cm2 respectively with age increasing by 10 years. The volume and length of the descending aorta (from PD to DP level) had the strongest correlation with age (R=0.63,0.46). Correspondingly, the volume and length of the V6_7 segment were

greatly affected by age, which increased by 9.03ml or 6.41mm with age increased by 10 years.*Conclusions AI can automatically measure the morphological features of thoracic aorta on non-enhanced chest CT, so that we can further understand the anatomical morphological features of normal thoracic aorta, and then establish the anatomical morphological basis for the diagnosis and treatment of thoracic aortic diseases.*Clinical Relevance/Application Automatic quantification of thoracic aorta using AI makes it possible to further understand the anatomical morphology of thoracic aorta, which helps to provide an anatomical basis for the diagnosis of thoracic aortic dilatation disease and the development of endovascular repair in surgery in the future.

RESULTS

It is feasible to use AI to automatically measure the morphological features of thoracic aorta, which is in good agreement with the results of manual measurement. In quantitative terms, the AI-based results achieved the mean Dice scores of 0.9511. Based on this, we conducted a comparative study on the morphology of aorta. The morphological features values of male were greater than that of female. The diameter and area of MD level had the strongest correlation with age (R=0.59). The diameter and area of MAs increased rapidly with age, and they increased by 2.05mm and 1.06cm2 respectively with age increasing by 10 years. The volume and length of the descending aorta (from PD to DP level) had the strongest correlation with age (R=0.63,0.46). Correspondingly, the volume and length of the V6_7 segment were greatly affected by age, which increased by 9.03ml or 6.41mm with age increased by 10 years.

CLINICAL RELEVANCE/APPLICATION

Automatic quantification of thoracic aorta using AI makes it possible to further understand the anatomical morphology of thoracic aorta, which helps to provide an anatomical basis for the diagnosis of thoracic aortic dilatation disease and the development of endovascular repair in surgery in the future.

HN04-B2 **Predictive Value Of Multiparametric MRI For Response To Single Cycle Induction Chemo-immunotherapy In Locally Advanced Head And Neck Squamous Cell Carcinoma**

Participants
Tobias Baeuerle, MD, Erlangen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To assess the value of multiparametric MRI for treatment response evaluation to induction chemo-immunotherapy in locally advanced head and neck squamous cell carcinoma (HNSCC).*Methods and Materials Patients with locally advanced, histologically confirmed HNSCC (n=21) were enrolled in the prospective multicenter phase II CheckRad-CD8 trial. All patients that received contrast enhanced MRI at baseline and in week 4 after single cycle induction therapy with cisplatin/docetaxel combined with the immune checkpoint inhibitors tremelimumab (anti-CTLA4) and durvalumab (anti-PDL1) were included. In week 4 re-biopsy was performed to assess tumor response and density of intratumoral CD8+ cells. In baseline and follow-up the primary tumors were segmented on MRI for assessment of the following parameters: Tumor volume, T1 signal intensity (SI), STIR SI, apparent diffusion coefficient (ADC) and dynamic contrast enhanced (DCE) values. A model based on parallel random forests incorporating the MRI parameters was used to predict tumor response to therapy at baseline MRI. All parameters were correlated with histologic tumor response.*Results Fifteen patients (71.4 %) showed pathologic complete response in the re-biopsy, while six patients revealed a residual tumor (28,6 %). In patients with complete pathologic response and residual tumor following treatment, the primary tumor volume was significantly lower after treatment, respectively (p<0.05). The MRI parameters T1 ratio, STIR ratio and ADC values of the tumors could not discriminate between the complete response and residual tumor groups or predict treatment response. The DCE parameters time to peak (TTP) and wash out (WO) on the contrary, indicated a significant difference between the complete response and residual tumor groups at follow-up (p<0.05). Using a model based on parallel random forests, therapy response could be predicted with a sensitivity of 78.7 % and a specificity of 78.6 % based on DCE parameters TTP and WO. The model featured an area under the Receiver Operating Characteristic curve of 0.866.*Conclusions Morphological MRI and ADC could not assess or predict response to single cycle induction chemo-immunotherapy in locally advanced HNSCC. However, DCE parameters indicated treatment response at follow-up, and a machine learning algorithm using parallel random forests based on these parameters was able to predict treatment response to chemo-immunotherapy.*Clinical Relevance/Application Quantitative imaging biomarkers are needed to assess and predict response from emerging treatment strategies including immunotherapy. Here we show that DCE MRI parameters are promising candidates for that purpose in locally advanced HNSCC.

RESULTS

Fifteen patients (71.4 %) showed pathologic complete response in the re-biopsy, while six patients revealed a residual tumor (28,6 %). In patients with complete pathologic response and residual tumor following treatment, the primary tumor volume was significantly lower after treatment, respectively (p<0.05). The MRI parameters T1 ratio, STIR ratio and ADC values of the tumors could not discriminate between the complete response and residual tumor groups or predict treatment response. The DCE parameters time to peak (TTP) and wash out (WO) on the contrary, indicated a significant difference between the complete response and residual tumor groups at follow-up (p<0.05). Using a model based on parallel random forests, therapy response could be predicted with a sensitivity of 78.7 % and a specificity of 78.6 % based on DCE parameters TTP and WO. The model featured an area under the Receiver Operating Characteristic curve of 0.866.

CLINICAL RELEVANCE/APPLICATION

Quantitative imaging biomarkers are needed to assess and predict response from emerging treatment strategies including immunotherapy. Here we show that DCE MRI parameters are promising candidates for that purpose in locally advanced HNSCC.

BR03-A10   Imaging Of Unusual Male Breast Lesions With Histopathologic Correlation

Awards
Certificate of Merit

Participants
Brian Guarnieri, MD, Cincinnati, Ohio (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Review male breast anatomy and development2. Characterize the mammographic, sonographic and MRI imaging findings of a spectrum of benign and malignant male breast lesions3. Correlate the imaging findings with the underlying histopathologic findings4. Discuss management and treatment for these male breast lesions

TABLE OF CONTENTS/OUTLINE

IntroductionMale breast anatomyMale breast developmentImaging protocols for male breast concernsCharacteristics and imaging overview of male breast lesionsWorkup of male breast lesionsDiscuss cases and imaging/pathology findings:Benign:MyofibroblastomaAngiolipomaLipomaGynecomastiaTubular adenomaAbscess cavityTraumatic fat necrosisSebaceous/epidermal inclusion cystMalignant:Lymphoma (T cell)Adenoid cystic carcinomaMetastasis to the breast (esophageal adenocarcinoma, melanoma)DCIS with intraductal papillomaInvasive ductal carcinoma subtypesInvasive locular carcinomaConclusionUnderstanding male breast anatomy is important to interpreting breast imaging studies and developing an appropriate differentialAlthough most breast conditions in men are benign, breast radiologists must be aware of imaging features in male breast lesions that warrant biopsy as approximately 1% of new breast cancers occur in menSpecific histopathologic findings of different male breast lesions allows for appropriate management and treatment of these patients

BR03-A2   Effect Of Artificial Intelligence Software On Digital Breast Tomosynthesis Screening Cancer Detection And Abnormal Interpretation Rates Among Subspecialized Breast Radiologists: A Real World Experience

Participants
Haley Letter, MD, Jacksonville, Florida (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study is to assess the "real world" impact of an artificial intelligence (AI) tool designed to detect breast cancer in digital breast tomosynthesis (DBT) screening exams. We estimated the effects of the AI tool on cancer detection rate per 1000 screened (CDR) and abnormal interpretation rate percent (AIR) following 6 months of utilization in a subspecialized academic breast center.*Methods and Materials Following IRB approval, Mammography Quality Standards Act (MQSA) reports were retrospectively generated for each of 5 subspecialized radiologists (breast imaging experience ranging 3-35 years) for each of 3 MQSA-accredited breast imaging centers during the time frame of September 1, 2020 through March 1, 2021. All mammograms included in the audit were performed with DBT (Hologic Dimensions®) and interpreted on Visage® PACS. Location 1 had the AI tool (iCAD ProFound AI® V2.0) available during the 6-month time period while the other two locations (Locations 2 and 3) did not. All 5 radiologists interpreted screening DBT studies at all 3 locations; 3,073 studies with AI and 3,690 studies without AI. All exams had follow-up up to May 4, 2021. The co-primary endpoints were estimation of CDR and AIR with and without AI available (Location 1 vs Locations 2 and 3 combined). Differences between the two groups in CDR and AIR were calculated with two-sided 95% confidence intervals (CIs) for each radiologist and summarized across radiologists using generalized estimating equations to perform logistic regression.*Results CDR per 1000 screened was 6.4 with AI, 5.3 without AI (odds ratio 1.2, 95% CI: 0.6, 2.3). AIR was 11.2% with AI, 10.2% without AI (odds ratio 1.1, 95% CI: 0.9, 1.3). Four of the 5 radiologists demonstrated increased CDR with AI compared to without. Three of the 5 radiologists saw a stable or decreased AIR.*Conclusions While we are unable to show statistically significant changes in CDR and AIR outcomes in the two groups given the low numbers of total cancers and relatively short time period, the results are consistent with prior reader studies. There are modest, yet noticeable, improvements in CDR with AI, without significant increases in AIR with AI. We expect to obtain more accurate estimates of the impact of DBT-AI as we accrue more patients.*Clinical Relevance/Application To our knowledge, our study is the first to assess the real-world application of a DBT-based AI algorithm to assist radiologists in the detection of breast cancer in screening exams.

RESULTS

CDR per 1000 screened was 6.4 with AI, 5.3 without AI (odds ratio 1.2, 95% CI: 0.6, 2.3). AIR was 11.2% with AI, 10.2% without AI (odds ratio 1.1, 95% CI: 0.9, 1.3). Four of the 5 radiologists demonstrated increased CDR with AI compared to without. Three of the 5 radiologists saw a stable or decreased AIR.

CLINICAL RELEVANCE/APPLICATION

To our knowledge, our study is the first to assess the real-world application of a DBT-based AI algorithm to assist radiologists in the detection of breast cancer in screening exams.

BR03-A3   High Performance Of An FDA-cleared Platform For Mammography Triage

Participants
Tara Retson, MD,PhD, San Diego, California (*Presenter*) Research writing, CureMetrix Inc

PURPOSE

Recent studies suggest that artificial intelligence (AI) based triage programs could improve detection of breast cancer on screening mammography and expedite radiologist workflow. Here, we sought to evaluate the performance of a commercial AI-based triage algorithm on exams with varying breast densities and lesion types.*Methods and Materials This retrospective, multi-center, and multi-vendor study examined 1255 screening mammograms consisting of 4 standard views (LCC, LMLO, RCC, RMLO). The population was enriched with biopsy-confirmed cancers, containing 400 positive and 855 normal (BIRADS 1 and 2) studies. Images were analyzed by a commercially available AI algorithm (cmTriage, Curemetrix) and given a quantitative score based on suspicion for cancer or recall. Triage was performed at a study level where exams were labeled "suspicious," or left unlabeled (indicating a low suspicion exam).*Results The algorithm demonstrated an area under the curve (AUC) of 0.95 (95% CI: 0.94 - 0.96) for lesion identification. This AUC held across densities (0.95) and lesion types (masses: 0.94, 95% CI: 0.92 to 0.96; or microcalcifications: 0.97, 95% CI: 0.96 to 0.99). While the algorithm has a default sensitivity of 93% (modifiable up to 99%), to evaluate real world performance we used 86.9% sensitivity (95% CI: 83.6% to 90.2%), as was observed for practicing radiologists by the Breast Cancer Surveillance Consortium (BCSC) study. Resulting algorithm specificity was 88.5% (95% CI: 86.4% to 90.7%), similar to BCSC radiologist specificity of 88.9%, and indicating that algorithm performance may be comparable to real-world practice.*Conclusions AI-based triage software can perform at and above the level of practicing radiologists. It has been shown that when radiologists work with AI there is a synergistic effect. By drawing attention to suspicious exams, AI triage may provide positive reader bias to improve accuracy, and act as a second reader, particularly for negative exams. As a workflow improvement, it could enable faster recall and immediate patient notification of low suspicion studies, reducing patient stress and improving care.*Clinical Relevance/Application AI-based triage software can perform at and above the level of practicing radiologists, is posed to streamline workflow, and step into the role of second reader.

RESULTS

The algorithm demonstrated an area under the curve (AUC) of 0.95 (95% CI: 0.94 - 0.96) for lesion identification. This AUC held across densities (0.95) and lesion types (masses: 0.94, 95% CI: 0.92 to 0.96; or microcalcifications: 0.97, 95% CI: 0.96 to 0.99). While the algorithm has a default sensitivity of 93% (modifiable up to 99%), to evaluate real world performance we used 86.9% sensitivity (95% CI: 83.6% to 90.2%), as was observed for practicing radiologists by the Breast Cancer Surveillance Consortium (BCSC) study. Resulting algorithm specificity was 88.5% (95% CI: 86.4% to 90.7%), similar to BCSC radiologist specificity of 88.9%, and indicating that algorithm performance may be comparable to real-world practice.

CLINICAL RELEVANCE/APPLICATION

AI-based triage software can perform at and above the level of practicing radiologists, is posed to streamline workflow, and step into the role of second reader.

BR03-A4   Subgroup Analysis Highlights Fairness Challenges For Deep Learning Algorithms In Breast Density Estimation

Participants
Charles Lu, Charlestown, Massachusetts (*Presenter*) Institutional support, General Electric Company;Institutional support, NVIDIA Corporation;Institutional support, Nuance Communications, Inc

PURPOSE

We investigate the impact of sampling strategies on performance disparities in patient race/ethnicity subgroups during the training of deep learning (DL) algorithms to automatically assess breast density (BD) in mammography.*Methods and Materials 108,190 mammograms were obtained from 21,759 patients (mean age 54 +/- 10 years old) through the Digital Mammographic Imaging Screening Trial (33 clinical sites). Each exam was interpreted by experts using ACR BI-RADS criteria We train a deep learning system to classify BD using different sampling techniques (randomly and equally adjusted for frequency between classes). We measure subgroup performance using linearly weighted Cohen's Kappa statistic with bootstrapping for 95% confidence interval.*Results The dataset had a BD distribution of 8% fatty, 33% scattered, 41% heterogeneously dense, and 18% extremely dense and had patient race demographics of 79% white, 15% black, 4% Hispanic, 2% Asian, <1% "other" or unknown. On a held-out validation set of 38,936 mammographs (8250 patients), we attain similar overall Kappa for both random and equal sampling, 0.67 [0.66-0.68] and 0.67 [0.66-0.68] respectively; however, we observe significant difference between racial subgroups. Notably, non-white patients show less agreement than white patients. For random sampling: White 0.67 [0.66-0.69], Black 0.65 [0.61-0.68], Hispanic 0.61 [0.55-0.67], Asian 0.64 [0.55-0.72], and Other 0.55 [0.41-0.66]. For equal sampling: White 0.67 [0.66-0.68], Black 0.63 [0.60-0.66], Hispanic 0.62 [0.56-0.68], Asian 0.64 [0.55-0.72], and Other 0.72 [0.60-0.82]. The equal sampling by race strategy performed significantly better on the "other" / unknown subgroup but not on other minority subgroups. Additionally, there were substantial differences in the important "dense" class between sampling strategies by class that was obscured by the overall performance metric as seen in figure 1.*Conclusions Overall performance metrics of DL algorithms can obscure differences in sub-classes or sub-groups. The optimal algorithm should be selected only after sub-group analysis to balance fairness constraints.*Clinical Relevance/Application Uninterpretable deep learning systems may exacerbate existing disparities in healthcare between protected subpopulations such as race. Subgroup analysis is a simple yet effective technique for uncovering disparate impact in black box tools.

RESULTS

The dataset had a BD distribution of 8% fatty, 33% scattered, 41% heterogeneously dense, and 18% extremely dense and had patient race demographics of 79% white, 15% black, 4% Hispanic, 2% Asian, <1% "other" or unknown. On a held-out validation set of 38,936 mammographs (8250 patients), we attain similar overall Kappa for both random and equal sampling, 0.67 [0.66-0.68] and 0.67 [0.66-0.68] respectively; however, we observe significant difference between racial subgroups. Notably, non-white patients show less agreement than white patients. For random sampling: White 0.67 [0.66-0.69], Black 0.65 [0.61-0.68], Hispanic 0.61 [0.55-0.67], Asian 0.64 [0.55-0.72], and Other 0.55 [0.41-0.66]. For equal sampling: White 0.67 [0.66-0.68], Black 0.63 [0.60-0.66], Hispanic 0.62 [0.56-0.68], Asian 0.64 [0.55-0.72], and Other 0.72 [0.60-0.82]. The equal sampling by race strategy performed significantly better on the "other" / unknown subgroup but not on other minority subgroups. Additionally, there were substantial differences in the important "dense" class between sampling strategies by class that was obscured by the overall performance metric as seen in figure 1.

BR03-A5   Replacing A Radiologist By AI In Dutch Population Based Breast Cancer Screening And The Impact Of Breast Density On Performance

Participants
Suzanne Van Winkel, RN,MSc, Nijmegen, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

Validation of the performance of a commercially available artificial intelligence (AI) system in the population based breast cancer screening program, considering the implementation of AI as a second reader, and to assess the effect of breast density.*Methods and Materials 2D Digital screening mammograms from a consecutive cohort including 43666 women screened between 2013 and 2014 in a region of the Dutch breast screening program were retrospectively collected. All exams were assigned a level of suspicion by an AI system on a continuous scale (Transpara, ScreenPoint Medical). Presence of cancers was verified using data from the national Dutch Cancer Registration (NKR - IKNL) until 2019. For each woman, 4-5 year of complete follow-up data on screen detected (SD), interval (IC) and future breast cancers (FBC) was available. Sensitivity, specificity and recall rate were compared for different reading scenarios: first reader (R1), stand-alone AI (recall rate R1 as operating point), double reading (R1 & R2), first reader and AI (R1&AI). Differences found were tested by McNemar and Wald tests. To examine the effect of density on cancers identified by human reading versus AI, volumetric density scores were obtained (Volpara). Differences were descriptively analyzed and tested by Wilcoxon signed-rank test.*Results The cohort included 987 cancers: 312 SD, 222 IC (within two years after screening) and 453 FBC (screen detected next round or after). 1071 cases were recalled by R1 (2.5.%, 95% CI = 2.3-2.6%), including 291 SD cancers, 3 IC and 16 FBC (sensitivity 31.4%, 95% CI =28.5-34.4%). The AI system recalled 1071 cases with 244 SD cancers, 23 IC and 69 FBC (sensitivity 34.0%, 95% CI = 31.1-37.1%). R1&R2 recalled 1143 cases after consensus (2.6%, 95%C =2.5-2.8%), including 312 SD, 2 IC and 18 FBC (sensitivity 33.6%, CI =30.7-36.7%). Replacing the second reader by AI (R1&AI) resulted in 1796 recalls (4.1%, 95% CI = 3.9-4.3%), including 306 SD, 26 IC and 74 FBC (sensitivity 41.1%, 95%CI = 38.0-44.3%), improving the sensitivity with 7.5% (95%CI=5.6-9.4%, p < 0.05). There was no significant difference in the relative performance of R1 and AI over density categories (p=0.4857). However, the additional cancers (n= 26) identified by the AI system and not by R1, were most observed in category A (+33.3% n=5) and D (+32.1% n=9) breasts.*Conclusions AI provides higher sensitivity than R1 and is complementary. AI has potential as second reader, but an effective arbitration process is necessary. This effect seems independent of breast density, albeit a remarkable amount of additional cancers detected was in highest and lowest density categories.*Clinical Relevance/Application The high rate of IC and FBC detected by AI, may enable earlier breast cancer detection using AI as second reader.

RESULTS

The cohort included 987 cancers: 312 SD, 222 IC (within two years after screening) and 453 FBC (screen detected next round or after). 1071 cases were recalled by R1 (2.5.%, 95% CI = 2.3-2.6%), including 291 SD cancers, 3 IC and 16 FBC (sensitivity 31.4%, 95% CI =28.5-34.4%). The AI system recalled 1071 cases with 244 SD cancers, 23 IC and 69 FBC (sensitivity 34.0%, 95% CI = 31.1-37.1%). R1&R2 recalled 1143 cases after consensus (2.6%, 95%C =2.5-2.8%), including 312 SD, 2 IC and 18 FBC (sensitivity 33.6%, CI =30.7-36.7%). Replacing the second reader by AI (R1&AI) resulted in 1796 recalls (4.1%, 95% CI = 3.9-4.3%), including 306 SD, 26 IC and 74 FBC (sensitivity 41.1%, 95%CI = 38.0-44.3%), improving the sensitivity with 7.5% (95%CI=5.6-9.4%, p < 0.05). There was no significant difference in the relative performance of R1 and AI over density categories (p=0.4857). However, the additional cancers (n= 26) identified by the AI system and not by R1, were most observed in category A (+33.3% n=5) and D (+32.1% n=9) breasts.

CLINICAL RELEVANCE/APPLICATION

The high rate of IC and FBC detected by AI, may enable earlier breast cancer detection using AI as second reader.

BR03-A7   Diagnostic Value Of Enhanced Spectral Mammography With Low Dose Contrast Agent In Comparison To Magnetic Resonance Imaging In Detecting Breast Cancer

Participants
Huizhi Cao, PhD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the diagnostic performance of contrast enhanced spectral mammography (CESM) wtih low contrast protocol to magnetic resonance imaging (MRI) in a prospective multi-center study.*Methods and Materials Three hundred fifty-one women with suspected breast abnormalities by clinical examination or mammography underwent CESM and MRI examination. Contrast medium protocol was used as 1.0ml/kg, decreased by 30% compared to that of standard protocol. Using histopathologic results as the criterion standard, the diagnostic performance of CESM and MRI was investigated. Receiver-operating characteristic (ROC) curves were compared. Size measurements for the lesions detected by all readers in each modality were correlated with pathology.*Results Three hundred seventy-four breast lesions were found in 351 patients, in which 264 were malignant and 110 were benign. By evaluating the diagnostic value, sensitivity, positive predictive value, negative predictive value, and false-negative rate from CESM examination were comparable to those from MRI (89.2%, 90.2%, 81.3%, and 9.2% vs 91.2%, 90.5%, 80.4%, and 8.9%). Importantly, the accuracy and the specificity were higher for CESM than those for MRI (84.2% and 89.5% vs 82.3% and 84.4%), whereas the false-positive rate was lower (12.5% vs 18.6%). The areas under receiver operating characteristic curves of CESM and MRI were 0.92 and 0.91, displaying the equivalent diagnostic efficiency (P = 0.45). For the agreement between measurements, mean tumor sizes were 2.9 cm for CESM and 3.2 cm for MRI compared with 3.1 cm on histopathologic results. The Pearson correlation coefficient of CESM versus histopathology (r = 0.732, P = 0.000) was consistent with MRI versus histopathology (r = 0.741, P = 0.000).*Conclusions In this study, CESM has comparable diagnostic performance (ROC-AUC) to MRI for breast cancer diagnostics. Contrast-enhanced spectral mammography displayed a good correlation with histopathology in assessing the lesion size of breast cancer.*Clinical Relevance/Application CESM with low contrast medium is as accurate as MRI. Patients with dense breasts benefitted most from CESM with the smallest additional dose compared to MG.

RESULTS

Three hundred seventy-four breast lesions were found in 351 patients, in which 264 were malignant and 110 were benign. By evaluating the diagnostic value, sensitivity, positive predictive value, negative predictive value, and false-negative rate from CESM

examination were comparable to those from MRI (89.2%, 90.2%, 81.3%, and 9.2% vs 91.2%, 90.5%, 80.4%, and 8.9%). Importantly, the accuracy and the specificity were higher for CESM than those for MRI (84.2% and 89.5% vs 82.3% and 84.4%), whereas the false-positive rate was lower (12.5% vs 18.6%). The areas under receiver operating characteristic curves of CESM and MRI were 0.92 and 0.91, displaying the equivalent diagnostic efficiency (P = 0.45). For the agreement between measurements, mean tumor sizes were 2.9 cm for CESM and 3.2 cm for MRI compared with 3.1 cm on histopathologic results. The Pearson correlation coefficient of CESM versus histopathology (r = 0.732, P = 0.000) was consistent with MRI versus histopathology (r = 0.741, P = 0.000).

CLINICAL RELEVANCE/APPLICATION

CESM with low contrast medium is as accurate as MRI. Patients with dense breasts benefitted most from CESM with the smallest additional dose compared to MG.

BR03-A8   First Experiences With Dedicated Photon-counting CT Of The Breast For Detection Of Microcalcifications.

Participants
Luisa Huck, MD, Aachen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

We present our first clinical experiences with a dedicated Photon-Counting breast CT (PC-BCT) system designed to offer unprecedented spatial resolution at low radiation dose on patients with microcalcifications.*Methods and Materials Intra-individual comparative study on 14 patients (mean age 57; 42-76) with microcalcs who underwent DBT and PC-BCT. DBT (Hologic) was performed in MLO/ML and CC projection plus C-view reconstruction (angle 15°). PC-BCT was obtained in prone position, one single breast at a time, at 60 kV, 32 mAs, with a non-interpolated spatial resolution of 0.15x0.15x0.15 mm (high resolution, HR); a second data set was reconstructed at 0.3x0.3x0.3 mm (standard resolution, SR). Two radiologists independently rated detectability of microcalcs on a 5-point scale and counted their number on (a) SR images, (b) HR images, and (c) regional MIPs (10 mm thick, reconstructed from HR). Then, on HR images and MIPs, radiologists independently compared morphology (roundish vs. not), and distribution.*Results Of the 14 patients, 10 had malignant lesions (DCIS or invasive cancer), and 4 had benign changes. In 2/14 (14%), calcifications were located in the back of the breast and were therefore not included in the PC-BCT volume. Considering only those women whose DBT findings were included in the volume, microcalcs were visible in all 12. Mean scores for detectability of microcalcs was: 1.5 ± 0.9 (SR) vs. 3.2 ± 0.6 (HR) vs. 4.7 ± 0.5 (MIP) vs. 4.9 ± 0.3 (DBT). On HR images and MIPs, morphology of individual calcifications appeared similar to DBT in 10/12; in the remaining 2 cases, calcifications were rated as "not round" on PC-BCT but "round" on DBT; one of them was a HG DCIS, the other adenosis. The total number of visible individual microcalcs was 31 on SR, 62 on HR, 126 on MIPs, and 197 on DBT. Distribution of microcalcs was identical on MIPs and on DBT in 11/12. Cohens ? for detectability of microcalcs yielded perfect agreement (? = 0,9) between readers.*Conclusions Our initial experience with head-to-head comparison of women with known microcalcs suggests that PB-CT depicts microcalcs with high sensitivity, and allows the assessment of their distribution and also of the morphology of individual calcium deposits, thus enabling a categorization of microcalcs that appears similar to DBT.*Clinical Relevance/Application PC-BCT allows detection and characterization of microcalcifications similar to DBT.

RESULTS

Of the 14 patients, 10 had malignant lesions (DCIS or invasive cancer), and 4 had benign changes. In 2/14 (14%), calcifications were located in the back of the breast and were therefore not included in the PC-BCT volume. Considering only those women whose DBT findings were included in the volume, microcalcs were visible in all 12. Mean scores for detectability of microcalcs was: 1.5 ± 0.9 (SR) vs. 3.2 ± 0.6 (HR) vs. 4.7 ± 0.5 (MIP) vs. 4.9 ± 0.3 (DBT). On HR images and MIPs, morphology of individual calcifications appeared similar to DBT in 10/12; in the remaining 2 cases, calcifications were rated as "not round" on PC-BCT but "round" on DBT; one of them was a HG DCIS, the other adenosis. The total number of visible individual microcalcs was 31 on SR, 62 on HR, 126 on MIPs, and 197 on DBT. Distribution of microcalcs was identical on MIPs and on DBT in 11/12. Cohens ? for detectability of microcalcs yielded perfect agreement (? = 0,9) between readers.

CLINICAL RELEVANCE/APPLICATION

PC-BCT allows detection and characterization of microcalcifications similar to DBT.

BR03-A9   Artificial Intelligence For Digital Breast Tomosynthesis: A Tool To Enhance Radiologist'S Performance And Efficiency

Participants
Pierre Fillard, PhD, Paris, France (*Presenter*) Employee, Therapixel SA;Stockholder, Therapixel SA

PURPOSE

To demonstrate and estimate the benefits that an artificial intelligence (AI) tool could bring to digital breast tomosynthesis (DBT) interpretation time and accuracy.*Methods and Materials An AI system was evaluated in a retrospective multi-reader multi-case study where 22 breast specialist radiologists (in practice from 3 to 37 years - median 10 years) were asked to interpret 240 DBT examinations with and without the help of AI. The dataset included 114 biopsy-proven cancers, 36 of which were classified as false negative, i.e., screening negative cases with a positive result at follow-up within 18 months. Performances were measured in terms of area under the receiver operating characteristic curve (AUC), sensitivity, specificity and reading time and analyzed with statistical methods for reader studies. As the sample was enriched with cancers, we applied an inverse probability weighting to obtain estimates of reading time reduction in a screening population. The study was conducted in accordance to the Health Insurance Portability and Accountability Act and approved by an institutional review board.*Results The average AUC across readers was 0.79 (95% CI: 0.75 to 0.84) without AI and 0.83 (95% CI: 0.79 to 0.87) with AI. Average improvement was 0.04 (95% CI: 0.02 to 0.06, P < 0.001). Sensitivity improved from 80% to 82% when using AI (2%; 95% CI: -0.4% to 0.4%). Average specificity increased from 56% without AI to 61% with AI (5%; 95% CI: 1.5% to 8.7%). Average reading time was 74.7 seconds without AI and 70.9 seconds with AI (average difference: -3.8; 95% CI: -8.4 to 0.8). The reading time reduction was found to vary in accordance with the likelihood of malignancy assigned by the AI going from -15.6% for cases assigned with a low likelihood of malignancy to -0.5% for the most suspicious cases. When transposing these results to a screening population, observed reading time was on average 76.2s without the help of AI, which lies in the lower bound of the reading time reported for real-word practice. Nonetheless, an average reduction of 8% (95% CI: -13% to 3.1%) was observed in assisted readers, which indicates that a regular batch reading (i.e., a sequential interpretation of screening mammograms without interruption) could include until 13% more cases (about 7 cases per hour) thus improving the efficiency of the screening program and reducing the time-to-diagnosis for

patients.*Conclusions We demonstrated that the concurrent use of an AI tool could improve the diagnostic performance of radiologists in the detection of breast cancer with DBT and the efficiency of their workflow.*Clinical Relevance/Application This AI system can be integrated into screening practice to improve both efficiency and accuracy of DBT.

RESULTS

The average AUC across readers was 0.79 (95% CI: 0.75 to 0.84) without AI and 0.83 (95% CI: 0.79 to 0.87) with AI. Average improvement was 0.04 (95% CI: 0.02 to 0.06, P < 0.001). Sensitivity improved from 80% to 82% when using AI (2%; 95% CI: -0.4% to 0.4%). Average specificity increased from 56% without AI to 61% with AI (5%; 95% CI: 1.5% to 8.7%). Average reading time was 74.7 seconds without AI and 70.9 seconds with AI (average difference: -3.8; 95% CI: -8.4 to 0.8). The reading time reduction was found to vary in accordance with the likelihood of malignancy assigned by the AI going from -15.6% for cases assigned with a low likelihood of malignancy to -0.5% for the most suspicious cases. When transposing these results to a screening population, observed reading time was on average 76.2s without the help of AI, which lies in the lower bound of the reading time reported for real-word practice. Nonetheless, an average reduction of 8% (95% CI: -13% to 3.1%) was observed in assisted readers, which indicates that a regular batch reading (i.e., a sequential interpretation of screening mammograms without interruption) could include until 13% more cases (about 7 cases per hour) thus improving the efficiency of the screening program and reducing the time-to-diagnosis for patients.

CLINICAL RELEVANCE/APPLICATION

This AI system can be integrated into screening practice to improve both efficiency and accuracy of DBT.

GI05-B7   Additional MRI For Initial M-staging In Pancreatic Cancer: A Cost-effectiveness Analysis

Participants
Felix Gassert, MD, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Pancreatic cancer (PDAC) is portrayed to become &9;the second leading cause of cancer-related death within the next years. Potentially complicating surgical resection and high toxicity of combination chemotherapy regimens emphasize the importance of an accurate TNM classification in the primary staging. In particular, the failure to detect metastases has profound consequences on patient outcomes and economic costs due to incorrect indication to resection. In the detection of liver metastases, contrast-enhanced MRI showed high sensitivity and specificity, however, the cost-effectiveness compared to the standard of care imaging (SCI) remains unclear. The aim of this study was to analyze whether combined contrast enhanced MRI and contrast enhanced computed tomography (CE-MR/CT) is a cost effective approach compared to routinely acquired contrast enhanced computed tomography (CE-CT) in detecting liver metastasis.*Methods and Materials To evaluate the cost-effectiveness of CE-MR/CT to CE-CT in detecting liver metastases in PDAC patients, a decision model based on Markov simulation was developed to estimate the quality-adjusted life-years (QALYs) and lifetime costs of the diagnostic modalities. Model input parameters were assessed based on evidence from recent literature. The willingness-to-pay (WTP) was set to $100,000/QALY. To evaluate model uncertainty, deterministic and probabilistic sensitivity analysis of the input parameters based on a Monte-Carlo simulation with 30000 iterations were performed.*Results In the base-case analysis the model yielded a total cost of 153367 $ and an effectiveness of 2,344 QALYs for CE-MR/CT and 155956 $ and 2,333 QALYs for CE-CT respectively. With a net monetary benefit (NMB) of 81004 $, CE-MR/CT is shown to be superior to CE-CT with a NMB of 77422 $. Deterministic and probalistic survival analysis showed model robustness for varying input parameters.*Conclusions Based on our results, combined CE-MR/CT can be regarded as a cost-effective imaging strategy for staging of pancreatic cancer.*Clinical Relevance/Application Based on our results, combined CE-MR/CT can be regarded as a cost-effective imaging strategy for staging of pancreatic cancer with high robustness for varying iput-parameters.

RESULTS

In the base-case analysis the model yielded a total cost of 153367 $ and an effectiveness of 2,344 QALYs for CE-MR/CT and 155956 $ and 2,333 QALYs for CE-CT respectively. With a net monetary benefit (NMB) of 81004 $, CE-MR/CT is shown to be superior to CE-CT with a NMB of 77422 $. Deterministic and probabilistic survival analysis showed model robustness for varying input parameters.

CLINICAL RELEVANCE/APPLICATION

Based on our results, combined CE-MR/CT can be regarded as a cost-effective imaging strategy for staging of pancreatic cancer with high robustness for varying iput-parameters.

GI05-B8   Diagnostic Value Of Dynamic CT Perfusion Imaging To Predict Tumor Response To Anti-angiogenic Therapy In Patients With Advanced HCC Lesions

Participants
Cesare Maino, MD, Milano, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To determine the efficacy of perfusion-CT (p-CT) imaging to evaluate both the inhibition of tumor neo-angiogenesis induced by Sorafenib and the survival during treatment in patients with advanced hepatocellular carcinoma (HCC).*Methods and Materials A total of ninety-eight p-CT examinations were performed on a 256-slice MDCT scanner, before treatment and every 2 months during administration of Sorafenib, in 29 cirrhotic patients with a diagnosis of advanced HCC.Perfusion parameters related to "responder" (complete response, stable disease or partial response) and "non responder" (progressive disease) groups were considered and compared according to baseline CT and follow-up CT scans.Kaplan-Meier analyses estimated the time-to-survival in the overall population, after stratifying patients according to mRECIST.*Results The "responder" group showed a significant reduction of perfusion values in HCC target lesions after anti-angiogenic therapy (p = 0.01), in comparison with the "non responder" group which demonstrated an increase or no significant variation. When patients were stratified according to mRECIST, higher survival rate was observed in "responder" group compared to the "non responder" one (48.6% vs 28.6%), and statistically significant correlation (p=0.01) was found between percentage variation of perfusion parameters and overall survival rate, in pre- and post-treatment CT scans.*Conclusions The quantitative assessment of perfusion parameters represents a prognostic indicator useful in the evaluation of response to anti-angiogenic therapy.*Clinical Relevance/Application The quantitative assessment of perfusion parameters with p-CT should be considered a useful tool for the optimization of individualized treatment.

RESULTS

The "responder" group showed a significant reduction of perfusion values in HCC target lesions after anti-angiogenic therapy (p = 0.01), in comparison with the "non responder" group which demonstrated an increase or no significant variation. When patients

were stratified according to mRECIST, higher survival rate was observed in "responder" group compared to the "non responder" one (48.6% vs 28.6%), and statistically significant correlation (p=0.01) was found between percentage variation of perfusion parameters and overall survival rate, in pre- and post-treatment CT scans.

CLINICAL RELEVANCE/APPLICATION

The quantitative assessment of perfusion parameters with p-CT should be considered a useful tool for the optimization of individualized treatment.

NR04-B1   Monitoring Hydrocephalus Using Portable, Low-Field Magnetic Resonance Imaging

Participants
Thomas Arnold, PhD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Patients with hydrocephalus require repeated neuroimaging to monitor ventricular volumes and avoid complications. Standard of care (SOC) imaging includes routine CT or MRI though both have some disadvantages. CT uses ionizing radiation and provides less soft-tissue contrast. MRI is less widely available, more expensive, and subject to imaging artifact from commonly used programmable ventricular shunts. Strong magnetic fields also change programmable shunt settings. Here we present early results on the use of a recently FDA-cleared, portable, low-field strength (64mT) MRI scanner to monitor hydrocephalus. We hypothesized that low-field imaging would provide a comparable and more convenient point-of-care assessment for alterations in ventricle size, less shunt-related artifact, and less need for programmable shunt checks.*Methods and Materials As part of an ongoing trial, we collected same-day low-field MRI and outpatient SOC imaging for 22 patients with known or suspected hydrocephalus (CT=10, MRI=12). Low-field images were acquired on a 64mT system (Hyperfine, Guilford, CT) and included T1w, T2w, and T2-FLAIR sequences. A neuroradiologist (JMS) qualitatively assessed ventricles as abnormally increased, decreased or within expected limits. Semi-automated ventricular volume segmentations were also generated for clinical MRI scans and compared to deep-learning based volumes automatically provided by the low-field device. For programmable shunts, we recorded shunt settings before and after low-field imaging.*Results Radiological assessments were comparable between low-field MRI and SOC imaging. In one patient, a shunt related hemorrhage was evident on both modalities. We found a strong correlation (R=0.97, p<0.001) between lateral ventricle volume measurements on low-field and clinical MRI. Low-field MRI demonstrated less signal dropout near programmable shunts. Programmable shunts were present in 10/22 patients and shunt settings were altered by the low-field MRI in 9/10 cases.*Conclusions Initial results suggest low-field MRI offers comparable performance to SOC imaging for following hydrocephalus and that deep-learning based lateral ventricle volume estimates from low-field MRI are accurate. Programmable shunts must still be checked by the clinical care team after low-field imaging.*Clinical Relevance/Application Low-field MRI may offer a cost-effective, radiation-free alternative to monitor ventricular volume changes in patients with hydrocephalus.

RESULTS

Radiological assessments were comparable between low-field MRI and SOC imaging. In one patient, a shunt related hemorrhage was evident on both modalities. We found a strong correlation (R=0.97, p<0.001) between lateral ventricle volume measurements on low-field and clinical MRI. Low-field MRI demonstrated less signal dropout near programmable shunts. Programmable shunts were present in 10/22 patients and shunt settings were altered by the low-field MRI in 9/10 cases.

CLINICAL RELEVANCE/APPLICATION

Low-field MRI may offer a cost-effective, radiation-free alternative to monitor ventricular volume changes in patients with hydrocephalus.

NR04-B2   Radiation Distribution In A Hybrid Operating Room, Utilizing Three Different Intraoperative X-ray Imaging Systems: Investigations To Minimize Occupational Exposure.

Participants
Paulina Cewe Jonsson, MD, Stockholm, Sweden (*Presenter*) Nothing to Disclose

PURPOSE

Evaluate the occupational radiation environment in a hybrid operating room (OR) used in neurosurgical procedures, considering typical staff positions, different free-standing protective lead shields and various x-ray imaging equipment.*Methods and Materials Radiation dose was measured using personal dosimeters and a large-volume ionization chamber. Patient x-ray scatter was simulated using a whole-body anthropomorphic phantom, spine levels Th11 - L4, and standard clinical imaging protocols for three different types of x-ray systems: hybrid ceiling-mounted c-arm cone-beam CT (hCBCT), o-arm cone-beam CT (oCBCT), and a 2D c-arm fluoroscopy system. Different lead protection shields at various positions were evaluated.*Results Scatter dose from the hCBCT system was consistently lower by about 30% (9.4 µGy/rotation) compared to the oCBCT system (12.9 µGy/rotation). One rotational acquisition using the hCBCT and oCBCT system corresponded, respectively, to 12 and 16 minutes of flouroscopy imaging with the 2D c-arm. A wider and thicker lead protection shield provided a reduction in the scatter dose compared to a smaller shield, as expected. Radiation dose measured behind both protective shields, increased as the distance from the shield increased, up to a maximum at approximately 0.6 meter from the shield. This build-up being caused by tertiary scatter from walls and ceiling in the OR. Scatter dose subsequently decreased with further increased distance from the shield and was negligible outside a 3-m radius behind the protective shield.*Conclusions Scatter radiation to staff can be reduced by using hCBCT compared to oCBCT during spine surgery in a hybrid OR. Radiation to staff can be lowered by optimal use of protective shielding, proper staff positioning and considering the proximity of walls and ceiling in the OR. Staff in a hybrid OR can during rotational (CBCT) imaging use free-standing protective lead shields instead of heavy protective aprons, achieving the same dose reduction while preventing possible future ergonomic injuries and fatigue.*Clinical Relevance/Application Occupational radiation is reduced using hCBCT compared to oCBCT.

Lead shields achieve the same dose reduction as heavy protective aprons, preventing possible future ergonomic injuries and fatigue.

RESULTS

Scatter dose from the hCBCT system was consistently lower by about 30% (9.4 µGy/rotation) compared to the oCBCT system (12.9 µGy/rotation). One rotational acquisition using the hCBCT and oCBCT system corresponded, respectively, to 12 and 16 minutes of flouroscopy imaging with the 2D c-arm. A wider and thicker lead protection shield provided a reduction in the scatter dose compared to a smaller shield, as expected. Radiation dose measured behind both protective shields, increased as the distance from the shield increased, up to a maximum at approximately 0.6 meter from the shield. This build-up being caused by tertiary scatter from walls and ceiling in the OR. Scatter dose subsequently decreased with further increased distance from the shield and was negligible outside a 3-m radius behind the protective shield.

CLINICAL RELEVANCE/APPLICATION

Occupational radiation is reduced using hCBCT compared to oCBCT. Lead shields achieve the same dose reduction as heavy protective aprons, preventing possible future ergonomic injuries and fatigue.

NR04-B4   Correlation Between Magnetic Susceptibility And Brain Volume In Different Brain Location Might Be Modulated By Apoe4, Age And Gender

Participants
Younghee Yim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to examine relationship between iron accumulation and brain volume and find out possible modulator in this association in subjects with various spectrum of memory symptom.*Methods and Materials Total 103 patients diagnosed with SMI (n=20), MCI (n=57) or AD (n=20) were enrolled retrospectively. QSM data were generated from 3D gradient echo data using QSMnet algorithm. Intracranial volume was measured using automatic segmentation method based on FreeSurfer 6.0 platform. VOI-based analysis with QSM was performed for deep gray matter and six location of cortex. Correlation between brain volume and magnetic susceptibility was calculated and modulating factor was speculated. Also, we divided patients into three groups based on the age to evaluate susceptibility changes in different age and genetic status.*Results Volume of frontal cortex (p = 0.0064) and caudate nucleus (p = 0.0262) are associated with the magnetic susceptibility of the corresponding areas. In subgroup analysis, subjects diagnosed as MCI, whom without APOE4 gene or male gender shows association in frontal cortex while age shows only correlation in caudate nucleus. Magnetic susceptibility of caudate, thalamus, frontal temporal, or insular cortex shows significant difference among three age group. Patients with APOE4 gene show significant different magnetic susceptibility in putamen (p = 0.0176), thalamus (p = 0.0241), insular cortex (p = 0.0017), while those who without APOE4 gene shows significant different magnetic susceptibility in thalamus (p < 0.0001), frontal (p = 0.071), temporal (p = 0.0396), insular cortex (p = 0.0103).*Conclusions Our study demonstrates that volume and magnetic susceptibility of frontal cortex and caudate are probably modulated by genetic factor (APOE4), disease severity, age or gender. It suggests the brain iron accumulation might be associated with brain volume with different regional predilection and modulating factors. Iron accumulation of insular cortex tends to be decreased and that of thalamus tends to be increased as patients getting older regardless of genetic status.*Clinical Relevance/Application We anticipate more accurate and faster diagnosis and regulate correctable modulators to slow down the disease progression and intervene actively before patients hinder their everyday life.

RESULTS

Volume of frontal cortex (p = 0.0064) and caudate nucleus (p = 0.0262) are associated with the magnetic susceptibility of the corresponding areas. In subgroup analysis, subjects diagnosed as MCI, whom without APOE4 gene or male gender shows association in frontal cortex while age shows only correlation in caudate nucleus. Magnetic susceptibility of caudate, thalamus, frontal temporal, or insular cortex shows significant difference among three age group. Patients with APOE4 gene show significant different magnetic susceptibility in putamen (p = 0.0176), thalamus (p = 0.0241), insular cortex (p = 0.0017), while those who without APOE4 gene shows significant different magnetic susceptibility in thalamus (p < 0.0001), frontal (p = 0.071), temporal (p = 0.0396), insular cortex (p = 0.0103).

CLINICAL RELEVANCE/APPLICATION

We anticipate more accurate and faster diagnosis and regulate correctable modulators to slow down the disease progression and intervene actively before patients hinder their everyday life.

NR04-B6   Development And Validation Of An Automatic Classification Algorithm For The Diagnosis Of Alzheimer's Disease Using A High-performance Interpretable Deep Learning Network

Participants
Jinyoung Kim, Chapel Hill, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate an automatic classification algorithm for diagnosing Alzheimer's disease (AD) using a high-performance interpretable deep learning network.*Methods and Materials A deep learning-based classification algorithm was developed using T1-weighted brain MRI. We evaluated two classifier techniques, including TabNet, which is a high-performance interpretable network, and XGBoost for AD prediction. Automatic brain segmentation was performed using an automatic volumetry software (DeepBrain, VUNO Inc.). TabNet and XGBoost were respectively trained on the volumes and radiomics shape features of 104 segmented brain regions for classifying subjects into AD or cognitively normal (CN). Stratified 5-fold cross validation was used for training, while average ensemble value of five models from the stratified 5-fold cross validation was used for prediction. The diagnostic performance of TabNet and XGBoost was compared using areas under the curves (AUCs) for differentiating AD from CN. In addition, deep learning-based, 20 AD signature areas were investigated.*Results Between December 2014 and March 2017, 161 AD patients who were referred to a memory clinic at our tertiary medical center and 306 CN subjects who visited our Health Screening & Promotion Center were consecutively included in the training dataset. In the validation dataset, the other 120 AD and 141 CN were included between March 2017 and June 2018. In differentiating AD from CN, TabNet using volume, shape feature, or both resulted in AUCs of 0.951-0.955, which were similar compared to XGBoost with AUCs of 0.950-0.953. TabNet using both volume and shape features showed a sensitivity of 90% and a specificity of 93%. TabNet using volume, shape feature, or both were not significantly different with XGBoost using volume data in AD detection (P = 0.151-0.477). In comparing deep learning-based AD signature areas, both XGBoost and TabNet using volume data focused on the same 13 regions, including bilateral hippocampus, bilateral inferior

lateral ventricles, left entorhinal, left fusiform, and left accumbens area. For the rest 7 regions, TabNet selected more semantically meaningful regions compared to XGBoost.*Conclusions The automatic classification algorithm using a high-performance interpretable deep learning network helps accurate AD detection using T1-weighted brain MRI and detailed interpretation on the selected regions. This algorithm has the potential to be widely applicable method for AD prediction.*Clinical Relevance/Application Considering the wide availability of T1-weighted MRI in the clinical fields, this automatic classification algorithm for AD could be commonly used as an accurate and interpretable diagnostic method for AD.

RESULTS

Between December 2014 and March 2017, 161 AD patients who were referred to a memory clinic at our tertiary medical center and 306 CN subjects who visited our Health Screening & Promotion Center were consecutively included in the training dataset. In the validation dataset, the other 120 AD and 141 CN were included between March 2017 and June 2018. In differentiating AD from CN, TabNet using volume, shape feature, or both resulted in AUCs of 0.951-0.955, which were similar compared to XGBoost with AUCs of 0.950-0.953. TabNet using both volume and shape features showed a sensitivity of 90% and a specificity of 93%. TabNet using volume, shape feature, or both were not significantly different with XGBoost using volume data in AD detection (P = 0.151-0.477). In comparing deep learning-based AD signature areas, both XGBoost and TabNet using volume data focused on the same 13 regions, including bilateral hippocampus, bilateral inferior lateral ventricles, left entorhinal, left fusiform, and left accumbens area. For the rest 7 regions, TabNet selected more semantically meaningful regions compared to XGBoost.

CLINICAL RELEVANCE/APPLICATION

Considering the wide availability of T1-weighted MRI in the clinical fields, this automatic classification algorithm for AD could be commonly used as an accurate and interpretable diagnostic method for AD.

NR04-B8   Alterations In Vertebrobasilar Arterial System In Migraine And Its Association With Migraine Severity-A Case Control Study

Participants
Aditi Saini, MBBS, Rishikesh, India (*Presenter*) Nothing to Disclose

PURPOSE

Migraine is one of the most prevalent yet least understood neurological disorder, with the medical field still at the crossroads of vascular and neurogenic theories of pathogenesis. Occipital cortex and brainstem have been proposed as the generator areas for migraine headache and aura, thus prompting us to evaluate the association of basilar artery displacement and other alterations in vertebrobasilar arterial system with the severity of migraine.*Methods and Materials A case control study at AIIMS Rishikesh was conducted with 150 migraine (ICHD-3) cases and 153 age-group and sex matched controls over a period of 18 months. Severity of migraine was assessed using the Migraine Disability Assessment (MIDAS) questionnaire. Basilar artery displacement was evaluated on Time of Flight (TOF) sequence of MRI Brain along with basilar and vertebral arteries diameter.*Results Mean displacement of basilar artery was significantly (p<0.001) greater in migraine cases as compared to the controls (5.6±2.3 mm in cases and 3± 2.4 mm in controls); and even more so in migraine with aura (6±2.8 mm, p<0.05). There was significant association between basilar artery displacement and the severity (p<0.001), frequency in last 3 months (p<0.001) and duration (p=0.002) of migraine. A cut off of > 6.6 mm was found to be significant (p<0.001); odd's ratio 132.3) with a specificity of 93.7% to diagnose a case as severe migraine. However, the basilar and vertebral arterial diameters did not show any significant (p>0.05) association with migraine.*Conclusions Basilar artery displacement is significantly associated with migraine with significant correlation with migraine severity. Basilar artery displacement also significantly increases with increase in duration of the disease and frequency.*Clinical Relevance/Application Assessment of vertebrobasilar system in migraine patients, especially the basilar artery and its displacement, can help in severity stratification of the patients, helping the clinicians to provide appropriate medical management.

RESULTS

Mean displacement of basilar artery was significantly (p<0.001) greater in migraine cases as compared to the controls (5.6±2.3 mm in cases and 3± 2.4 mm in controls); and even more so in migraine with aura (6±2.8 mm, p<0.05). There was significant association between basilar artery displacement and the severity (p<0.001), frequency in last 3 months (p<0.001) and duration (p=0.002) of migraine. A cut off of > 6.6 mm was found to be significant (p<0.001); odd's ratio 132.3) with a specificity of 93.7% to diagnose a case as severe migraine. However, the basilar and vertebral arterial diameters did not show any significant (p>0.05) association with migraine.

CLINICAL RELEVANCE/APPLICATION

Assessment of vertebrobasilar system in migraine patients, especially the basilar artery and its displacement, can help in severity stratification of the patients, helping the clinicians to provide appropriate medical management.

NR04-B9   Initial Clinical Experience With Bedside, Point Of Care Non-contrast Brain MRIs

Participants
Brian Yep, MD, Orange, California (*Presenter*) Nothing to Disclose

PURPOSE

While non-contrast computed tomography (CT) imaging of the head represents the first-line imaging choice for a variety of neuro-pathologies due to its acquisition speed and availability, MRI is widely used as a follow-up exam for unrevealing CT examinations due to its superior contrast resolution. The US Food & Drug Administration (FDA) has recently provided 510(k) premarket notification for a bedside, point-of-Care (POC) 0.064T MRI device. Currently, there are less than five of these devices operating clinically in the country, and we present our early institutional clinical experience utilizing POC MRI non-contrast brain exams in the emergency department (ED) and intensive care unit (ICU) patient settings.*Methods and Materials This HIPAA-compliant study was approved by the local institutional review board with informed consent waived. Data were collected on patients in the ED and ICU setting who received POC MRI non-contrast brain exams between January 2021-April 2021. We recorded relevant findings, and how often subsequent fixed 1.5T or 3.0T imaging was required. For those requiring a repeat exam, we recorded whether new findings were appreciated on the follow-up exam.*Results Over a 4-month period, a total of 24 POC MR non-contrast brain exams were performed (9 ED, 15 ICU) with axial DWI/ADC, axial T2, and axial T2/FLAIR images obtained. Clinical indications for these exams included stroke (18) and altered mental status (6). Of POC-MRIs, images provided diagnostic confidence for 75% (18/24) of exams with 25% (6/24) requiring a repeat exam. Of the 6 repeated exams, 3 identified a new finding that was previously not identified on the POC-MRI. This included a 6 mm right thalamic infarct, scattered punctate embolic infarcts, and a lower pontine infarct. Note, the lower pontine infarct was missed on the original POC-MRI due to motion artifact.*Conclusions Preliminary, POC MRI non-contrast brain

exams were diagnostic in the majority of our patients. Findings that were missed thus far include infarcts less than 6 mm. Future studies are needed to determine the resolution to detect subtle neuro-pathologies in order to determine the appropriateness of this new device.*Clinical Relevance/Application POC MRI noncontrast brain exams provide an alternative rapid diagnostic tool to detect recent infarctions, although the study is limited may be limited for smaller infarctions or with significant patient motion.

RESULTS

Over a 4-month period, a total of 24 POC MR non-contrast brain exams were performed (9 ED, 15 ICU) with axial DWI/ADC, axial T2, and axial T2/FLAIR images obtained. Clinical indications for these exams included stroke (18) and altered mental status (6). Of POC-MRIs, images provided diagnostic confidence for 75% (18/24) of exams with 25% (6/24) requiring a repeat exam. Of the 6 repeated exams, 3 identified a new finding that was previously not identified on the POC-MRI. This included a 6 mm right thalamic infarct, scattered punctate embolic infarcts, and a lower pontine infarct. Note, the lower pontine infarct was missed on the original POC-MRI due to motion artifact.

CLINICAL RELEVANCE/APPLICATION

POC MRI noncontrast brain exams provide an alternative rapid diagnostic tool to detect recent infarctions, although the study is limited may be limited for smaller infarctions or with significant patient motion.

GI04-B10   Combining Hepatic And Splenic CT Radiomic Features Improves Liver Fibrosis Staging

Participants
Yunchao Yin, MSc, Groningen, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning for CT-based liver fibrosis staging uses both hepatic and splenic information. Whether this also holds true for radiomics analysis is currently unknown. The primary aims of this study were to determine whether adding splenic information to hepatic information can improve the performance of liver fibrosis staging by CT-based radiomics analysis. The secondary aim was to compare the performance of radiomics analysis and deep learning in CT-based liver fibrosis staging on the same dataset.*Methods and Materials The radiomics features were extracted from both liver and spleen on contrast-enhanced CT images in the portal venous phase of 252 patients with histologically proven liver fibrosis stage. The radiomic analysis for liver fibrosis staging was done by hepatic and hepatic-splenic features, respectively. The most important radiomic features were analyzed to better understand the contribution of hepatic and splenic features in the models. Results were compared with a previously developed DL based algorithm for liver fibrosis staging using the same dataset.*Results When using both splenic and hepatic features in the CT-based radiomics analysis, the average accuracy rates of significant fibrosis, advanced fibrosis, and cirrhosis were 88%, 82%, and 86%, and area under the receiver operating characteristic curves (AUC's) were 0.92, 0.81, and 0.85. The micro-averaged AUC of hepatic-splenic based radiomic analysis based on ensemble classifier was significantly larger than that of hepatic-based analysis (P<0.05). The micro-averaged AUC of radiomic analysis was only 0.6% lower than deep learning on the same dataset. The top 5 most important features for radiomic analysis included both hepatic and splenic features.*Conclusions Adding CT-based splenic radiomic features to hepatic radiomic features increases radiomic analysis performance for liver fibrosis staging. Radiomic analysis shows promise as a non-inferior alternative to deep learning for liver fibrosis staging. Furthermore, analyzing important features in radiomic analysis make the prediction of the model easier to be understood.*Clinical Relevance/Application Our study analyzed the importance of splenic features in CT-based liver fibrosis staging and suggested radiomic analysis can be a non-inferiority approach compared to deep learning in this setting.

RESULTS

When using both splenic and hepatic features in the CT-based radiomics analysis, the average accuracy rates of significant fibrosis, advanced fibrosis, and cirrhosis were 88%, 82%, and 86%, and area under the receiver operating characteristic curves (AUC's) were 0.92, 0.81, and 0.85. The micro-averaged AUC of hepatic-splenic based radiomic analysis based on ensemble classifier was significantly larger than that of hepatic-based analysis (P<0.05). The micro-averaged AUC of radiomic analysis was only 0.6% lower than deep learning on the same dataset. The top 5 most important features for radiomic analysis included both hepatic and splenic features.

CLINICAL RELEVANCE/APPLICATION

Our study analyzed the importance of splenic features in CT-based liver fibrosis staging and suggested radiomic analysis can be a non-inferiority approach compared to deep learning in this setting.

GI04-B11   Body Diffusion MR Imaging With Compressed Sense Based On Single-shot Echo-planar Imaging: An Intra-individual Comparison.

Participants
Maike Bode, MD, Aachen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To investigate whether combining compressed SENSE (CS) based reconstruction and single-shot echo planar imaging (EPI) is useful in hepatic diffusion weighted imaging (DWI).*Methods and Materials Single-shot EPI-DWI with CS-based reconstruction (CS-DWI) and parallel imaging reconstruction (conv-DWI) in liver MRI was performed in volunteers and patients. In all individuals, conv-DWI was acquired with a spatial resolution of 1.7x1.7x6 mm3, within 3:31 min:sec. In 12 healthy volunteers, signal-to-noise ratio (SNR) and apparent diffusion coefficient (ADC) value were compared for conv-DWI and CS-DWI with the same spatial resolution. For the patient cohort, 75 subjects (60±13 years, 41 men) with 349 focal liver lesions (FLL) were included. In 28 patients (group A), CS was used to reduce acquisition time (3:00 min:sec); in 47 patients (group B), CS was invested to improve spatial resolution (1.48x1.48x6 mm3). Two radiologists independently rated several image quality parameters on a 5-point scale blinded to the applied techniques. The number of FLLs was recorded for both sequences; where FLLs were missed, a side-by-side comparison was added to analyze the reason for non-detectability.*Results In volunteers, higher SNR (19.3±2.8 vs. 9.8±1.6 at b=800) and lower SD of the ADC-values (0.17 vs. 0.20, p<0.05) were found on CS-DWI compared to conv-DWI. Image quality ratings in patients were similar for all parameters in both groups except for "conspicuity of FLLs" which was rated significantly lower on CS-DWI vs. conv-DWI (4.7±0.6 vs. 4.2±0.9; p<0.05) in group A. In 5 patients (1 of group A, 4 of group B), 11/349 FLLs, 3-7 mm in size, were not detectable on CS-DWI, but on conv-DWI.*Conclusions CS-based reconstruction of single-shot EPI-based DWI can accelerate image acquisition or improve spatial resolution in DWI. However, our finding that a small fraction of FLLs was non-detectable on CS-DWI is concerning and warrants further research before using CS-DWI in clinical practice.*Clinical Relevance/Application Although

CS-based reconstruction of single-shot EPI-DWI can be used to accelerate acquisition time and/or improve spatial resolution at comparable image quality, a small fraction of FLLs was not visualized on CS-DWI.

RESULTS

In volunteers, higher SNR (19.3±2.8 vs. 9.8±1.6 at b=800) and lower SD of the ADC-values (0.17 vs. 0.20, p<0.05) were found on CS-DWI compared to conv-DWI. Image quality ratings in patients were similar for all parameters in both groups except for "conspicuity of FLLs" which was rated significantly lower on CS-DWI vs. conv-DWI (4.7±0.6 vs. 4.2±0.9; p<0.05) in group A. In 5 patients (1 of group A, 4 of group B), 11/349 FLLs, 3-7 mm in size, were not detectable on CS-DWI, but on conv-DWI.

CLINICAL RELEVANCE/APPLICATION

Although CS-based reconstruction of single-shot EPI-DWI can be used to accelerate acquisition time and/or improve spatial resolution at comparable image quality, a small fraction of FLLs was not visualized on CS-DWI.

GI04-B4 Replacing Unintentional Weight Loss With CT-Assessed Sarcopenia In Physical Frailty Phenotype Construct For Clinical Use

Participants
Omid Shafaat, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Frailty defined as an aging-related syndrome of physiological decline and is associated with poor post kidney transplant (KT) outcomes. The Physical Frailty Phenotype (PFP) includes weakness, slowness, exhaustion, low physical activity, and unintentional weight loss (shrinking). Compared to the original definition based on subjective self-reported unintentional weight loss, sarcopenia, identified by objective CT measures, may be more appropriate for risk stratification of KT recipients. This study was designed to compare frailty defined by the original PFP (oPFP) using subjective unintentional weight loss vs. frailty defined by new PFP (nPFP) using objective CT-assessed sarcopenia for risk predictions of mortality and graft loss in KT recipients.*Methods and Materials In a prospective cohort of adult KT recipients we measured oPFP at admission (12/2008-2/2020), and skeletal muscle index (SMI) at L3 vertebral level from available CT scans using OsiriX by drawing a closed polygon and using the region of interest (ROI) tool within 1-year pre-KT and ascertained binary sarcopenia status (male SMI<50; female SMI<39 cm2/m2). nPFP score was calculated in the same way as oPFP score, while shrinking was determined by sarcopenia. Frailty by either PFP was defined as a score=3. Hazard ratios (HRs) of all-cause mortality and all-cause graft loss by frailty were estimated using adjusted Cox proportional hazard models for oPFP and nPFP, respectively. The model discriminations of outcomes using oPFP vs. nPFP were quantified using Harrell's C-statistic.*Results Among 1,113 KT recipients with both oPFP and nPFP scores, oPFP identified 16.5% while nPFP identified 15.1% of recipients being frail. After adjustment, frail recipients identified using oPFP had a 1.39-fold risk of mortality (95% CI: 1.03-1.87) and 1.42-fold risk of graft loss (95% CI: 1.11-1.83), compared to their non-frail counterparts; frail recipients identified using nPFP had a 1.45-fold risk of mortality (95% CI: 1.07-1.97) and 1.44-fold risk of graft loss (95% CI: 1.11-1.87), compared to their non-frail counterparts. The C-statistics of mortality and graft models for nPFP and oPFP were similar.*Conclusions Subjective unintentional weight loss used in the PFP construct can be replaced by objective sarcopenia in KT recipients with similar discriminations for post-KT mortality and graft loss risks. Radiologists in transplant centers may consider using sarcopenia identified by CT measures for PFP construct.*Clinical Relevance/Application Frailty is associated with postoperative complications and poor outcomes. Replacing unintentional weight loss with an objective CT-based measure of sarcopenia for the shrinking component in PFP resulted in more appropriate risk stratification.

RESULTS

Among 1,113 KT recipients with both oPFP and nPFP scores, oPFP identified 16.5% while nPFP identified 15.1% of recipients being frail. After adjustment, frail recipients identified using oPFP had a 1.39-fold risk of mortality (95% CI: 1.03-1.87) and 1.42-fold risk of graft loss (95% CI: 1.11-1.83), compared to their non-frail counterparts; frail recipients identified using nPFP had a 1.45-fold risk of mortality (95% CI: 1.07-1.97) and 1.44-fold risk of graft loss (95% CI: 1.11-1.87), compared to their non-frail counterparts. The C-statistics of mortality and graft models for nPFP and oPFP were similar.

CLINICAL RELEVANCE/APPLICATION

Frailty is associated with postoperative complications and poor outcomes. Replacing unintentional weight loss with an objective CT-based measure of sarcopenia for the shrinking component in PFP resulted in more appropriate risk stratification.

CH02-B2 **Localizing Peripherally Inserted Central Catheters (PICCs) Tips In Chest Radiographs With A Machine Learning Algorithm Trained Via Transfer Learning.**

Participants
Ravish Patel, Athens, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

Peripherally inserted central catheters (PICCs) are often placed by advanced practitioners (eg, physicians assistants and nurse practitioners) with limited training in chest radiograph interpretation. A system to detect PICC positioning may assist in confirming accurate placement of the line. Our primary objective in this study was to use transfer learning to train a machine learning (ML) algorithm to localize the tip of the PICC in chest radiographs.*Methods and Materials Chest radiographs were obtained from the NIH Chest X-ray Dataset. 677 cases with PICCs were identified, and 743 cases without PICCs, for a total of 1,420 total cases. Training chest radiographs were labeled as left or right PICC, and the tip was manually tagged with a small region of interest (ROI). Images were modified using adaptive histogram equalization to improve image contrast for the purpose of optimizing PICC tip detection. Transfer learning was used to train the YOLOv3 ML architecture on 1,220 images. 100 different images with PICCs were used for testing purposes.*Results The system was 98% accurate at producing a small ROI that contained the PICC tip and labeled each correctly as coming from the left or right side. In almost all cases, the tip was essentially in the exact center of the ROI. Failed cases contained PICC tips in non-standard locations.*Conclusions The YOLOv3 ML architecture trained via transfer learning can accurately localize the tips of PICC lines in chest radiographs. Image modification may assist in incrementally increasing the accuracy of the model.*Clinical Relevance/Application Peripherally inserted central catheters (PICCs) are often placed by advanced practitioners with limited training in chest radiography. A system to detect PICC positioning may assist in placement.

RESULTS

The system was 98% accurate at producing a small ROI that contained the PICC tip and labeled each correctly as coming from the left or right side. In almost all cases, the tip was essentially in the exact center of the ROI. Failed cases contained PICC tips in non-standard locations.

CLINICAL RELEVANCE/APPLICATION

Peripherally inserted central catheters (PICCs) are often placed by advanced practitioners with limited training in chest radiography. A system to detect PICC positioning may assist in placement.

CH02-B3 **Qualitative And Quantitative Characteristics Of Dark-field X-ray Imaging: First Results In Healthy Humans**

Participants
Florian Gassert, MD, Muenchen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To describe the qualitative and quantitative characteristics of X-ray dark-field images in healthy subjects for the first time and thus set a reference for future studies.*Methods and Materials Overall, 40 subjects without history of lung diseases and normal appearance of the lungs in a chest CT scan were included in this study and imaged using the novel clinical X-ray dark-field prototype, recently constructed and commissioned at our institution, simultaneously acquiring both conventional and dark-field thorax radiographs. The subject's total dark-field signal was correlated with the estimated number of alveoli in the lung, and the dark-field coefficient was correlated with the demographic parameters age, sex, weight, and height.*Results The properly ventilated lung tissue gives a strong signal while surrounding osseous structures and soft tissue result in very low or no signal, respectively. The average dark-field signal was 2.53 ± 0.44 per meter of examined lung tissue. There was a highly significant correlation between the total dark-field signal and the number of alveoli ($r = 0.61$; $p < 0.001$). No significant difference was found between males and females ($p = 0.78$). Also, age ($r = -0.18$; $p = 0.26$), weight ($r = 0.24$; $p = 0.13$), and height ($r = 0.01$; $p = 0.96$) did not influence the dark-field signal significantly.*Conclusions The X-ray dark-field signal intensity depends on the lung ventilation while being independent from demographic parameters. Therefore, the quantitative dark-field coefficient may serve as a robust novel imaging biomarker for the diagnostic assessment of lung function. This is the first study to introduce qualitative and quantitative reference values for X-ray dark-field imaging in healthy humans.*Clinical Relevance/Application New imaging techniques are needed to diagnose lung diseases in earlier stages to improve clinical outcome. In that respect, X-ray dark-field imaging may add to the currently existing lung imaging techniques.

RESULTS

The properly ventilated lung tissue gives a strong signal while surrounding osseous structures and soft tissue result in very low or no signal, respectively. The average dark-field signal was 2.53 ± 0.44 per meter of examined lung tissue. There was a highly significant correlation between the total dark-field signal and the number of alveoli ($r = 0.61$; $p < 0.001$). No significant difference was found between males and females ($p = 0.78$). Also, age ($r = -0.18$; $p = 0.26$), weight ($r = 0.24$; $p = 0.13$), and height ($r =

0.01; p = 0.96) did not influence the dark-field signal significantly.

CLINICAL RELEVANCE/APPLICATION

New imaging techniques are needed to diagnose lung diseases in earlier stages to improve clinical outcome. In that respect, X-ray dark-field imaging may add to the currently existing lung imaging techniques.

CH02-B5   **Image Quality Of Thorax On Dual-Energy Spectral CT With And Without The Deep Learning-Based Image Reconstruction: Visual And Quantitative Evaluations Of Virtual Monoenergetic Images**

Participants
Noriko Kikuchi, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To visually and quantitatively evaluate image quality of dual-energy CT in thorax by comparing virtual monoenergetic images reconstructed with filtered back projection (FBP), adaptive statistical iterative reconstruction (ASiR-V), and deep learning-based image reconstruction (DLIR).*Methods and Materials This retrospective study included 30 patients who underwent enhanced dual-energy CT for close examination of esophageal cancer. All images with 0.625-mm slice thickness were reconstructed using FBP, ASiR-V, and DLIR for 50keV and 70keV monochromatic images. ASiR-V degree of 60% was used. Two independent radiologists evaluated FBP-50KeV, ASiR-V-50KeV, DLIR-50KeV, ASiR-V-70KeV, and DLIR-70KeV compared with the conventional 70keV monochromatic images (FBP-70keV) on a 5-point scale (1=worst<2<3=FBP-70KeV<4<5=best) in terms of the visibility of lymph nodes, esophagus, aorta, and overall image quality on mediastinum window setting (width 400 HU; level 60 HU). Regions of interest were placed at the axillary fat (af) and the erector spinae muscle (esm) to measure CT values and standard deviation (SD). The signal-to-noise ratio (SNR=CTesm/SDesm) and the contrast-to-noise ratio (CNR=[CTesm-CTaf]/SDaf) were calculated objectively on the six image sets (FBP-50KeV, ASiR-V-50KeV, DLIR-50KeV, FBP-70KeV, ASiR-V-70KeV, and DLIR-70KeV). Visual evaluation scores were statistically analyzed using Wilcoxson signed-rank test with Bonferroni correction. For quantitative data, statistical analysis was performed using repeated measures analysis of variances followed by post-hoc tests. P values<0.005(0.05/10) were considered significant.*Results DLIR significantly improved visual image quality of lymph nodes, esophagus, aorta, and overall image quality more than ASiR-V-70keV, ASiR-V-50keV, FBP-70keV and FBP-50keV(median scores:3,3,3,and 2, respectively) (all p?0.0003). There was no significant difference between DLIR-70keV and DLIR-50keV. Image quality of DLIR was the best (all median scores:4-5) FBP-50keV was the worst. SNR and CNR of DLIR-70keV(mean±SD,3.96±1.37 and 16.9±5.70) were significantly higher than those of ASiR-V-70keV(2.49±0.66 and 9.44±2.25) and FBP-70keV(1.96±0.49 and 7.63±1.68) (all p<0.005). SNR and CNR of DLIR-50keV(mean±SD,3.68±1.23 and 15.3±5.05) were significantly higher than those of ASiR-V-70keV(2.25±0.60 and 8.41±1.97) and FBP-70keV(1.78±0.45 and 6.69±1.43) (all p<0.005).*Conclusions DLIR can provide the best image quality of thorax on dual-energy spectral CT. Image quality of DLIR-50KeV is visually equivalent to DLIR-70KeV.*Clinical Relevance/Application DLIR on dual-energy CT may be useful for evaluation of contrast effect and reduction of contrast agent by improving image quality.

RESULTS

DLIR significantly improved visual image quality of lymph nodes, esophagus, aorta, and overall image quality more than ASiR-V-70keV, ASiR-V-50keV, FBP-70keV and FBP-50keV(median scores:3,3,3,and 2, respectively) (all p?0.0003). There was no significant difference between DLIR-70keV and DLIR-50keV. Image quality of DLIR was the best (all median scores:4-5) FBP-50keV was the worst. SNR and CNR of DLIR-70keV(mean±SD,3.96±1.37 and 16.9±5.70) were significantly higher than those of ASiR-V-70keV(2.49±0.66 and 9.44±2.25) and FBP-70keV(1.96±0.49 and 7.63±1.68) (all p<0.005). SNR and CNR of DLIR-50keV(mean±SD,3.68±1.23 and 15.3±5.05) were significantly higher than those of ASiR-V-70keV(2.25±0.60 and 8.41±1.97) and FBP-70keV(1.78±0.45 and 6.69±1.43) (all p<0.005).

CLINICAL RELEVANCE/APPLICATION

DLIR on dual-energy CT may be useful for evaluation of contrast effect and reduction of contrast agent by improving image quality.

NR04-D2   **Welcome Pack: A Rapid Brain Screening Protocol Using Deep Learning Reconstruction.**

Participants
Yasutaka Fushimi, MD, PhD, Kyoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Reducing scan time is critical in MRI clinical routine to scan more patients per day to cope with the increasing number of demands and also critical for motion-prone patients or patients with time-sensitive diseases. Various previous reports developed ultrafast brain protocols by using rapid image sequences. In this context, we have optimized 5-minute routine screening protocol that we have called welcome pack (WP) utilizing deep learning reconstruction (DLR). Our main objective is to compare quality and diagnostic capability of WP with the conventional routine protocol.*Methods and Materials We optimized the rapid brain MRI screening protocol (WP) with a scan time of 4 minutes 36 seconds consisting of 2D axial images (T1WI, T2*WI, DWI), 2D coronal T2WI, 3D MR angiography, and 3D-FLAIR image with DLR. Scan time of our routine protocol (control) which included the same sequences as in WP was 11 minutes 47 seconds. A total of 60 patients (32 females, 71 [59-80] years) were enrolled in this study. All patients were explored with the WP and the control protocol during the same session on a Vantage Galan 3T / ZGO (Canon Medical Systems Corporation). Four radiologists separately read the cases of WP and control protocols for diagnosis purpose at 3-week interval in a blind manner. They also evaluated the image quality of each sequence. They classified Deep and Subcortical White Matter Hyperintensity (DSWMH) and Periventricular Hyperintensity (PVH) on 3D FLAIR images in 2 protocols. Statistical comparison for inter-sequence agreement was conducted.*Results Twenty-one lesions were diagnosed in the control protocol (2 patients had 2 lesions). The reading results by the neuroradiologist in control protocol were considered as the reference standard. Inter-sequence agreement of lesion detection for each rater was extremely high (0.971 in neuroradiologist, 0.719 in non-neuroradiologist, 0.928 in resident-1 and 0.917 in resident-2). Reader evaluated 94% sequences in WP as best image quality and 93% as same image quality as control. Concordance of DSWMH and PVH between 2 protocols was high as follows: neuroradiologist, 0.998, 1; non-neuroradiologist, 0.874, 0.873; resident-1, 0.936, 0.941; resident-2, 0.940, 0.929, respectively.*Conclusions Radiologists reached comparable results in lesion detection, image quality assessment, and classification of white matter hyperintensities between WP and control protocol.*Clinical Relevance/Application We have optimized a less than 5 minutes 6 sequences screening brain MR protocol using deep learning reconstruction (DLR) and radiologists reached statistically comparable results between the rapid and the routine control brain protocol, allowing the rapid protocol to be substituted as a clinical routine screening protocol.

RESULTS

Twenty-one lesions were diagnosed in the control protocol (2 patients had 2 lesions). The reading results by the neuroradiologist in control protocol were considered as the reference standard. Inter-sequence agreement of lesion detection for each rater was extremely high (0.971 in neuroradiologist, 0.719 in non-neuroradiologist, 0.928 in resident-1 and 0.917 in resident-2). Reader evaluated 94% sequences in WP as best image quality and 93% as same image quality as control. Concordance of DSWMH and PVH between 2 protocols was high as follows: neuroradiologist, 0.998, 1; non-neuroradiologist, 0.874, 0.873; resident-1, 0.936, 0.941; resident-2, 0.940, 0.929, respectively.

CLINICAL RELEVANCE/APPLICATION

We have optimized a less than 5 minutes 6 sequences screening brain MR protocol using deep learning reconstruction (DLR) and radiologists reached statistically comparable results between the rapid and the routine control brain protocol, allowing the rapid protocol to be substituted as a clinical routine screening protocol.

NR04-D4   **Hypoperfusion Lesion And Target Mismatch Prediction From Baseline Diffusion Imaging Using 3d U-net**

Participants
Yannan Yu, Palo Alto, California (*Presenter*) Nothing to Disclose

PURPOSE

Perfusion imaging is routinely used in acute ischemic stroke to assess target mismatch, but requires contrast agent injection and post-processing software. Clinical diffusion mismatch, such as the criteria used in DAWN trial, was reported to miss candidates that meet DEFUSE 3 criteria and could benefit from thrombectomy. We aim to explore whether neural network can predict hypoperfusion lesion and target mismatch from baseline diffusion-weighted imaging (DWI) and clinical information.*Methods and Materials Acute ischemic stroke cases with baseline MR perfusion and DWI were included from two multi-center trials and one single-center registry. MR perfusion images were post-processed by RAPID software, which automatically segments hypoperfusion lesion (Tmax = 6s) and ischemic core lesion (ADC = 620 ×10-6 mm2/s). All the images were normalized to template space (128 x 128 x 60 px). A 3D U-Net was trained using baseline DWI, Apparent diffusion coefficient, NIH stroke scale (NIHSS) and side of stroke as input, the union of hypoperfusion and ischemic core segmentation as ground truth. The ground truth segmentations were manually cleaned up to remove significant noises. Each training image and its ground truth were slabs extracted from the whole volume (128 x 128 x 16 px). 5-fold cross-validation was performed. Model performance was evaluated by dice score coefficient (DSC), volume difference, and absolute volume difference. DEFUSE 3 target mismatch (1) mismatch ratio = 1.8, 2) ischemic core = 70ml, 3) difference

between hypoperfusion and core lesion = 15 ml) was used as reference, the sensitivity, specificity, PPV, NPV of target mismatch from model and DAWN criteria were compared.*Results 368 patients were included (age 67±15 years, median NIHSS 14, median baseline core 17 ml, median baseline hypoperfusion 77 ml). The 3D U-Net reached a median DSC of 0.58 (interquartile range[IQR] 0.42, 0.69), volume difference 15 ml (IQR -24, 50), and absolute volume difference 40 ml (19, 71). Compared to DAWN criteria, The model reached a sensitivity of 94% vs 51%, a specificity of 61% vs 89%, PPV of 84% vs 91%, and NPV of 82% vs 46%.*Conclusions 3D U-Net can predict hypoperfusion lesion from baseline DWI and clinical information, which identify patients with DEFUSE3 target mismatch more sensitively than DAWN criteria.*Clinical Relevance/Application The model helps identify acute ischemic stroke patients with target mismatch using only baseline DWI and clinical information.

RESULTS

368 patients were included (age 67±15 years, median NIHSS 14, median baseline core 17 ml, median baseline hypoperfusion 77 ml). The 3D U-Net reached a median DSC of 0.58 (interquartile range[IQR] 0.42, 0.69), volume difference 15 ml (IQR -24, 50), and absolute volume difference 40 ml (19, 71). Compared to DAWN criteria, The model reached a sensitivity of 94% vs 51%, a specificity of 61% vs 89%, PPV of 84% vs 91%, and NPV of 82% vs 46%.

CLINICAL RELEVANCE/APPLICATION

The model helps identify acute ischemic stroke patients with target mismatch using only baseline DWI and clinical information.

NR04-D6   Disrupted Default Mode Network Functional Connectivity In Adolescents With Mild Traumatic Brain Injury

Participants
Thomas Johnson, MD,PhD, Rochester, New York (*Presenter*) Nothing to Disclose

PURPOSE

Use resting-state fMRI (rs-fMRI) to determine network connectivity measures in the 'default mode network' (DMN) of patients with mild traumatic brain injury (i.e., concussion - mTBI) with symptoms of post-concussion syndrome (PCS) and compare them to healthy controls.*Methods and Materials Concussion patients (n=142, 75M, 67F, mean age 18.2 yrs, range 9-60) with a history of clinically diagnosed mTBI and PCS and age and sex-matched controls (n=27, 15M, 12F, mean age 20.7 yrs, range 18-28) underwent rs-fMRI. The control group consisted of young athletes with no history of mTBI, as confirmed by a physician. A clinician extracted the number of previous concussions and time between injury and MRI from electronic medical records. Subjects were scanned anywhere between 3 days to 2 years after concussion. 3D MPRAGE sequence: TR/TE = 1200/2.29ms, voxel size = 1.0 x 1.0 x 1.0mm, matrix size = 256 x 256 x 208. Motion-corrected EPI sequence: TR/TE = 2200/30ms, voxel size = 4.0 x 4.0 x 4.0mm, matrix size 64 x 64 x 38 with 220 time points. Patients were instructed to close their eyes during rs-fMRI acquisition. Data analysis was performed using the FSL, and the pipeline and relevant modules are summarized below: 1. Data cleanup [FEAT], including brain extraction, field correction, linear motion correction, and registration to standard space [MNI atlas]. 2. Individual independent component analysis (ICA) [MELODIC], including finding the maximally independent components of the data in both space and time and classifying each as noise vs. signal. 3. Denoising data [FIX] by training a denoiser with hand-labeled components from ICA (10 controls, 20 subjects) and removing noisy components from fMRI data. 4. Group ICA [MELODIC] analysis, concatenating data from all subjects temporally. 5. Mapping group ICA components back to individual subjects [dual_regression] and performing a statistical comparison of groups [randomise].*Results 3-factor ANOVA (Control [CON], 1-2 concussions [C1-2], >=3 concussions [C3]) with posthoc F-test showed significant differences in DMN functional connectivity between C1-2 and C3 as well as CON and C1-2. There was also a trend between CON and C3 groups, p_min=0.055. The disrupted regions include the post-central and supramarginal gyri.*Conclusions DMN functional connectivity is disrupted in mTBI patients experiencing symptoms of PCS, with a significant difference in connectivity between low and high mTBI burden groups. This is congruent with previous data showing disrupted structural connectivity in the same patient group.*Clinical Relevance/Application The fact that disruption of connectivity is most pronounced in chronic mTBI patients suggests that a more severe disease process occurs in subjects with greater mTBI burden.

RESULTS

3-factor ANOVA (Control [CON], 1-2 concussions [C1-2], >=3 concussions [C3]) with posthoc F-test showed significant differences in DMN functional connectivity between C1-2 and C3 as well as CON and C1-2. There was also a trend between CON and C3 groups, p_min=0.055. The disrupted regions include the post-central and supramarginal gyri.

CLINICAL RELEVANCE/APPLICATION

The fact that disruption of connectivity is most pronounced in chronic mTBI patients suggests that a more severe disease process occurs in subjects with greater mTBI burden.

NR04-D8   Utility Of Synthetic MRI And Diffusion Measures In Predicting The Ki-67 Status Of Glioma: A Feasibility Study

Participants
Xin Ge, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the utility of synthetic magnetic resonance imaging (sy-MRI) and diffusion weight imaging (DWI) of glioma in predicting the Ki-67 status.*Methods and Materials From August 2020 to April 2021, forty-six patients with gliomas (including 13 LGGs and 33 HGGs) who underwent DWI and sy-MRI (magnetic resonance image compilation, MAGiC) on a 3.0T MR scanner (Signa Architect, GE, WI), were enrolled in the present study. Sy-MRI data were acquired using a multiple-dynamic, multiple-echo (MDME) sequence, which parameters follow: TR = 4177ms, TE = 20ms, slice thickness/gap = 5/1mm, FOV = 24cm, matrix = 320 × 256. The parameters of DWI sequence were as follows: TR = 3787ms, TE = 78ms, slice thickness/gap = 5/1mm, NEX = 2, FOV = 24cm, matrix = 160 × 166, b values = 0/1000 (sec/mm2). In the synthetic T2 FLAIR images, one radiologist drew the region of interests (ROIs) manually to encompass the largest area of the solid portion lesion, then the ROIs were copied onto T1 relaxometry (T1) / T2 relaxometry (T2) / proton density (PD) maps derived from MAGIC and ADC maps derived from DWI, as well as mean values were recorded. Correlations between the parameters and the label index of Ki-67 (KI-67 LI) were analyzed by using Spearman's correlation analysis.*Results Figure 1 show the representative images and Ki-67 staining of gliomas. Spearman's correlation analysis showed that the values of the tumor Ki-67 LI was correlated with the PD and ADC values (for PD, r = 0.402, P < 0.05; for ADC, r = -0.565, P < 0.001) but not any of the T1 or T2 relaxometry (Table 1).*Conclusions We found a negative correlation between ADC and Ki-67, which is associated with the activity of tumor cells proliferation of tumor cells. Importantly, PD values, were positively correlated with the Ki-67 LI, which may be used as an evaluation index of the cell proliferation state.*Clinical Relevance/Application

The PD represent the inherent properties of matter and the ADC show microstructural differences at the cellular level, which have an omni-directional and omni-depth role in assessing the tumor biological characteristics. Further, as a native parameter of tissue, PD, might be a novel predictor of Ki-67 LI.

RESULTS

Figure 1 show the representative images and Ki-67 staining of gliomas. Spearman's correlation analysis showed that the values of the tumor Ki-67 LI was correlated with the PD and ADC values (for PD, r = 0.402, P < 0.05; for ADC, r = -0.565, P < 0.001) but not any of the T1 or T2 relaxometry (Table 1).

CLINICAL RELEVANCE/APPLICATION

The PD represent the inherent properties of matter and the ADC show microstructural differences at the cellular level, which have an omni-directional and omni-depth role in assessing the tumor biological characteristics. Further, as a native parameter of tissue, PD, might be a novel predictor of Ki-67 LI.

NR04-D9   Validation Of A 3D Convolutional Neural Network For The Detection Of Large Vessel Occlusion In Acute Ischemic Stroke

Participants
Luis Souto Maior Neto, MSc, Calgary, Alberta (*Presenter*) Developer, Circle Cardiovascular Imaging Inc

PURPOSE

CT Angiography (CTA) is the imaging standard for the detection of large vessel occlusion (LVO) in acute ischemic stroke. Early detection of LVO is key for identifying eligible patients for endovascular treatment. StrokeSENS LVO utilizes a 3D convolutional neural network to automatically detect such occlusions on CTA images. The aim of this study was to validate the software's performance in LVO detection.*Methods and Materials 395 studies were used to build the reference dataset. Software performance in predicting LVO was evaluated using sensitivity, specificity and corresponding 95% confidence intervals. Results are reported on the entire reference dataset as well as on multiple subgroups.*Results For the entire reference dataset (184 LVO, 211 non-LVO), we report sensitivity of 0.897 [0.853, 0.941] and specificity of 0.900 [0.853, 0.934]. When testing for internal carotid artery (ICA) occlusion (54 yes vs 211 no), sensitivity of 0.926 [0.824, 0.971] and specificity of 0.900 [0.86, 0.941] was noted. For M1 middle cerebral artery (MCA) occlusion (130 yes vs. 211 no), sensitivity of 0.885 [0.83, 0.94] and specificity of 0.900 [0.86, 0.941] was noted. When testing including subjects with intracranial hemorrhage (62 yes vs. 184 no), sensitivity of 0.897 [0.853, 0.941] and specificity of 1.000 [0.942, 1.0] was noted. When testing for distal or no occlusion (149 yes vs. 184 no), sensitivity of 0.897 [0.853, 0.941] and specificity of 0.859 [0.803, 0.915] was noted. Furthermore, no significant difference in performance was noted when testing for subjects under/above 70 years of age, sex, range of slice thickness (0.5-0.8 mm and 0.9-2 mm), and scanner manufacturer (GE and Siemens).*Conclusions StrokeSENS LVO demonstrates high sensitivity and specificity in the detection of LVO in a large balanced dataset and across multiple subgroups.*Clinical Relevance/Application Patients with acute ischemic stroke due to LVO are candidates to receive lifesaving endovascular treatment. Timely and reliable detection of LVO on CTA is challenging in many centers and therefore automating the process is of great importance.

RESULTS

For the entire reference dataset (184 LVO, 211 non-LVO), we report sensitivity of 0.897 [0.853, 0.941] and specificity of 0.900 [0.853, 0.934]. When testing for internal carotid artery (ICA) occlusion (54 yes vs 211 no), sensitivity of 0.926 [0.824, 0.971] and specificity of 0.900 [0.86, 0.941] was noted. For M1 middle cerebral artery (MCA) occlusion (130 yes vs. 211 no), sensitivity of 0.885 [0.83, 0.94] and specificity of 0.900 [0.86, 0.941] was noted. When testing including subjects with intracranial hemorrhage (62 yes vs. 184 no), sensitivity of 0.897 [0.853, 0.941] and specificity of 1.000 [0.942, 1.0] was noted. When testing for distal or no occlusion (149 yes vs. 184 no), sensitivity of 0.897 [0.853, 0.941] and specificity of 0.859 [0.803, 0.915] was noted. Furthermore, no significant difference in performance was noted when testing for subjects under/above 70 years of age, sex, range of slice thickness (0.5-0.8 mm and 0.9-2 mm), and scanner manufacturer (GE and Siemens).

CLINICAL RELEVANCE/APPLICATION

Patients with acute ischemic stroke due to LVO are candidates to receive lifesaving endovascular treatment. Timely and reliable detection of LVO on CTA is challenging in many centers and therefore automating the process is of great importance.

MS04-D1 **Improving Radiographic Fracture Detection And Reducing Reading Time Using Artificial Intelligence: A Multi-center Study With Radiologists And Non-radiologists In The United States**

Participants
Daichi Hayashi, MD,PhD, Stony Brook, New York (*Presenter*) Author with royalties, Wolters Kluwer nv

PURPOSE

Missed fractures on radiographs are not an uncommon cause of diagnostic discrepancy between initial interpretation and the final read by board-certified radiologists, leading to delay in care and preventable harm to the patient. The aim of this study was to assess the effect of artificial intelligence (AI) assistance on fracture detection performance of physicians on radiographs.*Methods and Materials Our study is a retrospective diagnostic study that follows the Multiple Readers Multiple Cases methodology. The dataset was composed of 480 exams with at least 60 exams per body region (foot/ankle, knee/leg, hip/pelvis, hand/wrist, elbow/arm, shoulder/clavicle, rib cage, thoracolumbar spine) with a prevalence of fractures set at 50%; 25% obvious and 25% non-obvious. The ground truth was determined by two expert musculoskeletal radiologists, with discrepancies solved by a third. Twenty-four readers of diverse specialties (radiologists, orthopedists, emergency medicine physicians and physician assistants, rheumatologists, family physicians) and level of experience were presented, in random order, the whole validation dataset of 480 cases, with and without AI assistance, with a minimum washout period of one month. The primary analysis had to demonstrate superiority of sensitivity by patient (SEPW) and the non-inferiority of specificity by patient (SPEPW) at -3% margin with AI aid.*Results A total of 480 patients were included (327 women, mean (SD) age 58.3 (17.9) years). The SEPW was 10.4% higher (95% confidence interval (CI): 6.9 to 13.9%, p<.0001 for superiority) with AI aid (75.2%) than without AI (64.8%). The SPEPW with AI aid (95.6%) was non-inferior to that without AI aid (90.6%), with a difference of +5.0% (95%CI: +2.0 to +8.0%, p<.0001 for non-inferiority). The AI shortened the average reading time by 6.3 seconds per examination (95% CI: 0.1 to 12.5, p=.046). The SEPW gain was significant in all regions but shoulder/clavicle and thoracolumbar spine.*Conclusions Radiographic AI assistance improves both sensitivity and specificity of fracture detection by radiologists and non-radiologists of variable expertise involving various anatomical locations. It also slightly reduces the time needed to interpret radiographs.*Clinical Relevance/Application Artificial intelligence assistance with skeletal fracture detection on radiographs improves the sensitivity and specificity of readers and shortens their reading time. We used an external multicenter dataset from the United States including multi-vendor radiographic acquisition systems that were not related to the development set originating from Europe, providing the robust generalization capacity of the model.

RESULTS

A total of 480 patients were included (327 women, mean (SD) age 58.3 (17.9) years). The SEPW was 10.4% higher (95% confidence interval (CI): 6.9 to 13.9%, p<.0001 for superiority) with AI aid (75.2%) than without AI (64.8%). The SPEPW with AI aid (95.6%) was non-inferior to that without AI aid (90.6%), with a difference of +5.0% (95%CI: +2.0 to +8.0%, p<.0001 for non-inferiority). The AI shortened the average reading time by 6.3 seconds per examination (95% CI: 0.1 to 12.5, p=.046). The SEPW gain was significant in all regions but shoulder/clavicle and thoracolumbar spine.

CLINICAL RELEVANCE/APPLICATION

Artificial intelligence assistance with skeletal fracture detection on radiographs improves the sensitivity and specificity of readers and shortens their reading time. We used an external multicenter dataset from the United States including multi-vendor radiographic acquisition systems that were not related to the development set originating from Europe, providing the robust generalization capacity of the model.

PD02-B1   Whole Body And Pediatric Imaging With 3D Ultrasound Tomography (UT)

Participants
James Wiskin, PhD, Novato, California (*Presenter*) Employee, QT Imaging, Inc

PURPOSE

There is a clinical need for a body imaging modality that can be used for screening healthy people at high-risk for disease from genetic, environmental or familial factors and for patients who are at risk from complications of radiation, high magnetic fields, heavy metal-based contrast injections or anesthesia if imaged with other modalities. We are particularly thinking of the few options for infants, small children, and screening of healthy, at-risk individuals. Finally, there is need for a low-cost, comprehensive medical imaging modality that can be deployed in low-resource environments (LRE). We desire to show ultrasound tomography could be such a modality.*Methods and Materials The transmission and reflection data are collected on arrays which rotate in a water bath. 2D algorithms create 3D images slice by slice (tomography) in ~30 seconds but have artifacts. 3D algorithms have reported taking 32 hours on a 128 computer cluster. Our 3D algorithm (volography) is ideally suited to run on NIVIDIA GPU's, which enables reconstruction in ~25 minutes. Two 10-12 day old pigs were scanned at TIPS at Texas A&M. Whole body images were acquired using UT and MRI using a 3-T Siemens Magnetom Verio. Following freezing 1 cm thick transverse plane sections of each pig were acquired and photographed. The UT, MR images and gross sections were compared to correlate anatomic structures and volumetric segmentations were carried out to compare quantitative estimates of speed of sound with literature values.*Results Our 3D tomography algorithm is 64X faster (~25 minutes) than published results, using only 2 NVIDIA cards, We validated our speed of sound for the muscle, fat skin, nerve tissue, bone, kidney and liver using constrained segmentation and literature values. Sub-mm resolution is confirmed by detailed comparison of QT volography images with MRI and whole sections of pigs.*Conclusions The quantitative high resolution (sub-mm) estimation of tissue characteristics is shown in the presence of bone and air. These and reconstruction timing results indicate the utility of the QTUS volography in the clinic.*Clinical Relevance/Application The ability to collect and image data in clinically relevant times, the low cost of NVIDIA cards, the safety (lack of ionizing radiation, contrast agents, etc.) and the high resolution and quantitative accuracy make the scanner a potential pediatric clinical tool, especially for historically underserved populations in urban or rural areas. The scanner can easily be loaded into a self-contained mobile unit. It can be used to monitor therapy and biopsies by traversing a partial rotation leaving space for interventional tools. Meso-body imaging is an independent application. The SOS map can be used in ablation therapy.

RESULTS

Our 3D tomography algorithm is 64X faster (~25 minutes) than published results, using only 2 NVIDIA cards, We validated our speed of sound for the muscle, fat skin, nerve tissue, bone, kidney and liver using constrained segmentation and literature values. Sub-mm resolution is confirmed by detailed comparison of QT volography images with MRI and whole sections of pigs.

CLINICAL RELEVANCE/APPLICATION

The ability to collect and image data in clinically relevant times, the low cost of NVIDIA cards, the safety (lack of ionizing radiation, contrast agents, etc.) and the high resolution and quantitative accuracy make the scanner a potential pediatric clinical tool, especially for historically underserved populations in urban or rural areas. The scanner can easily be loaded into a self-contained mobile unit. It can be used to monitor therapy and biopsies by traversing a partial rotation leaving space for interventional tools. Meso-body imaging is an independent application. The SOS map can be used in ablation therapy.

PD02-B2   Ultrasound Guided Core Biopsy For Tissue Diagnosis In Pediatric Oncology - 16-year Experience With 597 Biopsies

Participants
Anat Ilivitzki, MD, Haifa, Israel (*Presenter*) Nothing to Disclose

PURPOSE

Percutaneous imaging guided core needle biopsies (CNB) for diagnosis of cancer in pediatric patients are gaining interest in recent years due to presumed easier availability, less complication rate and proclaimed high diagnostic power, compared to traditional surgical biopsies. Nevertheless, their precise role in the diagnostic algorithm of pediatric oncological subjects is still unsettled. The purpose of the present study is to report our accumulated 16 years' experience and discuss availability, safety and diagnostic accuracy, adequacy of ancillary testing and to compare it to the available literature.*Methods and Materials Pediatric Ultrasound-guided CNB performed in our hospital between November 2003 and December 2019 were retrospectively studied. Data collection included demographics, clinical and procedural parameters, complications and final diagnosis.*Results A total of 597 biopsies were performed on 531 patients: 132 known oncologic patients and 465 to establish diagnosis. The median availability of the procedure was one day. Twelve biopsies out of 432 malignancies (2.8%) were false negative. In 165 cases of benign pathology, all results were true negative. Ancillary testing was adequate in all malignant cases. Overall sensitivity, specificity and accuracy rates were 97.2%, 100% and 98% respectively. Complications were encountered in 5 patients (0.8%), including one major bleeding and another tract seeding.*Conclusions Our experience demonstrates that Ultrasound-guided CNB for suspected malignancy in pediatric patients has a high safety profile, availability and accuracy rate, compared to reported results. Our fast track strategy enables

early initiation of designated therapy and has the potential to become the procedure of choice.*Clinical Relevance/Application Our fast track strategy enables early initiation of designated therapy and has the potential to become the procedure of choice.

RESULTS

A total of 597 biopsies were performed on 531 patients: 132 known oncologic patients and 465 to establish diagnosis. The median availability of the procedure was one day. Twelve biopsies out of 432 malignancies (2.8%) were false negative. In 165 cases of benign pathology, all results were true negative. Ancillary testing was adequate in all malignant cases. CA02-A3   **Cardiac Magnetic Resonance Imaging Findings In College Athletes With Recent COVID-19 Infection: Not All Doom And Gloom**

Participants
Neo Poyiadji, MD, Canton, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

COVID-19 cardiac involvement and its implications for college athletes (CA) recovering from recent infection has raised significant concerns regarding return to play (RTP) decisions. Single center early Cardiac Magnetic Resonance (CMR) studies showed varying incidence of myocardial involvement ranging from almost 15 % to as low as 1.4 %. The aim of our study was to evaluate our CMR experience of CA after COVID-19.*Methods and Materials Single center retrospective study of 39 CA after COVID-19 infection (June 2020 -January 2021) undergoing CMR. Demographics and various CMR features were evaluated. Two cardiothoracic radiologists and one cardiologist independently re-reviewed CMRs specifically for certain findings which could have led to higher frequency of abnormal CMR in earlier studies, namely tiny foci of delayed enhancement (DE) at the right ventricle (RV) insertion point. Interobserver agreement analysis was performed.*Results No CA (0/39) had CMR imaging findings suggestive of myocarditis. Two CA(5%) had trace-small pericardial effusions. Mild enlarged left and right ventricular volumes (n = 7/39) as well as tiny foci of DE commonly at the inferior RV insertion site (n = 8/39) were noted. Interobserver agreement between the two most experienced readers for LGE at the RV insertion was good (kappa 0.65) and fair between all three readers (kappa 0.33).*Conclusions Our study reports the lowest incidence of abnormal MRI findings, specifically myocarditis which was 0%. Our study highlights the importance of recognizing normal variant findings sometimes found in athletes, such as mild biventricular enlargement and focal DE at the inferior RV insertion point, on CMR.*Clinical Relevance/Application The prevalence of abnormal CMR findings in CA recovering from COVID-19 is very low. Recognizing physiologic and normal variant findings on CMR, specifically RV insertion DE and mild chamber enlargement in CA, is essential to avoid over diagnosis which has significant negative RTP implications for these individuals.

RESULTS

No CA (0/39) had CMR imaging findings suggestive of myocarditis. Two CA(5%) had trace-small pericardial effusions. Mild enlarged left and right ventricular volumes (n = 7/39) as well as tiny foci of DE commonly at the inferior RV insertion site (n = 8/39) were noted. Interobserver agreement between the two most experienced readers for LGE at the RV insertion was good (kappa 0.65) and fair between all three readers (kappa 0.33).

CLINICAL RELEVANCE/APPLICATION

The prevalence of abnormal CMR findings in CA recovering from COVID-19 is very low. Recognizing physiologic and normal variant findings on CMR, specifically RV insertion DE and mild chamber enlargement in CA, is essential to avoid over diagnosis which has significant negative RTP implications for these individuals.

SDP-HN-1   **Comparison Of Imaging And Clinical Findings In Different Pathological Type Of Sinonasal Non-hodgkin Lymphoma**

Participants
Dandan Huang, MD, Xi'An, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the difference of clinical and imaging findings in different pathological type of sinonasal non-Hodgkin lymphoma and to improve the diagnostic accuracy.*Methods and Materials Pathology-proven fifteen patients with NK/T cell lymphoma (NKTCL) and nine patients with diffuse large B-cell lymphoma (DLBCL) were collected in this study. Patient's age, gender distribution, clinical symptoms, mass location, volume, morphology, T1WI and T2WI signal intensity, enhancement degree and homogeneity, surrounding tissue invasion of the two groups were retrospectively analyzed. Difference of measurement data was compared with independent samples t-test or Mann-Whitney U test, calculators information was compared using Fisher's exact test.*Results The mean age at diagnosis for DLBCL was significantly higher than NKTCL(P=0.001). Gender distribution did not have significant difference between the two groups(P=0.351). The most common symptom for patients with NKTCL was nasal congestion (93.3%) whereas ocular signs more often occur in patients with DLBCL (55.5%). The most common region of NKTCL was nasal cavity whereas DLBCL more often located in paranasal sinus(P=0.000). NKTCL was commonly diffuse infiltration growth and DLBCL commonly in mass, but there was no significant difference between the two groups in this study(P=0.099). The lesion of DLBCL was larger than NKTCL(P=0.019). There was no difference in T1WI, T2WI signal intensity and enhancement degree (P values were 0.669, 0.118 and 0.617, respectively). NKTCL was characterized by heterogeneous enhancement and DLBCL was homogeneous enhancement(P=0.009). NKTCL often involved nasal dorsum(70%), and the region invasion of orbital cavity was more often in DLBCL(62.5%). The bone destruction degree was more serious in DLBCL than NKTCL.*Conclusions Nasal obstruction was the most common presenting symptom in NKTCL patients, NKTCL was predominant in nasal cavity, with diffuse infiltration growth, small volume, MR heterogeneous enhancement, and bone destruction mildly. Proptosis and epiphora were the most common presenting symptoms in DLBCL patients, DLBCL often located in paranasal sinus, with mass growth, large volume, MR homogeneous enhancement, and osteolytic bone destruction.*Clinical Relevance/Application There were valuable differentiating clinical and imaging features between sinonasal NKTCL and DLBCL

RESULTS

The mean age at diagnosis for DLBCL was significantly higher than NKTCL(P=0.001). Gender distribution did not have significant difference between the two groups(P=0.351). The most common symptom for patients with NKTCL was nasal congestion (93.3%) whereas ocular signs more often occur in patients with DLBCL (55.5%). The most common region of NKTCL was nasal cavity whereas DLBCL more often located in paranasal sinus(P=0.000). NKTCL was commonly diffuse infiltration growth and DLBCL commonly in mass, but there was no significant difference between the two groups in this study(P=0.099). The lesion of DLBCL was larger than NKTCL(P=0.019). There was no difference in T1WI, T2WI signal intensity and enhancement degree (P values were 0.669, 0.118 and 0.617, respectively). NKTCL was characterized by heterogeneous enhancement and DLBCL was homogeneous enhancement(P=0.009). NKTCL often involved nasal dorsum(70%), and the region invasion of orbital cavity was more often in DLBCL(62.5%). The bone destruction degree was more serious in DLBCL than NKTCL.

CLINICAL RELEVANCE/APPLICATION

There were valuable differentiating clinical and imaging features between sinonasal NKTCL and DLBCL

SDP-HN-10   **Application Of 4d-CT Scanning In Differential Diagnosis Of Arytenoid Subluxation And Vocal Fold Paralysis**

Participants
Yong Wang, MD, Xiamen, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the application of 4D-CT scanning with three-dimensional image reconstruction in the differential diagnosis of arytenoid subluxation and vocal cord paralysis.*Methods and Materials Seventy-six patients were collected who were suspected with vocal cord dyskinesia during January 2019 and December 2020. All patients were examined by larynx CT in our hospital. The CT scan was performed under GE revolution CT Cine mode on the subjects who was ordered to inspire deeply and then make a "Yi" sound continuously, and the scanning time was totally 5.6s. The images of 20 phases were reconstructed using the post-processing workstation. The maximum open phase and minimum closed phase images of glottis were selected from these images, for three-dimensional reconstruction. The following parameters were measured: the length and introversion angle of of vocal cord, the width of glottis, and the anteversion, elevation, valgus, and inversion angles of cricoarytenoid joint. According to the characteristics of shape and position change, the vocal cord was divided into type I, type II and type III. The consistency between CT diagnosis and clinical diagnosis or laryngeal EMG diagnosis was analyzed using Kappa test. And the statistical differences of various parameters between arytenoid subluxation or vocal cord paralysis and normal vocal cord were analyzed with Single-factor analysis of variance (independent sample Kruskal Wallis test).*Results There was high consistency between CT

diagnosis and clinical diagnosis or laryngeal EMG diagnosis (k = 0.731 or 0.783, P<0.05). A significant difference was observed in the opening width of glottis between type I and type III vocal cords, the valgus and inversion angles of cricoarytenoid joint between type I and type II or type III vocal cords, and the convergence angle among three types of vocal cord.*Conclusions 4D-CT scanning combined with three-dimensional image reconstruction can intuitively display the differences among various laryngeal structure changes in vocal cord dyskinesia, and thus can be used for the differential diagnosis of arytenoid subluxation and vocal cord paralysis.*Clinical Relevance/Application CT scanning using 4D imaging mode combined with 3D reconstruction images can directly display the differences of various larynx structures when there is vocal cord dyskinesia, and it there by can be used for the differential diagnosis of arytenoid cartilage subluxation and vocal cord paralysis.

RESULTS

There was high consistency between CT diagnosis and clinical diagnosis or laryngeal EMG diagnosis (k = 0.731 or 0.783, P<0.05). A significant difference was observed in the opening width of glottis between type I and type III vocal cords, the valgus and inversion angles of cricoarytenoid joint between type I and type II or type III vocal cords, and the convergence angle among three types of vocal cord.

CLINICAL RELEVANCE/APPLICATION

CT scanning using 4D imaging mode combined with 3D reconstruction images can directly display the differences of various larynx structures when there is vocal cord dyskinesia, and it there by can be used for the differential diagnosis of arytenoid cartilage subluxation and vocal cord paralysis.

SDP-HN-11 Diffusion Weighted Imaging Of Sellar Region: A Comparison Study Of Turbo Gradient And Spin Echo-blade Dwi With Readout Segmentation Of Long Variable Echo-trains

Participants
Qing Fu, MS,MS, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

Purpose of this study was to compare turbo gradient and spin echo-BLADE DWI (TGSE-BLADE-DWI) with readout segmentation of long variable echo-trains, RESOLVE-DWI (RESOLVE-DWI) on the feasibility of imaging the sellar region and image quality.*Methods and Materials Thirty-eight patients with suspected sellar abnormalities were enrolled to perform RESOLVE-DWI and TGSE-BLADE-DWI at a 3.0T MR scanner, including 32 patients with sellar lesions and 6 patients without any sellar lesions. Two experienced radiologists scored the imaging of two DWI methods for anatomical structures (including internal carotid arteries, optic chiasm, pituitary stalk and pituitary gland), lesion conspicuity, susceptibility artifacts, geometric distortions and overall image quality using a five-point scale. Objective parameters on the two DWIs were compared and analyzed, including lesion size, signal to noise ratio (SNR)and apparent diffusion coefficient (ADC). Paired t-test, Mann-Whitney U test, Kappa statistics and Pearson correlation coefficient were used for statistical evaluation.*Results TGSE-BLADE-DWI performed significantly better than RESOLVE-DWI in depicting anatomical structures, lesion conspicuity, geometric distortions and overall image quality (All p<0.05). There was no significant difference of SNR and ADC between the two DWIs. There was a good agreement between the two radiologists in assessment of the two DWIs (all Kappa values>0.7).The maximum transverse and longitudinal lesion size measured in TGSE-BLADE-DWI were more closely related with those of contrast-enhanced T1WI (r=0.973,r=0.997,respectively)than those of RESOLVE-DWI(r=0.947, r=0.989,respectivley).*Conclusions Compared with RESOLVE-DWI, TGSE-BLADE-DWI performed superior in depicting anatomical structures and lesion sizes, decreased susceptibility artifacts and geometric distortions in sellar region and effectively improved the image quality of diffusion weighted imaging for sellar region, which has great potential and great value in clinical applications.*Clinical Relevance/Application TGSE-BLADE-DWI provides an alternative to RESOLVE-DWI for depicting sellar region with minimized geometric distortions and susceptibility artifacts and superior image quality, which is of great importance for clinical applications of DWI.

RESULTS

TGSE-BLADE-DWI performed significantly better than RESOLVE-DWI in depicting anatomical structures, lesion conspicuity, geometric distortions and overall image quality (All p<0.05). There was no significant difference of SNR and ADC between the two DWIs. There was a good agreement between the two radiologists in assessment of the two DWIs (all Kappa values>0.7).The maximum transverse and longitudinal lesion size measured in TGSE-BLADE-DWI were more closely related with those of contrast-enhanced T1WI (r=0.973,r=0.997,respectively)than those of RESOLVE-DWI(r=0.947, r=0.989,respectivley).

CLINICAL RELEVANCE/APPLICATION

TGSE-BLADE-DWI provides an alternative to RESOLVE-DWI for depicting sellar region with minimized geometric distortions and susceptibility artifacts and superior image quality, which is of great importance for clinical applications of DWI.

SDP-HN-12 The Value Of Spectral CT In Differentiating Between Benign And Malignant Thyroid Lesions

Participants
Li Li, MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the value of spectral CT in the differential diagnosis of thyroid lesions.*Methods and Materials Patients with thyroid lesions underwent neck spectral CT scan. The monochromatic images were used for the morphological features and iodine-based material decomposition (MD) images were used to measure the iodine concentration (IC) of lesions, and normal thyroid. The normalized iodine concentration to carotid artery (NICA), the normalized iodine concentration to normal thyroid (NICT) and slope of spectral curve (?HU) were calculated. The statistical analysis was performed and receiver operating characteristic (ROC) curve was used to determine the diagnostic capability of the lesion.*Results A total of 230 lesions were found in 225 patients (57 benign, 173 malignant). There were significant differences between benign and malignant lesions in the border, microcalcifications and lymph node metastasis (P<0.05). The accuracy was 73.0%, 43.0% and 75.2%, respectively using these parameters alone and 82.6% combined. There was no difference in the parameters between the three benign groups except the IC values. There was no significant difference in IC between nodular goiter and adenoma, nodular goiter and thyroiditis, while the IC value of adenoma was significantly higher than that of thyroiditis (P=0.006). The differences of IC, NICT and ?HU were significant between nodular goiter and malignant tumor, adenoma and malignant tumor, while there were no statistical differences between the thyroiditis and malignant tumors in all the parameters. The threshold of IC <3.16mg/ml was the predictor of malignancy demonstrating 71.1%, 68.4% and 70.4% in sensitivity, specificity and accuracy, respectively. The diagnostic parameters of IC, NICT, ?HU combined with morphological features were higher in the diagnosis of malignancy with 86.1% in sensitivity, 86.0% in specificity and 83.9%

accuracy.*Conclusions Spectral CT quantitatively evaluates the iodine concentration of thyroid lesions, which is valuable for benign and malignant identification. Combining spectral parameters with the morphological features is helpful for differentiating the thyroid lesions.*Clinical Relevance/Application Spectral CT imaging is helpful to differentiate malignant and benign thyroid lesions.

RESULTS

A total of 230 lesions were found in 225 patients (57 benign, 173 malignant). There were significant differences between benign and malignant lesions in the border, microcalcifications and lymph node metastasis (P<0.05). The accuracy was 73.0%, 43.0% and 75.2%, respectively using these parameters alone and 82.6% combined. There was no difference in the parameters between the three benign groups except the IC values. There was no significant difference in IC between nodular goiter and adenoma, nodular goiter and thyroiditis, while the IC value of adenoma was significantly higher than that of thyroiditis (P=0.006). The differences of IC, NICT and ?HU were significant between nodular goiter and malignant tumor, adenoma and malignant tumor, while there were no statistical differences between the thyroiditis and malignant tumors in all the parameters. The threshold of IC <3.16mg/ml was the predictor of malignancy demonstrating 71.1%, 68.4% and 70.4% in sensitivity, specificity and accuracy, respectively. The diagnostic parameters of IC, NICT, ?HU combined with morphological features were higher in the diagnosis of malignancy with 86.1% in sensitivity, 86.0% in specificity and 83.9% accuracy.

CLINICAL RELEVANCE/APPLICATION

Spectral CT imaging is helpful to differentiate malignant and benign thyroid lesions.

SDP-HN-13 Facial Injury Patterns In Intimate Partner Violence

Participants
Anji Tang, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Intimate partner violence (IPV) is a highly prevalent and critical public health issue in which radiologists play an increasingly pivotal role due to their ability to objectively assess injuries on imaging. Understanding facial injury patterns is critical for detection because the face is thought to be the most common target organ. The purpose of our study was therefore to evaluate imaging patterns of facial injuries in survivors of intimate partner violence.*Methods and Materials A retrospective review of all available radiological studies of 668 patients reporting IPV to our institution's violence prevention support program identified 96 patients with 152 facial injuries. Demographics, imaging findings, and clinical data obtained from a review of the electronic medical records were analyzed to categorize injury patterns. Sites of facial injuries were categorized into thirds—upper (frontal and supraorbital), mid (orbit, maxilla, zygoma), and lower face (mandibular and temporomandibular joint) fractures and soft tissue injuries.*Results The study cohort consisted of 93 women and 3 men with mean age 35 years (19-76 years; median 32). At the time of presentation, only 57 (59%) patients reported IPV as the mechanism of injury, with fall being the most common reported mechanism among patients who did not disclose IPV (16%). Facial fractures represented 61% of all facial injuries while isolated soft tissue swelling or hematoma was seen in 39%. The most frequent site of injury was the midface (68%) for both fractures and soft tissue injury, with left sided injuries slightly more common (59%). The most common fracture location was the nasal bone (45/152, 30%), followed by the mandible (17/152, 11%), and orbit (16/152, 11%). Most fractures (95%) showed no or minimal displacement (<2 mm). Associated injuries were seen most frequently in the upper extremity, occurring synchronously in 11 (11%) patients and preceding the index injury in 20 (21%) patients. Recurrent facial injuries were seen in 8/96 (8%) patients.*Conclusions The midface was the most frequent location of injury in IPV victims, with the nasal bone being the most commonly fractured facial bone. These were frequently either preceded by or occurred synchronously with upper extremity injuries. Both features, in the presence of an unclear presentation history, should prompt the radiologist to consider IPV in the differential.*Clinical Relevance/Application Recognizing facial injury patterns can help radiologists suspect IPV and prompt clinical providers to discuss the possibility of IPV with the patient. Early identification can facilitate early intervention, thereby preventing severe life-threatening injuries.

RESULTS

The study cohort consisted of 93 women and 3 men with mean age 35 years (19-76 years; median 32). At the time of presentation, only 57 (59%) patients reported IPV as the mechanism of injury, with fall being the most common reported mechanism among patients who did not disclose IPV (16%). Facial fractures represented 61% of all facial injuries while isolated soft tissue swelling or hematoma was seen in 39%. The most frequent site of injury was the midface (68%) for both fractures and soft tissue injury, with left sided injuries slightly more common (59%). The most common fracture location was the nasal bone (45/152, 30%), followed by the mandible (17/152, 11%), and orbit (16/152, 11%). Most fractures (95%) showed no or minimal displacement (<2 mm). Associated injuries were seen most frequently in the upper extremity, occurring synchronously in 11 (11%) patients and preceding the index injury in 20 (21%) patients. Recurrent facial injuries were seen in 8/96 (8%) patients.

CLINICAL RELEVANCE/APPLICATION

Recognizing facial injury patterns can help radiologists suspect IPV and prompt clinical providers to discuss the possibility of IPV with the patient. Early identification can facilitate early intervention, thereby preventing severe life-threatening injuries.

SDP-HN-14 Prognostic Value Of Whole-tumor Adc Histogram Analysis In Patients With Tongue Squamous Cell Carcinoma And Cervical Lymph Node Metastases

Participants
Yingwei Wu, MD, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

Objectives: To determine the prognostic value of whole-tumor apparent diffusion coefficient (ADC) histogram with histological heterogeneity and cervical lymph node metastases in patients with tongue squamous cell carcinoma (SCC)CONCLUSION*Methods and Materials Patients with SCC completed preoperative MRI were included. Volumetric MRI parameters including tumor volume, ADC histograms (mean ADC, standard deviation [SD], 10th, 25th, 50th, 75th, and 90th percentiles, variance, skewness and kurtosis) were measured. Surgical resection was performed on all patients. Uneven histological grade such as grade I-II or grade II-III were defined as hetero-group. The histological heterogeneity index (HHI) was calculated using the percentage of the larger sub-fraction*100% (range from 0.5-1). Follow-up biopsy, imaging, and clinical examinations were used to determine the cervical lymph node metastasis (CNM) status.*Results Forty-five patients with a mean follow-up period of 15.6 months were included. The histological heterogeneity accounted for 53.3% (24/45) patients. Whole-lesion ADC histogram metrics lower in hetero-group than homo-group were mean ADC, percentiles from 10th to 90th, SD and variance. Whole-lesion ADC histogram metrics lower in CNM+ group were mean ADC, percentiles from 10th to 90th and kurtosis. Higher incidence of CNM was observed in histological hetero-

group than that in homo-group. Larger tumor volume, kurtosis and lower HHI were independent prognostic factors for CNM status.*Conclusions Whole-tumor ADC histogram metrics may serve as non-invasive biomarkers of tumoral heterogeneity of SCC. ADC histogram metrics kurtosis on preoperative imaging is an independent predictor for CNM status.*Clinical Relevance/Application Tumor histological heterogeneity occurred frequently in patients with SCC and associated poor prognosis. Compared to clinic TNM stage or the histological grade, the histological heterogeneity has not been well addressed yet. Whole-tumor ADC histogram offered an approach for detecting intra-tumoral heterogeneity and complexity.

RESULTS

Forty-five patients with a mean follow-up period of 15.6 months were included. The histological heterogeneity accounted for 53.3% (24/45) patients. Whole-lesion ADC histogram metrics lower in hetero-group than homo-group were mean ADC, percentiles from 10th to 90th, SD and variance. Whole-lesion ADC histogram metrics lower in CNM+ group were mean ADC, percentiles from 10th to 90th and kurtosis. Higher incidence of CNM was observed in histological hetero-group than that in homo-group. Larger tumor volume, kurtosis and lower HHI were independent prognostic factors for CNM status.

CLINICAL RELEVANCE/APPLICATION

Tumor histological heterogeneity occurred frequently in patients with SCC and associated poor prognosis. Compared to clinic TNM stage or the histological grade, the histological heterogeneity has not been well addressed yet. Whole-tumor ADC histogram offered an approach for detecting intra-tumoral heterogeneity and complexity.

SDP-HN-15 Intraindividual Comparison Between Contrast-enhanced Golden-angle Radial Sparse Parallel Sequence And Conventional Fat-suppressed Contrast-enhanced T1-weighted Spin-echo Sequence For Head And Neck MRI

Participants
Yangsean Choi, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The golden-angle radial sparse parallel-volumetric interpolated breath-hold (GRASP-VIBE) sequence is a recently introduced imaging technique with high resolution. This study compared the image quality between conventional fat-suppressed T1-weighted TSE (T1-TSE) and GRASP-VIBE after gadolinium enhancement in the head and neck region.*Methods and Materials Data from 65 patients with clinical indications for head and neck MRI between September 2020 and January 2021 were retrospectively reviewed. Two radiologists assessed the overall image quality, overall artifacts, and image conspicuities in the oropharynx, hypopharynx, and cervical lymph nodes according to five-point scores (best score: 5). Interobserver agreement was assessed using weighted kappa statistics. SNR and contrast-to-noise ratio (CNR) were calculated and compared between the two sequences using a paired Wilcoxon signed-rank test.*Results The analysis included 52 patients (mean age, 60±14 years; male, 71.2% [37/52]) who were mostly diagnosed with head and neck malignancies (94.3% [50/52]). Kappa statistics ranged from slight agreement in cervical lymph node conspicuity (kappa=0.18) to substantial agreement in oropharyngeal mucosal conspicuity (kappa=0.80) (kappa range, 0.18-0.80). Moreover, GRASP-VIBE demonstrated significantly higher mean scores in overall image qualities (4.68±0.41 vs. 3.66±0.73), artifacts (4.47±0.48 vs. 3.58±0.71), oropharyngeal mucosal conspicuity (4.85±0.41 vs. 4.11±0.79), hypopharyngeal mucosal conspicuity (4.84±0.34 vs. 3.58±0.81), and cervical lymph node conspicuity (4.79±0.32 vs. 4.08±0.64) than T1-TSE (all, P<0.001). Furthermore, GRASP-VIBE demonstrated a higher SNR (22.8±11.5 vs. 11.3±5.6, P<0.001) and CNR (4.7±5.4 vs. 2.3±2.7, P=0.059) than T1-TSE.*Conclusions GRASP-VIBE provided better image quality with fewer artifacts than conventional T1-TSE for the head and neck regions.*Clinical Relevance/Application Compared to the conventional spin-echo contrast-enhanced T1-weighted imaging, GRASP-VIBE provides improved and motion-robust images of head and neck regions.

RESULTS

The analysis included 52 patients (mean age, 60±14 years; male, 71.2% [37/52]) who were mostly diagnosed with head and neck malignancies (94.3% [50/52]). Kappa statistics ranged from slight agreement in cervical lymph node conspicuity (kappa=0.18) to substantial agreement in oropharyngeal mucosal conspicuity (kappa=0.80) (kappa range, 0.18-0.80). Moreover, GRASP-VIBE demonstrated significantly higher mean scores in overall image qualities (4.68±0.41 vs. 3.66±0.73), artifacts (4.47±0.48 vs. 3.58±0.71), oropharyngeal mucosal conspicuity (4.85±0.41 vs. 4.11±0.79), hypopharyngeal mucosal conspicuity (4.84±0.34 vs. 3.58±0.81), and cervical lymph node conspicuity (4.79±0.32 vs. 4.08±0.64) than T1-TSE (all, P<0.001). Furthermore, GRASP-VIBE demonstrated a higher SNR (22.8±11.5 vs. 11.3±5.6, P<0.001) and CNR (4.7±5.4 vs. 2.3±2.7, P=0.059) than T1-TSE.

CLINICAL RELEVANCE/APPLICATION

Compared to the conventional spin-echo contrast-enhanced T1-weighted imaging, GRASP-VIBE provides improved and motion-robust images of head and neck regions.

SDP-HN-16 The Distinction Of Brain Network Topology And Structural-functional Connectivity Coupling In Tinnitus Patients With Different Outcomes After Sound Therapy

Participants
Qian Chen, MD,PhD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

As a first-line treatment, previous studies have shown that patients with effective and ineffective outcomes after the sound therapy have distinct reorganization patterns in brain structural changes and functional activations. This study was conducted to investigate whether the effective group (EG) and ineffective group (IG) after the treatment have different topological alterations of structural connectivity (SC), functional connectivity (FC), and the SC-FC coupling correlation with the tinnitus symptoms improvement.*Methods and Materials Resting-state functional magnetic resonance imaging (rs-fMRI) and diffusion tensor imaging (DTI) were prospectively acquired in 60 patients with idiopathic tinnitus (28 as EG and 32 as IG) and 57 healthy controls (HCs). Graph theoretical network analyses of SC and FC were performed. Associations between the symptom's improvement and graph-theoretical features were also studied.*Results For the FC, there were no differences in graph-theoretical features between the tinnitus patients (whether EG or IG) and HCs, whereas the EG showed higher local efficiency (Eloc) than the IG. For the SC, both the EG and IG displayed lower normalized characteristic path length (?), Lp, and global efficiency (Eg) than the HCs, whereas no significant differences existed between the EG and IG. Importantly, the IG had a higher coupling than the HCs, whereas there was no difference in coupling between the EG and HCs. In addition, significant associations existed between the SC graph-theoretical features and clinical performance in EG patients.*Conclusions The EG and IG tinnitus patients show distinct network-level

reorganization patterns, especially in SC and FC-SC coupling. Our findings help to better understand the anatomical-functional interaction mechanisms underlying tinnitus patients' different prognoses.*Clinical Relevance/Application Our study may provide useful information for individualized therapeutic strategies for tinnitus patients.

RESULTS

For the FC, there were no differences in graph-theoretical features between the tinnitus patients (whether EG or IG) and HCs, whereas the EG showed higher local efficiency (Eloc) than the IG. For the SC, both the EG and IG displayed lower normalized characteristic path length (?), Lp, and global efficiency (Eg) than the HCs, whereas no significant differences existed between the EG and IG. Importantly, the IG had a higher coupling than the HCs, whereas there was no difference in coupling between the EG and HCs. In addition, significant associations existed between the SC graph-theoretical features and clinical performance in EG patients.

CLINICAL RELEVANCE/APPLICATION

Our study may provide useful information for individualized therapeutic strategies for tinnitus patients.

SDP-HN-18 Rate Of Malignancy In Thyroid Nodules Classified As Highly Suspicious Using The TI-RADS System

Participants
Douglas Katz, MD, Mineola, New York (*Presenter*) Nothing to Disclose

PURPOSE

The TI-RADS classification of TR5 carries the highest risk of malignancy for the sonographic characterization of thyroid nodules, with studies having found varying wide rates of malignancy, ranging from 21-73%. The purpose of our study was to retrospectively analyze our own institutional rate of malignancy in biopsied TR5 nodules. We also aimed to determine if any particular features carry a higher risk.*Methods and Materials We evaluated 450 thyroid nodules which were classified as TR5 & which subsequently underwent fine-needle aspiration from September 2018 to December 2019. Final TR5 categorization and nodule description was based on the official sonographic reports; nodules were not included in this analysis if there was no specific mention of TR5 categorization in the reports. Overall demographic & nodule characteristics were summarized using median (Interquartile range) & frequency (percentages) as appropriate. Logistic regression models were used to find factors associated with malignancy versus benignity. Diagnostic accuracy was assessed by computing sensitivity, specificity, PPV, & NPV for various sonographic characteristics, using the fine-needle aspiration pathology results as the reference standard.*Results Of the 450 thyroid nodules evaluated, 96 (21.3%) were malignant. Mean patient age was 56.5 years, & 350 of the nodules occurred in women. Mean nodule size was 13 mm (10 to 20 mm, interquartile range). Individual sonographic features which were most strongly associated with malignancy were 'very hypoechoic' (2.93 unadjusted odds ratio (1.35 - 6.38 95% CI, p value 0.007)), & 'lobulated or irregular' (2.08 unadjusted odds ratio (1.24 - 3.50 95% CI, p value 0.006)). The sensitivity, specificity, PPV, & NPV value for individual sonographic thyroid features were: hypoechoic - 90.6%, 19.8%, 23.5%, & 88.6%; very hypoechoic - 13.5%, 95.5%, 44.8%, & 80.3%; taller than wide - 40.6%, 68.6%, 26.0%, 81.0%; microcalcifications - 67.7%, 28.0%, 20.3%, & 76.2%; & lobulated margin - 61.5%, 55.0%, 27.1%, & 84.0%.*Conclusions Our institutional malignancy rate was lower than expected, in our retrospective study of 450 individual thyroid nodules categorized as TR5 according to TI-RADS, & was on the lower end of the spectrum reported to date to our knowledge in the literature for nodules in this category. The nodule feature with the highest positive predictive value in our study was "very hypoechoic."*Clinical Relevance/Application The TR5 category should be viewed as a spectrum of risk, & not necessarily strongly indicative of malignancy. Clinicians should further consider malignancy risk & predicative sonographic thyroid nodule features when evaluating patients with TR5 nodules. Further analysis should consider combinations of sonographic features.

RESULTS

Of the 450 thyroid nodules evaluated, 96 (21.3%) were malignant. Mean patient age was 56.5 years, & 350 of the nodules occurred in women. Mean nodule size was 13 mm (10 to 20 mm, interquartile range). Individual sonographic features which were most strongly associated with malignancy were 'very hypoechoic' (2.93 unadjusted odds ratio (1.35 - 6.38 95% CI, p value 0.007)), & 'lobulated or irregular' (2.08 unadjusted odds ratio (1.24 - 3.50 95% CI, p value 0.006)). The sensitivity, specificity, PPV, & NPV value for individual sonographic thyroid features were: hypoechoic - 90.6%, 19.8%, 23.5%, & 88.6%; very hypoechoic - 13.5%, 95.5%, 44.8%, & 80.3%; taller than wide - 40.6%, 68.6%, 26.0%, 81.0%; microcalcifications - 67.7%, 28.0%, 20.3%, & 76.2%; & lobulated margin - 61.5%, 55.0%, 27.1%, & 84.0%.

CLINICAL RELEVANCE/APPLICATION

The TR5 category should be viewed as a spectrum of risk, & not necessarily strongly indicative of malignancy. Clinicians should further consider malignancy risk & predicative sonographic thyroid nodule features when evaluating patients with TR5 nodules. Further analysis should consider combinations of sonographic features.

SDP-HN-4 MRI Findings In Trigeminal Neuralgia Without Neurovascular Compression: Acute Angulation Of The Petrous Ridge And The Trigeminal Nerve

Participants
Yifan Bie, Jinan, China (*Presenter*) Nothing to Disclose

PURPOSE

To provide anatomical characteristics of the petrous ridge and the trigeminal nerve in trigeminal neuralgia (TN) without neurovascular compression (NVC) in MR imaging. *Methods and Materials From May 2017 to March 2021, 66 TN patients without NVC and 57 controls were enrolled and measured the angle of the petrous ridge(APR) and the angle of the trigeminal nerve(ATN) in MRI with the high-resolution three-dimensional T2 sequence. Data of the symptomatic side were compared with the asymptomatic side in patients and with the mean of bilateral sides in controls. Receiver operating characteristic (ROC) analysis was performed to examine the diagnostic performances of APR and ATN. The Youden index, sensitivity, specificity, positive and negative predictive values, and accuracy were calculated respectively. *Results In patients, the mean APR of the symptomatic side was 98.40±19.75°, significantly sharper than that of the asymptomatic side (105.59±22.45°, P=0.019) and controls(108.44±15.98°, P=0.003). The mean ATN of the symptomatic side was 144.4±8.92°, significantly sharper than that of the asymptomatic side (149.67±8.09°, P=0.003) and controls(150.45±8.48°, P<0.001). Areas under the ROC curve (AUC) and 95% Cis for APR and ATN were 0.673(0.574-0.772) and 0.700(0.605-0.795). Regarding the diagnostic performance for differentiating between TN patients and controls, the highest Youden index was 0.321 with the APR cutoff score of 94.40° (sensitivity, 82.10%; specificity, 50.00%; positive predictive value, 74.40%; negative predictive value, 57.50%; accuracy, 63.41%) and 0.333 with the ATN cutoff score of 148.26° (sensitivity, 66.10%; specificity, 67.20%; positive predictive value, 67.20%; negative predictive value, 66.10%; accuracy,

61.79%)*Conclusions In TN without NVC, the angulation of the petrous ridge and the trigeminal nerve was sharper compared with controls, which would provide additional information contributing to the diagnosis. *Clinical Relevance/Application The excessively acute petrous ridge may lead to an underlying entrapment of the trigeminal nerve. APR and ATN were recommended to be taken into consideration to make a comprehensive diagnosis pre- or post-operatively for TN patients without specific duty vessels.

RESULTS

In patients, the mean APR of the symptomatic side was 98.40±19.75°, significantly sharper than that of the asymptomatic side (105.59±22.45°, P=0.019) and controls(108.44±15.98°, P=0.003). The mean ATN of the symptomatic side was 144.4±8.92°, significantly sharper than that of the asymptomatic side (149.67±8.09°, P=0.003) and controls(150.45±8.48°, P<0.001). Areas under the ROC curve (AUC) and 95% Cis for APR and ATN were 0.673(0.574-0.772) and 0.700(0.605-0.795). Regarding the diagnostic performance for differentiating between TN patients and controls, the highest Youden index was 0.321 with the APR cutoff score of 94.40° (sensitivity, 82.10%; specificity, 50.00%; positive predictive value, 74.40%; negative predictive value, 57.50%; accuracy, 63.41%) and 0.333 with the ATN cutoff score of 148.26° (sensitivity, 66.10%; specificity, 67.20%; positive predictive value, 67.20%; negative predictive value, 66.10%; accuracy, 61.79%)

CLINICAL RELEVANCE/APPLICATION

The excessively acute petrous ridge may lead to an underlying entrapment of the trigeminal nerve. APR and ATN were recommended to be taken into consideration to make a comprehensive diagnosis pre- or post-operatively for TN patients without specific duty vessels.

SDP-HN-5   The Effect Of Facemasks For COVID-19 Prevention On Image Quality In Head And Face Computed Tomography Scans

Participants
Ji Ye Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Infectious disease caused by the novel coronavirus (SARS-CoV-2) are currently pandemic in the world. When it is appropriate for a patient to wear a facemask during the CT exam to prevent the spread of respiratory droplets, there is a concern of beam hardening artifacts and noise associated with the metallic nose piece of the facemask. To this end, no study have focused on how facemasks influence the image quality in face CT examinations and currently there is no clear consensus whether to guide patients to wear facemasks during their face CT examinations. Therefore, we aimed to compare the image quality of face CT images before and after applying facemasks.*Methods and Materials We retrospectively enrolled a total of 609 consecutive patients who underwent non-contrast face CT scans in our institution from two periods; before, and during the pandemic of SARS-CoV-2 (between Oct to Dec 2019 without facemasks and between Oct to Dec 2020 with face masks). Quantitative image quality measurements of image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) were compared between patients groups with and without facemasks. For subjective evaluation, two radiologists independently assessed noise, spatial resolution, presence of artifacts, and overall image quality.*Results The average measured noise for examinations with facemasks were 60.0 ± 13.4 and 47.7 ± 14.8 in the nasal dorsum and malar areas, respectively. Scans with facemasks showed significantly higher noise in the nasal dorsum (P < .001), with lower SNR (P = 0.007) and CNR (P = 0.004) than scans without facemasks. There was no significant difference in the noise in the malar area (P = 0.882). Upon subjective evaluation, images with facemasks showed overall poorer image quality (P < .001). However, there was no significant difference in the proportions of images sets which resulted in diagnostic limitation (P = 0.128).*Conclusions Facemasks resulted in overall image quality reduction in face CT examinations. However, CT scans with facemasks provided sufficient image quality to achieve its diagnostic purpose upon visual assessment. Therefore, it would be appropriate to fit all patients with facemasks including metallic nosepieces to prevent the spread of the disease in the era of SARS-CoV-2.*Clinical Relevance/Application Face CT scans with facemasks showed overall reduced image quality but provided sufficient image quality to achieve its diagnostic purpose. Therefore, all patients should wear facemasks when undergoing CT examinations in the face to prevent the spread of disease. Our results might provide a practical guide to various positions of medical personnels and might be a basis for a future clinical practice guideline for CT examinations

RESULTS

The average measured noise for examinations with facemasks were 60.0 ± 13.4 and 47.7 ± 14.8 in the nasal dorsum and malar areas, respectively. Scans with facemasks showed significantly higher noise in the nasal dorsum (P < .001), with lower SNR (P = 0.007) and CNR (P = 0.004) than scans without facemasks. There was no significant difference in the noise in the malar area (P = 0.882). Upon subjective evaluation, images with facemasks showed overall poorer image quality (P < .001). However, there was no significant difference in the proportions of images sets which resulted in diagnostic limitation (P = 0.128).

CLINICAL RELEVANCE/APPLICATION

Face CT scans with facemasks showed overall reduced image quality but provided sufficient image quality to achieve its diagnostic purpose. Therefore, all patients should wear facemasks when undergoing CT examinations in the face to prevent the spread of disease. Our results might provide a practical guide to various positions of medical personnels and might be a basis for a future clinical practice guideline for CT examinations

SDP-HN-6   Baseline MRI-based Radiomics Model Assisted Predicting Disease Progression In Nasopharyngeal Carcinoma Patients With Complete Response After Treatment.

Participants
Bao Dan, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Our aim was to evaluate the value of baseline MRI-based radiomics machine-learning models in predicting the disease progression in nasopharyngeal carcinoma patients who achieved complete response after treatment.*Methods and Materials Radiomic features were extracted with the least absolute shrinkage and selection operator method based on baseline fat suppression T2WI and contrast-enhanced T1WI of 171 patients in this retrospective study. After Pearson's correlation analysis of selected radiomic features, multivariate logistic regression analysis was applied to radiomic and clinical characteristics selection. Logistic regression analysis and support vector machine classifier were utilized to build the predictive model respectively. The predictive accuracy of the model was evaluated by ROC analysis along with sensitivity, specificity and AUC calculated.*Results In total, 13 radiomic features were selected. A prediction of disease progression MRI-based (PDPM) model (Model L4) using logistic regression analysis comprising 4 radiomics features (HGLZE_T2H, HGLZE_T1, LDLGLE_T1, and GLNU_T1) and 5 clinical features (histology, T stage, N

stage, smoking history, and age) showed the best performance with an AUC of 0.75 in the training cohort (95% CI: 0.66-0.83) and 0.77 in the validation cohort (95% CI: 0.64-0.90). The nine independent impact factors of Model L4 were entered into the nomogram. The calibration curves for probability of 3-year disease progression showed good agreement between nomogram-based predictions and actual observations. The features of Model L4 showed satisfactory clinical utility with decision curve analysis, and the predictive value of PDPM model was increased by incorporating both clinical variables and radiomic features.*Conclusions Radiomics models based on baseline MRI can be used as a reliable prognostic tool for predicting disease progression in nasopharyngeal carcinoma patients.*Clinical Relevance/Application The results of this study add to the growing evidence of using radiomics-based machine learning model in the assessment of disease progression for NPC patients. The addition of radiomics to clinical characteristics can improve the prediction of disease progression. Based on our nomogram, clinicians were able to stratify high-risk patients and accordingly facilitate the treatment decision-making process in individual cases.

RESULTS

In total, 13 radiomic features were selected. A prediction of disease progression MRI-based (PDPM) model (Model L4) using logistic regression analysis comprising 4 radiomics features (HGLZE_T2H, HGLZE_T1, LDLGLE_T1, and GLNU_T1) and 5 clinical features (histology, T stage, N stage, smoking history, and age) showed the best performance with an AUC of 0.75 in the training cohort (95% CI: 0.66-0.83) and 0.77 in the validation cohort (95% CI: 0.64-0.90). The nine independent impact factors of Model L4 were entered into the nomogram. The calibration curves for probability of 3-year disease progression showed good agreement between nomogram-based predictions and actual observations. The features of Model L4 showed satisfactory clinical utility with decision curve analysis, and the predictive value of PDPM model was increased by incorporating both clinical variables and radiomic features.

CLINICAL RELEVANCE/APPLICATION

The results of this study add to the growing evidence of using radiomics-based machine learning model in the assessment of disease progression for NPC patients. The addition of radiomics to clinical characteristics can improve the prediction of disease progression. Based on our nomogram, clinicians were able to stratify high-risk patients and accordingly facilitate the treatment decision-making process in individual cases.

SDP-HN-7 Comparison Of Image Quality And Diagnostic Performance On DWI Between FASE And EPI Sequences With And Without Deep Learning Reconstruction In Suspected Head And Neck Tumor

Participants
Hirotaka Ikeda, MD, Toyoake, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To compare the capability of DWI obtained by Fast Advanced Spin-Echo (FASE) and Echo-Planar Imaging (EPI) sequences with and without deep learning reconstruction (DLR) for image quality and diagnostic performance on DWI in patients suspected head and neck tumors.*Methods and Materials This study included with in vitro and in vivo studies. As in vitro study, a QIBA DWI phantom was scanned at a 3T scanner by DWIs with FASE and EPI sequences, and each data was reconstructed with and without DLR. On all DWIs, ADCs of each phantom was evaluated by ROI measurement. As in vivo study, 41 patients suspected head and neck tumors (malignant vs. benign: 17 vs. 24) obtained T2WI and both DWIs. Then, each DWI was also reconstructed with and without DLR. SNR and ADC of each lesion were assessed by ROI measurements. To compare deformation difference between all DWIs, the margin of lesion was traced by free hand ROI on each sequence to assess each lesion deformation. Then, deformation ratio (DR) was defined as free hand ROI area difference between each DWI and T2WI divided by ROI area on T2WI. On in vitro study, Pearson's correlations were performed for correlation analysis of ADC between each DWI and standard reference. On in vivo study, DR and SNR were compared among all DWIs by Student t-test. Feasible threshold values of each DWI for diagnosis was determined by ROC-based positive test. Finally, sensitivity, specificity and accuracy were compared among all DWIs by McNemar's test.*Results Correlation coefficient of ADC between each DWI and standard reference was excellent on in vitro study (0.95<r<0.99, p<0.0001). On in vivo study, DRs of FASE with and without DLR were significantly smaller than those of EPI with and without DLR (p<0.001). SNR of FASE with DLR was significantly better than that without DLR (p<0.05). When applied each threshold value, FASE with and without DLR were significantly more specific and accurate than EPI with and without DLR (p<0.05).*Conclusions FASE has a better capability than EPI for less deformation and better diagnostic performance on DWI in patients suspected with head and neck tumor. Moreover, DLR can improve image quality with accurate ADC measurement in routine clinical practice.*Clinical Relevance/Application FASE has a better capability than EPI for less deformation and better diagnostic performance on DWI in patients suspected with head and neck tumor.

RESULTS

Correlation coefficient of ADC between each DWI and standard reference was excellent on in vitro study (0.95<r<0.99, p<0.0001). On in vivo study, DRs of FASE with and without DLR were significantly smaller than those of EPI with and without DLR (p<0.001). SNR of FASE with DLR was significantly better than that without DLR (p<0.05). When applied each threshold value, FASE with and without DLR were significantly more specific and accurate than EPI with and without DLR (p<0.05).

CLINICAL RELEVANCE/APPLICATION

FASE has a better capability than EPI for less deformation and better diagnostic performance on DWI in patients suspected with head and neck tumor.

SDP-HN-8 A MRI Mp2rage And SMS-Rs-fMRI Study In Vestibular Migraine Patients

Participants
Ya Guo, MD, Xining, China (*Presenter*) Nothing to Disclose

PURPOSE

To apply Resting-state fMRI(Rs-fMRI) to explore the gray matter volume (GMV), brain function, and brain default in patients with vestibular migraine (VM).The unique change characteristics of the functional connection (FC) of the default mode network(DMN).*Methods and Materials 30 VM patients (VM group) who met the International Headache Association (3rd edition) diagnostic criteria for VM and 34 normal volunteers (control group) were enrolled in this study. All the scanning was performed on a 3T MR scanner(Magnetom Prisma, Siemens Healthineer, Germany) with a 64-channel head-neck coil. Brain structure image was acquired using magnetization-prepared two rapid acquisition gradient echoes sequence (MP2RAGE). The Rs-fMRI sequence was performed with a simultaneous multi-slice(SMS) technique for getting better SNR about the raw data.The related FC analysis method of posterior cingulate cortex (PCC) seed point was used to extract the brain areas changed by DMN in the resting state.*Results Compared with the control group, GMV was decreased in bilateral talus fissure cortex, bilateral lingual gyrus, bilateral

precuneus, bilateral cuneus, bilateral posterior cingulate gyrus, bilateral parahippocampal gyrus, left insula, and the bean-shaped putamen about the VM group (p<0.05, AlphaSim correction). The ALFF values about the VM group were increased in the bilateral precuneus, bilateral supplementary motor areas, bilateral medial and lateral cingulate gyrus, bilateral posterior cingulate gyrus, left posterior cingulate gyrus, right middle frontal gyrus, right middle temporal gyrus, right middle occipital gyrus, and right superior marginal gyrus. The ALFF values were decreased in the left postcentral gyrus and left superior temporal gyrus (p<0.05). The brain areas in the VM group with enhanced FC between DMN and PCC were bilateral cerebellar area IX, bilateral parahippocampal gyrus, bilateral hippocampus, left fusiform gyrus. The brain areas with weakened connections are bilateral supplementary motor areas, bilateral superior marginal gyrus, bilateral superior temporal gyrus, left cerebellar area VI, right dorsolateral superior frontal gyrus, right middle frontal gyrus, right triangular inferior frontal gyrus, right insular tegmental inferior frontal gyrus, right temporal pole, right middle temporal gyrus and left parietal-inferior marginal angular gyrus (p<0.05).*Conclusions Compared with the control group, patients with VM had abnormal GMV and ALFF values in multiple brain areas and had changes in the brain default network function connection in the Resting-state.*Clinical Relevance/Application The differences in brain structure, function, and FC provide theoretical support for the timely treatment of VM in clinical practice.

RESULTS

Compared with the control group, GMV was decreased in bilateral talus fissure cortex, bilateral lingual gyrus, bilateral precuneus, bilateral cuneus, bilateral posterior cingulate gyrus, bilateral parahippocampal gyrus, left insula, and the bean-shaped putamen about the VM group (p<0.05, AlphaSim correction). The ALFF values about the VM group were increased in the bilateral precuneus, bilateral supplementary motor areas, bilateral medial and lateral cingulate gyrus, bilateral posterior cingulate gyrus, left posterior cingulate gyrus, right middle frontal gyrus, right middle temporal gyrus, right middle occipital gyrus, and right superior marginal gyrus. The ALFF values were decreased in the left postcentral gyrus and left superior temporal gyrus (p<0.05). The brain areas in the VM group with enhanced FC between DMN and PCC were bilateral cerebellar area IX, bilateral parahippocampal gyrus, bilateral hippocampus, left fusiform gyrus. The brain areas with weakened connections are bilateral supplementary motor areas, bilateral superior marginal gyrus, bilateral superior temporal gyrus, left cerebellar area VI, right dorsolateral superior frontal gyrus, right middle frontal gyrus, right triangular inferior frontal gyrus, right insular tegmental inferior frontal gyrus, right temporal pole, right middle temporal gyrus and left parietal-inferior marginal angular gyrus (p<0.05).

CLINICAL RELEVANCE/APPLICATION

The differences in brain structure, function, and FC provide theoretical support for the timely treatment of VM in clinical practice.

SDP-HN-9   Automatic Segmentation Of Thyroid Cartilage Using Deep Learning

Participants
Farhad Maleki, PhD, Montreal, Quebec (*Presenter*) Nothing to Disclose

PURPOSE

Accurate evaluation of the thyroid cartilage (TC) is essential for staging and optimal treatment planning for laryngeal and hypopharyngeal squamous cell carcinomas. Automatic segmentation can be fundamental for downstream applications such as anomaly detection and autostaging of cartilage invasion. Threshold-based TC segmentation works poorly due to the extensive variations in Hounsfield unit attenuation related to variable ossification. Also, TC comprises a small fraction of a head and neck CT volume (about 0.0005%) making segmentation using standard deep learning pipelines challenging. To the best of our knowledge, there is no auto-segmentation of TC, and we aim to fill this gap.*Methods and Materials After obtaining institutional review board approval, 301 CTs at our institution were selected. Manual contouring was performed by a senior diagnostic radiology resident and then reviewed/edited by a head and neck radiologist with over 10 years of experience. Figure 1 illustrates the details of our modified UNet architecture and our model building procedure. We randomly selected 15% of CTs as an independent test set. The remaining CTs were partitioned to 5 groups to build 5 training/validation CT datasets. For each of these datasets an OTC (only including axial CT slices with TC) and BTC (including equal number of axial CT slices with and without TC) datasets were generated. Each model was first trained using OTC for 200 epochs; the model with the highest F1 score on the validation set was then retrained using a BTC dataset for 100 epochs, and the model with the highest F1 score was selected. Using the 5 CT datasets, we trained 5 models. For each CT in the test set, the predictions of these models were aggregated using a vote of majority to make the final segmentation.*Results Our ensemble model generated high-quality segmentations (Dice score: 86%) on the test set. In comparison, a standard UNet trained using all slices converged to a local optimum predicting no TC, which could be attributed to TC being a negligible fraction of a CT volume.*Conclusions The proposed ensemble model can serve as a building block for clinical applications involving thyroid cartilage. Also, our methodology can be used for developing auto-segmentation models for other small volume organs.*Clinical Relevance/Application Auto-segmentation of thyroid cartilage can represent the first and fundamental step for future detection of anomalies and computer-assisted staging of cartilage invasion.

RESULTS

Our ensemble model generated high-quality segmentations (Dice score: 86%) on the test set. In comparison, a standard UNet trained using all slices converged to a local optimum predicting no TC, which could be attributed to TC being a negligible fraction of a CT volume.

CLINICAL RELEVANCE/APPLICATION

Auto-segmentation of thyroid cartilage can represent the first and fundamental step for future detection of anomalies and computer-assisted staging of cartilage invasion.

GU05-B1   **Detection Rate Of Clinically Significant Prostate Cancer Using A Novel High Resolution Transrectal Ultrasound And Scoring System (PRIMUS V1.0). A Pilot Study.**

Participants
Matías Callejas, MD, Toronto, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

To determine the detection rate of clinically significant prostate cancer using a second-generation high resolution transrectal micro-ultrasound, ExactVuTM (MicroUS) applying PRIMUS (Prostate Risk Identification using Micro Ultrasound) score v1.0.*Methods and Materials MicroUS has two main differences with conventional transrectal ultrasound (TRUS): Frequency of 29 MHz (vs 9-12 MHZ for conventional TRUS); and fabrication techniques allowing 4-fold higher crystal density along the transducer (512 vs 128 crystals). The resolution of MicroUS is 70 microns, which is the diameter of a typical prostatic duct, as opposed to 200 microns or more of TRUS (300% higher resolution compared to conventional frequency TRUS). Second generation MicroUS has upgrades in electronics and image processing to further improve image quality.25 men who went to radical prostatectomy following MicroUS evaluation and biopsy were included in the study. Dynamic cine loops obtained with MicroUS for each of these patients were reviewed by an experienced radiologist. The radiologist was aware that these men went to radical prostatectomy but was blinded to pathological data, including cancer location, volume, grade and stage. Suspicious sites were assigned a prostate cancer risk score using the previously published PRIMUS v1.0. All patients had subsequent radical prostatectomy that were examined with quarter mount technique. Detection rate of clinically significant index lesion (ISUP =2) by MicroUS was assessed at a patient level.*Results MicroUS visualized 87% of the clinically significant index lesions (20/23). All these lesions where categorized PRIMUS score 4 or 5. The 3 missed index lesions where localized in the anterior transition zone of the prostate gland.*Conclusions MicroUS showed a high sensitivity, particularly in detecting index lesions in the peripheral zone using PRIMUS v1.0 (100%). This reflects further improvement in comparison to previously published data and may be explained by application of PRIMUS risk score in assessing suspicious sites for cancer in the prostate gland. PRIMUS V2.0 iterations are required for improvements in the detection of transition zone lesions.*Clinical Relevance/Application High resolution transrectal micro-ultrasound is a promising imaging modality for detection of clinically significant prostate cancer with the additional benefit of simultaneous guided biopsy.

RESULTS

MicroUS visualized 87% of the clinically significant index lesions (20/23). All these lesions where categorized PRIMUS score 4 or 5. The 3 missed index lesions where localized in the anterior transition zone of the prostate gland.

CLINICAL RELEVANCE/APPLICATION

High resolution transrectal micro-ultrasound is a promising imaging modality for detection of clinically significant prostate cancer with the additional benefit of simultaneous guided biopsy.

GU05-B2   **Multi-parametric Magnetic Resonance Imaging-based Radiomics Analysis Of Cervical Cancer For Preoperative Prediction Of Lymphovascular Space Invasion**

Participants
yaqiong cui, Lanzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To train and validate a mpMRI-based radiomics model to detect LVSI in patients with CC and investigate its potential as a complementary tool to enhance the efficiency of risk assessment strategies.*Methods and Materials The model was developed from the tumor volume of interest (VOI) of 125 patients with CC, with 1037 radiomics features obtained from conventional magnetic resonance imaging (MRI), including small field of view (sFOV) high-resolution (HR) T2-weighted MRI (T2WI), apparent diffusion coefficient (ADC), T2WI, and contrast-enhanced T1-weighted MRI (T1c). We conducted a radiomics-based characterization of each tumor region using pretreatment image data. Feature selection was performed using a LASSO (least absolute shrinkage and selection operator) method on the training set. A non-invasive radiological classifier capable of discriminating between CC with and without LVSI was proposed. The predictive performance was compared with that of single variates (clinical data and single-layer radiomics signatures) analyzed using a receiver operating characteristic (ROC) curve. Twenty times 3-fold cross-validation was used to evaluate the accuracy of the trained classifiers and the stability of the selected features. These radiomics models were validated using a validation set (n = 25).*Results Feature selection extracted the six most important features (3 from sFOV HR-T2WI, 2 from routine T2WI, and 1 from T1c) for model construction. The multi-parametric combined radiomics model (area under the curve [AUC], 0.940) reached a significantly higher performance (better than the clinical parameters [AUC, 0.730]), including any single-layer model using sFOV HR-T2WI (AUC, 0.840), conventional T2WI (AUC, 0.770, 0.710), ADC maps (AUC, 0.650), and T1c (AUC, 0.710, 0.680) in the validation set.*Conclusions Biomarkers using multi-parametric radiomics features derived from preoperative MR images could predict LVSI in CC.*Clinical Relevance/Application It is challenging to detect lymphovascular space invasion (LVSI) in early cervical cancer (CC). Thus far, no standard clinical markers or screening tests have been used to detect LVSI preoperatively; therefore, noninvasive risk stratification tools are highly desirable. We trained and tested an integrated radiomics model for LVSI prediction in women with CC using preoperative multi-parametric magnetic resonance imaging (mpMRI).

RESULTS

Feature selection extracted the six most important features (3 from sFOV HR-T2WI, 2 from routine T2WI, and 1 from T1c) for model construction. The multi-parametric combined radiomics model (area under the curve [AUC], 0.940) reached a significantly higher performance (better than the clinical parameters [AUC, 0.730]), including any single-layer model using sFOV HR-T2WI (AUC, 0.840), conventional T2WI (AUC, 0.770, 0.710), ADC maps (AUC, 0.650), and T1c (AUC, 0.710, 0.680) in the validation set.

CLINICAL RELEVANCE/APPLICATION

It is challenging to detect lymphovascular space invasion (LVSI) in early cervical cancer (CC). Thus far, no standard clinical markers or screening tests have been used to detect LVSI preoperatively; therefore, noninvasive risk stratification tools are highly desirable. We trained and tested an integrated radiomics model for LVSI prediction in women with CC using preoperative multi-parametric magnetic resonance imaging (mpMRI).

CA03-C3 **Reproducibility Of Radiomics Features Extracted From Late Gadolinium Enhancement Imaging In Patients With Acute Myocarditis**

Participants
Caterina Monti, MD, Milan, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To review the inter-reader reproducibility of various radiomics features extracted from late gadolinium enhancement (LGE) sequences at cardiac magnetic resonance (CMR) in patients with acute myocarditis.*Methods and Materials we retrospectively included all patients with acute myocarditis who underwent CMR at our institution between March 2014 and December 2020. From each CMR examination two readers segmented the epicardium and endocardium of the left ventricle on all short-axis slices from LGE sequences. Afterwards we performed a radiomics extraction from 5 individual classes using 7 image filters, totalling 1320 individual features. Features were deemed reproducible when their inter-reader intra-class correlation coefficient (ICC) was =0.8. Data were reported as median and interquartile range (IQR).*Results our final study population counted 66 patients with acute myocarditis, with a median age of 28 years (IQR 20-44 years), 56 (85%) of whom were males. Patients' median left ventricular ejection fraction was 67% (IQR 37-67%). Out of 1320 features, 820 appeared reproducible, with an ICC=0.8. The most reproducible features were the minimums of the original image and the logarithm and square root filtered image (all ICC=0.99), whereas the least reproducible features were the grey level non uniformity of the exponential and gradient filtered image (both ICC=0.00). Overall, features extracted from the original image showed the highest ICC, with a median of 0.91 (IQR 0.86-0.95), whereas features extracted from the exponential filtered image yielded the lowest ICC with a median of 0.82 (IQR 0.74-0.89).*Conclusions a considerable number of radiomics feature extracted from LGE sequences in patients with acute myocarditis could be used for further clinical models, as they present with a satisfactory reproducibility.*Clinical Relevance/Application Radiomics analyses on LGE imaging may offer a potential source of novel insight for the assessment of patients with acute myocarditis.

RESULTS

our final study population counted 66 patients with acute myocarditis, with a median age of 28 years (IQR 20-44 years), 56 (85%) of whom were males. Patients' median left ventricular ejection fraction was 67% (IQR 37-67%). Out of 1320 features, 820 appeared reproducible, with an ICC=0.8. The most reproducible features were the minimums of the original image and the logarithm and square root filtered image (all ICC=0.99), whereas the least reproducible features were the grey level non uniformity of the exponential and gradient filtered image (both ICC=0.00). Overall, features extracted from the original image showed the highest ICC, with a median of 0.91 (IQR 0.86-0.95), whereas features extracted from the exponential filtered image yielded the lowest ICC with a median of 0.82 (IQR 0.74-0.89).

CLINICAL RELEVANCE/APPLICATION

Radiomics analyses on LGE imaging may offer a potential source of novel insight for the assessment of patients with acute myocarditis.

NMMI05-B1 Anti-CD20 Radioimmunotherapy With 177Lu-ofatumumab Cures NHL In A Pre-clinical Model System

Participants
Kyuhwan Shim, PhD, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

PURPOSE

Ofatumumab (Ofa) is a fully human anti-CD20 antibody approved for use by the FDA. Despite greater potential for redosing than chimeric or mouse anti-CD20 antibodies, Ofa has not been investigated previously for lymphoma radioimmunotherapy. Here, we determine if Ofa radiolabeled with the beta-particle emitting radioisotope, lutetium 177 (177Lu), has therapeutic potential.*Methods and Materials Ofa and human IgG1 were conjugated to CHX-A"-DTPA and 177Lu chelated. Radiochemical purity and stability in serum were analyzed by thin-layer chromatography and immunoreactivity by binding to CD20-positive Raji cells expressing luciferase (Raji-luc). 177Lu-Ofa biodistribution was determined as % injected activity/gram (% IA/g) 7 days post injection into R2G2 mice with subcutaneous tumors. R2G2 mice were injected intravenously with Raji-luc cells and 4 days later with vehicle only, cold Ofa, 20 or 230 µCi/mouse 177Lu-IgG1 or 20 or 230 µCi/mouse 177Lu-Ofa (n=10 mice/group, 6 groups). Tumor-cell growth was followed by bioluminescence imaging (BLI) and survival was tracked.*Results Typical radiochemical yields were >85% with >98% radiochemical purity and specific activities of 458 ± 31 MBq/mg (n=3). 177Lu-Ofa retained 52 ± 5 % (n=3) immunoreactivity and 74 ± 5% (n=3) chelation in serum after 7 days. Biodistribution indicated 17 ± 5% IA/g in tumor and 7 ± 3, 5 ± 1 and 11 ± 4% IA/g in blood, liver and spleen, respectively. Median survivals for groups after 60 days for vehicle, cold Ofa, 20 µCi and 230 µCi 177Lu-IgG1 and 20 µCi 177Lu-Ofa groups were 15, 41.5, 31.5, 20 and 57.5 days, respectively, with no deaths in the 230 µCi 177Lu-Ofa group and no other group with over 3 surviving mice. BLI results corresponded well with survival. Log-rank Mantel-Cox tests of Kaplan-Meier curves show p values of <0.001 when comparing the 230 µCi 177Lu-Ofa group with each of the 5 other groups.*Conclusions 177Lu-ofatumumab was obtained with high specific activity, radiochemical yield, radiochemical purity and retention of immunoreactivity. 230 µCi 177Lu-Ofa showed apparent curative therapeutic efficacy for disseminated lymphoma in a mouse model.*Clinical Relevance/Application 177Lu-ofatumumab may be a candidate for radioimmunotherapy in patients with B-cell lymphoma and has the potential to improve patient outcomes.

RESULTS

Typical radiochemical yields were >85% with >98% radiochemical purity and specific activities of 458 ± 31 MBq/mg (n=3). 177Lu-Ofa retained 52 ± 5 % (n=3) immunoreactivity and 74 ± 5% (n=3) chelation in serum after 7 days. Biodistribution indicated 17 ± 5% IA/g in tumor and 7 ± 3, 5 ± 1 and 11 ± 4% IA/g in blood, liver and spleen, respectively. Median survivals for groups after 60 days for vehicle, cold Ofa, 20 µCi and 230 µCi 177Lu-IgG1 and 20 µCi 177Lu-Ofa groups were 15, 41.5, 31.5, 20 and 57.5 days, respectively, with no deaths in the 230 µCi 177Lu-Ofa group and no other group with over 3 surviving mice. BLI results corresponded well with survival. Log-rank Mantel-Cox tests of Kaplan-Meier curves show p values of <0.001 when comparing the 230 µCi 177Lu-Ofa group with each of the 5 other groups.

CLINICAL RELEVANCE/APPLICATION

177Lu-ofatumumab may be a candidate for radioimmunotherapy in patients with B-cell lymphoma and has the potential to improve patient outcomes.

PD04-B2   **Pre-operative Brain Network Architecture And Surgical Outcome In A Pediatric Cohort With Focal Epilepsy**

Participants
Michael Paldino, MD, Pittsburgh, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Converging evidence points to the role of large-scale cortical and subcortical neural networks in the genesis and expression of pediatric focal epilepsy. Neuroimaging assessments of network abnormalities are not currently used in the pre-surgical evaluation of epilepsy. However, a rapidly growing number of studies suggest that they may have clinical utility. The goal of this study was to measure the test characteristics of surgical outcome prediction using individualized network biomarkers derived from resting state functional MRI (rs-fMRI).*Methods and Materials Thirty-three pediatric patients (mean [SD] age: 11.8 [4.96] yrs) selected for surgical management of FE who had undergone pre-operative rs-fMRI were included. Outcomes were defined by the International League Against Epilepsy (ILAE) classification of post-operative outcome. Network nodes were defined by anatomic parcellation of whole-brain gray matter. Weighted graphs were constructed for each patient consisting of the pair-wise correlation of BOLD signal times series over all network nodes. Network metrics (path length, global efficiency, modularity, and clustering coefficient) were then computed for each graph. The relationship of network metrics to ILAE outcome was assessed by ordinal regression. Finally, a machine learning approach (logistic regression classifier) was used to predict surgical outcome (seizure-free [SF] versus non seizure-free [NSF]) based on pre-operative network metrics.*Results Clustering coefficient (p: 0.001), efficiency (p: 0.012) and path length (p:0.018) were significantly associated with ILAE outcome class. These metrics also demonstrated area under curve and test characteristics for outcome prediction greater than clinical predictors (Figure 1). The best prediction model, however, consisted of both clinical and network variables.*Conclusions Pre-operative brain network architecture improved the prediction of seizure-free outcome.*Clinical Relevance/Application Network biomarkers derived from rs-fMRI have the potential to add value to clinical prognostication in pediatric epilepsy surgery.

RESULTS

Clustering coefficient (p: 0.001), efficiency (p: 0.012) and path length (p:0.018) were significantly associated with ILAE outcome class. These metrics also demonstrated area under curve and test characteristics for outcome prediction greater than clinical predictors (Figure 1). The best prediction model, however, consisted of both clinical and network variables.

CLINICAL RELEVANCE/APPLICATION

Network biomarkers derived from rs-fMRI have the potential to add value to clinical prognostication in pediatric epilepsy surgery.

CH04-A2 Ultra-Low-Dose Computed Tomography Of The Chest Compared To Chest X-Ray In An Unfiltered Emergency Department Patient Cohort - A Prospective Interventional Cohort Study

Participants
Christian Wassipaul, MD, Vienna, Austria (*Presenter*) Institution has grants / grants pending from Siemens Healthineers.

PURPOSE

To conduct a prospective intra-patient comparison of Chest-X-Ray (CXR) and Ultra-Low-Dose CT (ULDCT) of the chest with regard to detected findings and their clinical relevance in an unfiltered non-traumatic patient cohort of an emergency department.*Methods and Materials 294 consecutive non-traumatic ED-patients with a clinically indicated CXR were included. Additional inclusion criteria were an age above 18 years and informed consent. For women under the age of 55 pregnancy was ruled out by ß-HCG testing. All participants received both, a CXR and an unenhanced ULDCT of the chest and were randomized into two arms. In arm A, radiologists first filed the report for the CXR followed by the report for the ULDCT by the same radiologist, in arm B the reporting order was inverted. CXRs were performed with standard imaging parameters. ULDCTs were acquired on a 3rd generation 256-row Multi-Detector Dual-Source CT System at 50 ref. mAs, a tube voltage of 100 kV, tin filtration and tube current modulation enabled. All prospectively detected findings were checked against the radiological reference standard built by an expert radiologist from all available imaging and clinical data. All elements of the reference standard were labelled regarding their clinical relevance by expert emergency physicians.*Results The mean total dose length product (DLP) for ULDCTs was 12.7 mGy*cm (range 5.2 - 34.3), equivalent to a mean effective dose of 0.21 mSv (range 0.09 - 0.58). This corresponds to about twice the reference dose of a CXR in two views. CXR was reported as first imaging modality in 147 patients (arm A), detecting 40 essential clinical findings in these reports. In the other 147 patients (arm B) ULDCT was reported as first imaging modality, showing 63 essential clinical findings. In arm A, the second examination (ULDCT) revealed another 24 additional essential clinical findings, whereas in arm B the second examination (CXR) did not provide any additional essential clinical findings (p < 0.01).*Conclusions In this study, Ultra-Low-Dose CT of the chest (about twice the reference dose of a CXR in two views) detected significantly more essential clinical findings than CXR in a non-traumatic patient cohort of an emergency department, irrespective of indication.*Clinical Relevance/Application ULDCT of the chest emerges as a superior alternative to CXR in non-traumatic ED patients at comparable radiation dose.

RESULTS

The mean total dose length product (DLP) for ULDCTs was 12.7 mGy*cm (range 5.2 - 34.3), equivalent to a mean effective dose of 0.21 mSv (range 0.09 - 0.58). This corresponds to about twice the reference dose of a CXR in two views. CXR was reported as first imaging modality in 147 patients (arm A), detecting 40 essential clinical findings in these reports. In the other 147 patients (arm B) ULDCT was reported as first imaging modality, showing 63 essential clinical findings. In arm A, the second examination (ULDCT) revealed another 24 additional essential clinical findings, whereas in arm B the second examination (CXR) did not provide any additional essential clinical findings (p < 0.01).

CLINICAL RELEVANCE/APPLICATION

ULDCT of the chest emerges as a superior alternative to CXR in non-traumatic ED patients at comparable radiation dose.

CH04-A3 In Vivo MRI Assessment Of Tumor Oxygenation In Non-small Cell Lung Cancer Patients Receiving Stereotactic Body Radiation Therapy

Participants
Xiangyu Yang, PhD, Columbus, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

Use Blood Oxygen Level Dependent (BOLD) MRI to assess tumor oxygenation in vivo in patients with non-small cell lung cancer (NSCLC) and to study its response to Stereotactic Body Radiation Therapy (SBRT) and correlation with tumor permeability, perfusion, and diffusion.*Methods and Materials Fifteen patients with pre- and post-treatment BOLD MRI of unresectable Stage I-III NSCLC treated with SBRT to the primary tumor were identified from two prospective trials for this analysis. All BOLD MRIs were acquired on a Philips Ingenia CX 3T scanner using a dynamic T2* mapping sequence and a dStream WholeBody coil. Tumor oxygenation was quantified by the BOLD response (the relative change in R2*) induced by an oxygen challenge delivered through a nasal cannula (15 L/min). Treatment response was measured within 30 hours after the first fraction of SBRT and correlated with Apparent Diffusion Coefficient (ADC) and pharmacokinetic rate constant kep (modified Brix's model) derived from Diffusion Weighted Imaging (DWI, b=0/600) and Dynamic Contrast Enhanced MRI (DCE-MRI) data acquired with the BOLD MRI.*Results Sixteen lesions were identified for analysis. Their mean T2* was 13 ± 5 ms prior to and 13 ± 6 ms post treatment. Their mean BOLD response was 3.56 ± 0.07% prior to and -2.31 ± 0.06% post treatment. SBRT induced a statistically significant decrease in BOLD response in NSCLC lesions (-5.9 ± 0.1%, P = 0.03) but not in contralateral skeletal muscle (-0.44 ± 0.03%, P = 0.6). The treatment-induced change in tumor oxygenation was strongly correlated with the pre-treatment BOLD response level (r = -0.74) but was not correlated with ADC (r = -0.1) or kep (r = 0.12). No significant change in tumor ADC (1.2 ± 0.3 to 1.3 ± 0.3 x 10-3 mm2/s, P = 0.6) or kep (2 ± 1 to 2 ± 1 min-1, P = 0.9) was observed at the post-treatment scan.*Conclusions In this study, BOLD MRI detected an

acute increase in tumor oxygenation after SBRT treatment of NSCLC. This response is tumor-specific and is more profound in lesions with higher levels of hypoxia prior to the therapy. It also precedes the occurrence of radiation-induced edema and any substantial changes in tumor perfusion or permeability.*Clinical Relevance/Application Our results demonstrated the feasibility of using BOLD MRI to monitor early responses to radiation therapy in patients with NSCLC, and suggested that it might be more sensitive than DWI and DCE-MRI.

RESULTS

Sixteen lesions were identified for analysis. Their mean T2* was 13 ± 5 ms prior to and 13 ± 6 ms post treatment. Their mean BOLD response was 3.56 ± 0.07% prior to and -2.31 ± 0.06% post treatment. SBRT induced a statistically significant decrease in BOLD response in NSCLC lesions (-5.9 ± 0.1%, P = 0.03) but not in contralateral skeletal muscle (-0.44 ± 0.03%, P = 0.6). The treatment-induced change in tumor oxygenation was strongly correlated with the pre-treatment BOLD response level (r = -0.74) but was not correlated with ADC (r = -0.1) or kep (r = 0.12). No significant change in tumor ADC (1.2 ± 0.3 to 1.3 ± 0.3 x 10-3 mm2/s, P = 0.6) or kep (2 ± 1 to 2 ± 1 min-1, P = 0.9) was observed at the post-treatment scan.

CLINICAL RELEVANCE/APPLICATION

Our results demonstrated the feasibility of using BOLD MRI to monitor early responses to radiation therapy in patients with NSCLC, and suggested that it might be more sensitive than DWI and DCE-MRI.

BR03-C1 Diagnostic Performance Of Diffusion-weighted Imaging For Detecting Breast Cancer In Asymptomatic Women With Dense Breasts

Participants
Hee Jeong Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Mammography has low sensitivity in dense breasts, and needs to be supplemented with another screening method for women with dense breasts. The purpose of our study is to assess the diagnostic performance of diffusion-weighted imaging (DWI) for breast cancer detection in asymptomatic women with dense breast tissue on mammography and to compare the diagnostic performance of mammography, dynamic contrast-enhanced MRI (DCE-MRI), and DWI.*Methods and Materials From August 2018 to January 2019, consecutive asymptomatic women with dense breast on mammography who underwent breast MRI including DWI and DCE protocols and mammography were retrospectively reviewed. Three readers independently reviewed the lesion visibility and level of suspicion on each modality. Diagnostic performance was assessed by using areas under the receiver operating characteristic curves (AUCs). The tumor histopathologic features on surgical specimen served as the standard of reference.*Results Among a total of 297 women (mean age, 51.2 years ± 9.4 [standard deviation]) there were 233 breast cancers in 230, benign lesions in 11, and normal breast in 56 women. Of the 233 cancers, there were ductal carcinoma in situ in 35 (15.0%), microinvasive ductal carcinoma in 28 (12.0%), and invasive carcinoma in 170 (73.0%). The overall sensitivity was 61.4% in mammography, 79.4% in DWI, 86.3% in DCE-MRI, and 91.8% in the combination of mammography and DWI. The sensitivities for noninvasive cancer in mammography, DWI, DCE-MRI, and the combination of mammography and DWI were 73.0%, 68.3%, 74.6%, and 92.1%, whereas those for invasive cancer smaller than 20 mm were 51.9%, 81.5%, 88.9% and 89.6%, and those for invasive cancer larger than 20 mm were 77.1%, 91.4%, 97.1%, and 100%, respectively. In the comparison of AUCs, DWI was superior to mammography (P < .001) and comparable to DCE-MRI when combined with mammography (P = .05).*Conclusions DWI was a sensitive and effective screening method for breast cancer detection in asymptomatic women with dense breast tissues.*Clinical Relevance/Application The present study suggests that DWI may be useful as a safe and effective screening tool for the supplementation of mammography in women with dense breast tissues.

RESULTS

Among a total of 297 women (mean age, 51.2 years ± 9.4 [standard deviation]) there were 233 breast cancers in 230, benign lesions in 11, and normal breast in 56 women. Of the 233 cancers, there were ductal carcinoma in situ in 35 (15.0%), microinvasive ductal carcinoma in 28 (12.0%), and invasive carcinoma in 170 (73.0%). The overall sensitivity was 61.4% in mammography, 79.4% in DWI, 86.3% in DCE-MRI, and 91.8% in the combination of mammography and DWI. The sensitivities for noninvasive cancer in mammography, DWI, DCE-MRI, and the combination of mammography and DWI were 73.0%, 68.3%, 74.6%, and 92.1%, whereas those for invasive cancer smaller than 20 mm were 51.9%, 81.5%, 88.9% and 89.6%, and those for invasive cancer larger than 20 mm were 77.1%, 91.4%, 97.1%, and 100%, respectively. In the comparison of AUCs, DWI was superior to mammography (P < .001) and comparable to DCE-MRI when combined with mammography (P = .05).

CLINICAL RELEVANCE/APPLICATION

The present study suggests that DWI may be useful as a safe and effective screening tool for the supplementation of mammography in women with dense breast tissues.

BR03-C2 Variability In Clinical And Imaging Follow Up Of Pediatric Breast Masses

Participants
Courtney Cave, MD, Detroit, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

Pediatric breast masses are almost always benign with approximately 95% of them representing fibroadenomas. On ultrasound, these are classically described as circumscribed, oval, hypoechoic solid masses. The current proposed recommendations in the pediatric literature for managing these masses include follow up ultrasound for a mass <3 cm, core biopsy for a mass 3-5 cm, and surgical excision for a mass >5 cm. We sought to determine how often these guidelines were appropriately applied and if the interpreting radiologist subspecialty (ie. pediatric, breast, or general radiologist) had a significant impact on the type of follow up recommended.*Methods and Materials Following IRB approval, pediatric patients who received a breast ultrasound for a solid mass between 2017-2020 were identified by retrospective query of the electronic medical record. This yielded 370 patients ranging in age from 9 to 18 years. 169 patients had a mass consistent with a fibroadenoma. The follow-up for these patients was categorized into clinical follow-up, ultrasound follow-up, core biopsy, or surgical excision.*Results Of the 169 patients included in the study, 26.03% underwent 6-12 month imaging follow up, 40.2% received core biopsy, and 18.3% underwent excisional biopsy. 6.5% had clinical follow up without either further imaging or biopsy. The remainder of the patients were lost to follow up. Data was further stratified by mass size and interpreting radiologist subspecialty. This demonstrated variability in management among radiologist subspecialist. Additionally, the data showed that masses <3 cm are the most frequently mismanaged with 53% of these masses undergoing biopsy rather than ultrasound follow-up as per the guidelines (p<0.00001).*Conclusions This data demonstrates variable follow up for pediatric breast masses within our institution. While multiple factors influence the decision to biopsy or surgically

excise a mass, published literature shows that follow up sonography is a safe, non-invasive management strategy for masses with specific sonographic characteristics and size in this patient population. Despite this, only 26.03% of the pediatric breast masses in this study were managed with follow up sonography regardless of the interpreting radiologist subspecialty, with the majority undergoing core biopsy. Better familiarity with the published guidelines among radiologists may help to avoid unnecessary procedures for pediatric patients.*Clinical Relevance/Application Increased familiarity with the published management guidelines of pediatric solid breast masses would decrease the number of unnecessary procedures and improve consistency in follow up recommendations by radiologists.

RESULTS

Of the 169 patients included in the study, 26.03% underwent 6-12 month imaging follow up, 40.2% received core biopsy, and 18.3% underwent excisional biopsy. 6.5% had clinical follow up without either further imaging or biopsy. The remainder of the patients were lost to follow up. Data was further stratified by mass size and interpreting radiologist subspecialty. This demonstrated variability in management among radiologist subspecialist. Additionally, the data showed that masses <3 cm are the most frequently mismanaged with 53% of these masses undergoing biopsy rather than ultrasound follow-up as per the guidelines (p<0.00001).

CLINICAL RELEVANCE/APPLICATION

Increased familiarity with the published management guidelines of pediatric solid breast masses would decrease the number of unnecessary procedures and improve consistency in follow up recommendations by radiologists.

BR03-C3   Discordance In Breast Biopsies: An Analysis Of Contributing Variables

Participants
Bill Zhou, Los Angeles, California (*Presenter*) Nothing to Disclose

PURPOSE

Image-guided core needle biopsy is a less invasive method than excisional biopsy. However, sampling error can occur. In discordant cases where there is concern for missed malignancy, additional evaluation such as imaging, repeat biopsy, or excisional biopsy is performed. These additional steps cause patient anxiety and financial burden. Our objective is to determine factors that contribute to discordant results.*Methods and Materials Our institutional database was searched for discordant biopsies performed between 2016-2021. Patient demographics, imaging features, biopsy method, needle gauge, and pathology findings were recorded.Discordant rates were calculated. True discordance was defined as additional evaluation that resulted in a final malignant pathology. False discordance was defined as additional evaluation that resulted in a final benign pathology. Statistical significance between the true and false discordance groups was assessed using IBM SPSS, with Pearson's chi-squared test used for categorical variables and independent-samples t test for numerical variables.*Results A total of 7635 biopsies, of which 71 discordant lesions were identified (0.9%). Of the 60 patients who underwent additional evaluation, 13 were true discordant (21.6%) and 47 were false discordant (78.4%). BI-RADS score (p = 0.02), axillary lymphadenopathy (p = 0.03), and lesion size (p = 0.005) were associated with true discordance. Age, breast atypia, family history, IBIS score, prior breast procedure, breast density, lesion type, and method of biopsy were non-significant variables.US-guided biopsies had a higher rate of true discordance compared to stereotactic-guided biopsies (33.3% versus 12.5%). Most discordances with calcifications was caused by lack calcifications on the initial pathology (90.9%). Common final pathologies in false discordance cases were stromal fibrosis, fat necrosis, and radial scar. Total of 17 (36.2%) of the false discordant cases demonstrated high risk lesions on final pathology. Four patients who obtained post-procedure MR breast had the BI-RADS score downgraded, which obviated the need for additional biopsy.*Conclusions Our institutional discordance rate (0.9%) was relatively low, with a true discordance rate of 21.6%. Important predictive factors for a true discordant lesion are BI-RADS score, axillary lymphadenopathy, and lesion size. US-guided biopsies are more prone to false discordance, likely due to technical challenges and smaller needle size. Additional evaluation with MR breast can help prevent patients from invasive excisional biopsy.*Clinical Relevance/Application This study emphasizes the need for careful radiological-pathologic review to help guide the radiologist in the setting of discordance.

RESULTS

A total of 7635 biopsies, of which 71 discordant lesions were identified (0.9%). Of the 60 patients who underwent additional evaluation, 13 were true discordant (21.6%) and 47 were false discordant (78.4%). BI-RADS score (p = 0.02), axillary lymphadenopathy (p = 0.03), and lesion size (p = 0.005) were associated with true discordance. Age, breast atypia, family history, IBIS score, prior breast procedure, breast density, lesion type, and method of biopsy were non-significant variables.US-guided biopsies had a higher rate of true discordance compared to stereotactic-guided biopsies (33.3% versus 12.5%). Most discordances with calcifications was caused by lack calcifications on the initial pathology (90.9%). Common final pathologies in false discordance cases were stromal fibrosis, fat necrosis, and radial scar. Total of 17 (36.2%) of the false discordant cases demonstrated high risk lesions on final pathology. Four patients who obtained post-procedure MR breast had the BI-RADS score downgraded, which obviated the need for additional biopsy.

CLINICAL RELEVANCE/APPLICATION

This study emphasizes the need for careful radiological-pathologic review to help guide the radiologist in the setting of discordance.

BR03-C5   Does Lateral Arm Technique Decrease The Rate Of Clip Migration In Stereotactic And Tomosynthesis-guided Biopsies?

Participants
Olena Weaver, MD, Houston, Texas (*Presenter*) Consultant, General Electric Company;Research Grant, General Electric Company

PURPOSE

Mammography-guided vacuum-assisted biopsies (MGVAB) can be done with stereotaxis or digital breast tomosynthesis (DBT)-guidance, and are used for sampling mammography-only detected findings. Both methods can be performed with a conventional biopsy approach (CBA) (needle perpendicular to the compression paddle) or with a lateral arm biopsy approach (LABA) (needle parallel to the compression paddle). Marker clip placement is required for biopsy site identification in both procedures. Clip migration is relatively frequent (up to 44%), which in cases requiring surgery carries a risk of positive margins or re-excision. Some proposed mechanisms of clip migration suggest that LABA may decrease clip migration rate. Meanwhile, the long needle travel in the plane of stretched breast tissues in LABA raises theoretical concern about increased hematoma formation. We aimed to compare the rates of clip migration and hematoma formation between the CBA and LABA techniques of prone MGVAB.*Methods and Materials Our HIPAA compliant retrospective study included all consecutive prone MGVAB performed in a single institution over a 20 month period. The LABA approach was used with DBT guidance; CBA utilized DBT or stereotactic guidance. The tissue sampling techniques were

otherwise identical.*Results After exclusion, 389 biopsies on 356 patients were analyzed. LABA was done in 97 (25%), and CBA in 292 (75%) cases. There was no statistical difference in clip migration rate with either 1 cm or 2 cm distance cut-off (15% for CBA and 10% for LABA for 1 cm threshold (p=0.31); 5.8% or CBA and 3.1% or LABA for 2 cm threshold (p=0.43)). There was no difference in the rate of hematoma formation (57.5% in CDB and 50.5% in LABA, p=0.24). The rates of technical failure were similar for both techniques (1.7% for CBA and 3% for LABA) with a combined failure rate of 1%.*Conclusions LABA and CBA had no statistical difference in clip migration or hematoma formation rates. Both techniques had similar success rates and may be helpful in different clinical situations.*Clinical Relevance/Application LABA cannot reliably decrease the rate of clip migration, but it is complementary to CBA for some clinical applications. Utilizing both techniques increases the overall technical success rate of biopsies to 99%.

RESULTS

After exclusion, 389 biopsies on 356 patients were analyzed. LABA was done in 97 (25%), and CBA in 292 (75%) cases. There was no statistical difference in clip migration rate with either 1 cm or 2 cm distance cut-off (15% for CBA and 10% for LABA for 1 cm threshold (p=0.31); 5.8% or CBA and 3.1% or LABA for 2 cm threshold (p=0.43)). There was no difference in the rate of hematoma formation (57.5% in CDB and 50.5% in LABA, p=0.24). The rates of technical failure were similar for both techniques (1.7% for CBA and 3% for LABA) with a combined failure rate of 1%.

CLINICAL RELEVANCE/APPLICATION

LABA cannot reliably decrease the rate of clip migration, but it is complementary to CBA for some clinical applications. Utilizing both techniques increases the overall technical success rate of biopsies to 99%.

BR03-C6   Cryoablation As Substitute For Surgery In Elderly Patients With Non Resected Breast Cancer: Pilot Study With Medium-term Outcomes

Participants
Jose Maria Oliver-Goldaracena, Madrid, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To review the tolerance and medium-term efficacy of ultrasound-guided cryoablation (USCr) as a replacement treatment for surgery in elderly patients (pts) with inoperable breast carcinoma (BC) due to associated comorbidity or rejection of surgical treatment.*Methods and Materials A retrospective study of the 29 BC (ranged 5-60mm, mean 22mm) treated with CrUS between March 2019 and December 2020, was carried out in 27 patients who were not candidates for surgery with ages ranged 80 and 94 years (mean 86). The histology was : 19 Invasive ductal carcinomas (IDC), 4 Invasive lobular carcinomas, 4 Mucinous carcinomas , 2 Papillary carcinomas. All BC were HER-2 negatives. All patients were treated with hormonal therapy (HT).Primary treatment with USCr was performed in 6 pts (6 BC) with negative axillary US , and adjuvant HT : a) 3 pts with BC ranged 5-10mm ; b) 3 pts with low hormone receptor expression BC.The treatment was started with HT and was completed later with USCr in 21 patientes (23 BC) with negative axillary US: a) Resistance to Primary Endocrine Therapy, between 8 years and 6 months , 7 pts. b) Neoadjuvant HT for 6-12 months reduced the size of the BC and later USCr was performed , 14 pts. procedures were outpatient and performed under local anesthesia.The follow-up protocol was to perform US and Large Needle Biopsy (LNB) of the treated bed in 2-3 months and subsequently US every 6 months. If suspicious findings of residual or recurrent BC were detected, a new rescue USCr was considered. Tolerance to the procedure and associated complications were collected.*Results In 23 patients (25 BC, between 5-60mm, mean 19mm), no residual lesion was detected in the first US control , nor local recurrence in the following US , between 6-22 months (mean 16 months). In 2 pts (BC 22, 18 mm) local recurrence was detected (1) in the cryoablation bed at 16 months , (1) multifocal recurrence separated from the cryoablation bed at 18 months . They were managed with a new USCr. In 2 patients, 2 CaMs of 40 and 45mm, residual lesions were detected in the first US control, which were treated with 1 and 2 successive CrR, respectively. Despite local BC control , 2 patients died from distant metastases and 1 patient from COVID at 13, 8 and 9 months after the CrUS, respectively. All patients tolerated the procedure well and there were no complications.*Conclusions Ultrasound-guided cryoablation of BC is a very well tolerated technique, without serious complication and effective in the medium term. Larger tumors may require more than one procedure to achieve complete ablation and local or regional recurrences can be managed with new rescue USCr.*Clinical Relevance/Application Ultrasound-guided cryoablacion can replace surgery in the management of breast cancer in elderly patients

RESULTS

In 23 patients (25 BC, between 5-60mm, mean 19mm), no residual lesion was detected in the first US control , nor local recurrence in the following US , between 6-22 months (mean 16 months). In 2 pts (BC 22, 18 mm) local recurrence was detected (1) in the cryoablation bed at 16 months , (1) multifocal recurrence separated from the cryoablation bed at 18 months . They were managed with a new USCr. In 2 patients, 2 CaMs of 40 and 45mm, residual lesions were detected in the first US control, which were treated with 1 and 2 successive CrR, respectively. Despite local BC control , 2 patients died from distant metastases and 1 patient from COVID at 13, 8 and 9 months after the CrUS, respectively. All patients tolerated the procedure well and there were no complications.

CLINICAL RELEVANCE/APPLICATION

Ultrasound-guided cryoablacion can replace surgery in the management of breast cancer in elderly patients

BR03-C7   Phase 0 Clinical Trial Using An Ultrasound-detectable Twinkling Marker For Preoperative Localization Of Positive Axillary Nodes In Patients With Breast Cancer: Initial Results

Participants
Benjamin Wood, BS, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

Positive axillary lymph nodes in breast cancer (cN+) which radiographically normalize following neoadjuvant chemotherapy are challenging to localize preoperatively with an I-125 seed for targeted surgical removal. The purpose of this study is to evaluate ultrasound color Doppler twinkling conspicuity of a proprietary marker in cN+ converted to cN0- with neoadjuvant chemotherapy in patients with breast cancer.*Methods and Materials In this ongoing study anticipated to complete by September 2021, six of ten patients with cN+ breast cancer have been recruited into this single arm, prospective study. During I-125 seed localization of the previously biopsy-confirmed positive axillary lymph node, we placed a proprietary marker and an I-125 seed using standard percutaneous techniques. After the post-localization mammogram, we performed ultrasound (GE Logiq E9, Wauwatosa, WI, USA) using a broad band linear (2-8 MHz, 9L) transducer to assess for twinkling conspicuity of the marker. Two board-certified

radiologists evaluated ultrasound conspicuity of the marker and the clip. The ease for detecting the clip or marker was categorized from 1 (&lt30 sec) to 5 (not detectable). At the time of surgery less than 5 days after localization, the previously placed biopsy clip and the proprietary marker were resected along with the specimen to assess pathologic response.*Results Diagnostic axillary ultrasound after neoadjuvant chemotherapy could not depict the clip associated with the positive node in 4 of the 6 (67%) patients. Three of these 4 sonographically occult clips were later identified by ultrasound at the time of localization, and 5 of the 6 patients underwent successful ultrasound-guided localization with the I-125 seed and our proprietary marker. One patient underwent CT-guided seed and marker localization. The average categorical ease for detecting the marker by ultrasound was 2.75 for the marker and 3.08 for the clip. Doppler ultrasound preliminarily demonstrates improvement in depicting the proprietary marker compared to standard B-mode imaging alone.*Conclusions Initial results for ultrasound detection of a proprietary marker in lymph nodes previously biopsy proven cN+ and normalized with neoadjuvant chemotherapy of patients with breast cancer are promising.*Clinical Relevance/Application Preliminary data from our ongoing clinical trial show promise using ultrasound color Doppler twinkling to detect a proprietary soft tissue marker in biopsy-positive axillary nodes that have normalized in patients with breast cancer.

RESULTS

Diagnostic axillary ultrasound after neoadjuvant chemotherapy could not depict the clip associated with the positive node in 4 of the 6 (67%) patients. Three of these 4 sonographically occult clips were later identified by ultrasound at the time of localization, and 5 of the 6 patients underwent successful ultrasound-guided localization with the I-125 seed and our proprietary marker. One patient underwent CT-guided seed and marker localization. The average categorical ease for detecting the marker by ultrasound was 2.75 for the marker and 3.08 for the clip. Doppler ultrasound preliminarily demonstrates improvement in depicting the proprietary marker compared to standard B-mode imaging alone.

CLINICAL RELEVANCE/APPLICATION

Preliminary data from our ongoing clinical trial show promise using ultrasound color Doppler twinkling to detect a proprietary soft tissue marker in biopsy-positive axillary nodes that have normalized in patients with breast cancer.

NPM02-A1   **RadDiscord: The Creation Of A Successful Online Community**

Participants
Grace Zhu, MD, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

PURPOSE

RadDiscord, a novel pandemic-era open access digital educational platform available to the global radiology community, has an impact on clinical radiology through transforming the education of radiology residents around the world and improving access to knowledge to radiologists. The goal is to showcase the perceived and tangible benefits of this type of educational platform.*Methods and Materials RadDiscord is hosted on the Discord platform (a web-based application that hosts communities for people to interact in real time online). To assess the impact of RadDiscord's efforts, the examinees in the community were anonymously surveyed after the February 2021 CORE exam to assess performance and overall RadDiscord usage and perception.*Results As of April 2021, 1,135 radiologists from 280+ institutions across 30+ countries have joined the community. The community has hosted 97 resident group study sessions and 84 faculty led case based reviews and didactics. 50 examinees (out of 270, 18%) responded to the survey. The average CORE exam score was 488.1 (stdev 84.9), higher in comparison to national mean of 457 (stdev 90.2, p=0.0189). RadDiscord faculty led board reviews were given an average rating of 4.29 (on a 5 point scale), compared to internal residency formal didactics of 2.86 (p=<0.0001). In terms of usage, 80% of respondents report using RadDiscord 1-5 hours per week, 14% 6-10 hours, and 6% 11-15 hours. Overall, the majority of survey responses were positive, with a majority reporting decreased isolation, more motivation, and expansion of knowledge. 92% of respondents would recommend the community to others.*Conclusions RadDiscord is a successful online community and has positively impacted clinical radiology as evidenced by the community's performance and overall positive survey responses.*Clinical Relevance/Application Knowledge empowers radiologists. RadDiscord impacts clinical radiology by democratizing knowledge through improving education and training, to improve global patient care.

RESULTS

CLINICAL RELEVANCE/APPLICATION

Knowledge empowers radiologists. RadDiscord impacts clinical radiology by democratizing knowledge through improving education and training, to improve global patient care.

NPM02-A3   **Global Health Radiology Planning Using Geographic Information Systems To Identify Populations With Decreased Access To Care**

Participants
Shan Sivanushanthan, Washington, Dist. of Columbia (*Presenter*) Nothing to Disclose

PURPOSE

A novel approach for improving access to radiology services for underserved populations is through use of a medical hybrid airship, which requires careful planning to identify regions with poor infrastructure. Through use of geographic information systems (GIS), we aimed to identify (1) high risk and medically underserved patient populations in northern Canada and (2) potential landing sites for a medical airship to allow for mobile delivery of radiology services.*Methods and Materials The northern region of Canada extending from the Rocky Mountains to the Atlantic Ocean was analyzed using multi-variable, multi-weighted GIS modeling. Based on population distance from hospitals (50% weight), health centers (e.g. clinic; 30% weight), remote communities (not connected to electric grid; 10% weight), and roads (10% weight), individuals were stratified into one of five health access severity index (HASI) categories (ranging from very low to very high severity). Topographic and land cover data were used to identify suitable landing sites for the medical airship. A coordinate data set was made from georeferenced healthcare facilities, and infrastructure data was obtained from OpenStreetMap.*Results GIS analyzed 815,772 Canadians. Of this population, 522,094 (64%) were found to live =60 km from a hospital, 326,309 (40%) were =45 km from the nearest health center, 65,262 (8%) were within 30 km of a remote community, and 57,104 (7%) lived =1 kilometer from the nearest road. Combined, the HASI identified 44% of the population as having decreased access to care (high or very high severity). Lastly, 27.5% of land analyzed was found to be suitable for airship operations.*Conclusions GIS identified medically underserved populations in northern Canada who may benefit from mobile radiology services. These techniques may help to guide future global health radiology outreach efforts.*Clinical Relevance/Application This study demonstrates the role of geographic information systems in quantifying healthcare disparities faced by residents in northern

Canada and identifying locations suitable for global health radiology outreach.

RESULTS

GIS analyzed 815,772 Canadians. Of this population, 522,094 (64%) were found to live =60 km from a hospital, 326,309 (40%) were =45 km from the nearest health center, 65,262 (8%) were within 30 km of a remote community, and 57,104 (7%) lived =1 kilometer from the nearest road. Combined, the HASI identified 44% of the population as having decreased access to care (high or very high severity). Lastly, 27.5% of land analyzed was found to be suitable for airship operations.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates the role of geographic information systems in quantifying healthcare disparities faced by residents in northern Canada and identifying locations suitable for global health radiology outreach.

NPM02-A4 **Optimizing Practice Management In Emergency Radiology: Lessons In Efficiency From A Large Emergency Radiology Division**

Participants
Scott Steenburg, MD, Indianapolis, Indiana (*Presenter*) Nothing to Disclose

TEACHING POINTS

Emergency Radiology is known for its high speed, high acuity, and high-volume environment.To succeed, emergency radiology practices must optimize the key practice management domains of recruitment, staffing, infrastructure development and support, and integrated use of data analytics.Workload and workflow are not synonymous. Workload is a measure of exams or RVUs per unit time. Workflow is the defined steps and processes that are performed to accomplish a specific task.Emergency radiology practices that focus on workload balancing and efficient workflow are most likely to be successful and sustainable.Creative scheduling to allow for sufficient recovery time is necessary to promote career longevity and radiologist retention.

TABLE OF CONTENTS/OUTLINE

Discuss how to recruit, retain, and staff for success in emergency radiology.Define and provide examples of workflow vs workload in an efficient emergency radiology practice.Delve into workflow considerations and optimization strategies.Provide case examples of workload and workflow balancing using historical data from our practice to create efficient and effective radiologist scheduling.Describe creative solutions to reduce distractions and interruptions in the reading room.

MK02-B1   Kypho-scoliosis In Neurofibromatosis Type 1 On Whole Body Mri: Frequency And Association With Intraspinal And Paraspinal Lesions And Tumors.

Participants
Shamrez Haider, BS, Dallas, Texas (*Presenter*) Nothing to Disclose

PURPOSE

Scoliosis is a common orthopedic problem in patients with Neurofibromatosis 1 (NF1). Spinal deformities have been reported to be found in 77% of all NF1 cases and 2% of all pediatric scoliosis cases have been attributed to NF1. A proposed etiology of scoliosis in NF1 patients states that paraspinal or intraspinal neurofibromas disrupt the normal orderly development of the spine. This study aimed to use whole-body MR imaging (WBMRI) to screen patients with NF1 for scoliosis and determine its association with locoregional spinal tumors.*Methods and Materials It was an Institutional Review Board (IRB) approved retrospective review of 122 NF1 patients with WBMRIs isolated from the electronic medical record (EMR). 97 cases that met inclusion criteria were identified. All patients underwent 3-Tesla MR imaging with automated software fusion of the three sets of inversion recovery and 3D T1W coronal images. Frequency of scoliosis and intra-spinal and paraspinal tumors was recorded. Patients with severe-dystrophic type scoliosis were separately identified, and Cobb angles were measured for all such cases. Association analysis was performed. P-value less than 0.05 was considered statistically significant.*Results 97 patients with NF1 were evaluated. Two had prior spinal surgery and were excluded. The final sample of 95 patients included 33 (35%) males and 62 (65%) females with a mean BMI of 25.82 (+/- 4.96). 43/95 (45.3%) patients had scoliosis and 13/43 (30.2%) of which were severely angled. ICC for Cobb's angles measured 0.99 (CI 0.98,1.0). Fisher's exact test determined no association between scoliosis and presence of either paraspinal or intraspinal tumors (p= 0.485). There was also no association between the tumors and severe dystrophic scoliosis (p =1).*Conclusions Understanding the etiology of scoliosis in NF1 patients has potential implication for treatment planning, imaging requirements, timely surgical correction, and interventions to prevent deformity at young age. This study contradicts the hypothesized association of the presence of locoregional spinal tumors and scoliosis in NF1 patients. The work adds to the body of knowledge of NF1 literature and infers that the presence of scoliosis in an NF1 patient should not require searching for causative locoregional spinal tumors.*Clinical Relevance/Application Scoliosis is a common issue in patients with Neurofibromatosis 1 and according to our results, its presence should not mandate an immediate search for intra or paraspinal tumors.

RESULTS

97 patients with NF1 were evaluated. Two had prior spinal surgery and were excluded. The final sample of 95 patients included 33 (35%) males and 62 (65%) females with a mean BMI of 25.82 (+/- 4.96). 43/95 (45.3%) patients had scoliosis and 13/43 (30.2%) of which were severely angled. ICC for Cobb's angles measured 0.99 (CI 0.98,1.0). Fisher's exact test determined no association between scoliosis and presence of either paraspinal or intraspinal tumors (p= 0.485). There was also no association between the tumors and severe dystrophic scoliosis (p =1).

CLINICAL RELEVANCE/APPLICATION

Scoliosis is a common issue in patients with Neurofibromatosis 1 and according to our results, its presence should not mandate an immediate search for intra or paraspinal tumors.

MK02-B2   Comparison Of Muscle Fat Fraction Measurements In The Lower Spine Musculature With Non-Contrast-Enhanced CT And Different MR Imaging Sequences (Two-Point Dixon, TRUFI) Using Multi-Point Dixon MR As Standard Of Reference

Participants
Jonas Getzmann, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To assess whether two-point Dixon (TPD) MRI, true fast imaging with steady-state free precession (TRUFI) MRI and non-contrast-enhanced CT (NECT) can accurately measure the muscle fat fraction (FF) in the autochthonous back muscles (AM) and the psoas muscle (PM) compared to the standard of reference multi-point Dixon (MPD) MRI.*Methods and Materials A total of 29 oncological patients who received MPD, TPD and NECT images in a period of three months were retrospectively analyzed. A sub-cohort of 16 patients also received a TRUFI MRI for radio-oncology planning and were included in a sub-analysis. The AM and the PM of all individuals were bilaterally analyzed at the height of L3. Region of interest (ROI) measurements for each muscle compartment of the AM and the PM were conducted independently by two examiners on respective FF maps. For CT, linear formulas were calculated to convert Hounsfield unit (HU) measurements into FF percentages. Additionally, the Goutallier classification was used to quantify the amount of fatty infiltration of each muscle by eye. Standard statistical tests were used to compare imaging sequences and modalities. Interreader agreement was assessed using the Pearson correlation coefficient (r) and Cohen's kappa coefficient (?) for Goutallier grades.*Results Good correlations with MPD were found for NECT (r = 0.969), TPD (r = 0.942) and TRUFI (r = 0.904, all P < 0.001) when assessing the FF in the AM. Intermodality correlations were slightly lower when measuring the FF in the PM and with generally higher muscle FF. Interreader agreement between readers showed good correlations and low median deviations (1.1 - 4.1 percentage points, depending on the modality). The Goutallier classification of the AM showed substantial overlap between FF

values especially in grades 2 and 3 but with substantial overall interreader agreement (? = 0.688, P < 0.005).*Conclusions ROI measurements of the AM in NECT highly correlate with muscle FF measurements in the standard of reference MPD MRI. TPD and TRUFI MRI show reliable values in patients only with a low muscle FF.*Clinical Relevance/Application High fat fraction (FF) of the lower spine muscles is associated with higher morbidity in oncological conditions. Our research suggests that the widely available NECT delivers reliable FF measurements.

RESULTS

Good correlations with MPD were found for NECT (r = 0.969), TPD (r = 0.942) and TRUFI (r = 0.904, all P < 0.001) when assessing the FF in the AM. Intermodality correlations were slightly lower when measuring the FF in the PM and with generally higher muscle FF. Interreader agreement between readers showed good correlations and low median deviations (1.1 - 4.1 percentage points, depending on the modality). The Goutallier classification of the AM showed substantial overlap between FF values especially in grades 2 and 3 but with substantial overall interreader agreement (? = 0.688, P < 0.005).

CLINICAL RELEVANCE/APPLICATION

High fat fraction (FF) of the lower spine muscles is associated with higher morbidity in oncological conditions. Our research suggests that the widely available NECT delivers reliable FF measurements.

SDP-CA-1   **Clinical Usability Of Free Breathing Three-dimensional Late Gadolinium Enhancement Cardiovascular Magnetic Resonance Using Compressed Sensing**

Participants
Masashi Nakamura, Toon, Japan (*Presenter*) Nothing to Disclose

PURPOSE

In Cardiovascular Magnetic Resonance (CMR), late gadolinium enhancement (LGE) is an important tool in the assessment of Myocardial scar and fibrosis. A two-dimensional (2D) LGE sequence acquired in multiple breath-holds may suffer from slice misregistration and artifacts due to respiratory motion. Alternatively, a three-dimensional (3D) LGE sequence has been proposed with the potential advantage of isotropic resolution and extended myocardial coverage. However, 3D LGE sequences suffered from long breath-hold duration. Recently, the mathematical theory of compressed sensing (CS) has also been applied in CMR, and it has been known to enable 3D imaging under free breathing. The purpose of this study was to evaluate the diagnostic performance of free-breathing 3D LGE using CS (CS 3D LGE) comparing with conventional breath hold 2D LGE (2D LGE).*Methods and Materials 91 consecutive patients of clinically suspected cardiovascular disease underwent both 2D LGE and CS 3D LGE on a clinical 3T MRI scanner (MAGNETOM Skyra, Siemens Healthcare). The slice thickness of CS 3D LGE protocol is 1.4 mm, conventional 2D LGE protocol is 6mm. We respectively assessed acquisition times, scores of image quality on a 4-point scale (1-4) and scar volume percentage (percentage of enhanced mass in total left ventricular mass). An enhanced mass and left ventricular mass were calculated by full-width at half-maximum method using a dedicated software (CMR42, Circle Cardiovascular Imaging).*Results The mean effective scan time was 388 ± 114 sec for CS 3D LGE and 411 ± 130 sec for 2D LGE (p=0.39). Image quality scores were significantly lower for CS 3D LGE than for 2D LGE (3.1 ± 0.7 for 3D vs. 3.5 ± 0.6 for 2D; p < 0.001). However, both scores were above the 3 points that does not interfere for diagnosis. Of all cases, 51 patients had visualized LGE. In these 51 patients, the scar volume percentage were 19.2 ± 16.2 % (3D) and 18.0 ± 14.2 % (2D) (p=0.473, R2=0.72).*Conclusions CS 3D LGE method allows complete whole heart coverage in a scan time of approximately 6 min while maintaining diagnostic performance.*Clinical Relevance/Application Free-breathing CS 3D LGE might be a suitable alternative to conventional breath hold 2D LGE for assessment of LGE for patients who cannot tolerate breath hold.

RESULTS

The mean effective scan time was 388 ± 114 sec for CS 3D LGE and 411 ± 130 sec for 2D LGE (p=0.39). Image quality scores were significantly lower for CS 3D LGE than for 2D LGE (3.1 ± 0.7 for 3D vs. 3.5 ± 0.6 for 2D; p < 0.001). However, both scores were above the 3 points that does not interfere for diagnosis. Of all cases, 51 patients had visualized LGE. In these 51 patients, the scar volume percentage were 19.2 ± 16.2 % (3D) and 18.0 ± 14.2 % (2D) (p=0.473, R2=0.72).

CLINICAL RELEVANCE/APPLICATION

Free-breathing CS 3D LGE might be a suitable alternative to conventional breath hold 2D LGE for assessment of LGE for patients who cannot tolerate breath hold.

SDP-CA-10   **Direct Comparison Of Motion Artifact Reduction Between The First And Second Generation Motion Correction Algorithms In Coronary Computed Tomography Angiography Using A 256-row CT**

Participants
Yuji Matsuzaki, RT, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

In coronary CTA (CCTA), motion correction algorithms contribute to improved image quality but have limited correcting only the area around the pre-segmented coronary arteries. We expected that the new generation of the algorithm correcting for the entire scanning area without any segmentation of coronary trees, lead to further improvement of the image quality. The aim was to visually evaluate the image quality of proximal and distal coronary arteries for each generation of the motion correction algorithm.*Methods and Materials We retrospectively reviewed 42 patients (11 women, median age 68 years) who underwent CCTA using 256-row CT from November 2020 to February 2021. We used automatic optimal cardiac phase reconstruction in the systolic and diastolic phases to minimize bias during phase selection. We adapted each motion correction algorithm (SSF and SSF2) with workstations. For image evaluation, two independent CT technologists divided proximal and distal in the three branches of the coronary artery into a total of six segments and performed a visual assessment of the degree of artifacts due to coronary artery motion on a five-point scale (0: artifacts are severe and inferior to 4: excellent). The lower score of the two observers was adopted; the score = 3 was defined as sufficient quality for investigation by radiologists. We used the sum of the scores as the overall coronary artery score. We used the Wilcoxon test to evaluate the difference between the two algorithms.*Results The median heart rate was 60.5 (41-145) bpm, and arrhythmia cases were 23.8%. SSF2 showed a significant improvement in image quality in the segmental evaluation compared to SSF in both diastolic and systolic images (P<.001 for each). As a result, 99.6% of the segments achieved readable image quality with SSF2, and 87.6% received an excellent rating. On a per-patient basis, SSF2 scored 24 [IQR 23-24] and significantly increased from the SSF (23 [IQR 22-24])(P<.001). Further, SSF2 showed an image quality improvement on the peripheral side in the diastole (P=.004) and on the proximal and distal sides in the systole (P<.001 for

each).*Conclusions The new motion correction algorithm, which can correct the entire heart, is more effective in reducing motion artifacts than the previous generation and showed a 99.6% test achievement rate for image quality.*Clinical Relevance/Application The new generation motion correction algorithm that corrects the motion for the entire scanning area can improve image quality, compared with previous algorithms, which only collect the area around the pre-segmented coronary arteries.

RESULTS

The median heart rate was 60.5 (41-145) bpm, and arrhythmia cases were 23.8%. SSF2 showed a significant improvement in image quality in the segmental evaluation compared to SSF in both diastolic and systolic images (P<.001 for each). As a result, 99.6% of the segments achieved readable image quality with SSF2, and 87.6% received an excellent rating. On a per-patient basis, SSF2 scored 24 [IQR 23-24] and significantly increased from the SSF (23 [IQR 22-24])(P<.001). Further, SSF2 showed an image quality improvement on the peripheral side in the diastole (P=.004) and on the proximal and distal sides in the systole (P<.001 for each).

CLINICAL RELEVANCE/APPLICATION

The new generation motion correction algorithm that corrects the motion for the entire scanning area can improve image quality, compared with previous algorithms, which only collect the area around the pre-segmented coronary arteries.

SDP-CA-11   Image Quality And Diagnosis Performance Of Myocardial Delayed Enhancement CT Improved By The Artificial Intelligence-based Denoising Method

Participants
Hironori Tanaka, RT, Suita, Japan (Presenter) Nothing to Disclose

PURPOSE

To improve the myocardial delayed enhancement (MDE) CT, we have developed an AI-based denoising method using a pair of images by adding three acquisitions and the original single acquisition as a teacher. The purpose is to evaluate the quantitative image quality of this AI denoised image and evaluate its diagnostic performance using reference cardiac MRI.*Methods and Materials We retrospectively reviewed 156 patients who underwent MDE CT (70-80kV, quality reference mAs, 580 mAs/80kVp; ECG triggered at 250ms after R wave) using 192-row dual-source CT from July 2020 to March 2021. We obtained the late phase image 5 minutes after injected the contrast material (median 415 mgI/kg). After developing a model that learned denoising using 100 cases as supervised data, we generated AI denoised images of the remaining fold outed 56 cases as tests. We used the pre-average images as inputs for a residual dense network and the average images as ground-truth images. Image analysis was performed on the original single-shot image, the average additive image, and the AI denoised image, respectively. In the first 40 cases, we placed ROIs in the left ventricular cavity, and septal myocardium and CT values and SD were measured to obtain contrast-to-noise ratio (CNR) of the myocardium and myocardial cavity. Sixteen patients who had cardiac MRI within two months were evaluated segmentally for the presence or absence of MDE; a radiologist evaluated the CTs using the serial confidence method to assess the sensitivity, specificity, and accuracy using the MRI diagnosis a reference, and AUC was measured.*Results The AI denoising method showed a 3.5-fold higher CNR (5.77 [IQR 4.94-6.76] from 1.66 [IQR 1.89-1.42], P<.001) compared to the input single acquisition image. Furthermore, the CNR was significantly higher (P<.001) than that of the averaged image (3.19 [IQR 2.63-3.65]). For the 250 segments diagnosable by MRI (113 segments of positive), the sensitivity, specificity, accuracy, and AUC of AI denoise images were 98.3%, 81.6%, 89.2%, and 0.954, respectively. The accuracy and AUC were significantly improved from 75.2% and 0.827 for the original image (P<.001); and were identical to the averaged image (92.4% and 0.959, respectively).*Conclusions AI-based denoising process learned from average additive images could significantly improve the CNR and diagnostic performance of the MDE CT.*Clinical Relevance/Application The AI denoising method, which learns noise reduction by additive averaging using MDE CT, can achieve high noise reduction and improved diagnostic performance, thus optimizing radiation exposure.

RESULTS

The AI denoising method showed a 3.5-fold higher CNR (5.77 [IQR 4.94-6.76] from 1.66 [IQR 1.89-1.42], P<.001) compared to the input single acquisition image. Furthermore, the CNR was significantly higher (P<.001) than that of the averaged image (3.19 [IQR 2.63-3.65]). For the 250 segments diagnosable by MRI (113 segments of positive), the sensitivity, specificity, accuracy, and AUC of AI denoise images were 98.3%, 81.6%, 89.2%, and 0.954, respectively. The accuracy and AUC were significantly improved from 75.2% and 0.827 for the original image (P<.001); and were identical to the averaged image (92.4% and 0.959, respectively).

CLINICAL RELEVANCE/APPLICATION

The AI denoising method, which learns noise reduction by additive averaging using MDE CT, can achieve high noise reduction and improved diagnostic performance, thus optimizing radiation exposure.

SDP-CA-12   Prognostic Value Of Cardiac Magnetic Resonance Assessed Myocardial Strain Among Ischaemic And Non-ischaemic Dilated Cardiomyopathy Patients

Participants
Hok Shing Tang, Hong Kong, Hong Kong (Presenter) Nothing to Disclose

PURPOSE

Studies comparing the cardiac magnetic resonance (CMR) strain parameters for predicting major adverse cardiovascular events in dilated cardiomyopathy (DCM) patients are lacking. Studies available are generally small with few outcomes and contradictory results. In this study, we aim to acquire a larger number of patients with longer term follow-up and significantly more major adverse cardiovascular events. The purpose is to determine which myocardial strain has the best prognostic value in patients with ischaemic and non-ischaemic DCM using CMR.*Methods and Materials 300 patients with ejection fraction (EF) <50% and ischaemic or non-ischaemic dilated cardiomyopathy underwent CMR at 4 different centres were included in this study. Feature tracking was used to assess the left ventricular (LV) and right ventricular (RV) global radial, global circumferential and global longitudinal strain. Outcomes include heart failure (HF) hospitalisation and all-cause mortality. Cox regression modelling was used to determine the association between myocardial strain and the outcomes.*Results 78.3% were male and mean age is 61.3±13.1. Outcomes occurred in 134 patients (74 all-cause deaths and 97 heart failure hospitalisations) during a median follow-up time period of 1095 days. Kaplan-Meier analysis and log-rank test showed statistical significance for all strain parameters while LV global longitudinal strain (GLS) had the largest area under curve (AUC). LV GLS is significantly better than other strain parameters (p<0.05) except for RV GLS. Multivariable Cox regression modelling with age, myocardial infarction (MI), late gadolinium enhancement (LGE) quantification and one strain parameter showed that all strain parameters were significant independent predictors of outcomes in DCM patients (p<0.01), while the extent of LGE and incidence of MI were not statistically significant. This indicates that myocardial strain is better in predicting the overall outcome.*Conclusions LV GLS was the best CMR parameter for predicting outcome in DCM

patients.*Clinical Relevance/Application LV GLS shows promise in predicting cardiovascular outcomes in DCM patients.

RESULTS

78.3% were male and mean age is 61.3±13.1. Outcomes occurred in 134 patients (74 all-cause deaths and 97 heart failure hospitalisations) during a median follow-up time period of 1095 days. Kaplan-Meier analysis and log-rank test showed statistical significance for all strain parameters while LV global longitudinal strain (GLS) had the largest area under curve (AUC). LV GLS is significantly better than other strain parameters (p<0.05) except for RV GLS. Multivariable Cox regression modelling with age, myocardial infarction (MI), late gadolinium enhancement (LGE) quantification and one strain parameter showed that all strain parameters were significant independent predictors of outcomes in DCM patients (p<0.01), while the extent of LGE and incidence of MI were not statistically significant. This indicates that myocardial strain is better in predicting the overall outcome.

CLINICAL RELEVANCE/APPLICATION

LV GLS shows promise in predicting cardiovascular outcomes in DCM patients.

SDP-CA-13   Feasibility Of Cardiac Imaging Using A Breast Coil For Cardiotoxicity Evaluation In Breast Cancer Patients: From The Carebest Study

Participants
Yoo Jin Hong, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to investigate whether the addition of cardiac imaging to breast MRI is feasible for routine surveillance of cardiotoxicity in patients with breast cancer who underwent chemotherapy.*Methods and Materials A preliminary study was conducted on 13 healthy controls without any history and 30 breast cancer patients who underwent chemotherapy. Cardiac imaging, including cine, pre-T1 map mapping using a cardiac coil in the supine position and cardiac imaging, including cine, pre-, and post-T1 mapping using a breast coil in the prone position was continuously performed in the healthy group. For 30 patients with breast cancer in the post-chemotherapy state, cardiac cine imaging using a breast coil with standard segmented cine imaging was performed, followed by two repeated low-resolution cine scans with a shorter scan time. For T1 mapping values, the reproducibility of native T1 values and the repeatability of native T1 and extracellular volume fraction (ECV) between the images using breast or cardiac coils was assessed with the intraclass correlation coefficient (ICC). For the interscan variability of cine imaging, standardized mean differences between sequences for the left ventricular ejection fraction (LVEF), LV mass, and right ventricular ejection fraction (RVEF) were measured.*Results For T1 mapping values, the mean global native T1 and ECV of the LV myocardium acquired using the breast coil were 1186.9 ± 33.6 ms and 28.6 ± 1.3%, respectively, and the native T1 with the cardiac coil was 1182.4 ± 36.4 ms. The repeatability of the native T1 value between two repeated scans using the breast coil was 0.774, while the reproducibility of the native T1 between images using the breast and cardiac coils was 0.809, which was higher on the septal wall. For functional parameters, the standardized mean difference of LVEF, LV mass, RVEF between standard and low-resolution cine imaging were very low (0.09, 0.01, and 0.02, respectively). Those between two repeated low-resolution cine scan were 0.03, 0.02, and 0.05, respectively). The additional scan time for cardiac imaging was an average of 50 seconds for cine imaging and 10-15 seconds for native T1, post T1 mapping, totaling approximately 3 minutes.*Conclusions Cardiac imaging protocol added to the breast MRI examination is a feasible routine surveillance imaging tool for cardiotoxicity evaluation in patients with breast cancer.*Clinical Relevance/Application The acquired cardiac imaging parameters using a breast coil showed low interscan variability for the functional assessment and high interscan reproducibility for tissue characterization of the left ventricle. This may have an important role in diagnosis and monitoring of cancer therapy related cardiac dysfunction in patents with breast cancer

RESULTS

For T1 mapping values, the mean global native T1 and ECV of the LV myocardium acquired using the breast coil were 1186.9 ± 33.6 ms and 28.6 ± 1.3%, respectively, and the native T1 with the cardiac coil was 1182.4 ± 36.4 ms. The repeatability of the native T1 value between two repeated scans using the breast coil was 0.774, while the reproducibility of the native T1 between images using the breast and cardiac coils was 0.809, which was higher on the septal wall. For functional parameters, the standardized mean difference of LVEF, LV mass, RVEF between standard and low-resolution cine imaging were very low (0.09, 0.01, and 0.02, respectively). Those between two repeated low-resolution cine scan were 0.03, 0.02, and 0.05, respectively). The additional scan time for cardiac imaging was an average of 50 seconds for cine imaging and 10-15 seconds for native T1, post T1 mapping, totaling approximately 3 minutes.

CLINICAL RELEVANCE/APPLICATION

The acquired cardiac imaging parameters using a breast coil showed low interscan variability for the functional assessment and high interscan reproducibility for tissue characterization of the left ventricle. This may have an important role in diagnosis and monitoring of cancer therapy related cardiac dysfunction in patents with breast cancer

SDP-CA-14   The Image Quality Of Sub-millimeter High-spatial-resolution 2D Late Gadolinium Enhancement Images In Cardiac MRI: A Feasibility Study

Participants
Yasutoshi Ohta, MD, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To examine the image quality of high-resolution 2D late gadolinium enhancement (LGE) cardiovascular magnetic resonance (CMR) by head-to-head comparison against conventional normal-resolution 2D LGE*Methods and Materials Sixty patients (53±19 years) referred for CMR examination were included in this study. Both normal resolution (NR, 1.5x1.5x6mm) and high resolution (HR, 0.6x0.6x6mm) 2D-LGE sequences of inversion recovery (IR) and phase-sensitive inversion recovery (PSIR) sequences were performed at 3T. The magnitude image obtained from the PSIR (PSIR-MAG) was also included in the evaluation. The resolution of the total cardiac anatomical structures (TCR), anterior interventricular groove (AIS), lateral wall-epicardial fat border (LWB), inferior interventricular groove (IIS), right ventricle wall, papillary muscle and trabeculae (PT), blurring of RV, septum, lateral wall, and total image quality (TIQ) were evaluated qualitatively in 5-point scale. Edge sharpness measurements, contrast-to-noise ratio (CNR) between scar and remote myocardium were compared among scan protocols. CNR was measured for LGE-positive cases in all sequences. Qualitative scores were evaluated in heart rate groups (low, middle, high, total). These parameters were compared with NR-IR images as reference.*Results In the resolution analysis, TCR, AIS, LWB, and IIS were improved in HR groups compared with NR groups (all, p<0.001). TIQ did not change significantly between the HR and NR groups, except for HR-PSIR in total heart rate groups(all, p<0.01). Both HR and NR images showed degradation of image resolution and blurring in the high heart rate group, but

the degradation was more noticeable in the HR group. LGE was observed in 32 patients, of whom 2 were false negative on HR-IR, both in the high heart rate group. The sharpness showed a significant reduction in the HR groups compared to the NR groups (all, p<0.001). The sharpness of HR-IR, HR-PSIR-MAG, HR-PSIR, NR-IR, NR-PSIR-MAG, and NR-PSIR were 1.43±0.52, 1.44±0.57, 1.42±0.53, 2.14±0.94 2.05±0.98, and 2.02±0.88, respectively.For CNR of LGE, no significant change was observed in IR images and PSIR-MAG compared to the reference (p<0.001).*Conclusions The high-resolution LGE images improved image resolution without loss of image quality or CNR.*Clinical Relevance/Application Since high-resolution LGE protocol improves cardiac structure resolution without compromising CNR, there is a possibility to observe the distribution and morphology of LGE precisely.

RESULTS

In the resolution analysis, TCR, AIS, LWB, and IIS were improved in HR groups compared with NR groups (all, p<0.001). TIQ did not change significantly between the HR and NR groups, except for HR-PSIR in total heart rate groups(all, p<0.01). Both HR and NR images showed degradation of image resolution and blurring in the high heart rate group, but the degradation was more noticeable in the HR group. LGE was observed in 32 patients, of whom 2 were false negative on HR-IR, both in the high heart rate group. The sharpness showed a significant reduction in the HR groups compared to the NR groups (all, p<0.001). The sharpness of HR-IR, HR-PSIR-MAG, HR-PSIR, NR-IR, NR-PSIR-MAG, and NR-PSIR were 1.43±0.52, 1.44±0.57, 1.42±0.53, 2.14±0.94 2.05±0.98, and 2.02±0.88, respectively.For CNR of LGE, no significant change was observed in IR images and PSIR-MAG compared to the reference (p<0.001).

CLINICAL RELEVANCE/APPLICATION

Since high-resolution LGE protocol improves cardiac structure resolution without compromising CNR, there is a possibility to observe the distribution and morphology of LGE precisely.

SDP-CA-15 Ca-scoring When The Subject Is Moving By Using TPVE And Ring ROI Method In X-ray CT

Participants
Katsumi Tsujioka, PhD, Toyota-city, Japan (*Presenter*) Scientist, Canon Medical Systems Corporation

PURPOSE

The Volumetric score has been assessed the progression of coronary artery disease. The score has been calculated by using the threshold and the basic of the isotropic interpolation. The threshold has been used to differentiate noncalcified and calcified artery lesion. We developed a new calcification method using the temporal partial volume effect (TPVE) and the ring region of interest (ROI) method without the threshold.*Methods and Materials To investigate useful for measurement of the calcification volume by using the TPVE and the Ring ROI method. We compared the measurement accuracy of the TPVE and the Ring ROI method with that of the conventional method.*Results When the subject moved, in the conventional method, the volume measurement of hydroxyapatite was not accurate. However, in the new method, even if the CT image had a motion artifact, we were able to measure the volume of hydroxyapatite with high acuuracy.*Conclusions When the subject moved, temporal partial volume effect occurs. However, the conventional method could not taking into account temporal partial volume effect. The new method was able to measure the volume of hydroxyapatite with high acuuracy by taking into account temporal partial volume effect.*Clinical Relevance/Application The motion arch fact is an important problem to reduce measurement accuracy in calcium scoring. TPVE and the ring ROI method that we developed are techniques to solve this problem. Our new method is effective for volume measurement of the moving objects.

RESULTS

When the subject moved, in the conventional method, the volume measurement of hydroxyapatite was not accurate. However, in the new method, even if the CT image had a motion artifact, we were able to measure the volume of hydroxyapatite with high acuuracy.

CLINICAL RELEVANCE/APPLICATION

The motion arch fact is an important problem to reduce measurement accuracy in calcium scoring. TPVE and the ring ROI method that we developed are techniques to solve this problem. Our new method is effective for volume measurement of the moving objects.

SDP-CA-16 Sex-specific Differences In Disease Progression And Treatment Response In Fabry Disease Assessed By Multiparametric Cardiac MRI

Participants
Victor Chan, FRCR, MBBS, Toronto, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

Fabry disease is an X-linked storage disorder leading to glycosphingolipid accumulation. The purpose of this study was to assess longitudinal changes in myocardial glycosphingolipid accumulation, hypertrophy and fibrosis in relation to sex and treatment.*Methods and Materials All gene-positive Fabry patients at our center with two sequential cardiac MRIs with native T1 mapping (MOLLI) and late gadolinium enhancement (LGE) imaging were included. For analysis across different scanners (1.5T and 3T), T1 values were converted to a z-score using scanner-specific local reference values (patient value - reference mean)/(reference SD), indicating how many SD each patient's T1 values are above/below the reference mean. Low T1 was defined as a z-score <-2. Interval change in MRI biomarkers was evaluated with respect to sex and enzyme replacement therapy (ERT).*Results 47 patients were included (44±16 years, 66% female, 30% on ERT) with mean inter-scan interval of 2.3±0.7 years. At baseline, 21% had left ventricular hypertrophy (LVH), 50% had LGE reflecting fibrosis, and 23% had low T1 reflecting glycosphingolipid accumulation. Two patients (4%) developed LGE at follow-up (both untreated, one male and one female). Increase in indexed left ventricular mass between baseline and follow-up was significantly higher in men than women (9±18 g/m2 vs. 1±8 g/m2, p=0.032) and did not differ by treatment group (p=0.65). Treatment naïve men and women both had a significant decrease in T1 over follow-up (z-score change -0.9±0.9, p=0.012 and -0.9+0.7, p<0.001, respectively) in keeping with progressive glycosphingolipid accumulation. However, treatment response differed by sex. Women on ERT had a significant increase in T1 (z-score change 0.5±0.4, p=0.011) while T1 did not change significantly in treated men (0.02±0.7, p=0.29). Study conclusions remained unchanged when restricted to patients who had undergone both MRIs on the same 3T scanner (n=28).*Conclusions There are sex-specific differences in myocardial response in Fabry disease. Men had a greater rate of LVH progression than women. ERT improves glycosphingolipid storage in women, however the response is less pronounced in men.*Clinical Relevance/Application Judicious use of serial cardiac MRI in Fabry patients can provide valuable information. Further research is needed to evaluate the prognostic significance of sex-specific differences in disease progression and treatment response.

RESULTS

47 patients were included (44±16 years, 66% female, 30% on ERT) with mean inter-scan interval of 2.3±0.7 years. At baseline, 21% had left ventricular hypertrophy (LVH), 50% had LGE reflecting fibrosis, and 23% had low T1 reflecting glycosphingolipid accumulation. Two patients (4%) developed LGE at follow-up (both untreated, one male and one female). Increase in indexed left ventricular mass between baseline and follow-up was significantly higher in men than women (9±18 g/m2 vs. 1±8 g/m2, p=0.032) and did not differ by treatment group (p=0.65). Treatment naïve men and women both had a significant decrease in T1 over follow-up (z-score change -0.9±0.9, p=0.012 and -0.9+0.7, p<0.001, respectively) in keeping with progressive glycosphingolipid accumulation. However, treatment response differed by sex. Women on ERT had a significant increase in T1 (z-score change 0.5±0.4, p=0.011) while T1 did not change significantly in treated men (0.02±0.7, p=0.29). Study conclusions remained unchanged when restricted to patients who had undergone both MRIs on the same 3T scanner (n=28).

CLINICAL RELEVANCE/APPLICATION

Judicious use of serial cardiac MRI in Fabry patients can provide valuable information. Further research is needed to evaluate the prognostic significance of sex-specific differences in disease progression and treatment response.

SDP-CA-17   Extracellular Volume Fraction As A Quantitative Disease-biomarker In Cardiac Amyloidosis: Influence Of Non-specific Myocardial Edema

Participants
Seitaro Oda, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Amyloid fibril deposition and non-specific myocardial edema coexist in the myocardium of cardiac amyloidosis (CA). This non-specific myocardial edema can affect the quantitative values of various disease-biomarkers of CA including extracellular volume fraction (ECV). This study aimed to assess the influence of non-specific myocardial edema on ECV as a quantitative disease-biomarker in CA.*Methods and Materials Seventy-four patients with wild-type transthyretin CA who underwent cardiovascular magnetic resonance (CMR), 99mTc-labeled pyrophosphate (99mTc-PYP) scintigraphy, and echocardiography were evaluated. We assessed the quantitative disease-biomarkers, e.g. global longitudinal strain (GLS) by echocardiography, native T1, ECV, and T2 value by CMR, heart to contralateral ratio (H/CL) by 99mTc-PYP, and high-sensitive cardiac troponin T (hs-cTnT). Myocardial T2 value = 50 ms was defined as myocardial edema. The ECV was compared with other biomarkers in CA patients with/without myocardial edema.*Results Myocardial T2 values showed a moderate correlation with native T1 (r=0.41), and a weak correlation with ECV and hs-cTnT (r=0.30-0.32). In patients with myocardial edema, ECV showed a moderate correlation with native T1, hs-cTnT and H/CL (r=0.45-0.55), and a weak correlation with T2 value (r=0.22). In patients without myocardial edema, ECV showed a strong correlation with GLS and hs-cTnT (r=0.73-0.82), and a moderate correlation with H/CL (r=0.50).*Conclusions Myocardial edema affected the ECV value in CA. When myocardial edema was excluded, ECV showed a significant correlation with various quantitative disease-biomarker and can be a disease-monitoring marker in patients with CA.*Clinical Relevance/Application The presence or absence of myocardial edema should be considered when conducting disease-monitoring with myocardial ECV in patients with CA.

RESULTS

Myocardial T2 values showed a moderate correlation with native T1 (r=0.41), and a weak correlation with ECV and hs-cTnT (r=0.30-0.32). In patients with myocardial edema, ECV showed a moderate correlation with native T1, hs-cTnT and H/CL (r=0.45-0.55), and a weak correlation with T2 value (r=0.22). In patients without myocardial edema, ECV showed a strong correlation with GLS and hs-cTnT (r=0.73-0.82), and a moderate correlation with H/CL (r=0.50).

CLINICAL RELEVANCE/APPLICATION

The presence or absence of myocardial edema should be considered when conducting disease-monitoring with myocardial ECV in patients with CA.

SDP-CA-18   Multiparametric Cardiac MRI Differentiation Of Antimalarial Induced Cardiomyopathy And Myocarditis In Patients With Systemic Lupus Erythematosus

Participants
Kate Hanneman, MD, FRCPC, Toronto, Ontario (*Presenter*) Speaker, sanofi-aventis Group;Speaker, Amicus Therapeutics, Inc

PURPOSE

Patients with systemic lupus erythematosus (SLE) are at risk of myocarditis and antimalarial (AM)-induced cardiomyopathy (AMIC). Differentiating between these disease processes can very challenging due to overlapping clinical features. The purpose of this study was to evaluate cardiac MRI findings in patients with SLE.*Methods and Materials Patients with SLE who had undergone cardiac MRI with native T1/T2 mapping (MOLLI/FLASH) and late gadolinium enhancement (LGE) imaging were compared with 30 healthy controls (39±15 years, 60% female). T1/T2 values were converted to a z-score using scanner-specific local reference values (patient value - reference mean)/(reference SD), indicating how many SD each patient's T1/T2 values are above/below the reference mean. Patients were classified into three groups blinded to MRI findings: AMIC, myocarditis, and no AMIC or myocarditis (other SLE). One-way ANOVA was used to compare findings between groups with Bonferroni post-hoc analysis.*Results 45 SLE patients were included (47±17 years, 80% female, 84% treated with AMs): 8 (11%) with AMIC and 7 (9%) with myocarditis. T1 and T2 were significantly higher in myocarditis compared to AMIC (z-score 3.7±1.6 vs. 1.2±1.3, p<0.001 and 4.0±2.0 vs. 1.3±0.8, p<0.001, respectively), other SLE (0.4±0.9, p<0.001 and 0.2±1.0, p<0.001, respectively), and controls (0±0.6, p<0.001 and 0±1.0, p<0.001, respectively). LGE presence and extent did not differ significantly between SLE groups (p>0.05 for both). However, in myocarditis the pattern of LGE was subepicardial or mid-wall often at the interventricular septum, while in AMIC LGE was most frequently mid-wall located at the basal inferolateral segment. Native T1 correlated negatively with AM treatment duration in other SLE (r=-0.43, p=0.012). However, there was a strong positive correlation between T1 and AM treatment duration in AMIC (r=0.95, p=0.001). AM treatment duration did not correlate significantly with T1 in myocarditis or with T2 in any group.*Conclusions Myocardial native T1 and T2 are significantly higher in patients wtih myocarditis compared to AMIC. Native T1 decreases with AM treatment duration in SLE patients without AMIC or myocarditis. This raises the possibility of glycosphingolipid accumulation concordant with the hypothesis that AMIC is caused by inhibition of myocyte lysosomal activity. Increasing T1 with longer AM treatment in AMIC could reflect progressive myocardial fibrosis.*Clinical Relevance/Application Multiparametric cardiac MRI differentiates between AMIC and myocarditis in patients with SLE. Further longitudinal evaluation is needed to establish whether T1 mapping is useful in detecting pre-clinical AMIC.

RESULTS

45 SLE patients were included (47±17 years, 80% female, 84% treated with AMs): 8 (11%) with AMIC and 7 (9%) with myocarditis. T1 and T2 were significantly higher in myocarditis compared to AMIC (z-score 3.7±1.6 vs. 1.2±1.3, p<0.001 and 4.0±2.0 vs. 1.3±0.8, p<0.001, respectively), other SLE (0.4±0.9, p<0.001 and 0.2±1.0, p<0.001, respectively), and controls (0±0.6, p<0.001 and 0±1.0, p<0.001, respectively). LGE presence and extent did not differ significantly between SLE groups (p>0.05 for both). However, in myocarditis the pattern of LGE was subepicardial or mid-wall often at the interventricular septum, while in AMIC LGE was most frequently mid-wall located at the basal inferolateral segment. Native T1 correlated negatively with AM treatment duration in other SLE (r=-0.43, p=0.012). However, there was a strong positive correlation between T1 and AM treatment duration in AMIC (r=0.95, p=0.001). AM treatment duration did not correlate significantly with T1 in myocarditis or with T2 in any group.

CLINICAL RELEVANCE/APPLICATION

Multiparametric cardiac MRI differentiates between AMIC and myocarditis in patients with SLE. Further longitudinal evaluation is needed to establish whether T1 mapping is useful in detecting pre-clinical AMIC.

SDP-CA-20   Myocardial Extracellular Volume Fraction Quantification In Patients With Heart Failure Using Late Iodine Enhancement From Dual-energy Computed Tomography:Comparison With MRI T1 Mapping

Participants
Jie Deng, Kunming, China (*Presenter*) Nothing to Disclose

PURPOSE

To validate the quantification of myocardial extracellular volume fraction (ECV) by using late iodine enhancement (LIE) derived from dual-energy computed tomography (DECT), with the ECV based on cardiac MR (CMR) as the reference standard.*Methods and Materials 22 patients with suspected heart failure (49±11years, 15 men) underwent both DECT and CMR . 9 subjects (56±9 years, 4 men), who underwent DECT for chest pain and were found to have no coronary abnormalities with negative electrocardiogram and myocardial enzyme testing, were serve as a control group. CCTA was performed by intravenous injection of 0.9ml/kg of iopamidol to assess coronary arteries. LIE was acquired 7 minutes after iodine administration. Iodine images were reconstructed at 8mm slice thickness and 6 mm slice gap to the short-axis plane of the left ventricular (LV) myocardium and then the basal, mid and apical slices were extracted. CMR T1maps were obtained in short-axis consistent with the LIE images before and 10 minutes after intravenous administration of 0.1mmol/kg of Gadobutrol by using the modified Look-Locker inversion recovery sequence. ROIs were manually drawn on myocardium using the AHA's 16-segment model of the LV and the LV blood pool (Fig.A). CT-ECV and CMR-ECV were calculated, respectively (Fig.B, C, D, E, F). Correlation between groups were evaluated with Pearson correlation analysis. Differences between groups were determined with test. The bias and the 95% limits of agreement was assessed with Bland-Altman analysis.*Results Among the 22 patients, 17 were diagnosed as nonischemic heart failure (NIHF) according to the results of CCTA and CMR, were enrolled in this study. The mean radiation dose of the DECT in NIHF and HCs has no statistic difference (10.35 ± 1.67 mSv vs 10.78 ± 3.01 mSv, P=0.699). In patients with NIHF, CT-ECV correlated with CMR-ECV (r= 0.856, P<0.001) and there was no significant difference between the mean values of CT-ECV and CMR-ECV (33.57 ± 2.96% vs 33.16 ± 3.17% , P=0.322). Bland-Altman analysis showed CT-ECV was comparable to CMR-ECV with small bias (95%CI: -11.2% to 8.6%, bias = -1.3%). The CT-ECV in patients with NIHF was significantly higher than that in HCs (33.57 ± 2.96% vs 27.06 ± 2.59%, P<0.001).*Conclusions CT-ECV derived from LIE can serve as an excellent alternative to CMR-ECV in noninvasively quantifying diffused myocardial fibrosis (DMF). Furthermore, CT-ECV have the potential to be used for risk stratification in patients with heart failure.*Clinical Relevance/Application CCTA combined with LIE has relatively low radiation and is highly useful not only in assessments of coronary arteries and cardiac structure, but also meriting in quantifying DMF. in one stop examination, as CT-ECV derived from LIE can serve as an excellent alternative to CMR-ECV.

RESULTS

Among the 22 patients, 17 were diagnosed as nonischemic heart failure (NIHF) according to the results of CCTA and CMR, were enrolled in this study. The mean radiation dose of the DECT in NIHF and HCs has no statistic difference (10.35 ± 1.67 mSv vs 10.78 ± 3.01 mSv, P=0.699). In patients with NIHF, CT-ECV correlated with CMR-ECV (r= 0.856, P<0.001) and there was no significant difference between the mean values of CT-ECV and CMR-ECV (33.57 ± 2.96% vs 33.16 ± 3.17% , P=0.322). Bland-Altman analysis showed CT-ECV was comparable to CMR-ECV with small bias (95%CI: -11.2% to 8.6%, bias = -1.3%). The CT-ECV in patients with NIHF was significantly higher than that in HCs (33.57 ± 2.96% vs 27.06 ± 2.59%, P<0.001).

CLINICAL RELEVANCE/APPLICATION

CCTA combined with LIE has relatively low radiation and is highly useful not only in assessments of coronary arteries and cardiac structure, but also meriting in quantifying DMF. in one stop examination, as CT-ECV derived from LIE can serve as an excellent alternative to CMR-ECV.

SDP-CA-21   Dual Energy Cardiac Computed Tomography For Evaluating Late Iodine Enhancement: Usefulness Of Electron Density Map And Mixed Image

Participants
Takeshi Nakaura, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Previous studies have demonstrated that low keV images or iodine maps using dual energy computed tomography (CT) are more suitable than single energy CT to evaluate late iodine enhancement (LIE) in cardiac CT. However, no previous report has evaluated the usefulness of other quantitative maps and mixed images to evaluate LIE in cardiac CT.The purpose of this study was to establish optimal virtual monochromatic energy images, optimal quantitative maps, and mixed images to depict LIE in dual energy cardiac CT.*Methods and Materials We retrospectively enrolled 15 patients with obsolete myocardial infarction (OMI) who underwent dual energy cardiac CT. We generated virtual monochromatic energy image (VMI) sets at 10-keV intervals from 40 to 200 keV and quantitative maps (iodine concentration, effective Z, and electric density). We calculated the contrast-to-noise ratio (CNR) between the OMI area and normal myocardium as well as the OMI area and left intraventricular space. We selected the VMI with the highest average CNR as the optimal keV image. We compared CT values of the optimal keV image and quantitative values of iodine concentration, effective Z, and electric density of the OMI area, normal myocardium, and left intraventricular space. Two radiologists evaluated overall image quality in mixed images of optimal keV images and quantitative maps.*Results Average CNR increased as energy level decreased; we defined 40-keV images as the optimized energy level. The CT value of 40 keV and all quantitative values were significantly higher in the OMI area than in the normal myocardium (p < 0.01). The electron density of the OMI was significantly higher in the OMI area than in the normal myocardium (p < 0.01); however, no significant differences were observed in CT value, iodine concentration, or effective Z (p > 0.05). In qualitative analysis of mixed images, the overall image

quality score of mixed images with the electron density map was significantly higher than those of other mixed images.*Conclusions Compared with low keV images or the iodine map, the electron density map provides better contrast between the LIE area and left intraventricular space in cardiac dual energy CT. A mixed image of low keV image and electron density map offers better image quality than other mixed images.*Clinical Relevance/Application The mixed image of low keV image and electron density map has the capability to offer additional information for LIE analysis in cardiac dual energy CT.

RESULTS

Average CNR increased as energy level decreased; we defined 40-keV images as the optimized energy level. The CT value of 40 keV and all quantitative values were significantly higher in the OMI area than in the normal myocardium (p < 0.01). The electron density of the OMI was significantly higher in the OMI area than in the normal myocardium (p < 0.01); however, no significant differences were observed in CT value, iodine concentration, or effective Z (p > 0.05). In qualitative analysis of mixed images, the overall image quality score of mixed images with the electron density map was significantly higher than those of other mixed images.

CLINICAL RELEVANCE/APPLICATION

The mixed image of low keV image and electron density map has the capability to offer additional information for LIE analysis in cardiac dual energy CT.

SDP-CA-22   A Comparative Study On The Detection Efficiency For Different Types Of Coronary Plaque Based On Deep Learning (dl) Algorithm

Participants
Yanhong Zhao, MMed,MMed, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore differences in the detection efficiency using deep learning (DL) based artificial intelligence (AI) diagnostic system for calcified plaque, noncalcified plaque and mixed plaques.*Methods and Materials In this retrospective study, a total of 50 patients with acute chest pain underwent coronary CT angiography using a 256-detector row CT (Revolution CT, GE healthcare) were collected. CCTA AI-assisted Diagnostic System (CoronaryDoc, Shukun Technology) was used to detect the presence of coronary plaque. The reference standard for the presence of coronary plaque was finally annotated by two radiologists with more than 15 years of experience based on the review of AI results. Coronary plaques were classified into three groups, calcified plaque, noncalcified plaque and mixed plaques. The detection number of different types of coronary plaque by the system was recorded and the sensitivity of different types of fractures compared using chi-square test.*Results A total of 330 plaque including 149 calcified plaque, 109 noncalcified plaque and 72 mixed plaque were established as the gold standard. Based on the results obtained using AI system, we detected a total of coronary plaque,140 were marked as calcified plaque, along with 82 noncalcified plaque and 67 mixed plaques. Therefore, the sensitivity of AI for coronary plaque detection was 87.58%. The detection rate for calcified plaque, noncalcified plaque and mixed plaques was 93.96%, 75.23% and 93.06%, respectively. There was a statistically significant differences in sensitivity among three types of coronary plaque detected by AI (P=0.000). Particularly, the diagnostic rate in the detection of calcified plaque and mixed plaques was found to be significantly greater than that of noncalcified plaque.*Conclusions The diagnostic efficiency using AI in the detection of coronary plaque was found to be correlated with the plaque type. Particularly, calcified plaque and mixed plaques was found to be best identified by the AI system compared to noncalcified plaque.*Clinical Relevance/Application AI system demonstrated different performances in the detection of different types of plaque, and the effectiveness of calcified plaque and mixed plaques examination is found to be better than noncalcified plaque.

RESULTS

A total of 330 plaque including 149 calcified plaque, 109 noncalcified plaque and 72 mixed plaque were established as the gold standard. Based on the results obtained using AI system, we detected a total of coronary plaque,140 were marked as calcified plaque, along with 82 noncalcified plaque and 67 mixed plaques. Therefore, the sensitivity of AI for coronary plaque detection was 87.58%. The detection rate for calcified plaque, noncalcified plaque and mixed plaques was 93.96%, 75.23% and 93.06%, respectively. There was a statistically significant differences in sensitivity among three types of coronary plaque detected by AI (P=0.000). Particularly, the diagnostic rate in the detection of calcified plaque and mixed plaques was found to be significantly greater than that of noncalcified plaque.

CLINICAL RELEVANCE/APPLICATION

AI system demonstrated different performances in the detection of different types of plaque, and the effectiveness of calcified plaque and mixed plaques examination is found to be better than noncalcified plaque.

SDP-CA-23   Improvement Of Spatial Resolution By Using Super-resolution Deep Learning Reconstruction At Coronary CT Angiography

Participants
Fuminari Tatsugami, Hiroshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Coronary CT angiography (CTA) is a robust noninvasive imaging modality that can yield an accurate diagnosis and exclude coronary artery disease (CAD). At coronary CTA, higher spatial resolution is desirable for the precise assessment of CAD. Recently developed deep learning-based reconstruction (DLR) reduces image noise and improves the image quality of CT scans, but it does not improve spatial resolution. We developed a super-resolution DLR (SR-DLR) for conventional CT images, that convert conventional resolution-to high-resolution CT images. The purpose of this study was to compare the image noise and spatial resolution on SR-DLR images and conventional hybrid iterative reconstruction (IR) images.*Methods and Materials The SR-DLR was implemented using super-resolution deep convolutional neural network (SR-DCNN). Firstly, we trained the SR-DCNN with pairs of high-resolution- and conventional resolution images. The high-resolution images were acquired using an actual ultra-high-resolution CT scanner (Aquilion Precision, Canon), and reconstructed with advanced reconstruction technique. The conventional resolution images were generated using a sinogram-based normal resolution (NR) simulation technique. The clinical study included 10 patients who underwent coronary CTA on a 320-slice CT scanner. The images were reconstructed with hybrid IR and with SR-DLR. We measured the image noise in the ascending aorta on the two reconstruction images. The modulation transfer function (MTF) was the index for spatial resolution; it was measured on edge of the left ventricle and septum using the circular edge method. Two radiologists visually evaluated the image quality based on the noise-related blurring, margin sharpness, and blooming artifacts using a 4-point scale (1 = poor, 4 = excellent).*Results The mean image noise on the SR-DLR images was significantly lower than hybrid IR images (17.5±1.5

vs. 23.1±4.8 [HU]; p < 0.05), while there was no change in the CT attenuation of the coronary arteries. Based on the 10% MTF, spatial resolution was higher on SR-DLR image than hybrid IR image (0.94±0.14 vs. 0.58±0.04 [cy/mm]; p < 0.01). The mean image quality score was also improved with SR-DLR images (3.8 vs. 2.6; p < 0.05).*Conclusions The use of SR-DLR reduces image noise and improves spatial resolution at cardiac CT compared to conventional hybrid IR.*Clinical Relevance/Application A super-resolution deep learning reconstruction for conventional coronary CT images reduces image noise and improves spatial resolution.

RESULTS

The mean image noise on the SR-DLR images was significantly lower than hybrid IR images (17.5±1.5 vs. 23.1±4.8 [HU]; p < 0.05), while there was no change in the CT attenuation of the coronary arteries. Based on the 10% MTF, spatial resolution was higher on SR-DLR image than hybrid IR image (0.94±0.14 vs. 0.58±0.04 [cy/mm]; p < 0.01). The mean image quality score was also improved with SR-DLR images (3.8 vs. 2.6; p < 0.05).

CLINICAL RELEVANCE/APPLICATION

A super-resolution deep learning reconstruction for conventional coronary CT images reduces image noise and improves spatial resolution.

SDP-CA-24   Photon Counting CT Based Virtual Non-contrast Reconstructions: Feasibility Of Coronary Artery Calcium Scoring On CTA Series.

Participants
Katharina Rippel, Augsburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the feasibility of using virtual non-contrast-enhanced (VNC) series derived from coronary CT-angiography scans on a photon counting CT for coronary artery calcium quantification.*Methods and Materials Here, we present the interim analysis of an ongoing study which will include 100 patients. This study was institutional review board approved and all patients provided written informed consent. All patients underwent noncontrast CT of the heart followed by CT angiography of the heart, aorta and iliac arteries on a novel photon counting dual-source CT (NAEOTOM Alpha, Siemens Healthineers, Erlangen, Germany) prior to transcatheter aortic valve replacement (TAVR). Two readers evaluated noise and efficiency of virtual iodine removal for different VNC reconstruction algorithms. Furthermore, they independently quantified calcium on VNC images and true non contrast-enhanced (TNC) calcium score series. Calcium scores and volumes were correlated both on a per patient and on a per vessel level.*Results Correlation between VNC and TNC series regarding calcium volumes as well as calcium scores was excellent on a per-patient level (r = 0.91 and r = 0.90, p<0.05). On a per-vessel level, correlation of calcium volumes and calcium scores between VNC and TNC series was excellent for the left circumflex artery (r = 0,97, r = 0,99) and left anterior descending artery (r = 0,94, r = 0,95). Very good correlation was observed for the left main coronary artery (r = 0,85, r = 0,83) and the right coronary artery (r = 0,84, r = 0,81).*Conclusions PCD-based VNC series provide excellent correlations of coronary artery calcium scores compared with TNC series and are highly likely interchangeable. This might replace dedicated TNC calcium scoring studies in the immediate future.*Clinical Relevance/Application Radiation exposure from cardiac CT remains a concern - particularly with the expected rapid rise in cardiac CT scans worldwide. Coronary artery calcium scoring using PCD-based VNC series will likely be able to replace dedicated TNC studies thereby reducing total radiation dose.

RESULTS

Correlation between VNC and TNC series regarding calcium volumes as well as calcium scores was excellent on a per-patient level (r = 0.91 and r = 0.90, p<0.05). On a per-vessel level, correlation of calcium volumes and calcium scores between VNC and TNC series was excellent for the left circumflex artery (r = 0,97, r = 0,99) and left anterior descending artery (r = 0,94, r = 0,95). Very good correlation was observed for the left main coronary artery (r = 0,85, r = 0,83) and the right coronary artery (r = 0,84, r = 0,81).

CLINICAL RELEVANCE/APPLICATION

Radiation exposure from cardiac CT remains a concern - particularly with the expected rapid rise in cardiac CT scans worldwide. Coronary artery calcium scoring using PCD-based VNC series will likely be able to replace dedicated TNC studies thereby reducing total radiation dose.

SDP-CA-3   Effect Of Low Tube Voltage On Image Quality And Radiationdose Of Cta:: A Phantom Study

Participants
Qi Hao, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the effect of image quality and radiation dose of CTA on spectral CT at low tube voltage state.*Methods and Materials A polypropylene cylindrical phantom (QSP Phantom) with nine tubes containing varying concentrations of iodine (20 mgl/ml) was scanned with both Conventional CT .Group A,B and C were divided according to different CT tube voltage , the group A ,B and C were set to 120kV,100kV and 80kV,respectively. Group A,B and C with conventional spiral CT scan mode by spectral CT scanner was defined as follows: tube current was set to 480mA; the detector width was 8cm;pitch value in helical mode was 0.992:1; the noise index (NI) was set to 10, the slice thickness and slice increment were 1.25mm.The CDTI ,CT values and SD values the three groups were recorded separately, and the signal-to-noise ratio (SNR) of within each group was calculated. All statistical tests were performed using SPSS version 26.0 (SPSS, Chicago, IL), the independent t-test was used to compare the difference of CDTI and SNR between different tube voltage. For all tests, the level of statistical significance was set at P<0.05.*Results The radiation doses of energy spectrum CT were 6.2 mGy, 12.15 mGy, and 19.58 mGy in different groups ranging from 80 kVp to140 kVp, respectively.The differences in radiation doses between different groups were statistically significant (P < 0.05), and the differences in SD values (F = 350.328,P = 0.000) and SNR (F = 7.271,P = 0.000) for each group were statistically significant (P < 0.05). The SD values were 19.72±1.535 and 13.069±0.647, and the CNR values were 52.314±3.256 and 58.614±3.443 for the low-tube voltage 80 kVp and 100 kVp groups, respectively, and the SD and CNR values were 9.878±0.733 and 60.344±3.259 respectively for the conventional voltage 120 kVp group.The differences in radiation dose and SNR between the low-tube voltage 80 kV group and the conventional tube voltage 120 kV group were statistically significant (P < 0.05), and the radiation dose in the low-voltage 80kV group was 68.34% lower than that in the conventional 120kV group.The differences in radiation dose between the two groups were statistically significant (P < 0.05), and the radiation dose in the low tube voltage 100kV group is reduced by 37.95% compared to the conventional tube voltage 120kV group., but there was no significant difference in the noise ratio between the two groups (P > 0.05).*Conclusions In conventional spiral CT , low-tube voltage 100 kV scanning can obtain the same

image quality (CNR) as conventional 120 kV scanning, and its radiation dose is lower and the SD is higher significantly.*Clinical Relevance/Application In CT angiography, the application of the spiral CT low tube voltage 100kV scanning can replace the conventional tube voltage 120kv image.

RESULTS

The radiation doses of energy spectrum CT were 6.2 mGy, 12.15 mGy, and 19.58 mGy in different groups ranging from 80 kVp to 140 kVp, respectively.The differences in radiation doses between different groups were statistically significant (P < 0.05), and the differences in SD values (F = 350.328,P = 0.000) and SNR (F = 7.271,P = 0.000) for each group were statistically significant (P < 0.05). The SD values were 19.72±1.535 and 13.069±0.647, and the CNR values were 52.314±3.256 and 58.614±3.443 for the low-tube voltage 80 kVp and 100 kVp groups, respectively, and the SD and CNR values were 9.878±0.733 and 60.344±3.259 respectively for the conventional voltage 120 kVp group.The differences in radiation dose and SNR between the low-tube voltage 80 kV group and the conventional tube voltage 120 kV group were statistically significant (P < 0.05), and the radiation dose in the low-voltage 80kV group was 68.34% lower than that in the conventional 120kV group.The differences in radiation dose between the two groups were statistically significant (P < 0.05), and the radiation dose in the low tube voltage 100kV group is reduced by 37.95% compared to the conventional tube voltage 120kV group., but there was no significant difference in the noise ratio between the two groups (P > 0.05).

CLINICAL RELEVANCE/APPLICATION

In CT angiography, the application of the spiral CT low tube voltage 100kV scanning can replace the conventional tube voltage 120kv image.

SDP-CA-4   The Value Of Coronary Computed Tomography Angiography Derived Plaque Features In Diagnosis Of Vulnerable Plaques Defined By Optical Coherence Tomography

Participants
Liu Xiaojing, Kaifeng, China (*Presenter*) Nothing to Disclose

PURPOSE

Identification of vulnerable plaque is essential to pre-estimate the risk of cardiovascular disease (CVD) and stratify major adverse cardiac events (MACEs) risks. This study aims to evaluating the diagnosis ability of coronary computed tomography angiography (CCTA) derived qualitative and quantitative plaque features on detecting optical coherence tomography (OCT) defined vulnerable plaques.*Methods and Materials 31 Patients who underwent both CCTA and OCT were retrospectively included in this study. Results of OCT and CCTA were blindly analysis on a segment-to-segment comparison. The qualitative and quantitative plaque parameters derived by CCTA were recorded. Univariate analysis and multivariate logistic regression analysis were performed to reveal the independent predictors. The diagnostic efficacy of quantitative parameters was evaluated by receiver operating characteristic (ROC) curve and area under curve (AUC).*Results 76 plaques in 31 patients were included for analysis, of which 19.7% (15/76 plaques, 10 patients) was vulnerable plaques. Low-density plaques, punctate calcification, positive remodeling, number of high-risk plaque signs, non-calcified fraction and lipid fraction were shown significant differences between vulnerable and non-vulnerable plaques (p < 0.05). The lipid fraction (odd ratio (OR) = 1.148, 95% CI 0.993 ~ 1.327), punctate calcification (OR = 4.521, 95% CI 1.022 ~ 20.008) and low-density plaques (OR = 8.012, 95% CI 2.024 ~ 31.718) were independent predictors of vulnerable plaques. Compared with qualitative and quantitative models, the mixed model integrating all significant CCTA derived plaque characteristics own the highest AUC and accuracy (mixed model AUC = 0.869, 95% CI: 0.808 to 0.979; qualitative model AUC = 0.798, 95% CI: 0.654 to 0.941; quantitative Model AUC = 0.638, 95% CI: 0.528~0.866).*Conclusions The CCTA derived plaque characteristics were able to detect the OCT-defined vulnerable plaques and the diagnosis performance was enhanced by integrating significant qualitative and quantitative plaque parameters.*Clinical Relevance/Application CCTA derived plaque parameters show great potentials as a non-invasive biomarker for early diagnosis and treatment of coronary vulnerable plaques.

RESULTS

76 plaques in 31 patients were included for analysis, of which 19.7% (15/76 plaques, 10 patients) was vulnerable plaques. Low-density plaques, punctate calcification, positive remodeling, number of high-risk plaque signs, non-calcified fraction and lipid fraction were shown significant differences between vulnerable and non-vulnerable plaques (p < 0.05). The lipid fraction (odd ratio (OR) = 1.148, 95% CI 0.993 ~ 1.327), punctate calcification (OR = 4.521, 95% CI 1.022 ~ 20.008) and low-density plaques (OR = 8.012, 95% CI 2.024 ~ 31.718) were independent predictors of vulnerable plaques. Compared with qualitative and quantitative models, the mixed model integrating all significant CCTA derived plaque characteristics own the highest AUC and accuracy (mixed model AUC = 0.869, 95% CI: 0.808 to 0.979; qualitative model AUC = 0.798, 95% CI: 0.654 to 0.941; quantitative Model AUC = 0.638, 95% CI: 0.528~0.866).

CLINICAL RELEVANCE/APPLICATION

CCTA derived plaque parameters show great potentials as a non-invasive biomarker for early diagnosis and treatment of coronary vulnerable plaques.

SDP-CA-5   Proof-of-principle Demonstration Of Left Atrial Hemodynamics In Patients With Atrial Fibrillation Before And After Left Atrial Appendage Occlusion: A Study With 3D-printed Model Using 4d Flow MRI

Participants
Min Jae Cha, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Percutaneous left atrial appendage occlusion (LAAO) is currently performed to reduce thromboembolic event in patients with atrial fibrillation (AF). However, little is known about the actual flow dynamic changes within the left atrium (LA) before and after LAAO. The aim of this study is to visualize LA hemodynamic changes after LAAO by use of 4D flow magnetic resonance imaging (MRI) using a 3D-printed phantom model.*Methods and Materials This proof-of-concept study was approved by institutional review board, and performed based on the CT images of 86-year-old male patient with chronic AF and history of cerebral infarction and subdural hemorrhage. Three life-sized LA phantoms, including pre-occluded, correctly-occluded, and mal-occluded models, were constructed based on CT images of pre-LAAO ECG-gated cardiac CT and 3D-pinted models (Fig.1). Pulsatile pulmonary venous flow obtained from transesophageal echocardiography were entered through four inlets (pulmonary veins) from output-adjustable pump. 4D flow MRI of three phantom models with flow simulation were acquired using 3T scanner (Fig.2) and data were extracted and analyzed using a MATLAB-based software.*Results 4D flow MRI visualized the internal flow with virtual particles tracing during the cardiac cycle. The particles inside the appendage of the pre-occluded model remained almost in place despite pulsatile flow, which may

lead to thrombus formation. We defined an area that satisfies |V | < 2 cm/s as a "stagnant zone", and cross-sectional view demonstrated that the stagnant zone is formed in the 'unintended space' near the LAA ostium of the mal-occluded model for a longer time than the correctly-occluded model (Fig. 3).*Conclusions 4D flow MRI directly visualized different flow dynamics of LA before and after LAAO in the phantom study. We demonstrated sparse flow within the LAA before LAAO and maloccluded LAA could adversely lead to thrombus formation adjacent to the LAA ostium.*Clinical Relevance/Application 4D flow MRI visualize little flow within LAA in patient with AF, which may result in thrombus formation. Mal-occluded LAA can also lead to adverse thrombus formation.

RESULTS

4D flow MRI visualized the internal flow with virtual particles tracing during the cardiac cycle. The particles inside the appendage of the pre-occluded model remained almost in place despite pulsatile flow, which may lead to thrombus formation. We defined an area that satisfies |V | < 2 cm/s as a "stagnant zone", and cross-sectional view demonstrated that the stagnant zone is formed in the 'unintended space' near the LAA ostium of the mal-occluded model for a longer time than the correctly-occluded model (Fig. 3).

CLINICAL RELEVANCE/APPLICATION

4D flow MRI visualize little flow within LAA in patient with AF, which may result in thrombus formation. Mal-occluded LAA can also lead to adverse thrombus formation.

SDP-CA-6   Comparison Of Cardiovascular Magnetic Resonance Characteristics And Clinical Prognosis In Left Ventricular Non-compaction Patients With And Without Arrhythmia

Participants
Ziqi Zhou, MD,BMBCh, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

Left ventricular non-compaction (LVNC) is a rare cardiomyopathy whose main clinical manifestations include arrhythmia. Although cardiovascular magnetic resonance (CMR) is increasingly used in the diagnosis and prognosis of LVNC, there are still insufficient studies of CMR on LVNC patients with arrhythmia.This study was performed to characterize and compare CMR features and prognosis in LVNC patients with and without arrhythmias.*Methods and Materials 84 LVNC patients diagnosed by CMR were collected retrospectively. Clinical data, arrhythmia characteristics and CMR parameters were collected. Patients were divided into different groups according to their arrhythmia characteristics and CMR manifestations for statistical analysis and comparison. One-way ANOVA and Kaplan-Meier survival curves were used for statistical comparison. The outcome events defined as a composition event of cardiac death, rehospitalization of heart failure, heart transplantation and pacemaker implantation.*Results Sixty-seven LVNC patients (79.76%) mainly presented with arrhythmia, including premature ventricular beat (33, 27.73%), bundle branch block (14, 11.77%), ECG waveform changes (18, 15.13%), ventricular tachycardia (11, 9.24%). The cardiac function and structure parameters had no significant difference among non-arrhythmia group, benign arrhythmia group and malignant arrhythmia group, but the LGE presence was higher in the malignant arrhythmia group than other two groups (p=0.023). At a mean follow-up of 46 ± 27 months, cardiac events occurred in 23 patients (46.94%). Kaplan-Meier analysis showed no statistically significant difference in prognosis among the non-arrhythmia, benign and malignant arrhythmia groups,but the arrhythmia patients with LGE+ or LVEF <30% had higher risk than patients with LGE- or LVEF>30%(p=0.003, HR=4.035, 95%CI:1.475-11.035; p=0.003, HR=8.131, 95%CI:1.805-36.636).*Conclusions In LVNC patients, the types of arrhythmia are numerous and unrepresentative, and arrhythmia is not the prognostic factors. Arrhythmia combined with imaging indicators may more useful for risk stratification. Arrhythmia LVNC patients with combined LGE positive or LVEF <30% patients are at higher risk.*Clinical Relevance/Application Arrhythmia is one of the most common clinical features in LVNC patients, with many types and no specificity. LGE is more common in LVNC patients with malignant arrhythmia, and patients with LGE have a higher incidence of adverse cardiovascular events and a lower survival rate than arrhythmic patients without LGE. In addition, in LVNC patients with arrhythmia, the more the LVEF decreased, the worse the prognosis. The combination of imaging indicators may be more useful for risk stratification in LVNC patients.

RESULTS

Sixty-seven LVNC patients (79.76%) mainly presented with arrhythmia, including premature ventricular beat (33, 27.73%), bundle branch block (14, 11.77%), ECG waveform changes (18, 15.13%), ventricular tachycardia (11, 9.24%). The cardiac function and structure parameters had no significant difference among non-arrhythmia group, benign arrhythmia group and malignant arrhythmia group, but the LGE presence was higher in the malignant arrhythmia group than other two groups (p=0.023). At a mean follow-up of 46 ± 27 months, cardiac events occurred in 23 patients (46.94%). Kaplan-Meier analysis showed no statistically significant difference in prognosis among the non-arrhythmia, benign and malignant arrhythmia groups,but the arrhythmia patients with LGE+ or LVEF <30% had higher risk than patients with LGE- or LVEF>30%(p=0.003, HR=4.035, 95%CI:1.475-11.035; p=0.003, HR=8.131, 95%CI:1.805-36.636).

CLINICAL RELEVANCE/APPLICATION

Arrhythmia is one of the most common clinical features in LVNC patients, with many types and no specificity. LGE is more common in LVNC patients with malignant arrhythmia, and patients with LGE have a higher incidence of adverse cardiovascular events and a lower survival rate than arrhythmic patients without LGE. In addition, in LVNC patients with arrhythmia, the more the LVEF decreased, the worse the prognosis. The combination of imaging indicators may be more useful for risk stratification in LVNC patients.

SDP-CA-7   Endogenous Contrast T1 Rho Mapping For Myocardial Fibrosis In Non-ischemic Cardiomyopathy: Comparison With Extracellular Volume Fraction Using T1 Mapping

Participants
Yoshiaki Morita, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

T1 rho mapping with endogenous MRI contrast, which is sensitive to macromolecular interaction and differs from conventional T1- and T2-based MRI contrast, has been used to assess the tissue damage of articular cartilage, brain and liver, but less in heart. The aim was to evaluate the feasibility of T1 rho mapping for the detection of myocardial fibrosis in patients with non-ischemic cardiomyopathy, by comparison with pre- and post-contrast T1 maps derived extracellular volume (ECV) fraction as indicator of extracellular space expansion including diffuse interstitial fibrosis that is difficult to detect in late gadolinium enhancement (LGE).*Methods and Materials Thirty-five patients with non-ischemic cardiomyopathy and 5 patients with normal myocardium (mild arrhythmia without organic cardiac disease) underwent cardiac MRI with 3T machine. T1 rho mapping was performed at short-axial

slice in basal, mid-ventricular and apical level. T1 rho map was reconstructed using three source images with different spin-lock preparation times (1, 20 and 40msec). T1 mapping using MOLLI method and LGE were also performed. Using pre- and post-contrast T1 maps, ECV map was reconstructed. We measured the T1 rho, pre-contrast T1 (=native T1) and ECV at septum in each level. The presence of LGE was also decided visually.*Results The meanT1 rho value in patients with non-ischemic cardiomyopathy showed significantly higher than that in normal patients (62.1and 53.1msec, p<0.001). Further, not only LGE positive but apparently LGE negative segments also showed higher ECV and T1 rho values than normal myocardium (p<0.01 for all). T1 rho values was well correlated with ECV (r=0.63). Whereas, native T1 values showed weak correlation with ECV (r=0.19). The cut-off value for T1 rho values to differentiate between higher ECV (>30%), suggesting interstitial space expansion due to fibrosis, and normal ECV was 58.5msec (sensitivity 81 %, specificity 76%, area under the curve 0.85).*Conclusions Myocardial T1 rho mapping showed good association with ECV in non-ischemic cardiomyopathy and enabled the detection of abnormal ECV with high diagnostic accuracy. Further, T1 rho of apparently LGE-negative segments, as well as of LGE-positive, was significantly higher than normal myocardium in the same way as ECV.*Clinical Relevance/Application T1 rho mapping permit the detection of myocardial fibrosis, including diffuse interstitial involvement that is difficult to evaluate by conventional LGE, without the need for gadolinium, which would be useful particularly in patients with a higher risk of contrast administration. This novel endogenous mapping could be a useful and practical biomarker for evaluation of the early cardiac involvement, disease severity and prognostic information.

RESULTS

The meanT1 rho value in patients with non-ischemic cardiomyopathy showed significantly higher than that in normal patients (62.1and 53.1msec, p<0.001). Further, not only LGE positive but apparently LGE negative segments also showed higher ECV and T1 rho values than normal myocardium (p<0.01 for all). T1 rho values was well correlated with ECV (r=0.63). Whereas, native T1 values showed weak correlation with ECV (r=0.19). The cut-off value for T1 rho values to differentiate between higher ECV (>30%), suggesting interstitial space expansion due to fibrosis, and normal ECV was 58.5msec (sensitivity 81 %, specificity 76%, area under the curve 0.85).

CLINICAL RELEVANCE/APPLICATION

T1 rho mapping permit the detection of myocardial fibrosis, including diffuse interstitial involvement that is difficult to evaluate by conventional LGE, without the need for gadolinium, which would be useful particularly in patients with a higher risk of contrast administration. This novel endogenous mapping could be a useful and practical biomarker for evaluation of the early cardiac involvement, disease severity and prognostic information.

SDP-CA-8　Usefulness Of Compressed Sensing Cine For Feature Tracking Strain Analysis On Left Ventricle Compared To Conventional Cine Imaging

Participants
Yasuhiro Nagai, Osaka, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Myocardial strain analysis has been used to assess the detailed regional cardiac function. The feature tracking method, which allows direct derivation of myocardial strain from conventional cine MRI sequences, was introduced as novel technique. Recently, compressed sensing (CS) technique with incoherent sampling and iterative reconstruction has been applied to cine MRI, which has reduced acquisition time. However, the effects of CS imaging for feature tracking strain analysis is still unclear. We investigated the impact of acceleration factor and ECG-gating technique of CS cine for feature tracking strain analysis compared to conventional cine imaging.*Methods and Materials We obtained CS cine and conventional cine images at short-axis and 4-chamber plane in 26 healthy volunteers (44.3±18.8 years, man: woman = 21:5). CS cine with comparable temporal and spatial resolution to conventional method were performed with acceleration factor (factor) of 4, 6, 8 and with two different ECG-gating technique: retrospective trigger and prospective trigger (=Real time cine). We measured peak strain [%] in the Radial, Circumferential and Longitudinal direction according to the AHA16segment model using dedicated feature tracking software (Circle cardiovascular Imaging Inc, cvi42). The mean peak strain values and variability in CS cine were compared with conventional cine. Significant differences were determined by the Welch test.*Results Peak Radial Strain in retrospective CS cine (factor of 6,8) and real-time CS cine (factor of 4,6,8) were underestimated. Peak Circumferential Strain in retrospective CS cine (factor of 6,8) and real-time CS cine (factor of 4,6,8) were also underestimated, with especially lower in the mid inferior to mid inferoseptal wall. Peak Longitudinal Strain in retrospective CS cine (factor of 6,8) and real-time CS cine (factor of 4,6,8) were underestimated, with especially lower in the basal anterolateral wall. Peak Radial Strain showed the larger variation than other strain in all cine imaging technique. There were no significant differences in Peak Strain of three directions between conventional and retrospective CS cine (factor of 4).*Conclusions CS cine using retrospective ECG triggering and acceleration factor of 4 could be used for feature tracking strain analysis as well as conventional cine imaging.*Clinical Relevance/Application The acceleration factor and ECG triggering method in CS cine influence the peak strain values. CS cine using our proposed adequate parameter setting enable the accurate and reproducible strain analysis, thus reducing the cine scan time and improving the patient compliance, especially in patients who have difficulties in the repeated breath-hold and the constant holding position during scan.

RESULTS

Peak Radial Strain in retrospective CS cine (factor of 6,8) and real-time CS cine (factor of 4,6,8) were underestimated. Peak Circumferential Strain in retrospective CS cine (factor of 6,8) and real-time CS cine (factor of 4,6,8) were also underestimated, with especially lower in the mid inferior to mid inferoseptal wall. Peak Longitudinal Strain in retrospective CS cine (factor of 6,8) and real-time CS cine (factor of 4,6,8) were underestimated, with especially lower in the basal anterolateral wall. Peak Radial Strain showed the larger variation than other strain in all cine imaging technique. There were no significant differences in Peak Strain of three directions between conventional and retrospective CS cine (factor of 4).

CLINICAL RELEVANCE/APPLICATION

The acceleration factor and ECG triggering method in CS cine influence the peak strain values. CS cine using our proposed adequate parameter setting enable the accurate and reproducible strain analysis, thus reducing the cine scan time and improving the patient compliance, especially in patients who have difficulties in the repeated breath-hold and the constant holding position during scan.

SDP-CA-9　Feasibility Of Whole Heart 3D Cine MRI With Highly-accelerated Technique Using Hyperkat Method: Evaluation By Automatic Left And Right Ventricular Volumetry Based On Deep Learning In Comparison With Conventional 2D Cine Imaging.

Participants

Tatsuhiro Yamamoto, Osaka, Japan (*Presenter*) Nothing to Disclose

PURPOSE

3D cine imaging using HyperKat method which is parallel imaging with k-t space data under-sampling enable to obtain the whole heart volume images with the reduction of acquisition time and to reconstruct any cardiac-axis as post-processing. Recently, automatically identified ventricular segmentation and volumetric cine MRI analysis based on deep learning architectures has become as accurate and reproducible method. This study aims to investigate the feasibility of our proposed 3D cine imaging for automatic biventricular analysis compared with conventional 2D cine imaging.*Methods and Materials We obtained 3D cine and conventional 2D cine images in 10 healthy volunteers using a 3T-MRI. Highly-accelerated 3D cine imaging using HyperKat technique of acceleration factor=8 were performed covering whole heart in transverse plane with two or three breath-hold. 3D cine were obtained with same spatial and temporal resolution as 2D cine images which need the 10 or more breath-holds including determination of cardiac axis. The obtained 3D volume data was reconstructed in short-axis and 4 chamber plane from original transverse images. We measured the volumetric parameters (EDV, ESV and EF) of left and right ventricle (LV and RV) using automatic ventricular function module programmed based on deep learning (Circle cardiovascular Imaging Inc, cvi42). Then, these parameters between 3D and 2D cine images were compared. The visual assessment score using a 4-point scale and contrast ratio between myocardium and lumen were also assessed.*Results Despite slight degradation in image quality and contrast ratio for 3D cine imaging, automatic ventricular segmentation and volumetric analysis of both ventricles were successful with some manual correction in all 3D cine images equivalent to 2D images. The good correlations between 3D and 2D cine were shown for the functional parameters (LV: EDV r=0.961, ESV r=0.960, EF r=0.899, RV: EDV r=0.986, ESV r=0.986, EF r=0.848). The Bland-Altman plot showed a good agreement between both methods.*Conclusions The highly-accelerated whole heart 3D cine imaging using HyperKat methods permit the accurate assessment of cardiac volume and function using automatically identified volumetry method based on deep learning, equivalent to conventional 2D cine imaging.*Clinical Relevance/Application The highly-accelerated 3D cine imaging using HyperKat methods can be implemented with a simple scan plan and evaluate the accurate ventricular function with equivalent to conventional 2D cine images. Our proposed method is useful and practical approach for the reduction of acquisition time and the reconstruction of any cardiac-axis as post-processing without complicated determination of cardiac axis during scan.

RESULTS

Despite slight degradation in image quality and contrast ratio for 3D cine imaging, automatic ventricular segmentation and volumetric analysis of both ventricles were successful with some manual correction in all 3D cine images equivalent to 2D images. The good correlations between 3D and 2D cine were shown for the functional parameters (LV: EDV r=0.961, ESV r=0.960, EF r=0.899, RV: EDV r=0.986, ESV r=0.986, EF r=0.848). The Bland-Altman plot showed a good agreement between both methods.

CLINICAL RELEVANCE/APPLICATION

The highly-accelerated 3D cine imaging using HyperKat methods can be implemented with a simple scan plan and evaluate the accurate ventricular function with equivalent to conventional 2D cine images. Our proposed method is useful and practical approach for the reduction of acquisition time and the reconstruction of any cardiac-axis as post-processing without complicated determination of cardiac axis during scan.

NPM04-D1   **Where Is The Zoom Link? Impact Of Remote Learning On Radiology Residents During COVID-19**

Participants
Michael Jin, MD, Coram, New York (*Presenter*) Nothing to Disclose

PURPOSE

The COVID-19 pandemic had tremendous impact on residency programs throughout the country. With novel tools to facilitate distant learning, radiology residencies were quick to implement remote education curriculums. The purpose of this study is to investigate the impact of remote learning on radiology residents' education and wellness.*Methods and Materials A 26-item questionnaire was distributed to radiology residency programs throughout the United States with targeted audience of PGY2 to PGY 5 radiology residents. The survey was open for 10 days between the month of March and April of 2021 and asked participants to rank the impact of remote learning on various aspects of radiology residency on a 1 to 5 scale (1: significantly negatively affected, 5: significantly positively affected). Survey results were analyzed using normal distribution and was considered significant when 95% confidence interval did not include 3 (neutral). Two-sample t-test was used to compare our results with results from prior studies (P = 0.05).*Results The survey respondents breakdown includes 28.57% PGY 2, 26.19% PGY 3, 21.42% PGY 4, and 23.82% PGY 5 radiology residents. Out of 42 survey responses, 67% of respondents reported rotations with supervision by faculty who work remotely >50% of the time. Residents reported decreased quality of faculty interactions (x =2.4; 95% CI 2.2-2.7), preparedness for independent call (2.5; 2.2-2.9), professional relationships with attendings (2.3; 2.0-2.6), and education in diagnostic radiology (2.5; 2.3-2.8), ultrasound (2.3; 2.1-2.6), and procedural studies (2.4; 2.1-2.6). Compared with prior studies, residents reported higher support from co-residents (p=0.04), lower support from administrative staff (p=0.004), and decreased satisfaction with educational experience (p=0.0003), particularly with faculty's commitment to resident education (p=.02). No differences were detected between preference for in-person vs virtual conference, research involvement, or amount of attending feedback.*Conclusions Our survey results show the COVID-19 had significant impact on radiology residents and suggests factors that can contribute to successful radiology residency experiences. While COVID 19 may have been perceived to unanimously negatively impact resident education, our survey poses a different perspective.*Clinical Relevance/Application While COVID has universally impacted resident education in other specialties negatively, its effect on radiology highlights a unique set of challenges and potential opportunities in training the next generation of radiologists.

RESULTS

The survey respondents breakdown includes 28.57% PGY 2, 26.19% PGY 3, 21.42% PGY 4, and 23.82% PGY 5 radiology residents. Out of 42 survey responses, 67% of respondents reported rotations with supervision by faculty who work remotely >50% of the time. Residents reported decreased quality of faculty interactions (x =2.4; 95% CI 2.2-2.7), preparedness for independent call (2.5; 2.2-2.9), professional relationships with attendings (2.3; 2.0-2.6), and education in diagnostic radiology (2.5; 2.3-2.8), ultrasound (2.3; 2.1-2.6), and procedural studies (2.4; 2.1-2.6). Compared with prior studies, residents reported higher support from co-residents (p=0.04), lower support from administrative staff (p=0.004), and decreased satisfaction with educational experience (p=0.0003), particularly with faculty's commitment to resident education (p=.02). No differences were detected between preference for in-person vs virtual conference, research involvement, or amount of attending feedback.

CLINICAL RELEVANCE/APPLICATION

While COVID has universally impacted resident education in other specialties negatively, its effect on radiology highlights a unique set of challenges and potential opportunities in training the next generation of radiologists.

PH02-B4   Performance Evaluation Of A Dual Source CT With Two Photon Counting Detectors

Participants
Thomas G. Flohr, PhD, Forchheim, Germany (*Presenter*) Employee, Siemens AG

PURPOSE

To evaluate image quality parameters of a new clinical dual source CT (DSCT) with two photon counting detectors (PCD).*Methods and Materials The DSCT is equipped with two PCDs with pixel apertures of 0.151x0.176 mm2 (UHR) and 0.302x0.352 mm2 (standard, combining 2x2 UHR pixels) at the isocenter. Detector collimation is 144x0.4 mm (standard) and 120x0.2 mm (UHR). Each PCD is read-out with 4 energy thresholds. The minimum gantry rotation time is 0.25 s, the field of view is 50 cm for PCD A and 35.6 cm for PCD B. We evaluated in-plane spatial resolution with the QRM D100 HCR bar pattern phantom and minimum spiral slice width with a gold plate phantom (both standard and UHR). We measured iodine contrast-noise ratios (CNR) in pseudo-monoenergetic images at 40, 50, 60 and 70 keV derived from a 120 kVp acquisition and compared it to the CNR in lowest energy threshold images both at 120 kVp and at 90 kVp. We evaluated the accuracy of iodine quantification in iodine base material images using iodine inserts with 2.0, 5.0, 10.0 and 15.0 mg/ml concentration in the GammexTM multi-energy CT phantom (40 cm x 30 cm).*Results Maximum spatial resolution was 20 lp/cm (standard) and 40 lp/cm (UHR). Minimum spiral slice width (full width at half maximum FWHM) was 0.53 mm (standard) and 0.33 mm (UHR) at isocenter. Pseudo-monoenergetic images of the GammexTM phantom had iodine CNRs in the 15 mg/ml insert of 35.7, 29.8, 23.4, and 19.8 at 40, 50, 60, and 70 keV, respectively, compared to 21.1 and 26.5 in the lowest threshold images at 120 kVp and at 90 kVp, all at CTDIvol = 9.7mGy. Measured iodine concentrations were 2.3, 5.6, 10.5 and 15.5 mg/ml for the 2, 5, 10 and 15 mg/ml inserts.*Conclusions Dual source photon counting CT provides in-plane and through-plane spatial resolution moderately better (standard) and significantly better (UHR) than conventional CT. Pseudo-monoenergetic images at low keV demonstrate increased iodine CNR comparable to low kVp data acquisition. Iodine quantification is accurate down to low concentrations of 2 mg/ml.*Clinical Relevance/Application Image quality characterization of a clinical photon counting dual source CT. Results indicate very high spatial resolution combined with spectral imaging capabilities.

RESULTS

Maximum spatial resolution was 20 lp/cm (standard) and 40 lp/cm (UHR). Minimum spiral slice width (full width at half maximum FWHM) was 0.53 mm (standard) and 0.33 mm (UHR) at isocenter. Pseudo-monoenergetic images of the GammexTM phantom had iodine CNRs in the 15 mg/ml insert of 35.7, 29.8, 23.4, and 19.8 at 40, 50, 60, and 70 keV, respectively, compared to 21.1 and 26.5 in the lowest threshold images at 120 kVp and at 90 kVp, all at CTDIvol = 9.7mGy. Measured iodine concentrations were 2.3, 5.6, 10.5 and 15.5 mg/ml for the 2, 5, 10 and 15 mg/ml inserts.

CLINICAL RELEVANCE/APPLICATION

Image quality characterization of a clinical photon counting dual source CT. Results indicate very high spatial resolution combined with spectral imaging capabilities.

PH02-B5   Comparison of Two Versions of The Deep Learning Image Reconstruction Algorithm Aice on CT Image Quality and Dose Reduction: A Phantom Study

Participants
Joel Greffier, PhD, Nimes, France (*Presenter*) Nothing to Disclose

PURPOSE

To compare the impact on image quality and dose reduction of two versions of the Deep Learning Image Reconstruction algorithm Advanced intelligent Clear-IQ Engine (AiCE).*Methods and Materials Acquisitions were performed at five dose levels (CTDIvol: 10/7.5/5/2.5/1 mGy) using an image quality phantom. Raw data were reconstructed using the three levels of AiCE (Mild, Standard and Strong) for the two versions (AiCE V8 vs AiCE V10). The noise power spectrum (NPS) and task-based transfer function (TTF) for bone and acrylic were computed. The detectability index (d') was computed to model the detectability of either a large mass in the liver or lung or a small calcification or high contrast tissue boundaries.*Results The noise magnitude was lower with AiCE V10 than with AiCE V8 (-4±6% for Mild, -14±3% for Standard, and -48±1% for Strong levels). The average NPS spatial frequencies shifted towards higher frequencies with AiCE V10 as compared with AiCE V8 (45 ±4%, 36±4%, and 5±4% for all levels, respectively). The TTF50% values shifted towards higher frequencies with AiCE V10 as compared with AiCE V8 for both inserts, except for the Strong level for the acrylic insert. Whatever the dose and AiCE levels, d' values were on average 10±3% higher with AiCE V10 than with AiCE V8 for the small object/calcification and by 11±5% for the large object/lesion.*Conclusions As compared to AiCE V8, AiCE V10 reduced noise and improved spatial resolution and detectability without changing the noise texture, except for the Strong level. AiCE V10 seemed to have a greater potential for dose reduction than AiCE V8*Clinical Relevance/Application The new version of AiCE demonstrated an improvement in image quality and lesion detectability, thus showing great potential for dose reduction in patients

RESULTS

The noise magnitude was lower with AiCE V10 than with AiCE V8 (-4±6% for Mild, -14±3% for Standard, and -48±1% for Strong

levels). The average NPS spatial frequencies shifted towards higher frequencies with AiCE V10 as compared with AiCE V8 (45 ±4%, 36±4%, and 5±4% for all levels, respectively). The TTF50% values shifted towards higher frequencies with AiCE V10 as compared with AiCE V8 for both inserts, except for the Strong level for the acrylic insert. Whatever the dose and AiCE levels, d' values were on average 10±3% higher with AiCE V10 than with AiCE V8 for the small object/calcification and by 11±5% for the large object/lesion.

CLINICAL RELEVANCE/APPLICATION

The new version of AiCE demonstrated an improvement in image quality and lesion detectability, thus showing great potential for dose reduction in patients

PH02-B6   From The Phantom To The Patient: Can We Use Simple Geometric Phantoms For Image Quality Evaluation Of CT With Anatomical Model- Based Reconstructions?

Participants
Oleksandra Ivashchenko, PhD, Leiden, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning (DL) and iterative (IR) model-based reconstructions can facilitate significant artifact and radiation dose reduction in CT. Many DL/IR algorithms are trained using patient data, whereas quality control programs are designed and performed using simplified geometric phantoms. The question posed in this work is, if these phantoms are able to realistically evaluate image quality (IQ) performance of CT systems with model-based image reconstruction.*Methods and Materials IQ performance of CT (Prism, Canon) was evaluated using three objects of increasing complexity: Catphan (simple geometry), CTU41 anthropomorphic phantom (KyotoKagaku), and, retrospectively, a single patient scan. Each phantom was scanned 5 times with a clinical abdominal protocol (approx. CTDIvol=3.7mGy, 120kVp, SD=12.5) and reconstructed with 1 mm slices, using FBP, IR (AIDR3De, clin. standard with FC18 filter) and two DL-based methods (AiCE-Body-std and BodySharp-std). The same CT protocol was used for the patient (IR and Body-Sharp DL reconstruction). The materials attenuation (HU), CNR (Catphan CTP515 insert, CTU41- liver vessel-to-parenchyma contrast, patient - hypodense liver lesion), as well as 2D NPS trends for both phantoms were analyzed.*Results Catphan inserts did not reveal any significant HU variation for all reconstructions, while CNR improved by 0.8 to 1 point (1% supra-slice) for DL-based methods. For anthropomorphic phantom and patient data, no significant difference was found in most tissues (fat, liver parenchyma, muscle/fat), yet an increase in HU was observed for high attenuation areas (bone, calcifications ~40HU). Liver CNR (anthropomorphic phantom) was the best for Body-DL-based reconstruction (2.6/2.4/1.7/0.8 for Body/BodyS/IR/FBP). Patient CNR for a hypodense liver lesion improved by 33% in the DL images (3.2 to 4.8), even when comparing 0.5 mm DL- to 1mm IR-slices. NPS peak in the phantoms shifted by 20/30/35% to lower frequencies for IR and DL-based methods, respectfully, while noise levels were consistent for all test objects and reconstructions.*Conclusions Simplified geometric phantoms allow for basic CT reconstruction IQ assessment. However, clinically important performance parameters (CNR of low contrast detail) in these objects do not reveal the same IQ-trend as those calculated on anthropomorphic phantom or clinical images. Our results highlight the importance of new IQ metrics and phantoms (with realistic anatomical representation) for evaluation of reconstructions developed using patient data.*Clinical Relevance/Application widely accepted IQ metrics/phantoms may deviate from actual quality of patient images for DL/IR model-based reconstructions.

RESULTS

Catphan inserts did not reveal any significant HU variation for all reconstructions, while CNR improved by 0.8 to 1 point (1% supra-slice) for DL-based methods. For anthropomorphic phantom and patient data, no significant difference was found in most tissues (fat, liver parenchyma, muscle/fat), yet an increase in HU was observed for high attenuation areas (bone, calcifications ~40HU). Liver CNR (anthropomorphic phantom) was the best for Body-DL-based reconstruction (2.6/2.4/1.7/0.8 for Body/BodyS/IR/FBP). Patient CNR for a hypodense liver lesion improved by 33% in the DL images (3.2 to 4.8), even when comparing 0.5 mm DL- to 1mm IR-slices. NPS peak in the phantoms shifted by 20/30/35% to lower frequencies for IR and DL-based methods, respectfully, while noise levels were consistent for all test objects and reconstructions.

CLINICAL RELEVANCE/APPLICATION

widely accepted IQ metrics/phantoms may deviate from actual quality of patient images for DL/IR model-based reconstructions.

PH02-B8   Convolutional Neural Network Based Ultra-low Kev Virtual Monoenergetic Imaging For Maximizing Soft-tissue Contrast In Neuro CT

Participants
Hao Gong, PhD, Rochester,, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

CT is limited in its ability to resolve small contrast differences, e.g., gray/white matter. Although low energy (e.g. 50 keV) virtual monoenergetic imaging (VMI) derived from dual energy CT (DECT) can improve iodine contrast, it is not optimized for differentiating non-iodinated soft tissue. Commercial VMI amplifies image noise / artifacts at low energy levels, therefore limiting VMI to typically 40 keV or higher. We aim to maximize low contrast resolution of soft tissue by using ultra-low energy VMI (e.g. 18 keV) created from a deep learning based direct VMI synthesis.*Methods and Materials A convolutional neural network (CNN) was developed to model the mapping between dual- / multi-energy CT images and VMI. The CNN used customized structure and loss function to suppress noise / artifact and enforce CT number accuracy, structural consistency, and texture validity. The training used image data from phantom materials with varying densities that mimic x-ray attenuation of human tissues (i.e. hydroxyapatite, blood, adipose, etc.). DECT image patches were used as inputs, and the corresponding theoretical monoenergetic CT numbers were used as labels. Random-shaped numerical phantom materials were generated to boost training sample diversity. The trained CNN was used to process testing phantom materials (mass densities unseen in training) at two low dose levels (12.7 & 6.4 mGy) and routine patient images. For demonstration purposes, the CNN was implemented for clinical head CT images from a clinical DECT system and evaluated at 18 keV, which approximately maximized gray / white matter contrast. Visual inspection was used to compare CNN results with commercial 40 / 50 keV VMI and clinical mix images. The bias and variance of CT number was gauged by normalized mean absolute error (NMAE). Contrast noise ratio (CNR) of soft tissue was also compared.*Results In phantom study, CNN 18 keV VMI demonstrated high CT number accuracy at both lower dose levels: NMAE ranged from 0.87% (Calcium 300mg/cc: un-normalized MAE 45HU) to 8.3% (blood: un-normalized MAE 3HU) in target materials with varying densities (e.g. calcium to lung tissue). Commercial 40 / 50 keV VMI had obvious image artifacts and did not provide better brain tissue CNR than clinical mixed images. The CNN-synthesized 18 keV images improved gray / white matter contrast (up to 100%) and provided the best brain tissue CNR (e.g. ~75% improvement over clinical mixed images).*Conclusions The CNN-based ultra-low energy VMI has the potential of boosting

soft tissue differentiation in neurological CT exams.*Clinical Relevance/Application Compared to commercial CT systems, the presented method enables better differentiation in non-iodinated brain tissue and may improve the visualization of normal brain anatomy and pathology.

RESULTS

In phantom study, CNN 18 keV VMI demonstrated high CT number accuracy at both lower dose levels: NMAE ranged from 0.87% (Calcium 300mg/cc: un-normalized MAE 45HU) to 8.3% (blood: un-normalized MAE 3HU) in target materials with varying densities (e.g. calcium to lung tissue). Commercial 40 / 50 keV VMI had obvious image artifacts and did not provide better brain tissue CNR than clinical mixed images. The CNN-synthesized 18 keV images improved gray / white matter contrast (up to 100%) and provided the best brain tissue CNR (e.g. ~75% improvement over clinical mixed images).

CLINICAL RELEVANCE/APPLICATION

Compared to commercial CT systems, the presented method enables better differentiation in non-iodinated brain tissue and may improve the visualization of normal brain anatomy and pathology.

PH02-B9   Evaluation Of Low Dose Urinary Stone CT Scanning Protocols Using Two Torso Phantom Sizes And Human Calcium Oxalate Stone Samples - With A Focus On The Impact Of Reconstruction Method And Spectral Analysis On Stone Detectability

Participants
Michael Abel, Zionsville, Indiana (*Presenter*) Manager, Cardinal Health, Inc

PURPOSE

The objective of this study is to establish urinary stone detectability benchmarks in low dose CT using phantoms implanted with human kidney stones. A robust quantitative method was implemented as a complement to human observational review to determine optimal acquisition and reconstruction parameters for patient size dependent, low dose renal stone CT protocols.*Methods and Materials A tissue equivalent torso phantom (30x20 cm) was implanted with 12 test tubes, each containing water and a single human calcium oxalate urinary stone. Stone diameters ranged from 1.8 to 11.9 mm. The phantom was scanned on an iQon Spectral CT scanner (Philips Healthcare, Best, The Netherlands) at 120 kVp and the following mAs: 10, 20, 30, 40, and 120. Multiple recons were performed for comparison, including statistical iterative (iDose4), model based iterative (IMR3), and spectral (40-keV MonoE SPR4). The process was replicated after wrapping the phantom in 4 cm of bolus material to simulate a larger patient. Stone CNR was calculated in each case using a VOI encompassing each stone. One radiologist and two physicists evaluated stone detectability.*Results In the normal sized phantom, 10 mAs acquisitions demonstrated adequate detectability for stones as small as 1.8 mm with all recon techniques. In the bolus wrapped phantom, the smallest 1.8 mm stone was visible at 20 mAs with iDose4 but not with IMR3, likely due to the impact of increased smoothing at the threshold of detectability. Conversely, relative to iDose4 recon, stones less than 3 mm in diameter yielded an aggregate CNR about 10X greater in the smaller phantom when reconstructed using IMR3 at a minimal CTDIvol of 0.9 mGy (10 mAs).*Conclusions Radiation doses for renal stone detectability may be decreased significantly by combining very low mAs acquisitions with iterative reconstruction techniques and novel spectral capabilities. Radiation doses as low as 10 mAs (CTDIvol 0.9 mGy) may be adequate for renal CT in average sized patients. This needs further validation in clinical studies. Protocols may be optimized by correlating observational studies with novel image quality metrics. With model based iterative techniques, CNR is not entirely indicative of stone detectability suggesting the need for more comprehensive image quality indices which incorporate MTF and NPS.*Clinical Relevance/Application CT has higher sensitivity for renal stone detection than plain radiography and ultrasound, but these modalities are commonly favored in renal stone follow up due to concern of increased radiation exposure. As a result, low dose CT protocols are increasingly utilized. This study demonstrates the feasibility of further reducing radiation doses for renal stone CT, potentially in the range of plain radiographs.

RESULTS

In the normal sized phantom, 10 mAs acquisitions demonstrated adequate detectability for stones as small as 1.8 mm with all recon techniques. In the bolus wrapped phantom, the smallest 1.8 mm stone was visible at 20 mAs with iDose4 but not with IMR3, likely due to the impact of increased smoothing at the threshold of detectability. Conversely, relative to iDose4 recon, stones less than 3 mm in diameter yielded an aggregate CNR about 10X greater in the smaller phantom when reconstructed using IMR3 at a minimal CTDIvol of 0.9 mGy (10 mAs).

CLINICAL RELEVANCE/APPLICATION

CT has higher sensitivity for renal stone detection than plain radiography and ultrasound, but these modalities are commonly favored in renal stone follow up due to concern of increased radiation exposure. As a result, low dose CT protocols are increasingly utilized. This study demonstrates the feasibility of further reducing radiation doses for renal stone CT, potentially in the range of plain radiographs.

SDP-NR-10 Development And Validation Of A Deep Machine Learning Tool For Automated Intraventricular Hemorrhage Segmentation And Volume Measurement Using 3d Convolutional Neural Networks

Participants
Alexander Wong, BSC, MPH, Richmond, British Columbia (*Presenter*) Nothing to Disclose

PURPOSE

Development of new intraventricular hemorrhage (IVH) within 24 hours of presentation or expansion of 1mL or more independently predicts poor outcome. Current methods for IVH volume estimation lack sufficient precision to detect this level of change. The gold-standard method of quantification with manual/semi-automated segmentation remain impractical in the clinical setting. We aimed to train and validate a convolutional neural network (CNN) to autonomously segment and quantify IVH volume in acute intracerebral hemorrhage (ICH) patients.*Methods and Materials Imaging data for training and validation was obtained from 3 international multicenter studies. IVH volumes were assessed using CNN, IVH Score (IVHS), Original Graeb Score (oGS), Modified Graeb Score (mGS), and manual segmentation using ITK-SNAP. Agreement between CNN volume and IVHS estimated volume compared to manual segmentation was assessed using intraclass correlation coefficient (ICC) and Bland-Altman charts. Accuracy of CNN segmentation was compared to manual segmentation with Dice similarity coefficient (DSC). Accuracy of hematoma expansion detection was assessed using receiver operating characteristic curves.*Results 172 patients and 311 CT scans were included. Intra-rater reliability was significantly greater for CNN versus IVHS method (ICC 0.99 [95%CI 0.99 - 1.00] vs 0.76 [95%CI 0.66 - 0.83]). Accuracy of CNN segmentation compared to manual segmentation was satisfactory (DSC 0.76 [95%CI 0.75 - 0.78]). Accuracy of hematoma expansion detection was substantially greater in CNN (AUC 0.91 [95%CI 0.85 - 0.97]) versus IVHS, oGS and mGS when compared to reference standard of manual segmentation.*Conclusions Our results demonstrate that a fully automated CNN algorithm is capable of segmenting IVH volumes on multi-center data with higher-intra-rater reliability and satisfactory accuracy over the current methods of IVH volume measurement tools. The algorithm has proven to be capable of detecting hematoma expansion with substantially greater accuracy over existing methods of IVH measurement.*Clinical Relevance/Application Classification and measurement of IVH is a rapidly developing field, and there is currently a great need for a tool that can accomplish this with great accuracy, reliability, and without the highly labour and time intensive processes required in current methods; both in the clinical and research environment. The results of this project will yield a clinically applicable tool that will greatly inform radiologists, clinicians, patients, and their family members in prognostication of ICH, improve clinical workflow, and patient care. We also see this tool being highly relevant for use in research and development of experimental ICH and IVH therapies.

RESULTS

172 patients and 311 CT scans were included. Intra-rater reliability was significantly greater for CNN versus IVHS method (ICC 0.99 [95%CI 0.99 - 1.00] vs 0.76 [95%CI 0.66 - 0.83]). Accuracy of CNN segmentation compared to manual segmentation was satisfactory (DSC 0.76 [95%CI 0.75 - 0.78]). Accuracy of hematoma expansion detection was substantially greater in CNN (AUC 0.91 [95%CI 0.85 - 0.97]) versus IVHS, oGS and mGS when compared to reference standard of manual segmentation.

CLINICAL RELEVANCE/APPLICATION

Classification and measurement of IVH is a rapidly developing field, and there is currently a great need for a tool that can accomplish this with great accuracy, reliability, and without the highly labour and time intensive processes required in current methods; both in the clinical and research environment. The results of this project will yield a clinically applicable tool that will greatly inform radiologists, clinicians, patients, and their family members in prognostication of ICH, improve clinical workflow, and patient care. We also see this tool being highly relevant for use in research and development of experimental ICH and IVH therapies.

SDP-NR-11 Favorable Cortical Vein Opacification Was Associated With Favorable Collateral And Perfusion

Participants
Dongshan Han, Bei Jing, China (*Presenter*) Nothing to Disclose

PURPOSE

The study aimed to explore the relationship between cortical vein opacification and collateral and perfusion in patients with symptomatic non-acute intracranial artery severe stenosis/occlusion. We hypothesized that favourable cortical vein opacification was associated with favourable collateral and perfusion.*Methods and Materials Patients with symptomatic non-acute ICA/MCA severe stenosis/occlusion were enrolled retrospectively. The hypoperfusion volume of Tmax>4s on the lesion side was obtained by auto-quantitative software. Simulated mCTA were reconstructed from CTP data and collateral score were assessed on mCTA (range, 0-5). Enhancement of the vein of Labbé, sphenoparietal sinus, and superficial middle cerebral vein was graded on vein phase CTP source images (VCTP-SI), as follows: 0, not visible; 1, moderate opacification; and 2, full opacification. The sum for the affected hemisphere was calculated, resulting in the cortical vein opacification score (COVES) (range, 0-6). The association between COVES and collateral score and the hypoperfusion volume were analyzed. The ability of COVES to predict poor collateral circulation (collateral score<4) was assessed using receiver operating characteristic curve.*Results A total of 191 patients with

ICA/MCA severe stenosis/occlusion were enrolled in this study. The COVES were positively correlated with collateral score (r=0.725, p<0.001). 74 patients showed collateral score<4 and 117 patients showed collateral score=3. The COVES were lower in poor collateral group[2(0~3)vs 5(4~6),p<0.001]. After univariate analysis, the results with significant differences were included in multivariate Logistic regression analysis, which showed that the COVES were independently related to collateral score (R=2.550, 95% CI: 4.070-12.887, p<0.001). A COVES=3 best predicted the collateral score<4 (sensitivity, 85.41%; specificity, 77.03%),and an area under the receiver operating characteristics curve was 0.883. The COVES were negatively correlated with hypoperfusion volume (r=-0.735, p<0.001). After multivariate linear regression, there was a significant relationship between COVES and hypoperfusion volume(ß=-0.687, p<0.001).*Conclusions In this study, patients with non-acute symptomatic intracranial arterial severe stenosis/occlusion with higher COVES showed favourable collateral and perfusion. COVES=3 predicted the poor collateral circulation.*Clinical Relevance/Application COVES may be useful imaging biomarkers to assess collateral circulation and cerebral perfusion in patients with symptomatic non-acute intracranial artery severe stenosis/occlusion and play a role in screening for high-risk patients.

RESULTS

A total of 191 patients with ICA/MCA severe stenosis/occlusion were enrolled in this study. The COVES were positively correlated with collateral score (r=0.725, p<0.001). 74 patients showed collateral score<4 and 117 patients showed collateral score=3. The COVES were lower in poor collateral group[2(0~3)vs 5(4~6),p<0.001]. After univariate analysis, the results with significant differences were included in multivariate Logistic regression analysis, which showed that the COVES were independently related to collateral score (R=2.550, 95% CI: 4.070-12.887, p<0.001). A COVES=3 best predicted the collateral score<4 (sensitivity, 85.41%; specificity, 77.03%),and an area under the receiver operating characteristics curve was 0.883. The COVES were negatively correlated with hypoperfusion volume (r=-0.735, p<0.001). After multivariate linear regression, there was a significant relationship between COVES and hypoperfusion volume(ß=-0.687, p<0.001).

CLINICAL RELEVANCE/APPLICATION

COVES may be useful imaging biomarkers to assess collateral circulation and cerebral perfusion in patients with symptomatic non-acute intracranial artery severe stenosis/occlusion and play a role in screening for high-risk patients.

SDP-NR-12 Predicting Middle Cerebral Artery Aneurysms Rupture With A Machine Learning-based, Radiomics-morphological Model: A Multicentral Study

Participants
Yunjun Yang, Wenzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To determine robust radiomics feature related to middle cerebral artery (MCA) aneurysms rupture and evaluate the additional value of combining morphological and radiomics features in MCA aneurysms rupture prediction.*Methods and Materials A total of 668 MCA aneurysms from five hospitals were included. Radiomics and morphological features of aneurysms were extracted on computed tomography angiography images. The support vector machine method was applied for model construction. Optimal radiomics and morphological features were used to develop the radiomics model (R model), morphological model (M model), and radiomics-morphological model (RM model), respectively. A comprehensive nomogram integrating clinical, morphological, and radiomics predictors was generated.*Results Seven radiomics features and four morphological predictors of MCA aneurysms rupture were found. The R model obtained an AUC of 0.822 (95% CI, 0.776, 0.867), 0.817 (95% CI, 0.744, 0.890), and 0.691 (95% CI, 0.567, 0.816) in the training, temporal validation, and external validation cohort, respectively. The RM model showed an AUC of 0.909 (95% CI, 0.874, 0.943), 0.861 (95% CI, 0.806, 0.917) and 0.758 (95% CI, 0.645, 0.871) in the training, temporal validation, and external validation cohort, respectively. The RM model outperformed the single R model and M model. Decision curve analysis further confirmed the clinical usefulness of the RM model.*Conclusions Robust radiomics features were determined related to MCA aneurysm rupture. The RM model exhibited excellent ability in predicting MCA aneurysm rupture. The combination of radiomics and morphological features could improve the predictive performance.*Clinical Relevance/Application Middle cerebral artery aneurysm is the most common subtype of unruptured aneurysms. As the rupture of aneurysms could cause catastrophic consequences, it is vital to screen rupture-prone aneurysms.

RESULTS

Seven radiomics features and four morphological predictors of MCA aneurysms rupture were found. The R model obtained an AUC of 0.822 (95% CI, 0.776, 0.867), 0.817 (95% CI, 0.744, 0.890), and 0.691 (95% CI, 0.567, 0.816) in the training, temporal validation, and external validation cohort, respectively. The RM model showed an AUC of 0.909 (95% CI, 0.874, 0.943), 0.861 (95% CI, 0.806, 0.917) and 0.758 (95% CI, 0.645, 0.871) in the training, temporal validation, and external validation cohort, respectively. The RM model outperformed the single R model and M model. Decision curve analysis further confirmed the clinical usefulness of the RM model.

CLINICAL RELEVANCE/APPLICATION

Middle cerebral artery aneurysm is the most common subtype of unruptured aneurysms. As the rupture of aneurysms could cause catastrophic consequences, it is vital to screen rupture-prone aneurysms.

SDP-NR-13 Automated Classification Of Alzheimer'S Disease By Graph Convolutional Network In Multimodal MR Images

Participants
Aonan Wang, MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

A graph convolutional network(GCN) was used for automated identification of Alzheimer's Disease from the healthy and mild cognition impairment*Methods and Materials 149 Alzheimer's disease (AD) cases and 95 mild cognition impairment (MCI) cases and 102 healthy controls (HCs) were investigated. Diffuse tensor imaging (DTI) and high-resolution 3D T1WI images were acquired on a SIEMENS Trio 3T scanner. The acquisition parameters were: TR/TE = 2530/3.44 ms, voxel size = 1 × 1 × 1 mm3. The DTI data were first processed using the FMRIB's Diffusion Toolbox and Brain Extraction Tool in the FSL toolkit [1]. The inverse transformations were used to transform the anatomical automatic labeling (AAL) [2] atlas into the DTI space, which was used to define the region of interest (ROI) for each person. Voxel-based morphometry (VBM) method was used and the same normalized T1 gray matter data were statistically analyzed on Statistical Parametric Mapping 8(SPM8). The volume feature and diffusion features including the average fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AxD) and radial diffusivity (RD) of each ROIs

were calculated. Graph convolutional network (GCN) was used the as the classifier. The diffusion features of each person were used as features of the vertices of the graph. The connectivity between the vertices were represented using each person's gender, age and mini-mental state examination (MMSE) score*Results 1. The diffusion features extracted from DTI have the best effect on the identification between AD and HC (accuracy 0.824), followed by AD and MCI (accuracy 0.741), and the identification effect between MCI and HC (accuracy 0.700) is slightly lower. 2. After considering the volume changes of each ROI, there is a great improvement in the identification between AD and MCI (accuracy improved from 0.741 to 0.811), while the other two have little effect.*Conclusions 1. Our results revealed high classification accuracy for AD diagnosis by using Graph convolutional network. 2. We can infer that during the transition from MCI to AD, the patients' brain volume begins to shrink significantly. The volume feature becomes one of the important features to distinguish MCI from AD. That is why we can improve the effect of identification between AD and MCI while adding the volume feature.*Clinical Relevance/Application Graph convolutional network is an effective computer-aided method to help clinician to identify AD from MCI and the healthy. Our findings also demonstrated correlation between brain volume and transition from MCI to AD, which provides a novel perspective for understanding the pathophysiological mechanisms underlying AD

RESULTS

1. The diffusion features extracted from DTI have the best effect on the identification between AD and HC (accuracy 0.824), followed by AD and MCI (accuracy 0.741), and the identification effect between MCI and HC (accuracy 0.700) is slightly lower. 2. After considering the volume changes of each ROI, there is a great improvement in the identification between AD and MCI (accuracy improved from 0.741 to 0.811), while the other two have little effect.

CLINICAL RELEVANCE/APPLICATION

Graph convolutional network is an effective computer-aided method to help clinician to identify AD from MCI and the healthy. Our findings also demonstrated correlation between brain volume and transition from MCI to AD, which provides a novel perspective for understanding the pathophysiological mechanisms underlying AD

SDP-NR-14 Prognostic Value Of Diffusion-weighted Imaging In Patients With Newly Diagnosed Sporadic Creutzfeldt-jakob Disease

Participants
Ho Young Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate clinico-radiologic markers that predict poor overall survival in sporadic Creutzfeldt-Jakob disease (sCJD).*Methods and Materials Patients with newly diagnosed sCJD were included who underwent diffusion-weighted imaging (DWI) from February 2000 to July 2020. The impact of 9 clinico-radiologic features on overall survival was analyzed using univariable Cox proportional hazards regression model. The DWI prognostic score model was generated and the adjusted effect of the model on overall survival was evaluated. The weighted kappa was calculated for interobserver agreement.*Results Sixty patients (mean age ± SD, 61.0 ± 9.7 years, 32 women) were included. Univariable analysis showed positive associations between poor overall survival and patient age (P = 0.003), extent of involved cortical lobes (P = 0.11), involvement of caudate nucleus (P = 0.07), and putamen (P = 0.04). Based on these features, the DWI prognostic score model was generated (0-4 points). Three risk groups were classified into group A (0 point), B (1-2 points) and C (3-4 points). Multivariable analysis demonstrated two independent prognostic factors: Group C (hazard ratio [HR], 4.84 [95% CI, 1.12-1.20.97], P = 0.04), and age (HR, 1.08 [95% CI, 1.04-1.11], P < 0.001). Interobserver agreements were excellent (? = 0.91-0.92).*Conclusions High risk group based on the DWI prognostic score model as well as patient age at diagnosis was associated with poorer overall survival. Our model may be useful in clinical settings for disease stratification.*Clinical Relevance/Application The proposed DWI prognostic score model may be useful in clinical settings for disease stratification in sporadic Creutzfeldt-Jakob disease.

RESULTS

Sixty patients (mean age ± SD, 61.0 ± 9.7 years, 32 women) were included. Univariable analysis showed positive associations between poor overall survival and patient age (P = 0.003), extent of involved cortical lobes (P = 0.11), involvement of caudate nucleus (P = 0.07), and putamen (P = 0.04). Based on these features, the DWI prognostic score model was generated (0-4 points). Three risk groups were classified into group A (0 point), B (1-2 points) and C (3-4 points). Multivariable analysis demonstrated two independent prognostic factors: Group C (hazard ratio [HR], 4.84 [95% CI, 1.12-1.20.97], P = 0.04), and age (HR, 1.08 [95% CI, 1.04-1.11], P < 0.001). Interobserver agreements were excellent (? = 0.91-0.92).

CLINICAL RELEVANCE/APPLICATION

The proposed DWI prognostic score model may be useful in clinical settings for disease stratification in sporadic Creutzfeldt-Jakob disease.

SDP-NR-15 Microstructural White Matter Alterations In Media Multitasking; A Gender-based Diffusion Magnetic Resonance Imaging Study

Participants
Mohammad Mehrabinejad, Istanbul, Iran, Islamic Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Media multitasking (MMT) is defined as the simultaneous use of different forms of media. Herein, we implemented diffusion MRI (dMRI) connectometry to identify the microstructural alterations in individuals with MMT.*Methods and Materials A total of 120 healthy adults (67 (55.8%) male, mean age = 36.83 ± 18.86 years), who were assessed for MMT were enrolled in the current study. Multimedia Multitasking Index (MMI) questionnaire was used for assessing participant's MMT behavior. Images were analyzed for diffusion connectometry metrics (spin distribution function). A multiple regression model was adopted to consider MMI scores among both sexes, separately.*Results dMRI connectometry findings showed a direct correlation of MMI scores with the quantitative anisotropy (QA) value of both fornices, corpus callosum (CC), bilateral cingulum, middle cerebellar peduncle (MCP), left corticothalamic pathway, and left parieto-pontine tract in females (FDR=0.049). The CC, right cerebellum, right parieto-pontine tract, right corticospinal tract (CST), and left cingulum had a negative correlation with MMI scores in females (FDR=0.037). Finally, the CC, bilateral cerebellar hemispheres, left arcuate fasciculus, and MCP showed the same inverse correlation in males (FDR<0.001).*Conclusions Our findings suggested that microstructures with functional connection to the limbic or motor system may play a critical role in MMT. Furthermore, neurobiological differences were observed between males and females regarding MMT.*Clinical Relevance/Application MMT is relatively a new concept and, although there have been some functional MRI (fMRI)

studies of dual-tasking, there is no evidence regarding the microstructural correlates of MMT in the normal population. Our results provided a preliminary meanwhile novel insight into the WM microstructural correlates of MMT in gender subgroups.

RESULTS

dMRI connectometry findings showed a direct correlation of MMI scores with the quantitative anisotropy (QA) value of both fornices, corpus callosum (CC), bilateral cingulum, middle cerebellar peduncle (MCP), left corticothalamic pathway, and left parieto-pontine tract in females (FDR=0.049). The CC, right cerebellum, right parieto-pontine tract, right corticospinal tract (CST), and left cingulum had a negative correlation with MMI scores in females (FDR=0.037). Finally, the CC, bilateral cerebellar hemispheres, left arcuate fasciculus, and MCP showed the same inverse correlation in males (FDR<0.001).

CLINICAL RELEVANCE/APPLICATION

MMT is relatively a new concept and, although there have been some functional MRI (fMRI) studies of dual-tasking, there is no evidence regarding the microstructural correlates of MMT in the normal population. Our results provided a preliminary meanwhile novel insight into the WM microstructural correlates of MMT in gender subgroups.

SDP-NR-16 Explainable And Fully Automated Clinical Referral Suggestion For Mass Like Lesions In The Brain Using Multi-contrast MRI

Participants
Ji Eun Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning of multi-contrast MRI with explainable algorithm holds potential to decide tumorous condition and suggest clinical referral for patients with intraaxial mass like lesion (IMLL) in brain. The purpose of this study was to apply a deep learning algorithm to learn multi-contrast MRI for clinical referral suggestion of IMLL and validate the AI system and to explore clinical value in the setting of nontraumatic emergency neuroradiology.*Methods and Materials In this population-based cohort study, AI system was developed in 690 patients across 30 diseases between January 2015 and November 2019. Pre-and post-contrast T1 weighted (CE-T1w), FLAIR, diffusion-weighted imaging (DWI), and apparent diffusion coefficient map were obtained. A fully automated AI system combines detection, segmentation, and classification to clinical referral of surgery, systematic work-up, medical treatment, or conservative treatment using multi-contrast MRI. The model was validated using 130 consecutive cases who manifested with IMLL in emergency room between December 2019 and November 2020, and performance for clinical referral suggestion and tumor prediction was compared with radiology residents and neuroradiologists by accuracy and using area-under-the curve (AUC) of the receiver operating characteristic curve analysis. Explainability was quantified with layer-wise relevance propagation (LRP) by calculating Dice coefficient of high relevance regions between CE-T1w and DWI imaging.*Results The AI system correctly placed the referral suggestion to given patients in 93 of 130 (71.5%) of validation set and performed comparably to the human readers (mean accuracy 71.5%, McNemar test; P >.05). For distinguishing tumor from non-tumorous condition, the AI system (AUC 0.877) performed similarly to neuroradiologists (AUC 0.835-0.878) and better than radiology residents (AUC 0.75-0.796, largest P =.043). On LRP, tumors showed matched relevance between contrast-enhancement and diffusion restriction on solid portion while non-tumors showed matched relevance between contrast-enhancement and diffusion restriction on solid portion while non-tumors did not (Dice coefficient 0.636 vs. 0.385, P <.001), demonstrating AI's decision basis.*Conclusions Our work verifies AI system learns and explains decision among from multi-contrast MRI and suggests patients' referrals, thereby provides clinical value in a real-world setting.*Clinical Relevance/Application Our AI system can triage patients with raw multi-modal MRI images to clinical referral pathway and the clinicians can be aided in challenging cases of brain IMLL in nontraumatic neurological emergencies where expert neuroradiologists are not attended. AI's decision bases were quantitatively calculated and improved explainability.

RESULTS

The AI system correctly placed the referral suggestion to given patients in 93 of 130 (71.5%) of validation set and performed comparably to the human readers (mean accuracy 71.5%, McNemar test; P >.05). For distinguishing tumor from non-tumorous condition, the AI system (AUC 0.877) performed similarly to neuroradiologists (AUC 0.835-0.878) and better than radiology residents (AUC 0.75-0.796, largest P =.043). On LRP, tumors showed matched relevance between contrast-enhancement and diffusion restriction on solid portion while non-tumors did not (Dice coefficient 0.636 vs. 0.385, P <.001), demonstrating AI's decision basis.

CLINICAL RELEVANCE/APPLICATION

Our AI system can triage patients with raw multi-modal MRI images to clinical referral pathway and the clinicians can be aided in challenging cases of brain IMLL in nontraumatic neurological emergencies where expert neuroradiologists are not attended. AI's decision bases were quantitatively calculated and improved explainability.

SDP-NR-17 D-dimer And Ferritin As Biomarkers Of Acute Stroke Risk In Patients With Severe COVID-19: A Case Series

Participants
Adam Holmes, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

Previous studies have shown that patients with COVID-19 are predisposed to a hypercoagulable state and consequently are at an increased risk of thromboembolic events, including ischemic stroke. Herein, we sought to identify biomarkers that are associated with symptomatic ischemic stroke in patients hospitalized with COVID-19.*Methods and Materials A single institution retrospective chart review was conducted on patients hospitalized with COVID-19 between March 2020 and April 2021 who concurrently suffered an ischemic stroke as documented on head CT or brain MRI. Laboratory data was collected and recorded according to blood draws most immediately prior to the time of imaging.*Results A total of 13 patients were identified with findings of acute ischemia on either head CT or brain MRI while hospitalized with COVID-19. Among these patients, median international normalized ratio, prothrombin time, activated partial thromboplastin time, and fibrinogen were within normal limits. Median (IQR) level of D-dimer was 2.60 (2.15) mcg/mL, a 4.4-fold increase from the upper limit of normal (ULN). Additionally, median (IQR) level of ferritin, an acute phase reactant, was 1219 (455) mcg/L, a 3.8-fold increase from the ULN.*Conclusions Analysis of biomarkers in patients hospitalized with severe COVID-19 complicated by ischemic stroke displays that D-dimer and ferritin levels were the most aberrantly increased from normal range. This suggests that tracking levels of D-dimer and ferritin may be a useful way to stratify risk of ischemic stroke in patients with severe COVID-19.*Clinical Relevance/Application D-dimer and ferritin may be useful biomarkers to guide initiation of thromboprophylaxis for ischemic stroke prevention in patients with severe COVID-19 infection.

RESULTS

A total of 13 patients were identified with findings of acute ischemia on either head CT or brain MRI while hospitalized with COVID-19. Among these patients, median international normalized ratio, prothrombin time, activated partial thromboplastin time, and fibrinogen were within normal limits. Median (IQR) level of D-dimer was 2.60 (2.15) mcg/mL, a 4.4-fold increase from the upper limit of normal (ULN). Additionally, median (IQR) level of ferritin, an acute phase reactant, was 1219 (455) mcg/L, a 3.8-fold increase from the ULN.

CLINICAL RELEVANCE/APPLICATION

D-dimer and ferritin may be useful biomarkers to guide initiation of thromboprophylaxis for ischemic stroke prevention in patients with severe COVID-19 infection.

SDP-NR-18 The Relationship Between Perfusion Reduction On Arterial Spin Labeling And The Occurrence Of Cerebrovascular Events In Patients With Bilateral Moyamoya Angiography

Participants
Maoxue Wang, Nanjing, China (Presenter) Nothing to Disclose

PURPOSE

To investigate the correlation between decreased cerebral perfusion on arterial spin labeling and cerebrovascular events in patients with bilateral moyamoya angiography (MMA).*Methods and Materials 27 patients with bilateral MMA, who had stroke or hemorrhage in the unilateral hemisphere, hospitalized in the neurosurgery department of Nanjing Drum Tower Hospital were recruited from April to November 2020. There were 10 male and 17 female, aged 35-66 (54.5±8.8) years. The arterial transit artifact (ATA) of bilateral cerebral hemispheres were qualitative analyzed using Wilcoxon paired signed rank test. The mean gray value, kurtosis and skewness of gray distribution of bilateral cerebral hemispheres on cerebral blood flow (CBF) images with post labeling delay (PLD) is 1.5s and 2.5s were quantitative analyzed using paired sample T test. The relationship between ASL and cerebrovascular event was determined using binary logistics regression analysis.*Results No significant difference was found in ATA between bilateral hemispheres on CBF images with PLDs of 1.5s and 2.5s (P>0.05). The mean value in cerebral hemispheres with lesions (17.50±5.88) was lower than that in the contralateral side (20.80±5.51) on CBF images with the PLD of 1.5s (P<0.001). The kurtosis and skewness of gray distribution were also significantly different between bilateral cerebral hemispheres (P<0.05). The mean value and skewness of gray distribution were significantly different between bilateral cerebral hemispheres on CBF images with the PLD of 2.5s (P<0.05). However, the kurtosis of gray distribution was not significantly different (P>0.05). Multivariate regression analysis showed that the reduction of gray value on the side of the lesion was independently associated to the occurrence of the cerebrovascular events (OR=0.192, 95% CI: 0.047~0.783;OR=0.175, 95% CI: 0.05~0.615) (Table 1, Fig 1).*Conclusions The decreased perfusion detected by ASL was independently associated with cerebrovascular events in patients with MMA.*Clinical Relevance/Application It is suggested that bilateral moyamoya vasculopathy patients with severe cerebral hemisphere perfusion reduction on ASL should have the priority of surgery.

RESULTS

No significant difference was found in ATA between bilateral hemispheres on CBF images with PLDs of 1.5s and 2.5s (P>0.05). The mean value in cerebral hemispheres with lesions (17.50±5.88) was lower than that in the contralateral side (20.80±5.51) on CBF images with the PLD of 1.5s (P<0.001). The kurtosis and skewness of gray distribution were also significantly different between bilateral cerebral hemispheres (P<0.05). The mean value and skewness of gray distribution were significantly different between bilateral cerebral hemispheres on CBF images with the PLD of 2.5s (P<0.05). However, the kurtosis of gray distribution was not significantly different (P>0.05). Multivariate regression analysis showed that the reduction of gray value on the side of the lesion was independently associated to the occurrence of the cerebrovascular events (OR=0.192, 95% CI: 0.047~0.783;OR=0.175, 95% CI: 0.05~0.615) (Table 1, Fig 1).

CLINICAL RELEVANCE/APPLICATION

It is suggested that bilateral moyamoya vasculopathy patients with severe cerebral hemisphere perfusion reduction on ASL should have the priority of surgery.

SDP-NR-19 Association Between The Drd3 Ser9gly Polymorphism And Striatum Volumes In Parkinsonprimes Disease: Voxel-based Morphometry Analysis

Participants
Kenji Ohira, MD, Chiba, Japan (Presenter) Nothing to Disclose

PURPOSE

Recent studies have shown that the dopamine receptor D3 gene (DRD3) plays an important role in the clinical manifestations and treatment of Parkinson's disease (PD). DRD3 Ser9Gly polymorphism is the most frequently studied variant point among DRD3 variants. Since DRD3 is well expressed in the striatum, DRD3 Ser9Gly polymorphism is expected to affect volume changes in this area. However, morphological changes in PD regarding this polymorphism remain unclear. The purpose of our study was to estimate volume changes in the striatum, including the caudate and putamen, in relation to this polymorphism.*Methods and Materials We recruited 59 PD patients from our institute. According to their DRD3 Ser9Gly polymorphism, they were divided into 2 groups: Ser/Ser (S/S) carriers and Ser/Gly (S/G) carriers. All patients fulfilled the criteria of PD defined by Movement Disorder Society (MDS) Clinical Diagnostic Criteria for Parkinson's disease. We also recruited 54 age-matched healthy subjects (HS) without any mental or neurological disorders. Total brain volume (TBV) and the volumes of the caudate nucleus and putamen were calculated via 3D volume analysis by MR imaging.*Results There were no significant differences among the groups with regard to the distribution of gender, age, and total GM volume. The results of analysis of covariance (ANCOVA) using the covariates of age and TBV showed that the volume of the bilateral caudate was significantly smaller for PD patients with S/G than for HS (P < .05).*Conclusions We suggest that the interaction between PD and DRD3 Ser9Gly polymorphism may have an effect on brain morphology in the caudate nucleus.*Clinical Relevance/Application Voxel based morphometry (VBM) allows for investigation of focal differences in brain morphology due to SNPs, which leads to the procession of precision medicine for PD categorized by SNPs

RESULTS

There were no significant differences among the groups with regard to the distribution of gender, age, and total GM volume. The results of analysis of covariance (ANCOVA) using the covariates of age and TBV showed that the volume of the bilateral caudate was significantly smaller for PD patients with S/G than for HS (P < .05).

CLINICAL RELEVANCE/APPLICATION

Voxel based morphometry (VBM) allows for investigation of focal differences in brain morphology due to SNPs, which leads to the procession of precision medicine for PD categorized by SNPs

SDP-NR-2 Altered Spontaneous Brain Activity In Subjects With Different Cognitive States Of Biologically Defined Alzheimer's Disease: A Surface-based Functional Brain Imaging Study

Participants
Yunjun Yang, Wenzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

As previous studies investigating local brain activity may suffer from the problem of cortical signal aliasing during volume-based analysis, we aim to investigate cortical functional alterations in the AD continuum using a surface-based approach.*Methods and Materials Based on biomarker profile "A/T", we included 11 healthy controls (HC, A-T-), 22 preclinical AD (CU, A+T+), 33 prodromal AD (MCI, A+T+), and 20 AD with dementia (d-AD, A+T+) from the Alzheimer's Disease Neuroimaging Initiative (ADNI) database. The amplitude of low frequency fluctuation (ALFF) method was used to evaluate the changes of spontaneous brain activity, which was performed in classic frequency band (0.01-0.08Hz), slow-4 (0.027-0.073 Hz) band and slow-5 (0.01-0.027 Hz) band.*Results Under classic frequency band and slow-4 band, analysis of covariance (ANCOVA) showed that there were significant differences of standardized ALFF (zALFF) in the left posterior cingulate cortex (PCC) among the four groups. Post-hoc analyses showed that under the classic frequency band, AD group had significantly decreased zALFF compared with the other three groups, and CU group had decreased zALFF compared with HC group. Under the slow-4 band, more group differences were detected (HC > CU/MCI > d-AD). The accuracy of classifying CU, MCI and AD from HC by left PCC activity under slow-4 band were 0.774, 0.744 and 0.920, respectively. Moreover, the zALFF values of the left PCC had significant correlations with cerebrospinal fluid (CSF) biomarkers and neuropsychological tests.*Conclusions Spontaneous brain activity in the left PCC may decrease in preclinical AD when cognitive functions were relatively normal. The combination of surfaced-based approach and specific frequency band analysis may increase sensitivity for the identification of preclinical AD subjects.*Clinical Relevance/Application Before apparent cognitive decline, subjects on the course to Alzheimer's disease (AD) can have significantly altered spontaneous brain activity, which could be potentially used for early diagnosis.

RESULTS

Under classic frequency band and slow-4 band, analysis of covariance (ANCOVA) showed that there were significant differences of standardized ALFF (zALFF) in the left posterior cingulate cortex (PCC) among the four groups. Post-hoc analyses showed that under the classic frequency band, AD group had significantly decreased zALFF compared with the other three groups, and CU group had decreased zALFF compared with HC group. Under the slow-4 band, more group differences were detected (HC > CU/MCI > d-AD). The accuracy of classifying CU, MCI and AD from HC by left PCC activity under slow-4 band were 0.774, 0.744 and 0.920, respectively. Moreover, the zALFF values of the left PCC had significant correlations with cerebrospinal fluid (CSF) biomarkers and neuropsychological tests.

CLINICAL RELEVANCE/APPLICATION

Before apparent cognitive decline, subjects on the course to Alzheimer's disease (AD) can have significantly altered spontaneous brain activity, which could be potentially used for early diagnosis.

SDP-NR-20 Is It Possible To Evaluate Morphological Carotid Artery Stenosis Information Using NASCET Criteria?

Participants
Naoki Maeda, Tokushima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To assess flow analysis parameters derived from four-dimensional flow magnetic resonance imaging (4D-flow MRI) for the morphological classification of carotid artery stenosis.*Methods and Materials In this study, we investigated cervical MR imaging for 26 patients with cervical vascular stenosis (mean age, 75±7.1 years). Firstly, on a 3 Tesla MR scanner (GE Healthcare), MRI data was obtained using phase contrast (PC) imaging for 4D-flow MRI and time of flight MR angiography (TOF-MRA) sequences. These imaging parameters were as follows; PC imaging: repetition time (TR), 5.3 ms; echo time (TE), 2.0 ms; velocity encoding, 100 cm/sec; flip angle (FA), 8 degrees; TOF-MRA: TR, 19 ms; TE, 5.2 ms; FA, 20 degrees. Next, 4D-flow analysis was performed using cardiovascular imaging software. Parameters for blood flow and wall shear stress were calculated. Then, a region of interest was set on the most stenotic area of the short axis of the artery. For the calculation method of percent stenosis, we used the criteria set by North American Symptomatic Carotid Endarterectomy Trial (NASCET) for each patient using TOF-MRA; here based on the original study of NASCET and classified as six narrow morphological patterns (A to F). Finally, we compared results for the 4D-flow parameters and the percent stenosis.*Results For all patients, there were negative correlations between percent stenosis of NASCET and some 4D-flow parameters: total volume (R = -0.44), average wall shear stress (R = -0.31), and maximum wall shear stress (R = -0.38). There was no significant correlation between the percent stenosis and other flow parameters, e.g., maximum pressure gradient and peak velocity. On the other hand, the relationships between the percent stenosis and the other parameters (maximum pressure gradient and peak velocity) in narrow pattern B (n = 9) were shown with negative correlation (R = -0.50 and R = -0.48, respectively).*Conclusions Hemodynamic analysis using 4D-flow MRI enabled quantitative evaluation with more detailed information of morphological stenosis patterns. This information may indicate implicit risk factor (e.g., plaque rapture) which is inapplicable to NASCET criteria.*Clinical Relevance/Application 4D-flow MRI analysis may be useful to determine treatment approaches such as carotid endarterectomy, carotid artery stenting and clinical follow-up.

RESULTS

For all patients, there were negative correlations between percent stenosis of NASCET and some 4D-flow parameters: total volume (R = -0.44), average wall shear stress (R = -0.31), and maximum wall shear stress (R = -0.38). There was no significant correlation between the percent stenosis and other flow parameters, e.g., maximum pressure gradient and peak velocity. On the other hand, the relationships between the percent stenosis and the other parameters (maximum pressure gradient and peak velocity) in narrow pattern B (n = 9) were shown with negative correlation (R = -0.50 and R = -0.48, respectively).

CLINICAL RELEVANCE/APPLICATION

4D-flow MRI analysis may be useful to determine treatment approaches such as carotid endarterectomy, carotid artery stenting and clinical follow-up.

David K. Li, MD, Vancouver, British Columbia (*Presenter*) Speaker, Biogen Idec Inc;Speaker, sanofi-aventis Group;;

PURPOSE

To harmonize and update previous guidelines and recommendations from the European MAGNetic resonance Imaging in MS (MAGNIMS) group and the Consortium of MS Centers (CMSC) and North American Imaging in MS (NAIMS) cooperative, on the use of standardized magnetic resonance imaging (MRI) in multiple sclerosis (MS), .*Methods and Materials Two panels were convened to update existing guidelines for a standardized MRI protocol, one in Graz, Austria in April 2019 to update the 2015 MAGNIMS guidelines and a second, which in addition to MS neurologists and radiologists also included MR technologists, imaging scientists, MS patient advocacy groups and MRI vendors, meeting separately and independently in Newark, NJ, USA in October 2019 to update the 2016 CMSC guidelines and to discuss advocacy efforts. Subsequently, the leadership of the MAGNIMS, NAIMS, and CMSC working groups combined their efforts to produce these international consensus guidelines.*Results Topics discussed included advances in using MRI to establish an earlier diagnosis of MS, including the 2017 revisions of the McDonald diagnostic criteria; safety concerns regarding gadolinium-based contrast agents (GBCA); the value of spinal cord MRI for diagnosis, prognosis and monitoring and the changing role of MRI for MS patient management and care. 3D acquisitions were emphasized over 2D as they allow for more optimum comparison. Core brain sequences include a 3D-T2weighted FLuid Attenuated Inversion Recovery (FLAIR) for lesion identification and treatment monitoring. GBCA is helpful for identifying lesion dissemination in time for diagnosis and for unexpected clinical worsening but not necessary for routine monitoring. Diffusion-weighted sequences are recommended for progressive multifocal leukoencephalopathy safety monitoring. Optional sequences that could be incorporated into future recommendations include high resolution 3D-T1weighted gradient echo for brain volume monitoring; double and phase-sensitive inversion recovery for identifying cortical lesions; and susceptibility weighted imaging for central vein and paramagnetic rim lesion evaluation.*Conclusions The 2021 evidence-based MAGNIMS-CMSC-NAIMS international consensus recommendations on the use of standardized MRI in MS unify recommendations from European and North American expert groups and address major issues concerning the use of MRI in clinical practice that have arisen in the past few years.*Clinical Relevance/Application Use of a standardized MRI will improve the quality of care for patients with MS by improving diagnostic accuracy and reducing the need and the additional cost for repeat studies because scans cannot be adequately compared.

RESULTS

Topics discussed included advances in using MRI to establish an earlier diagnosis of MS, including the 2017 revisions of the McDonald diagnostic criteria; safety concerns regarding gadolinium-based contrast agents (GBCA); the value of spinal cord MRI for diagnosis, prognosis and monitoring and the changing role of MRI for MS patient management and care. 3D acquisitions were emphasized over 2D as they allow for more optimum comparison. Core brain sequences include a 3D-T2weighted FLuid Attenuated Inversion Recovery (FLAIR) for lesion identification and treatment monitoring. GBCA is helpful for identifying lesion dissemination in time for diagnosis and for unexpected clinical worsening but not necessary for routine monitoring. Diffusion-weighted sequences are recommended for progressive multifocal leukoencephalopathy safety monitoring. Optional sequences that could be incorporated into future recommendations include high resolution 3D-T1weighted gradient echo for brain volume monitoring; double and phase-sensitive inversion recovery for identifying cortical lesions; and susceptibility weighted imaging for central vein and paramagnetic rim lesion evaluation.

CLINICAL RELEVANCE/APPLICATION

Use of a standardized MRI will improve the quality of care for patients with MS by improving diagnostic accuracy and reducing the need and the additional cost for repeat studies because scans cannot be adequately compared.

SDP-NR-22 An Interpretable Multiparametric Radiomics Model For The Diagnosis Of Schizophrenia From Corpus Callosum

Participants

Yaewon Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to investigate the robustness of the diagnostic model for schizophrenia using radiomic features from diffusion tensor imaging and T1-weighted images (T1) of the corpus callosum (CC).*Methods and Materials A total of 165 participants [86 with schizophrenia and 79 healthy controls (HCs)] were allocated to training (N = 115) and test (N = 50) sets. Radiomic features of the CC subregions were extracted from T1, apparent diffusion coefficient, and fractional anisotropy maps (N = 1,605). Following feature selection, various combinations of classifiers were trained, and Bayesian optimization was adopted in the best performing classifier. Discrimination, calibration, and clinical utility of the model were assessed. An online calculator was constructed to offer the probability of schizophrenia to clinicians. SHapley Additive exPlanations (SHAP) was applied to explore the interpretability of the model.*Results We identified 30 first- and second-order radiomic features to differentiate participants with schizophrenia from HCs. The Bayesian optimized model achieved the highest performance, with an area under the curve, accuracy, sensitivity, and specificity of 0.89 (95% confidence interval: 0.81-0.98), 80.0%, 83.3%, and 76.9%, respectively, in the test set. The final model offers clinical probability in an online calculator (https://nhimc.shinyapps.io/sirano-schizoml/). The model explanation by SHAP suggested that second-order features from the posterior CC were highly associated with the risk of schizophrenia.*Conclusions The multiparametric radiomics model focusing on the CC shows its robustness for the diagnosis of schizophrenia. Radiomic features could be a potential source of biomarkers that support the objective diagnosis of schizophrenia and improve the understanding of its neurobiology.*Clinical Relevance/Application Radiomic features extracted from neuroimaging data could be a potential source of biomarkers that support the objective diagnosis of schizophrenia and improve the understanding of its neurobiology.

RESULTS

We identified 30 first- and second-order radiomic features to differentiate participants with schizophrenia from HCs. The Bayesian optimized model achieved the highest performance, with an area under the curve, accuracy, sensitivity, and specificity of 0.89 (95% confidence interval: 0.81-0.98), 80.0%, 83.3%, and 76.9%, respectively, in the test set. The final model offers clinical probability in an online calculator (https://nhimc.shinyapps.io/sirano-schizoml/). The model explanation by SHAP suggested that second-order features from the posterior CC were highly associated with the risk of schizophrenia.

CLINICAL RELEVANCE/APPLICATION

Radiomic features extracted from neuroimaging data could be a potential source of biomarkers that support the objective diagnosis

of schizophrenia and improve the understanding of its neurobiology.

SDP-NR-23 A Magnetic Resonance Imaging-based Radiomic Model For The Noninvasive Preoperative Differentiation Between Transitional And Atypical Meningiomas

Participants
Jing Zhang, Zhuhai, China (*Presenter*) Nothing to Disclose

PURPOSE

Preoperative distinction between transitional meningioma and atypical meningioma would aid the selection of appropriate surgical techniques, as well as the prognosis prediction. Here, we aimed to differentiate between these two tumors using radiomic signatures based on preoperative, contrast-enhanced T1-weighted and T2-weighted magnetic resonance imaging.*Methods and Materials A total of 141 transitional meningioma and 101 atypical meningioma cases between January 2014 and December 2018 with a histopathologically confirmed diagnosis were retrospectively reviewed. All patients underwent magnetic resonance imaging before surgery. For each patient, 1227 radiomic features were extracted from contrast-enhanced T1-weighted and T2-weighted images each. Least absolute shrinkage and selection operator regression analysis was performed to select the most informative features of different modalities. Subsequently, multivariate logistic regression was chosen to build classification models that can distinguish transitional from atypical meningioma. The diagnostic abilities were evaluated by receiver operating characteristic analysis. Furthermore, a nomogram was built by incorporating clinical characteristics, radiological features, and radiomic signatures, and decision curve analysis was used to validate the clinical usefulness of the nomogram.*Results Sex, tumor shape, brain invasion, and four radiomic features differed significantly between transitional meningioma and atypical meningioma. The clinicoradiomic model derived by fusing the above features resulted in the best discrimination ability, with areas under the curves of 0.809 (95% confidence interval, 0.743-0.874) and 0.795 (95% confidence interval, 0.692-0.899) and sensitivity values of 74.0% and 71.4% in the training and validation cohorts, respectively.*Conclusions The clinicoradiomic model demonstrated good performance for the differentiation between transitional and atypical meningioma. It is a quantitative tool that can potentially aid the selection of surgical techniques and the prognosis prediction.*Clinical Relevance/Application The clinicoradiomic model showed good discrimination ability and can thus be applied in patients with these two meningioma subtypes.

RESULTS

Sex, tumor shape, brain invasion, and four radiomic features differed significantly between transitional meningioma and atypical meningioma. The clinicoradiomic model derived by fusing the above features resulted in the best discrimination ability, with areas under the curves of 0.809 (95% confidence interval, 0.743-0.874) and 0.795 (95% confidence interval, 0.692-0.899) and sensitivity values of 74.0% and 71.4% in the training and validation cohorts, respectively.

CLINICAL RELEVANCE/APPLICATION

The clinicoradiomic model showed good discrimination ability and can thus be applied in patients with these two meningioma subtypes.

SDP-NR-24 Changes In Apparent Diffusion Coefficient During Cardiac Cycle In Cerebrospinal Fluid Tap Test Response In Possible Idiopathic Normal Pressure Hydrocephalus

Participants
Ryo Yagawa, Kanazawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

We previously reported that the apparent diffusion coefficient (ADC) obtained from diffusion magnetic resonance imaging (MRI) in the cerebral white matter significantly changed during the cardiac cycle, and this change (?ADC) aided in the diagnosis of idiopathic normal pressure hydrocephalus (iNPH). Although one of the most important criteria for iNPH is the cerebrospinal fluid (CSF) tap test, it is unclear how ?ADC is associated with this test response in "possible iNPH," defined by ventricular dilation and clinical triad (more than one symptom: gait disturbance, cognitive impairment, and urinary incontinence) and not caused by other neurological or non-neurological disease. Therefore, we assessed ?ADC of the brain between positive and negative CSF tap test groups in possible iNPH.*Methods and Materials This study assessed 22 patients with possible iNPH who either showed symptomatic improvements (positive group, n = 17) and those without improvement (negative group, n = 5) after the CSF tap test. On a 1.5-T MRI, electrocardiogram-triggered single-shot diffusion echo planar imaging (b = 0 and 1000 s/mm2) of the brain was used with parallel imaging and half-scan techniques to minimize the sampling window. The ?ADC image was calculated from the maximum-minus-minimum ADC value of all cardiac phase images on a pixel-by-pixel basis. Then, the ?ADC, the mean ADC during the cardiac cycle (ADCmean), and the rates of change before and after CSF tap test of the white matter were determined and compared between positive and negative groups in possible iNPH.*Results Before the CSF tap test, the ?ADC in the positive group was significantly higher than that in the negative group (P < .05), but there was no significant difference in the ?ADC between positive and negative groups after the CSF tap test. No significant difference was observed in the ADCmean between positive and negative groups both before and after the CSF tap test. The ?ADC change rate before and after CSF tap test in the positive group was significantly higher than that in the negative group (P < .05), but there was no significant difference in the ADCmean change rate before and after CSF tap test between positive and negative groups.*Conclusions The ?ADC follows the CSF tap test response in possible iNPH. Therefore, ?ADC analysis makes it possible to predict the CSF tap test response in possible iNPH.*Clinical Relevance/Application Analysis of changes in the apparent diffusion coefficient during the cardiac cycle makes it possible to predict the cerebrospinal fluid tap test response in possible idiopathic normal pressure hydrocephalus.

RESULTS

Before the CSF tap test, the ?ADC in the positive group was significantly higher than that in the negative group (P < .05), but there was no significant difference in the ?ADC between positive and negative groups after the CSF tap test. No significant difference was observed in the ADCmean between positive and negative groups both before and after the CSF tap test. The ?ADC change rate before and after CSF tap test in the positive group was significantly higher than that in the negative group (P < .05), but there was no significant difference in the ADCmean change rate before and after CSF tap test between positive and negative groups.

CLINICAL RELEVANCE/APPLICATION

Analysis of changes in the apparent diffusion coefficient during the cardiac cycle makes it possible to predict the cerebrospinal fluid tap test response in possible idiopathic normal pressure hydrocephalus.

SDP-NR-25 Amplified Flow To Assess Wall Motion Of Intracranial Aneurysms: A Comparative Analysis Between Unstable Vs. Stable Aneurysms

Participants
Kambiz Nael, MD, Los Angeles, California (*Presenter*) Consultant, Canon Medical Systems Corporation;Consultant, Brainomix Limited

PURPOSE

Intracranial aneurysm (IA) wall motion has been suggested as a potential biomarker of instability (Vanrossomme A.E. et al. AJNR. PMID: 25929878). Detection and accurate assessment of wall motion however are challenging considering the small size of IA. Recently, a new image processing algorithm called amplified Flow (aFlow) has been used to successfully track IA wall by combining the amplification of cine and 4D flow MRI (Abderezaei J et al. IEEE Trans Med Imaging. PMID: 32746150). We sought to apply aFlow to assess wall motion as a potential marker of instability in a paired-wise analysis of patients with unstable vs. stable aneurysms.*Methods and Materials In this prospective study, patients with IA underwent MRI including MRA and 4D flow at baseline, and were followed up to 5 years. After a cross-sectional analysis at the end of the 5th year from initial imaging, 10 patients were identified with growing IA. These were matched with a cohort of patients with similar size and location of IA, whose aneurysms remained stable in size. 4D flow imaging parameters: (3D phase-contrast peripherally-gated sequence, TR/TE: 5.5/2.8 ms; FOV: 160 x 112 mm, matrix: 224 x 224 mm2, 40 x 0.8 mm slices, 3D-velocity encoding value: 80 cm/s). The aFlow algorithm was applied to the 4D flow MRI data to visualize and quantify the 3D displacement of the IA wall at selected frequency ranges. The associations of aFlow parameters with commonly used risk factors and morphometric features were assessed using paired-wise univariate and multivariate analyses.*Results The age, sex, race, IA-size, aspect-ratio, and PHASES scores were not significantly different between the two groups. 90th percentile IA wall displacement acquired from the aFlow was 68% higher in unstable IAs (P<0.05). Unstable IAs also showed higher variability of deformation across their geometry evident by dispersion variables including standard deviation (SD) and interquartile range (IQR) with values being 153% and 164% higher in unstable vs. stable IA, respectively (p<0.01). ROC analysis showed AUC/sensitivity/specificity of 0.91/90%/90% for SD and 0.85/100%/70% for 90th% wall motion in differentiating unstable from stable IAs.*Conclusions aFlow MRI-derived wall motion variables including 90th percentile wall displacement and dispersion variables including SD and IQR at baseline may be able to identify unstable from stable IAs.*Clinical Relevance/Application Given that aFlow is a post-processing algorithm carried out on standard 4D flow MRI data, it holds great promise to identify unstable aneurysms with potential value in treatment decision making of IAs.

RESULTS

The age, sex, race, IA-size, aspect-ratio, and PHASES scores were not significantly different between the two groups. 90th percentile IA wall displacement acquired from the aFlow was 68% higher in unstable IAs (P<0.05). Unstable IAs also showed higher variability of deformation across their geometry evident by dispersion variables including standard deviation (SD) and interquartile range (IQR) with values being 153% and 164% higher in unstable vs. stable IA, respectively (p<0.01). ROC analysis showed AUC/sensitivity/specificity of 0.91/90%/90% for SD and 0.85/100%/70% for 90th% wall motion in differentiating unstable from stable IAs.

CLINICAL RELEVANCE/APPLICATION

Given that aFlow is a post-processing algorithm carried out on standard 4D flow MRI data, it holds great promise to identify unstable aneurysms with potential value in treatment decision making of IAs.

SDP-NR-26 Automated Detection Of Descending Transtentorial Hernia On Computed Tomography Images Using A Convolutional Neural Network

Participants
Meng-Hsuan Chiang, Kaohsiung, Taiwan (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study is to investigate the possibility of automated detection of transtentorial hernia (DTH) using an automated shape-detection orientation convolutional neural network (CNN) technique for prompt diagnosis on computed tomography (CT) images.*Methods and Materials IRB approved retrospective study with the requirement for informed consent waived. Included cases were identified through a keyword search of our radiological information system (RIS) for head CT (HCT) with DTH and normal HCT between 1/1/2000-1/1/2020. A total of 402 DTH cases and 260 normal HCT cases were included. Ground truth labeling structure focused on the cerebellar tentorium level, about 4-5 sequent DICOM files (slice thickness: 5mm), were labeled with slice-level bounding boxes and approved by a board-certified radiologist. The total number of positive DTH images is 1831 and the number of normal images is 1328. The DTH image and normal image are each divided into training data, verification data, and testing data in sequence at a ratio of 7:2:1. In our research, based on shape-detection orientation, we used You Only Look Once version 3 (YOLOv3) to train our well-prepared dataset. The evaluation of our inference result is the Intersection over Union (IOU) index and the threshold is 0.5. The positive result for each image slice was defined as 1 when the number of percentages is larger than 0.5, and negative is zero. Once the result we identified, we use sensitivity, specificity, accuracy rate?to evaluate our model.*Results The 402 patients with DTH (mean age, 59 years +/- 19[standard deviation]; 246 men) and 260 normal HCT cases (mean age, 55 years +/- 18[standard deviation]; 133 men) were involved. The testing data including 182 positive DTH images and 133 negative images, shows sensitivity 0.887, specificity 0.862, PPV 0.878, NPV 0.854 and accuracy rate 0.824 for DTH detection (classified testing data number of true positive: 180, false positive: 2; true negative:127, false negative:6).*Conclusions We successfully proposed a shape-detection model to detect DTH well on HCT examinations with general ground truth, which is not necessary to be annotated with bounding box "very precisely" by radiologists. With good accuracy, making a prompt diagnosis by the model is promising for the patient's safety.*Clinical Relevance/Application DTH is a life-threatening condition that requires prompt accurate image diagnosis and treatment in emergency. CT is the imaging modality of choice used for establishing a correct diagnosis and guiding therapeutic decisions. We developed the inference model with one of the deep learning algorithm, YOLO, that will be a promising approach to solve delayed and missed diagnosis of DTH.

RESULTS

The 402 patients with DTH (mean age, 59 years +/- 19[standard deviation]; 246 men) and 260 normal HCT cases (mean age, 55 years +/- 18[standard deviation]; 133 men) were involved. The testing data including 182 positive DTH images and 133 negative images, shows sensitivity 0.887, specificity 0.862, PPV 0.878, NPV 0.854 and accuracy rate 0.824 for DTH detection (classified testing data number of true positive: 180, false positive: 2; true negative:127, false negative:6).

CLINICAL RELEVANCE/APPLICATION

DTH is a life-threatening condition that requires prompt accurate image diagnosis and treatment in emergency. CT is the imaging

modality of choice used for establishing a correct diagnosis and guiding therapeutic decisions. We developed the inference model with one of the deep learning algorithm, YOLO, that will be a promising approach to solve delayed and missed diagnosis of DTH.

SDP-NR-27 A Novel Habitat Co-localization Descriptor For Predicting Survival In Glioblastoma

Participants
Xuan Xu, Centereach, New York (*Presenter*) Nothing to Disclose

PURPOSE

Glioblastoma Multiforme (GBM) is a highly aggressive primary brain tumor with a median survival of 12 months. Tumor shape and texture have been proposed as prognostic markers. Intra-tumor heterogeneity has been linked to uncontrolled cellular proliferation and angiogenesis leading to poor prognosis. Spatial heterogeneity in GBM, as manifested on multi-protocol MRI (mp-MRI), can be categorized into physiologically similar sub-regions called "habitats". Studies have correlated survival rate with radiomic analysis on global habitats; however, interactions within the local habitats or "microhabitats" have been unexplored. We quantify the spatial diversity of global and microhabitats on mp-MRI by constructing region adjacency graphs (RAGs) using a novel 3D spatial co-localization descriptor. We hypothesize that the adjacency of such habitats contributes to intralesional heterogeneity and overall survival (OS).*Methods and Materials We used leveraged GBM cases with corresponding OS information from TCIA. Global habitats are identified by ground truth tumor sub-compartment segmentations including enhancing tumor (ET), peritumoral edema (ED), and necrotic and non-enhancing tumor core (NET). Microhabitats are obtained via resegmentation of the tumor into 20 supervoxels based on their intensity distribution. Connected components (CCs) are calculated within the global and microhabitats independently. Two voxels are connected if they are adjacent and share the same label. A RAG is constructed based on CCs. All the CCs with neighbors are denoted as graph nodes and an edge is built between two nodes if these components are adjacent. We extracted general graph measurements including nodes, edges, and degree. Graph embedding is computed for each graph with GL2Vec. Principal component analysis (PCA) is leveraged to extract 10 PCs of the embedded representation. The computed features including general graph information and graph embedding information are used as inputs to a Cox model to predict personalized survival risk.*Results Compared to the baseline model with clinical features, incorporation of global and microhabitat graph features improved C-index from 0.64 to 0.66 and HR from 1.73 to 2.19 . This integrated model also outperformed a textural radiomic model (C-index = 0.63, HR=1.91).*Conclusions Intra-tumoral phenotypic diversity, quantified by graph-based analysis of radiologically defined global and microhabitats, can provide valuable prognostic information at early stages of GBM to direct patient-specific management.*Clinical Relevance/Application Our model demonstrates the significance of radiologically defined features in providing early personalized risk prediction and characterizing overall survival rates in GBM.

RESULTS

Compared to the baseline model with clinical features, incorporation of global and microhabitat graph features improved C-index from 0.64 to 0.66 and HR from 1.73 to 2.19 . This integrated model also outperformed a textural radiomic model (C-index = 0.63, HR=1.91).

CLINICAL RELEVANCE/APPLICATION

Our model demonstrates the significance of radiologically defined features in providing early personalized risk prediction and characterizing overall survival rates in GBM.

SDP-NR-28 Deep Learning-based Reconstruction Of Accelerated 2d T2 Flair: A Clinical Feasibility Study

Participants
Jeongmin Yim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

We compared a prototype DL based reconstruction algorithm in accelerated 2D T2 FLAIR images (P4) with standard images (P2), and conventionally reconstructed images.*Methods and Materials 56 subjects who underwent brain MRI with 2D T2 FLAIR images were included in this study. We obtained two separate scans for each subject, GRAPPA factors, 2 and 4. Other parameters were the same for two scans; TR/TI/TE = 8000/2370/131 msec, FA 150', 0.7 x 0.7 x 4 mm3, turbo factor 25. Scan time was 288 sec for P2 and 240 sec for P4. From them, we obtained three different MR images, P2 (standard, factor 2), P4 (factor4), and P4-DL (factor 4 with DL reconstruction).The prototype DL reconstruction comprised a variational network that alternates data consistency based on a parallel imaging signal model and regularization based on convolution neural networks. The network receives undersampled k-space data, pre-calculated coil sensitivity maps and a bias field as input and delivers a coil-combined reconstructed image as output. For training more than 10000 slices covering a broad range of image contrasts and body regions were acquired and the training performed in a supervised manner performing retrospective undersampling for the data input.We compared the subjective image quality, presence of artifacts, and lesion clarity for three sets of images, P2, P4 and P4-DL. Subjective analysis was done by two reviewers independently. We also measured SNR of each images and compared.*Results While most P4 images suffered from low image quality (bad or poor image quality 45/56 for reviewer 1, 53/56 for reviewer 2), which might be associated to under-sampling, P4-DL shows similar or sometimes higher image quality (51/56 good or above for reviewer, 39/56 for reviewer 2), as compared to P2 images (54/56 good for reviewer 1, 55/56 for reviewer 2). This was closely related to the successful suppression of grappa artifacts (P4-DL acceptable or better 43/56 for both reviewers, P4 mild or severe 55/56 for both reviewers), especially at the central portion of the images. In 30 cases of the brain lesions, P4-DL showed similar lesion clarity to P2. Interestingly, measured SNR was not different in P4 (195 ± 43) and P4-DL (193± 43) images.*Conclusions DL reconstructed 2D TSE T2 FLAIR images had suppressed artifacts from highly undersampled data, preserving image quality and reducing scan time.*Clinical Relevance/Application Using deep learning, we can reduce acquisition time of 2D TSE FLAIR images, preserving image quality, which is useful in patients with acute ischemic stroke or other acutely ill patients.

RESULTS

While most P4 images suffered from low image quality (bad or poor image quality 45/56 for reviewer 1, 53/56 for reviewer 2), which might be associated to under-sampling, P4-DL shows similar or sometimes higher image quality (51/56 good or above for reviewer, 39/56 for reviewer 2), as compared to P2 images (54/56 good for reviewer 1, 55/56 for reviewer 2). This was closely related to the successful suppression of grappa artifacts (P4-DL acceptable or better 43/56 for both reviewers, P4 mild or severe 55/56 for both reviewers), especially at the central portion of the images. In 30 cases of the brain lesions, P4-DL showed similar lesion clarity to P2. Interestingly, measured SNR was not different in P4 (195 ± 43) and P4-DL (193± 43) images.

CLINICAL RELEVANCE/APPLICATION

Using deep learning, we can reduce acquisition time of 2D TSE FLAIR images, preserving image quality, which is useful in patients

with acute ischemic stroke or other acutely ill patients.

SDP-NR-29   Association Of Signal Intensity Ratio On Fluid-attenuated Inversion Recovery-MRI With Time From Stroke Onset And Clinical Outcomes In Acute Anterior Circulation Ischemic Stroke

Participants
Kehui Nie, MSc, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to explore the relationship between signal intensity ratio (SIR) of ischemic lesions on FLAIR and time from stroke onset (TSO) in patients, and revealed the correlation of volumes of different SIR values in specific TSO with clinical outcome.*Methods and Materials Tissue at-risk regions of ischemic infarction on DWI were segmented and co-registered on the corresponding FLAIR to locate target lesions. The FLAIR signal intensity of the target lesions and of the mirror regions on the side of normal (contralateral) brain tissue was obtained, with cerebrospinal fluid and extracerebral space excluded. The SIR value was calculated as a ratio of mean signal intensity of voxels in the target lesions relative to those in the contralateral brain regions. The volumes of SIR>1.05, SIR>1.10, SIR>1.15 and SIR>1.2 were used for the correlation with primary clinical outcome, mRS at 90 days after stroke.*Results A total of 99 acute anterior circulation stroke patients with clear TSO were included in this multi-center retrospective study. Eighty-six patients underwent DWI and FLAIR examinations immediately after the thrombolysis and 13 underwent MRI at admission before treatments. The median TSO of all patients was 194 minutes (IQR:120-334.5), with the mean age of 70.4±12.2 years and male-to-female ratio of 1.8:1. The median NIHSS at admission was 10 (IQR:4.75-17), and 90-day mRs was 2 (IQR:1-4). A higher SIR was significantly associated with a longer elapsed TSO (P=0.002). The volumes of SIR>1.05, SIR>1.10, SIR>1.15 and SIR>1.2 were all significantly associated with a higher (worse) 90-day mRs (P=0.001) as well as a higher admission NIHSS (P<0.001), elucidating evolution of the lesion size measured on our quantitative FLAIR in terms of stroke severity and outcome within certain TSO period.*Conclusions The evolution of ischemic stroke could be measured quantitatively as SIR on FLAIR within 9 hours of TSO in our study, and the larger lesion volume at SIR>1.05 may be predictive of a worse clinical outcome.*Clinical Relevance/Application The quantitative signal intensity ratio of positive DWI-FLAIR stroke lesions can help elucidate evolution after stroke onset and possibly predict clinical outcome.

RESULTS

A total of 99 acute anterior circulation stroke patients with clear TSO were included in this multi-center retrospective study. Eighty-six patients underwent DWI and FLAIR examinations immediately after the thrombolysis and 13 underwent MRI at admission before treatments. The median TSO of all patients was 194 minutes (IQR:120-334.5), with the mean age of 70.4±12.2 years and male-to-female ratio of 1.8:1. The median NIHSS at admission was 10 (IQR:4.75-17), and 90-day mRs was 2 (IQR:1-4). A higher SIR was significantly associated with a longer elapsed TSO (P=0.002). The volumes of SIR>1.05, SIR>1.10, SIR>1.15 and SIR>1.2 were all significantly associated with a higher (worse) 90-day mRs (P=0.001) as well as a higher admission NIHSS (P<0.001), elucidating evolution of the lesion size measured on our quantitative FLAIR in terms of stroke severity and outcome within certain TSO period.

CLINICAL RELEVANCE/APPLICATION

The quantitative signal intensity ratio of positive DWI-FLAIR stroke lesions can help elucidate evolution after stroke onset and possibly predict clinical outcome.

SDP-NR-3   Assessment Of Intracranial Culprit Plaque Vulnerability After Stroke Within Three Months: A 3-dimensional High-resolution Magnetic Resonance Imaging Study

Participants
Zelan Ma, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to assess HRMRI-detected plaque features after stroke within three months, and compare intracranial plaque vulnerability in the acute phase after stroke with that of in the subacute phase.*Methods and Materials Seventy-eight patients with ischemic stroke due to middle cerebral artery or basilar artery stenosis underwent HRMRI within 90 days of symptom onset. The relationship between features of vulnerability (intraplaque hemorrhage, surface irregularity, positive remodeling and plaque enhancement) in plaques and degree of stenosis was analyzed. And in the low- and high-grade stenotic arteries, the difference of vulnerability features in plaques between the acute phase group and the subacute phase group was analyzed respectively.*Results Fifty-four patients with acute stroke (range, 1-28 days after onset) and twenty four patients with subacute stroke (range, 32-88 days after onset) underwent HRMRI. The incidence of positive remodeling was significantly higher in the high-grade stenosis group than in the low-grade stenosis group (P=0.023). There were no statistical differences in vulnerability features of culprit plaques between the acute group and the subacute group, both in patients with low-grade stenosis and high-grade stenosis.*Conclusions HRMRI-detected features of vulnerability have no statistical differences in the acute phase and the subacute phase after stroke, which providing important insight into the secondary prevention of ischemic stroke.*Clinical Relevance/Application Knowledge of plaque vulnerability in the acute (within one month) and subacute (between 1 and 3 months) phase after stroke would be helpful to assist decision-making in the secondary prevention of ischemic stroke.

RESULTS

Fifty-four patients with acute stroke (range, 1-28 days after onset) and twenty four patients with subacute stroke (range, 32-88 days after onset) underwent HRMRI. The incidence of positive remodeling was significantly higher in the high-grade stenosis group than in the low-grade stenosis group (P=0.023). There were no statistical differences in vulnerability features of culprit plaques between the acute group and the subacute group, both in patients with low-grade stenosis and high-grade stenosis.

CLINICAL RELEVANCE/APPLICATION

Knowledge of plaque vulnerability in the acute (within one month) and subacute (between 1 and 3 months) phase after stroke would be helpful to assist decision-making in the secondary prevention of ischemic stroke.

SDP-NR-30   Deep Learning Reconstruction For Unenhanced Brain CT: Assessment Of Image Quality And Dose Optimization Potential

Participants
Yasunori Nagayama, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

This study aims to evaluate the subjective and objective image quality of the deep-learning reconstruction (DLR) algorithm for reduced-dose unenhanced brain CT and compare it with those of standard-dose hybrid iterative reconstruction (HIR) images.*Methods and Materials This retrospective study included 74 patients who underwent unenhanced brain CT with standard-dose (STD group, n = 37) or low-dose (LD group, n = 37) protocol on a 320-row multidetector CT. The STD images were reconstructed with HIR (AIDR-3D), whereas LD images were reconstructed with HIR (LD-HIR) and DLR (AiCE brain LCD; LD-DLR). The section thickness of all images was 2 mm. The image noise, grey-white matter (GM-WM) contrast, and contrast-to-noise ratio (CNR) at section levels of the centrum semiovale, basal ganglia, and posterior fossa were quantified and compared among three images series. The noise magnitude, noise texture, GM-WM contrast, margin sharpness of cerebrospinal fluid space, and overall image quality were subjectively scored on a four-point scale (1 = worst, 4 = best).*Results The radiation dose in the LD group was 25% lower than that in the STD group (p < 0.01). In quantitative assessment, the LD-DLR images yielded significantly lower image noise, higher GM-WM contrast, and higher CNR at all section levels than STD and LD-HIR images (all p < 0.01). In all subjective criteria, the scores assigned for LD-DLR images were significantly higher than those assigned to STD and LD-HIR images (all p < 0.01).*Conclusions For unenhanced brain CT obtained at 75% radiation dose, DLR yielded superior subjective and objective image quality compared with standard-dose HIR images.*Clinical Relevance/Application DLR allows for 25% radiation dose reduction in unenhanced brain CT while reducing image noise and improving GM-WM contrast without degrading sharpness and noise texture relative to the current standard-of-care HIR algorithm.

RESULTS

The radiation dose in the LD group was 25% lower than that in the STD group (p < 0.01). In quantitative assessment, the LD-DLR images yielded significantly lower image noise, higher GM-WM contrast, and higher CNR at all section levels than STD and LD-HIR images (all p < 0.01). In all subjective criteria, the scores assigned for LD-DLR images were significantly higher than those assigned to STD and LD-HIR images (all p < 0.01).

CLINICAL RELEVANCE/APPLICATION

DLR allows for 25% radiation dose reduction in unenhanced brain CT while reducing image noise and improving GM-WM contrast without degrading sharpness and noise texture relative to the current standard-of-care HIR algorithm.

SDP-NR-31 ASSESSMENT OF BAYESIAN VERSUS SINGULAR VALUE DECONVOLUTION CT PERFUSION MODELS TO PREDICT INFARCT VOLUME FROM ACUTE ISCHEMIC STROKE FROM M2 OR DISTAL BRANCHES

Participants
Ivano Chiarotti, Siena, Italy (*Presenter*) Nothing to Disclose

PURPOSE

In Patients with acute ischemic stroke (AIS), cerebral computed tomography-perfusion (CTP) poses various technical issues including different models used by automated softwares processing hemodynamic parameters. Few data exist in AIS from M2 or smaller branches of medium cerebral artery. In this clinical scenario, we retrospectively evaluated two CTP models measuring infarct volume.*Methods and Materials Patients with AIS, NIHSS score at admission, complete multimodal CT protocol including unenhanced brain CT (NCCT), cervico-cranial arteries CT-angiography and brain CTP, isolated unilateral occlusion of M2 or distal branch(es), and 1 to 7 days follow-up brain NCCT or MRI were included. A commercial software (Olea Sphere 3.0, Olea Medical, La Ciotat, France) processed CTP images for "core" and "penumbra" estimation by blockcirculant singular value deconvolution (cSVD) Tmax/CBF-based (vSP16) and bayesian TTP/CBF-based (vSP22) models. Estimates were compared with infarct lesion volumes manually assessed at follow-up.*Results From July 2015 to February 2021, 75 patients (40 females, 35 males) met inclusion criteria. They had been treated by intravenous thrombolysis with (n:12) or without (n:17) mechanical thrombectomy, mechanical thrombectomy alone (n:28), or conservative medical management (n:18). Mean "core" estimates were 5,8 mL and 16,1 mL by SP16 and SP22, respectively; mean ischemic "penumbra" estimates were 49,8 mL 39,9 mL. Mean infarct volume at follow-up was 14,0 mL. At correlation analysis, infarct volume was predicted by SP22 (?=0,506) significantly better than SP16 (?=0,472; p<4e-12).*Conclusions In our Patients' population with M2 or distal branches AIS, a bayesian TTP/CBF-based model was superior to a sCVD Tmax/CBF-based one in assessing the evolution of infarct volume.*Clinical Relevance/Application The algorithm model of softwares evaluating CT perfusion data in AIS patients is one of the major factors affecting their results and predictive value in assessing "core" and "penumbra", and thus their use in clinical practice.

RESULTS

From July 2015 to February 2021, 75 patients (40 females, 35 males) met inclusion criteria. They had been treated by intravenous thrombolysis with (n:12) or without (n:17) mechanical thrombectomy, mechanical thrombectomy alone (n:28), or conservative medical management (n:18). Mean "core" estimates were 5,8 mL and 16,1 mL by SP16 and SP22, respectively; mean ischemic "penumbra" estimates were 49,8 mL 39,9 mL. Mean infarct volume at follow-up was 14,0 mL. At correlation analysis, infarct volume was predicted by SP22 (?=0,506) significantly better than SP16 (?=0,472; p<4e-12).

CLINICAL RELEVANCE/APPLICATION

The algorithm model of softwares evaluating CT perfusion data in AIS patients is one of the major factors affecting their results and predictive value in assessing "core" and "penumbra", and thus their use in clinical practice.

SDP-NR-32 Effect Of Small Vessel Disease Burden On Collateral Perfusion In Symptomatic Large Vessel Stenosis Or Occlusion

Participants
Liu-Xian Wang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

The effect of small vessel disease (SVD) burden on collateral circulation in acute ischemic stroke reached different conclusions. We sought to identify whether the SVD burden could also impact collateral circulation in symptomatic ICA/MCA severe stenosis or occlusion patients.*Methods and Materials All included patients underwent pseudo-continuous arterial spin labeling (pCASL) with post-labeling delay (PLD) of 1.5s and 2.5s. The total SVD burden were assessed by four separate features: white matter hyperintensity, perivascular space (PVS), lacunes and cerebral microbleed. Cerebral blood flow (CBF) of MCA territory was calculated by manually drawing region of interest. Collateral perfusion was defined as (CBF 2.5s minus CBF 1.5s) at lesion side minus

(CBF 2.5s minus CBF 1.5s) at normal side.*Results A total of 91 patients with symptomatic ICA/MCA severe stenosis/occlusion met the inclusion criteria. Compared with patients with no SVD burden (N = 24), those with any SVD (N = 67) were older (p = 0.01), and showed higher incidence of diabetes mellitus (p = 0.001). Furthermore, the mean CBF at PLD 2.5s in patients with any SVD was lower than those without SVD (p = 0.003). Collateral perfusion was significantly correlated with total SVD score in univariate linear regression (b = -1.29, p = 0.04). However, such correlation disappeared after adjusted for age and interval from symptom onset to imaging (b = -1.03, p = 0.14). In the subgroup analysis, PVS could still significantly impact collateral circulation (F = 3.21, p = 0.02) after adjusted for age, sex and interval from symptom onset to imaging.*Conclusions Our results suggested that collateral circulation may not be affected by total SVD burden in chronic symptomatic large vessel stenosis or occlusion. However, PVS may affect the collateral perfusion after a relatively long time from symptom onset. Our results suggested that PVS could be one of the possible therapeutic targets for improvement of collateral circulation.*Clinical Relevance/Application The effect of SVD burden on collaterals in acute stroke reached different conclusions. In patients with relatively chronic ICA/MCA severe stenosis or occlusion, our results suggested that the total SVD burden showed no obvious impact on collateral perfusion. However, the collateral perfusion showed significant difference among different PVS grades. PVS may be considered as one possible therapeutic target in patients with ICA/MCA severe stenosis or occlusion.

RESULTS

A total of 91 patients with symptomatic ICA/MCA severe stenosis/occlusion met the inclusion criteria. Compared with patients with no SVD burden (N = 24), those with any SVD (N = 67) were older (p = 0.01), and showed higher incidence of diabetes mellitus (p = 0.001). Furthermore, the mean CBF at PLD 2.5s in patients with any SVD was lower than those without SVD (p = 0.003). Collateral perfusion was significantly correlated with total SVD score in univariate linear regression (b = -1.29, p = 0.04). However, such correlation disappeared after adjusted for age and interval from symptom onset to imaging (b = -1.03, p = 0.14). In the subgroup analysis, PVS could still significantly impact collateral circulation (F = 3.21, p = 0.02) after adjusted for age, sex and interval from symptom onset to imaging.

CLINICAL RELEVANCE/APPLICATION

The effect of SVD burden on collaterals in acute stroke reached different conclusions. In patients with relatively chronic ICA/MCA severe stenosis or occlusion, our results suggested that the total SVD burden showed no obvious impact on collateral perfusion. However, the collateral perfusion showed significant difference among different PVS grades. PVS may be considered as one possible therapeutic target in patients with ICA/MCA severe stenosis or occlusion.

SDP-NR-33   Neuroradiology Protocol Selection By Natural Language Processing

Participants
Daniel J. Blezek, PhD, Mantorville, Minnesota (*Presenter*) Founder, FLOWSIGMA Inc;Shareholder, FLOWSIGMA Inc

PURPOSE

High quality care requires radiologists to specifically craft an MR imaging study to best answer the clinical question posed by the referring physician. Neuroadiologists must balance often competing concerns when selecting an imaging protocol e.g. scan time, patient tolerance, department throughput, scanner capabilities, technologist expertise, series selection, etc. This protocoling process has been shown to require significant non-image-interpretive time. In this study, we construct a natural language processing (NLP) algorithm to provide protocol suggestions and evaluate the system's performance.*Methods and Materials Our IRB approved a waiver of HIPPA authorization for this retrospective study. Data were collected between 1/1/2019 and 3/24/2021 for 19 MR scanners primarily used for outpatient neuroradiology imaging including: age, gender, ordered procedure, protocol, indication, most recent applicable clinical notes, and ordering department. Non neuro protocols were removed from the dataset. The remaining protocols were grouped into standard protocols and custom protocols, and all protocols were ranked. An algorithm was constructed to classify an input string into the corresponding protocol. Data from 2019 and 2020 were used for training and validation, with 2021 data held out for testing. Multi-class accuracy, kappa, F1, recall, precision, and Matthews correlation coefficient(MCC) metrics were calculated.*Results After removing non-neuro protocols from 99,503 total protocols, 54,329 standard protocols were divided into training (N=19,839), validation (N=4,730) and test (N=7,038). The system was trained to classify the top 12 protocols and an "other" class representing all remaining protocols. The top protocols were chosen by taking any standard protocol representing > 2% of the data. The system achieved an overall accuracy of 86%, kappa of 0.83, F1 (micro) of 0.86, recall of 0.86, precision of 0.86, and MCC of 0.83.*Conclusions We have demonstrated a system that is able to predict neuroradiology protocols with high accuracy. This inital model was trained using a very restricted set of data available in the EHR suggesting room for accuracy improvement. Significant further study is required to evaluate performance relative to MR technologists, residents, fellows and experienced radiologists.*Clinical Relevance/Application Large institutions face many challenges in efficiently imaging patients to best diagnose clinical unknowns. Determining the most helpful and customized imaging protocols requires time and expertise. Automation removes this time and energy consuming process off the shoulders of radiologists who can then better use these precious resources to improve their interpretations and overall care of patients.

RESULTS

After removing non-neuro protocols from 99,503 total protocols, 54,329 standard protocols were divided into training (N=19,839), validation (N=4,730) and test (N=7,038). The system was trained to classify the top 12 protocols and an "other" class representing all remaining protocols. The top protocols were chosen by taking any standard protocol representing > 2% of the data. The system achieved an overall accuracy of 86%, kappa of 0.83, F1 (micro) of 0.86, recall of 0.86, precision of 0.86, and MCC of 0.83.

CLINICAL RELEVANCE/APPLICATION

Large institutions face many challenges in efficiently imaging patients to best diagnose clinical unknowns. Determining the most helpful and customized imaging protocols requires time and expertise. Automation removes this time and energy consuming process off the shoulders of radiologists who can then better use these precious resources to improve their interpretations and overall care of patients.

SDP-NR-34   Increased Confidence Of Radiomics Facilitating Pretherapeutic Differentiation Of BRAF-altered Pediatric Low-grade Glioma

Participants
Kareem Kudus, Toronto, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

Pediatric low-grade glioma (pLGG) is the most common pediatric brain tumor and affected children suffer from multiple recurrences.

Radiomics-based prediction of molecular markers (BRAF V600E mutation vs. BRAF fusion) has recently demonstrated improved diagnosis and prognosis. In this work, we evaluate the predictive value of a radiomics model combined with clinical data. We also introduce a confidence measure for radiomics results enabling the radiomics model to achieve a desired level of accuracy by identifying patients for whom the model is confident enough to produce reliable results.*Methods and Materials In this REB approved retrospective study, we included pretherapeutic data from two independent hospitals consisting of 213 (internal/training cohort) and 31 patients (external/test cohort). Clinical data was comprised of age, gender, and tumour location. Radiologic data consisted of FLAIR MR images with manual segmentation of the tumour volume. This was used to extract 851 (Py-)radiomic features. A Random Forest model was trained on the internal dataset, and the external dataset was reserved for testing. In training where hyperparameters were fine-tuned, we added a new hyperparameter to determine the model's confidence for the produced results so the model refrains from making a prediction, when it is not confident. This threshold was chosen based on the accuracy deemed necessary for the model.*Results Adding a confidence hyperparameter resulted in a more precise determination of BRAF status. Higher confidence thresholds resulted in more accurate predictions for a subset of test dataset, while the results for the remaining patients were flagged by the model as unreliable. On the external dataset, the mean accuracy of the model with a specific confidence threshold (95%, set during the training) was 88.7%, 95% confidence interval (CI) [82.1%, 95.4%], while making a prediction for 67.5% of patients, compared to mean accuracy of 76.2%, 95% CI [72.5%, 80.0%] for the model without the threshold, making a prediction for all patients. For internal 5-fold cross validation, the mean accuracy for the model with the confidence threshold was 93.4%, 95% CI [82.3%, 100%], while making a prediction for 66.6% of the patients, compared to 83.9%, 95% CI [72.6%, 95.1%] for all patients.*Conclusions BRAF status can be classified using a machine learning model trained on radiomic and clinical data. Precision can be improved by tuning the model to only make predictions where it has a high level of confidence.*Clinical Relevance/Application BRAF status of pLGG is assessed through biopsy, which is invasive and has significant side effects. Prediction of the molecular marker via MRI-based radiomics provides increased reliability and confidence for clinical deployment.

RESULTS

Adding a confidence hyperparameter resulted in a more precise determination of BRAF status. Higher confidence thresholds resulted in more accurate predictions for a subset of test dataset, while the results for the remaining patients were flagged by the model as unreliable. On the external dataset, the mean accuracy of the model with a specific confidence threshold (95%, set during the training) was 88.7%, 95% confidence interval (CI) [82.1%, 95.4%], while making a prediction for 67.5% of patients, compared to mean accuracy of 76.2%, 95% CI [72.5%, 80.0%] for the model without the threshold, making a prediction for all patients. For internal 5-fold cross validation, the mean accuracy for the model with the confidence threshold was 93.4%, 95% CI [82.3%, 100%], while making a prediction for 66.6% of the patients, compared to 83.9%, 95% CI [72.6%, 95.1%] for all patients.

CLINICAL RELEVANCE/APPLICATION

BRAF status of pLGG is assessed through biopsy, which is invasive and has significant side effects. Prediction of the molecular marker via MRI-based radiomics provides increased reliability and confidence for clinical deployment.

SDP-NR-35   Brain Atrophy Significantly Modulates The Association Betwwen Infarct Volume And National Institutes Of Health Stroke Scale In Acute Ischemic Stroke

Participants
Jia-Ying Zhou, Nanjing, China (*Presenter*) Nothing to Disclose

PURPOSE

The National Institutes of Health Stroke Scale (NIHSS) provides a reliable, quantitative measure of ischemic stroke severity and is predicted by the infarct core volume. We aim to determine whether brain atrophy assessed quantitatively could have an impact on the association between NIHSS and the infarct core volume.*Methods and Materials We retrospectively studied consecutive patients with supratentorial, ischemic strokes between Aug 2016 to Sep 2020. We evaluated their severity of brain frailty quantitatively on baseline non-contrast-enhanced CT using CTseg algorithm (https://github.com/WCHN/CTseg) in SPM12. The ratio of brain parenchymal volume to total intracerebral volumes (brain parenchymal fraction [BPF]) was assessed. Infarct volume was assessed on diffusion-weighted images 24 hours after admission. Multivariable linear regression models were used to test the interaction of atrophy with infarct volume, and assess whether the association of brain atrophy and infarct volume on NIHSS was independent of other clinically relevant covariates.*Results A total consecutive 224 patients (mean age 71±12years; 53% men) were enrolled for the final analysis. Overall, there was a significant correlation between the infarct volume and NIHSS (r=0.52, P<0.001), and between BPF and NIHSS (r=-0.61, P<0.001). Multivariable adjusted leaner regression model disclosed that BPF (OR, 0.11 [95%CI 0.04-0.18], P=0.016) and infarct core volume (OR, 1.36, [95%CI 1.31-1.42], P<0.001) were independently associated with a greater NIHSS deficit, and that there is a significant interaction between BPF and infarct volume (OR, 1.017 [95%CI, 1.013-1.019], P=0.026) in determining a higher NIHSS score.*Conclusions Preexisting brain atrophy significantly modulates the association between infarct core and NIHSS at baseline. This finding may be relevant to mitigate outcome differences in stroke patients by aiding treatment decisions that rely on the NIHSS, and have significant implications to improve selection for acute stroke therapies.*Clinical Relevance/Application Preexisting brain atrophy significantly modulates the association between infarct core and NIHSS at baseline. This may explain outcome differences in stroke patients by aiding treatment decisions that rely on the NIHSS, and have a significant implication to improve selection for acute stroke therapies.

RESULTS

A total consecutive 224 patients (mean age 71±12years; 53% men) were enrolled for the final analysis. Overall, there was a significant correlation between the infarct volume and NIHSS (r=0.52, P<0.001), and between BPF and NIHSS (r=-0.61, P<0.001). Multivariable adjusted leaner regression model disclosed that BPF (OR, 0.11 [95%CI 0.04-0.18], P=0.016) and infarct core volume (OR, 1.36, [95%CI 1.31-1.42], P<0.001) were independently associated with a greater NIHSS deficit, and that there is a significant interaction between BPF and infarct volume (OR, 1.017 [95%CI, 1.013-1.019], P=0.026) in determining a higher NIHSS score.

CLINICAL RELEVANCE/APPLICATION

Preexisting brain atrophy significantly modulates the association between infarct core and NIHSS at baseline. This may explain outcome differences in stroke patients by aiding treatment decisions that rely on the NIHSS, and have a significant implication to improve selection for acute stroke therapies.

SDP-NR-36   Noninvasive Prediction Of Molecular Subtypes In WHO Iii~iv Grade Gliomas Using Multiparametric MR Radiomic Features

Participants

Jian Jiang, MS, Lan Zhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Noninvasive detection of isocitrate dehydrogenase 1 mutation (IDH1(+)), Telomerase reverse transcriptase (TERT), O6-methylguanine (O6-MeG)-DNA methyltransferase (MGMT) promoter methylation status are clinically meaningful for molecular stratification in WHO III~IV gliomas. To study a radiomic approach based on multiparametric MR for noninvasively determining molecular subtypes in patients with WHO III~IV gliomas.*Methods and Materials POPULATION: 114 patients with pathologically confirmed gliomas were divided into 3 molecular subtypes: IDH1(+), MGMT(+), TERT(+) (n?=?32); IDH1(-), MGMT(-), TERT(+) (n?=? 45); IDH1(-), TERT(+), MGMT(+) (n?=?37).FIELD STRENGTH/SEQUENCE: 3.0T MRI, containing contrast-enhanced T 1 -weighted (CET 1 WI), axial T 2 -weighted (T 2 WI), T2/fluid-attenuated inversion recovery (T2FLAIR), and apparent diffusion coefficient (ADC) sequences.ASSESSMENT: In all, 205 high-throughput radiomic features were extracted on each tumor volume of interest from T 2 FLAIR and the other three multiparametric MR. Optimal feature subsets were selected as using the support vector machine with a recursive feature elimination algorithm (SVM-RFE). Receiver operating characteristic curve (ROC) analysis was employed to assess the efficiency for identifying the 3 molecular subtypes.STATISTICAL TESTS: Correlations between the radiomics features and molecular pathology were revealed by partial correlation analysis, and multivariate models were built to identify the best predictive models.*Results Optimal SVM predictive models of 3 molecular subtypes were established using 17 features from T 2 Flair, ADC, CET 1 WI. In differentiating among 3 molecular subtypes, the best AUC was 0.884 for IDH1(+), MGMT(+), TERT(+) , 0.876 for IDH1(-), MGMT(-), TERT(+) , and 0.861 for IDH1(-), TERT(+), MGMT(+).*Conclusions Using the optimal texture features extracted from multiple MR sequences, a promising stratifying strategy was acquired for predicting molecular subtypes of IDH1, TERT and MGMT in WHO III~IV gliomas.*Clinical Relevance/Application The establishment of the prediction model will be able to predict the molecular subtypes and other genetic characteristics of high-grade glioma through non-invasive imaging examination, so as to provide a scientific basis for the formulation of individualized treatment of glioma.

RESULTS

Optimal SVM predictive models of 3 molecular subtypes were established using 17 features from T 2 Flair, ADC, CET 1 WI. In differentiating among 3 molecular subtypes, the best AUC was 0.884 for IDH1(+), MGMT(+), TERT(+) , 0.876 for IDH1(-), MGMT(-), TERT(+) , and 0.861 for IDH1(-), TERT(+), MGMT(+).

CLINICAL RELEVANCE/APPLICATION

The establishment of the prediction model will be able to predict the molecular subtypes and other genetic characteristics of high-grade glioma through non-invasive imaging examination, so as to provide a scientific basis for the formulation of individualized treatment of glioma.

SDP-NR-37 Branch-like Enhancement, A Specific Enhancement Pattern In Cerebellar Malignant Lymphoma.

Participants
Kota Yokoyama, MD, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Recently, A contrast enhanced magnetic resonance imaging (CE-MRI) finding, branch-like enhancement (BLE) was reported to be useful in differentiating primary central nervous system lymphoma (PCNSL) from high grade glioma (HGG) in cerebellum (Sci Rep. 2020 Jun 19;10(1):10007). Whether it could be applied to secondary CNSL or other cerebellar lesions is unknown. Herein, we attempted to investigate the frequency and utility of BLE in differentiating cerebellar lymphoma (CL) including both primary and secondary from other cerebellar lesions.*Methods and Materials We retrospectively reviewed our radiology information system and searched for suspected CL lesions in CE-MRI. Patients without CE-MRI data at the time of diagnosis, only with small nodular lesions in known cancer patients, patients without any lesion in cerebellum, and patients without certain final diagnosis were excluded. For the included patients, clinical data and MRI findings were recorded. We qualitatively evaluated CE-T1 weighted images for presence and degree of BLE and if multiple views were available, BLE was evaluated for each of the view, and the view in which the findings were most visible was determined. As a secondary analysis, we qualitatively evaluated the the presence of restricted diffusion and streak-like edema. In addition, CT hyperdensity and high Fluorodeoxyglucose (FDG) uptake were recorded if images were available.*Results A total of 75 patients (mean age 55.8, range 3-88 years; 28 women) were included in the study. We identified 17 CNSL, 30 metastasis, 12 hemangioblastoma, 9 HGG and 3 pilocytic astrocytoma, 2 medulloblastoma, 1 ependymoma, and 1 radiation necrosis (RN). The median age in CL was 64.1 years (range 9-79 years) and 4 were women (23.5%). Twelve were PCNSL and five were SCNSL. Within the 17 CL cases, 15 (88%) showed BLE, while three cases out 58 cases (5%) in non-CL group showed BLE; Two HGG cases and one RN case which had a history of gamma knife surgery for lung cancer metastasis to cerebellum showed BLE. In CL group, all the patients were assessed by multiple views and, sagittal image was the most visible for detecting BLE followed by coronal image. Diffusion restriction (81%), streak-like edema (82%), CT hyperdensity (93%), and high FDG uptake (93%) were frequently observed however not that specific to CL compared with BLE.*Conclusions The present study revealed that BLE observed in CE-MRI is a highly specific finding for CL both in primary and secondary CNSL which is useful to distinguish from the other pathologies in cerebellum and sagittal view is valuable to evaluate the finding.*Clinical Relevance/Application It is useful for evaluating undiagnosed cerebellar lesions.

RESULTS

A total of 75 patients (mean age 55.8, range 3-88 years; 28 women) were included in the study. We identified 17 CNSL, 30 metastasis, 12 hemangioblastoma, 9 HGG and 3 pilocytic astrocytoma, 2 medulloblastoma, 1 ependymoma, and 1 radiation necrosis (RN). The median age in CL was 64.1 years (range 9-79 years) and 4 were women (23.5%). Twelve were PCNSL and five were SCNSL. Within the 17 CL cases, 15 (88%) showed BLE, while three cases out 58 cases (5%) in non-CL group showed BLE; Two HGG cases and one RN case which had a history of gamma knife surgery for lung cancer metastasis to cerebellum showed BLE. In CL group, all the patients were assessed by multiple views and, sagittal image was the most visible for detecting BLE followed by coronal image. Diffusion restriction (81%), streak-like edema (82%), CT hyperdensity (93%), and high FDG uptake (93%) were frequently observed however not that specific to CL compared with BLE.

CLINICAL RELEVANCE/APPLICATION

It is useful for evaluating undiagnosed cerebellar lesions.

SDP-NR-38 Fast 3D Wheel (Fast 3Dw) On Cerebral MR Angiography: Capability For Examination Time Reduction Without Degradation Of Image Quality And Aneurysm Evaluation In Candidates With Cerebral Aneurysm Treatment

Participants
Satomu Hanamatsu, Toyoake, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To compare the capability of wheel encoding order (Fast 3D wheel: i.e. Fast 3Dw) method for examination time reduction with no degradation of image quality and aneurysm evaluation on MR angiography (MRA) with parallel imaging (PI) in candidates for cerebral aneurysm treatment.*Methods and Materials 50 consecutive candidates with unruptured cerebral aneurysm underwent conventional MRA by PI and two types of Fast 3Dw methods at a 3T scanner. On PI and Fast 3Dw-A methods, same scan parameters were applied. On MRA by Fast 3Dw-B, matrix, section thickness and slice number were slightly reduced for further examination time reduction. To compare examination time, all examination times were recorded in each patient. For comparison of image quality improvement, SNRs at internal carotid artery (ICA), middle cerebral artery (MCA) and white matter and CNRs between white matter and ICA or MCA were assessed by ROI measurements. Moreover, diameters of each aneurysm, ICA and MCA on each MRA data were semi-automatically measured. For qualitative comparison among three methods, overall image quality and aneurysm depiction level were assessed by 5-point scales by consensus of two readers in each patient. Then, mean examination time, SNR, CNR and diameters of aneurysm, ICA and MCA were compared among three methods by Tukey's HSD test. Moreover, mean scores of image quality and lesion depiction were compared among all methods by Steel-Dwass test.*Results Each Fast 3Dw showed significantly shorter examination time than PI (p<0.05). SNR of Fast 3Dw-B was significantly higher than that of PI (p<0.05), although other quantitative indexes showed no significant differences among three methods. Overall image quality of PI was significantly higher than that of Fast 3Dw-B (p<0.05), although there were no significant difference of aneurysm depiction level among three methods.*Conclusions Fast 3Dw is considered more useful than PI for reducing examination time without any degradation of image quality and aneurysm evaluation on cerebral MRA. If further reduction of examination time is warranted, Fast 3Dw can reduce examination time without degradation of aneurysm evaluation in routine clinical practice.*Clinical Relevance/Application Fast 3Dw is considered more useful than PI for reducing examination time without any image quality degradation and aneurysm evaluation on cerebral MRA.

RESULTS

Each Fast 3Dw showed significantly shorter examination time than PI (p<0.05). SNR of Fast 3Dw-B was significantly higher than that of PI (p<0.05), although other quantitative indexes showed no significant differences among three methods. Overall image quality of PI was significantly higher than that of Fast 3Dw-B (p<0.05), although there were no significant difference of aneurysm depiction level among three methods.

CLINICAL RELEVANCE/APPLICATION

Fast 3Dw is considered more useful than PI for reducing examination time without any image quality degradation and aneurysm evaluation on cerebral MRA.

SDP-NR-39   **Noninvasive Assessment Of The Cerebrospinal Fluid Composition By MRI: Does Electric Properties Tomography Have A Role?**

Participants
Khin Khin Tha, MBBS, PhD, Sapporo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Lumbar puncture is a standard test to diagnose altered cerebrospinal fluid (CSF) composition in various diseases, including meningitis and malignancy. However, this procedure is invasive and can lead to serious side effects. This study aimed to evaluate if electric properties tomography (EPT), an MRI technique that noninvasively estimates tissue electrical conductivity (s), be sensitive to alterations in CSF composition.*Methods and Materials This study was conducted as ex vivo and in vivo examinations. As ex vivo examinations, cadaveric CSF samples (6-15 ml per sample) were collected over 6 months. EPT was performed using a 3D steady-state free precession (3D-SSFP) sequence (TR/TE = 3.5/1.7 ms, FA = 25°, voxel size = 1 x 1 x 1 mm3, non-selective RF pulse), at 3T. Routine CSF laboratory investigation was also done in all samples. For in vivo examinations, EPT scans of the brain acquired in 4 years and under the same scan conditions as ex vivo examinations were reviewed. The exclusion criteria were a lack of CSF laboratory investigation results and motion artifacts. For both ex vivo and in vivo image data, s maps were reconstructed from the phase of 3D-SSFP using the formula s = ?2 f+ / µ0?, where f+ = the phase of H+ [the positive circularized of the magnetic field H+ = (Hx + iHy)/2], µ0 = magnetic vacuum permeability, and ? = Larmor frequency. The s histogram metrics were measured for each CSF sample and CSF within the lateral ventricles. These metrics were then tested for correlation with the CSF laboratory investigation results (i.e., specific gravity, pH, protein concentration, and cell count). Pearson's product-moment correlation analyses were used to determine statistical significance at P<0.05.*Results Altogether 38 cadaveric CSF samples and 13 patients were included. Tests of correlation revealed significant weak to moderate positive correlation between the mean (r=0.387, P=0.018), median (r=0.366, P=0.026), and maximum (r=0.466, P=0.004) s of cadaveric CSF samples with polymorph count. As for in vivo examinations, significant strong positive correlation was observed between the mean (r=0.750, P=0.020), mode (r=0.743, P=0.022), median (r=0.743, P=0.022), minimum (r=0.749, P=0.020), and maximum (r=0.731, P=0.025) s and albumin concentration, as well as between the minimum s (r=0.607, P=0.036) and total cell count.*Conclusions Our observations suggest that s by EPT is sensitive to alterations in CSF composition. s measurable by EPT can become a noninvasive imaging biomarker that quantifies the CSF biochemical composition.*Clinical Relevance/Application 1. s measured noninvasively by MRI can become an imaging biomarker that quantifies the CSF biochemical composition. 2. This is the first report on its correlation with CSF biochemical composition.

RESULTS

Altogether 38 cadaveric CSF samples and 13 patients were included. Tests of correlation revealed significant weak to moderate positive correlation between the mean (r=0.387, P=0.018), median (r=0.366, P=0.026), and maximum (r=0.466, P=0.004) s of cadaveric CSF samples with polymorph count. As for in vivo examinations, significant strong positive correlation was observed between the mean (r=0.750, P=0.020), mode (r=0.743, P=0.022), median (r=0.743, P=0.022), minimum (r=0.749, P=0.020), and maximum (r=0.731, P=0.025) s and albumin concentration, as well as between the minimum s (r=0.607, P=0.036) and total cell count.

CLINICAL RELEVANCE/APPLICATION

1. s measured noninvasively by MRI can become an imaging biomarker that quantifies the CSF biochemical composition. 2. This is the first report on its correlation with CSF biochemical composition.

SDP-NR-4   **Additional Use Of A Deep Learning Algorithm In Detecting Intracranial Hemorrhages On Emergency Computed Tomographies Of A Radiology And Neuroradiology Department With Teleradiology**

Participants
Leonie Goelz, PhD, Berlin, Germany (*Presenter*) Nothing to Disclose

PURPOSE

As teleradiology continues to be on the rise, diagnostic imaging of varying quality is increasingly bundled at big centers during any time of the day. This trend demands for prioritization and speediness of reporting in radiology1. Deep learning algorithms could support radiologist in meeting these challenges2-6. This study analyzes the number of additionally detectable intracranial hemorrhages (ICH) by a commercially available artificial intelligence (AI) analysis software and evaluates reasons for false results at a (neuro-)radiology department of a level 1 trauma center with teleradiology.*Methods and Materials Retrospective cohort-study (1) Analysis of consecutive emergency non-contrast head computed tomographies (hCT) by the AI. (2) Review of hCT with deviating results between the AI analysis and the initial radiology report (RR) by a blinded neuroradiologist (NR). (3) Evaluation of the number of additionally detected ICH using the AI and of reasons for false results.*Results 4946 hCT were included between 05/2020 and 09/2020 from 19 different CT scanners. 205 reports (4.1%) were classified by both the RR and the AI as bleedings. 162 (3.3%) diverging reports were identified, 62 of these were confirmed as bleedings by a NR. The RR identified 33 ICH and analysis by the AI detected 29 additional ICH. 88 (1.8%) hCT flagged by the AI as bleedings and 10 (0.2%) positive RR were evaluated as incorrect findings by the NR. ICH missed by the AI were often located in the subarachnoid space (41.2%) and immediately underneath the calvaria (47.1%). 85% of ICH missed by the RR but detected by AI occurred beyond regular working hours. Calcifications (39.3%), beam hardening artifacts (18%), tumors (15.7%), and vessels (7.9%) were the most common reasons for incorrectly positive flagged hCT. There was no significant association between size of the ICH or image quality and probability of incorrect AI results.*Conclusions The disagreement rate between AI analysis and primary RR was 3.3 %. 12.2 % ICH were identified additionally by the AI. 1.8 % hCT were falsely flagged by the AI often caused by calcifications, whereas ICH missed by the AI were mainly located in the subarachnoid space or underneath the calvaria.*Clinical Relevance/Application Combining radiological experience and an AI algorithm is a promising strategy for maximizing detection of ICH in high-volume radiology departments with teleradiology especially during on-call duty.

RESULTS

4946 hCT were included between 05/2020 and 09/2020 from 19 different CT scanners. 205 reports (4.1%) were classified by both the RR and the AI as bleedings. 162 (3.3%) diverging reports were identified, 62 of these were confirmed as bleedings by a NR. The RR identified 33 ICH and analysis by the AI detected 29 additional ICH. 88 (1.8%) hCT flagged by the AI as bleedings and 10 (0.2%) positive RR were evaluated as incorrect findings by the NR. ICH missed by the AI were often located in the subarachnoid space (41.2%) and immediately underneath the calvaria (47.1%). 85% of ICH missed by the RR but detected by AI occurred beyond regular working hours. Calcifications (39.3%), beam hardening artifacts (18%), tumors (15.7%), and vessels (7.9%) were the most common reasons for incorrectly positive flagged hCT. There was no significant association between size of the ICH or image quality and probability of incorrect AI results.

CLINICAL RELEVANCE/APPLICATION

Combining radiological experience and an AI algorithm is a promising strategy for maximizing detection of ICH in high-volume radiology departments with teleradiology especially during on-call duty.

SDP-NR-40   **Difference In Topological Organization Of White Matter Structural Connectome Between Methamphetamine And Heroin Use Disorder**

Participants
Wei Li, Xian, China (*Presenter*) Nothing to Disclose

PURPOSE

Both methamphetamine use disorder (MAUD) and heroin use disorder (HUD) were related to the activation of the dopamine transmission, while the psychological symptoms caused by HUD and MAUD were significantly different. The purpose of this study is to explore the difference in the topological organization of white matter structural between MAUD and HUD, and identify the relationship between structural alteration and psychological symptoms.*Methods and Materials Demographic matched 23 male MAUD patients, 20 HUD patients, and 21 healthy controls (HC) participated in the analysis. Diffusion tensor imaging and probabilistic tractography were used for white matter network construction. Psychological symptoms were evaluated by the Symptom Checklist-90. Schizophrenia nuclear symptoms dimension was used to identify the core symptoms. Differences of global-level and nodal-level properties among groups, and the network Hubs distribution were explored by FSL6.0. Partial correlation analysis was used for identifying the relationship between the network alteration and psychological status.*Results MAUD demonstrated significantly increased scores in anxiety, hostility, and schizophrenia nuclear symptoms. Higher hostility score was found in MAUD compared with HUD. HUD showed significantly increased global efficiency and network strength than HC, and increased network strength than MAUD. Compared with the HUD, MAUD showed significantly decreased Nodal Strength and efficiency distributed in the temporal, parietal and occipital regions. We also found the network Hubs were decreased in MAUD but increased in HUD. Nodal Strength in right superior temporal gyrus was positively correlated with depression, anxiety, hostile, paranoid, and psychoticism score in MAUD.*Conclusions These findings reflect the significant differences in topological structural connection between HUD and MAUD patients. Significantly increased global/nodal strength and efficiency in HUD indicate the imbalance between the efficiency and cost of the information transmission within the network. Decreased Nodal Strength and efficiency in the limbic system, parietal, temporal, and occipital regions and the relationship with the psychological scores may suggest the structural alteration underlying MAUD related psychological disorder.*Clinical Relevance/Application This evidence help shed some light on the neurobiological mechanisms of the psychological difference between HUD and MAUD. Understanding the structural disruption underline the MAUD related psychological symptoms may play an important role in the identification of potential new biomarkers and therapeutic targets.

RESULTS

MAUD demonstrated significantly increased scores in anxiety, hostility, and schizophrenia nuclear symptoms. Higher hostility score was found in MAUD compared with HUD. HUD showed significantly increased global efficiency and network strength than HC, and increased network strength than MAUD. Compared with the HUD, MAUD showed significantly decreased Nodal Strength and efficiency distributed in the temporal, parietal and occipital regions. We also found the network Hubs were decreased in MAUD but increased in HUD. Nodal Strength in right superior temporal gyrus was positively correlated with depression, anxiety, hostile, paranoid, and psychoticism score in MAUD.

CLINICAL RELEVANCE/APPLICATION

This evidence help shed some light on the neurobiological mechanisms of the psychological difference between HUD and MAUD. Understanding the structural disruption underline the MAUD related psychological symptoms may play an important role in the identification of potential new biomarkers and therapeutic targets.

SDP-NR-41 CT Perfusion Deficit Volumes Predict Functional Outcome In Patients With Basilar Artery Occlusion

Participants
Matthias Fabritius, MD, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Basilar artery occlusion (BAO) is associated with high morbidity and mortality. Optimal imaging and treatment strategy are still controversial and prognosis estimation challenging. We therefore aimed to determine the predictive value of CT perfusion (CTP) parameters for functional outcome in patients with BAO in the context of endovascular treatment (EVT).*Methods and Materials Patients with BAO who underwent EVT were selected from a prospectively acquired cohort. Ischemic changes were assessed with the posterior-circulation-Acute-Stroke-Prognosis-Early-CT-Score (pc-ASPECTS) on non-contrast CT, CT angiography (CTA) source images and CTP maps. Basilar artery on CTA (BATMAN) score, posterior circulation CTA score and posterior circulation collateral score were evaluated on CTA. Perfusion deficit volumes were quantified on CTP maps. Good functional outcome was defined as modified Rankin scale smaller/equal 3 at 90 days. Statistical analysis included binary logistic regressions, and receiver operating characteristics (ROC) analyses.*Results Among 49 patients who matched the inclusion criteria, 24 (49.0%) achieved a good outcome. In univariate analysis, age, National Institutes of Health Stroke Scale (NIHSS) score on admission, posterior cerebral artery (PCA) involvement, absence of or hypoplastic posterior communicating arteries, BATMAN score, pc-ASPECTS and perfusion deficit volumes on all CTP parameter maps presented significant association with functional outcome (p smaller 0.05). In multivariate analyses, BATMAN score, pc-ASPECTS (odds ratio [OR] range: 1.31-2.10, 95%-confidence interval [CI] range: 1.00-7.24) and perfusion deficit volumes on all CTP maps (OR range: 0.77-0.98, 95%-CI range: 0.63-1.00) remained as independent outcome predictors. Cerebral blood flow (CBF) deficit volume yielded the best performance for the classification of good clinical outcome with an AUC of 0.92 (95%-CI: 0.84-0.99). Age and admission NIHSS had lower discriminatory power (AUC smaller 0.7).*Conclusions CTP imaging parameters contain prognostic information for functional outcome in patients with stroke due to BAO and may identify patients with higher risk of disability at an early stage of hospitalization.*Clinical Relevance/Application Predictive baseline image parameters can contribute to therapy decision making in BAO. Our findings challenge the concept of randomized controlled BAO trials without imaging selection criteria.

RESULTS

Among 49 patients who matched the inclusion criteria, 24 (49.0%) achieved a good outcome. In univariate analysis, age, National Institutes of Health Stroke Scale (NIHSS) score on admission, posterior cerebral artery (PCA) involvement, absence of or hypoplastic posterior communicating arteries, BATMAN score, pc-ASPECTS and perfusion deficit volumes on all CTP parameter maps presented significant association with functional outcome (p smaller 0.05). In multivariate analyses, BATMAN score, pc-ASPECTS (odds ratio [OR] range: 1.31-2.10, 95%-confidence interval [CI] range: 1.00-7.24) and perfusion deficit volumes on all CTP maps (OR range: 0.77-0.98, 95%-CI range: 0.63-1.00) remained as independent outcome predictors. Cerebral blood flow (CBF) deficit volume yielded the best performance for the classification of good clinical outcome with an AUC of 0.92 (95%-CI: 0.84-0.99). Age and admission NIHSS had lower discriminatory power (AUC smaller 0.7).

CLINICAL RELEVANCE/APPLICATION

Predictive baseline image parameters can contribute to therapy decision making in BAO. Our findings challenge the concept of randomized controlled BAO trials without imaging selection criteria.

SDP-NR-42 Quantitative Muscle Mass Biomarkers Are Independent Prognosis Factors In Primary Central Nervous System Lymphoma: The Role Of L3-skeletal Muscle Index And Temporal Muscle Thickness

Participants
Riccardo Leone, MD, Milan, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Appropriate patient stratification is critical in patients with primary central nervous system lymphomas (PCNSL) to improve therapeutic choices and to reduce treatment-related neurotoxicity. Quantitative muscle biomarkers, such as the skeletal-muscle-index at the third lumbar vertebra (L3-SMI) and temporal muscle thickness (TMT) are associated with worse prognosis in several diseases. We aim to evaluate the role of these biomarkers in predicting survival in patients with PCNSL.*Methods and Materials L3-SMI and TMT were calculated on abdominal CT and brain high-resolution 3D-T1-weighted-MR images, respectively, using predefined validated methods. Standardized sex-specific cut-offs were used to divide patients in different risk categories. Kaplan-Meier plots were calculated, and survival analysis was performed using log-rank tests, univariate, and multivariable Cox-regression models, calculating hazard ratios (HR) and 95% confidence intervals (CI), also adjusting for potential confounders (age, sex, and performance status).*Results Forty-three patients were included in this study. Median follow-up was 23 months (IQR 12-40); at median follow-up, rates of progression-free and overall survival for the cohort were 46% and 57%, respectively. Thirteen (30%) and 11 (26%) patients showed L3-SMI or TMT values below the predefined cut-offs. A significant association was found between quantitative muscle mass biomarkers and progression-free and overall survival. One-year progression free and overall survival rates were 8% and 21% for the 13 patients with L3-SMI below the standard cut-off value, respectively, compared to 66% and 68% for the 30 patients with L3-SMI above the cut-off values. Likewise, one-year progression free and overall survival rates were 10% and 15% for the 11 patients with low TMT, respectively, compared to 61% and 70% for the 32 patients with high TMT. In Cox-regression multivariable analysis patients with low L3-SMI or TMT showed significantly worse progression-free (HR 4.40, 95%CI 1.66-11.61, p = 0.003; HR 4.40, 95%CI 1.68-11.49, p=0.003, respectively) and overall survival (HR 3.16, 95%CI 1.09-9.11, p = 0.034; HR 4.93, 95%CI 1.78-13.65, p=0.002, respectively) compared to patients with high L3-SMI or TMT.*Conclusions Quantitative muscle mass evaluation assessed by both L3-SMI and TMT is a promising tool to identify PCNSL patients at high risk of negative outcome. Confirmatory studies on larger independent series are warranted.*Clinical Relevance/Application Quantitative mass biomarkers could be used to further improve prognostic patient stratification in PCNSL and allow a better therapeutic allocation

RESULTS

Forty-three patients were included in this study. Median follow-up was 23 months (IQR 12-40); at median follow-up, rates of progression-free and overall survival for the cohort were 46% and 57%, respectively. Thirteen (30%) and 11 (26%) patients

showed L3-SMI or TMT values below the predefined cut-offs. A significant association was found between quantitative muscle mass biomarkers and progression-free and overall survival. One-year progression free and overall survival rates were 8% and 21% for the 13 patients with L3-SMI below the standard cut-off value, respectively, compared to 66% and 68% for the 30 patients with L3-SMI above the cut-off values. CLINICAL RELEVANCE/APPLICATION

Quantitative mass biomarkers could be used to further improve prognostic patient stratification in PCNSL and allow a better therapeutic allocation

SDP-NR-43 Radiomics Features From Multi-sequence Conventional MRI Predict TERT Promoter Mutation Status In Glioblastomas

Participants
Jun Lu, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

The mutation status of telomerase reverse transcriptase(TERT) promoter has been proven to be a diagnostic and prognostic biomarker for glioblastoma(GBM). The purpose of this study was to construct a radiomic model to noninvasively predict the TERT promoter mutation status in GBM.*Methods and Materials 116 GBM patients(81 in the training cohort and 35 in the validation cohort) were retrospectively enrolled. A total of 558 radiomics features of the whole tumor were extracted from apparent diffusion coefficient(ADC) and isotropic volumetric contrast-enhanced T1-weighted magnetization prepared rapid acquisition gradient echo(iso-CE-T1-MPRAGE) MRI images, including 18 first order(gray level histogram, GLH), 490 second order[gray level concurrence matrix(GLCM); run length matrix; absolute gradient], and 50 high order(autoregressive model; wavelet transform). The radiomics features were selected by the Fisher coefficient, probability of classification error and average correlation coefficient(POE+ACC) and mutual information. The inter-group comparison was compared with the t test or Mann-Whitney U test. The univariate and multivariate logistic regression were performed to explore potential variables as predictors of TERT status. Multiparameter models were established and receiver operating characteristic analysis was used to evaluate the models. Kaplan-Meier analyses were used to evaluate the progress free survival(PFS) and overall survival(OS) of GBM with different TERT mutation status.*Results Three radiomics prediction models, namely, ADC single model(M1), iso-CE-T1 single model(M2) and integrated multi-sequence model(M3) were built, all of which displayed good performance. The integrated multi-sequence radiomics model, constructed from the combination of both sequences, showed the best performance, with an area under the curve (AUC) of 0.881(0.790-0.942) in the training dataset, and an AUC of 0.933(0.795-0.990) in the validation dataset. Kaplan-Meier curve showed a significant difference of overall survival between different TERT mutation status with an optimal threshold of M3 for discrimination of TERT mutation status(log-rank = 5.2274, p = 0.022).*Conclusions Multi-sequence conventional MRI radiomics models are useful for noninvasively predicting TERT promoter mutation status in GBM patients. The combination of radiomics features from different sequences may be potential for improving the prediction performance and for prognostic assessment of glioblastoma.*Clinical Relevance/Application This study aimed to find imaging biomarkers for noninvasively predicting the TERT mutation status for a tailored treatment plan and prognosis assessment in GBM patients from the initial stage of the tumor diagnosis.

RESULTS

Three radiomics prediction models, namely, ADC single model(M1), iso-CE-T1 single model(M2) and integrated multi-sequence model(M3) were built, all of which displayed good performance. The integrated multi-sequence radiomics model, constructed from the combination of both sequences, showed the best performance, with an area under the curve (AUC) of 0.881(0.790-0.942) in the training dataset, and an AUC of 0.933(0.795-0.990) in the validation dataset. Kaplan-Meier curve showed a significant difference of overall survival between different TERT mutation status with an optimal threshold of M3 for discrimination of TERT mutation status(log-rank = 5.2274, p = 0.022).

CLINICAL RELEVANCE/APPLICATION

This study aimed to find imaging biomarkers for noninvasively predicting the TERT mutation status for a tailored treatment plan and prognosis assessment in GBM patients from the initial stage of the tumor diagnosis.

SDP-NR-44 Deep Learning Reconstruction Helps To Quantify Multiple Sclerosis Lesion Load On Fast Flair Imaging

Participants
Takayuki Yamamoto, MD, Bordeaux, France (*Presenter*) Nothing to Disclose

PURPOSE

Image denoising based on deep learning technology (so called deep learning reconstruction, DLR) can efficiently improve image quality. Our aim is to quantify the diagnostic capability of DLR for lesion detection of multiple sclerosis (MS) for short scan time.*Methods and Materials Twenty-eight MS patients were examined on a Vantage Galan 3T / ZGO (Canon Medical Systems, Japan) using four 3D FLAIR sequences with different TR times (scan time of 4:54; 2:35; 1:40 and 1:15 min, respectively). Each FLAIR was reconstructed with and without DLR. Two experienced neuroradiologists collaboratively created a lesion load gold standard on the longest scan. One neuroradiologist blindly assessed image quality (from -2 "not diagnostic" to +2 "excellent") and delineated the lesion on each scan. Automatic lesion segmentation was also performed by using lesionBrain software freely available on the volBrain platform. The following metrics evaluated manual and automatic segmentation: DICE, absolute volume difference (AVD), Hausdorff distance (HD), F1 score based on the lesion count (F1).*Results DLR was implemented directly in the scanner, and the reconstruction finished within 1 minute. As expected, both image quality evaluations and the various metrics were found decreased by scan time reduction. However, DLR improved all these metrics, particularly for human evaluation. Especially, for the 1:40 min long FLAIR, DLR helped to reach sufficient quality and significantly improved all metrics both in manual delineation and auto-segmentation.*Conclusions Our results evaluated the added value of DLR, in the MS context. The significant improvement in homology metrics such as AVD, DICE, and HD demonstrates that DLR helped to recognize the boundaries of lesions even in short time acquisition. The increase of F1 meant that DLR can retrieve lesions buried in noise or contrast loss.*Clinical Relevance/Application DLR can reduce the scan time while preserving the image quality and lesion detectability. It is highly valuable for mitigating the patient burden by rapid imaging acquisition.

RESULTS

DLR was implemented directly in the scanner, and the reconstruction finished within 1 minute. As expected, both image quality evaluations and the various metrics were found decreased by scan time reduction. However, DLR improved all these metrics, particularly for human evaluation. Especially, for the 1:40 min long FLAIR, DLR helped to reach sufficient quality and significantly improved all metrics both in manual delineation and auto-segmentation.

CLINICAL RELEVANCE/APPLICATION

DLR can reduce the scan time while preserving the image quality and lesion detectability. It is highly valuable for mitigating the patient burden by rapid imaging acquisition.

SDP-NR-45   Multi-parametric Radiogenomic Model To Predict 1p/19q Co-deletion In Patients With Glioma: Added Value To The T2-flair Mismatch Sign

Participants
Arya Derakhshani, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

PURPOSE

The "T2-FLAIR mismatch" sign has shown promising results in determination of IDH-mutant 1p/19q non-codeleted gliomas1. We aimed to develop a multiparametric radiogenomic model using a combination of MRI texture features to predict 1p/19q codeletion status in patients with IDH-mutant glioma and to perform a comparative analysis to T2-FLAIR mismatch sign.*Methods and Materials Inclusion criteria for this retrospective study were 1) diagnosis of IDH mutant glioma with known 1p/19q status and 2) availability of preoperative MRI (T2 and FLAIR). Two board certified neuroradiologists reviewed the images independently for T2-FLAIR mismatch sign. In each patient, tumor segmentation was performed to encompass the entire FLAIR hyperintense volume and a total of 92 texture features were extracted using Olea Sphere SP.22. From texture features, an imaging model was developed to predict 1p/19q codeletion status using Least Absolute Shrinkage and Selection Operator (LASSO) regularization to reduce the risk of overfitting. This imaging model was then inserted into a backward stepwise logistic regression in conjunction with variables such as age, sex, tumor volume, tumor location and T2-FLAIR mismatch scores. Receiver-operating characteristic was performed to provide accuracy statistics.*Results A total of 103 patients (age: 41.1 ± 13.2; M 66) were included. 1p/19q status: intact (n=68) and codeleted (n=35). Interobserver agreement between two neuroradiologists in defining T2-FLAIR mismatch was modest (k=0.49). The overall diagnostic performance (sensitivity/specificity/accuracy) of T2-FLAIR mismatch sign in determining 1p/19q status was: 52.9% / 80% / 66.5%. Our imaging model generated from a combination of three texture features (first order uniformity, grey-level run length matrix run percentage, and neighborhood gray tone difference matrix strength) resulted in sensitivity/specificity/accuracy: 75% / 80% / 77.5%. In logistic regression analysis, this radiomic model remained as a significant contributor to the final model. Addition of this radiomic model to T2-FLAIR mismatch, resulted in improving the sensitivity by 14% while maintaining the specificity at 80%.*Conclusions Results show that application of multiparametric radiomic model provides added diagnostic value and in particular increases the sensitivity of the T2-FLAIR mismatch sign in determination of 1p/19q codeletion status in patients with glioma.*Clinical Relevance/Application Despite promising results in prediction of IDH mutant 1p/19q non-codeleted gliomas, T2-FLAIR mismatch sign has limited sensitivity. The described radiomic model provides added sensitivity and an opportunity for a more balance predictive performance.

RESULTS

A total of 103 patients (age: 41.1 ± 13.2; M 66) were included. 1p/19q status: intact (n=68) and codeleted (n=35). Interobserver agreement between two neuroradiologists in defining T2-FLAIR mismatch was modest (k=0.49). The overall diagnostic performance (sensitivity/specificity/accuracy) of T2-FLAIR mismatch sign in determining 1p/19q status was: 52.9% / 80% / 66.5%. Our imaging model generated from a combination of three texture features (first order uniformity, grey-level run length matrix run percentage, and neighborhood gray tone difference matrix strength) resulted in sensitivity/specificity/accuracy: 75% / 80% / 77.5%. In logistic regression analysis, this radiomic model remained as a significant contributor to the final model. Addition of this radiomic model to T2-FLAIR mismatch, resulted in improving the sensitivity by 14% while maintaining the specificity at 80%.

CLINICAL RELEVANCE/APPLICATION

Despite promising results in prediction of IDH mutant 1p/19q non-codeleted gliomas, T2-FLAIR mismatch sign has limited sensitivity. The described radiomic model provides added sensitivity and an opportunity for a more balance predictive performance.

SDP-NR-46   Development Of Machine Learning Algorithms For The Differentiation Of Glioma And Brain Metastases - A Systematic Review

Participants
Waverly Rose Brim, BS, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

Medical staging, surgical planning, and therapeutic decisions are significantly different for brain metastases (BM) versus gliomas; yet both pathologies can present similarly on MR imaging. Machine learning (ML) algorithms have been developed as noninvasive techniques for brain metastases and glioma differentiation. We performed a systematic review to characterize these methods and to evaluate their accuracy.*Methods and Materials Studies on the application of ML in neuro-oncology were searched in Ovid Embase, Ovid MEDLINE, Cochrane trials (CENTRAL) and Web of Science Core - Collection. A neuroradiologist, neuroradiology resident, and AI graduate student designed a search strategy alongside two clinical librarians in October 2020 and February 2021. The search strategy comprised of controlled vocabulary including artificial intelligence, machine learning, deep learning, magnetic resonance imaging, and glioma. Candidate articles were screened in Covidence by at least two reviewers each. Bias analysis was conducted in agreement with TRIPOD, a bias assessment tool similar to CLAIM.*Results The search identified 11,727 candidate articles, 1,135 underwent full text review, and after applying our exclusion criteria 29 were used for data extraction. Classical ML (cML) algorithms represented 85% of models used, deep learning (DL) accounted for 15%. cML performed with an average accuracy, sensitivity, and specificity of 82%, 78%, 88%, respectively; DL performed 84%, 79%, 81%. Support vector machine (SVM) was the most commonly used cML model and convolutional neural networks (CNN) were standard for DL. We also found that T1, T1 post-gadolinium and T2 sequences were frequently used for feature extraction. Preliminary TRIPOD analysis yielded an average score of 14.25 (range 8-18).*Conclusions Brain metastases and glioma differentiation ML models have been developed with SVM and CNN being leading approaches.*Clinical Relevance/Application ML offers noninvasive methods for differentiation of gliomas from BM; critical information when biopsy is undesirable. This systematic review identifies leading algorithms for clinical implementation.

RESULTS

The search identified 11,727 candidate articles, 1,135 underwent full text review, and after applying our exclusion criteria 29 were used for data extraction. Classical ML (cML) algorithms represented 85% of models used, deep learning (DL) accounted for 15%. cML performed with an average accuracy, sensitivity, and specificity of 82%, 78%, 88%, respectively; DL performed 84%, 79%, 81%. Support vector machine (SVM) was the most commonly used cML model and convolutional neural networks (CNN) were standard for DL. We also found that T1, T1 post-gadolinium and T2 sequences were frequently used for feature extraction. Preliminary TRIPOD analysis yielded an average score of 14.25 (range 8-18).

CLINICAL RELEVANCE/APPLICATION

ML offers noninvasive methods for differentiation of gliomas from BM; critical information when biopsy is undesirable. This systematic review identifies leading algorithms for clinical implementation.

SDP-NR-48   Choroid Plexus Volume Is A Novel Imaging Marker For Predicting Cognitive Functioning In Elderly Subjects With Cognitive Impairments.

Participants
JONG DUCK CHOI, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Choroid plexus change is recently implicated in AD pathologic process. Our aim was to evaluate whether the volume of choroid plexus on T1-weighted imaging differs between patients with cognitive impairment spectrum and cognitively normal subjects.*Methods and Materials In this IRB-approved retrospective study, we enrolled a total of 616 subjects (73 normal cognition, 296 clinical MCI, 143 clinical AD, 91 other dementia) who underwent cognitive assessments and 3T brain MRI between Jan 2013 and May 2020. After excluding13 subjects due to the poor imaging quality, 603 patients were included in the final analysis. FreeSurfer 6.0 based volumetric segmentation was used to analyze the MRI volumetric data with the help of the deep learning algorithm for the analysis-failure prediction, brain extraction, and structure segmentation. Mean differences of normalized choroid plexus volume (ratio of choroid plexus volume to total intracranial volume) were compared with the Analysis of variance. Effect of choroid plexus volume on cognitive function (MMSE score) were evaluated with linear regression analysis after adjusting confounding factors.*Results AD and other dementia patients were older than MCI and normal cognition subjects (p<0.001). Normalized choroid plexus volume was significantly different between groups (p < 0.001). However, AD and other dementia subjects did not show significant difference in choroid plexus volume (p=0.205).After adjusting age and education, both increased choroid plexus volume (beta -3.183, standard error [SE]=0.505, p < 0.001) and hippocampal atrophy (beta 1.991, SE=0.283, p < 0.001) were the significant predictors of the cognitive declining.*Conclusions Our result suggests that choroid plexus volume predicts cognitive functioning. Choroid plexus volume may be a useful imaging marker for cognitive dysfunction in patients with cognitive complaints.*Clinical Relevance/Application Our study indicates that normalized choroid plexus volume can be an early imaging marker for representing underlying pathologic process in the cognitively impaired subjects.

RESULTS

AD and other dementia patients were older than MCI and normal cognition subjects (p<0.001). Normalized choroid plexus volume was significantly different between groups (p < 0.001). However, AD and other dementia subjects did not show significant difference in choroid plexus volume (p=0.205).After adjusting age and education, both increased choroid plexus volume (beta -3.183, standard error [SE]=0.505, p < 0.001) and hippocampal atrophy (beta 1.991, SE=0.283, p < 0.001) were the significant predictors of the cognitive declining.

CLINICAL RELEVANCE/APPLICATION

Our study indicates that normalized choroid plexus volume can be an early imaging marker for representing underlying pathologic process in the cognitively impaired subjects.

SDP-NR-49   Comparison Of Arterial Spin Labelling (ASL) Metrics And Dynamic Susceptibility Enhanced Perfusion Imaging (DSC-PWI) Parameters In The Diagnosis Of Ischemic Stroke And Prediction Of Patient Outcome

Participants
Liu Chang, Hefei, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the correlation between arterial spin labeling (ASL) indexes (PLD1.5s, 2.5s) and dynamic susceptibility contrast-enhanced perfusion imaging (DSC-PWI) parameters in hemodynamic changes of ischemic stroke patients.And to explore the predictive value of the middle artery crossing artifact (ATA) in ASL for the outcome of stroke patients.*Methods and Materials Eighty patients with arterial stenosis / occlusion treated in the inpatient department between May 2019 and May 2020 were selected. ASL and DSC-PWI scans were completed.After one-year follow-up, patients were divided into groups with and without recurrent ischemic stroke, and the correlation between imaging parameters (ASL-CBF, PWI-CBF,CBV, MTT,TTP) in assessing cerebral hemodynamics was compared.In addition, imaging and parameters were also compared between the two groups to determine whether these parameters were associated with patient outcomes.*Results 1.ASL-CBF(PLD1.5s) was statistically different from PWI-CBF and PWI-CBV (P < 0.05), but ASL-CBF (PLD1.5s) was not statistically different from PWI-MTT,TTP (P > 0.05);After kappa analysis,ASL-CBF (PLD1.5s) showed good agreement with PWI-TTP. 2. Statistically significant differences were found between ASL-CBF (PLD 2.5s) and PWI-MTT,TTP (P < 0.05), but not between ASL-CBF (PLD2.5s) and PWI-CBF, CBV (P > 0.05);After kappa analysis, ASL-CBF (PLD2.5s) showed good agreement with PWI-CBF. 3.80 patients, a total of 46 patients had arterialpenetration artifacts in their ASL maps.As a result of follow-up, 24 patients in the recurrent ischemic stroke group, including 8 patients with arterial penetration artifacts in the ASL maps and 56 patients in the no recurrent group, including 38 patients with arterial penetration artifacts in the ASL maps, showed statistically significant differences between the two groups (P < 0.05).It follows that arterial travel artifacts occur in the ASL map, more often in good prognosis patients, which is helpful in predicting the prognosis of patients.*Conclusions 1. Ischemic stroke patients showed better agreement between ASL-CBF (PLD1.5s) and PWI-TTP parameter results in DSC-PWI technique, better agreement between ASL-CBF (PLD2.5s) and PWI-CBF parameter results in DSC-PWI technique, noninvasive, reproducible, safety and other characteristics of ASL examination. 2. Arterial penetration artifact (ATA) in the ASL perfusion map may serve as a predictor of outcome in patients with ischemic stroke.*Clinical Relevance/Application Magnetic resonance of the nervous system two different methods of perfusion, correlation studies of different parameters between the two groups of methods.Arterial travel artifacts (ATA) arising in ASL, predictive value for outcome of ischemic stroke patients.

RESULTS

1.ASL-CBF(PLD1.5s) was statistically different from PWI-CBF and PWI-CBV (P < 0.05), but ASL-CBF (PLD1.5s) was not statistically different from PWI-MTT,TTP (P > 0.05);After kappa analysis,ASL-CBF (PLD1.5s) showed good agreement with PWI-TTP. 2. Statistically significant differences were found between ASL-CBF (PLD 2.5s) and PWI-MTT,TTP (P < 0.05), but not between ASL-CBF (PLD2.5s) and PWI-CBF, CBV (P > 0.05);After kappa analysis, ASL-CBF (PLD2.5s) showed good agreement with PWI-CBF. 3.80 patients, a total of 46 patients had arterialpenetration artifacts in their ASL maps.As a result of follow-up, 24 patients in the recurrent ischemic stroke group, including 8 patients with arterial penetration artifacts in the ASL maps and 56 patients in the no recurrent group, including 38 patients with arterial penetration artifacts in the ASL maps, showed statistically significant differences between the two groups (P < 0.05).It follows that arterial travel artifacts occur in the ASL map, more often in good prognosis patients, which is helpful in predicting the prognosis of patients.

CLINICAL RELEVANCE/APPLICATION

Magnetic resonance of the nervous system two different methods of perfusion, correlation studies of different parameters between the two groups of methods.Arterial travel artifacts (ATA) arising in ASL, predictive value for outcome of ischemic stroke patients.

SDP-NR-5   Altered Glymphatic Function In Parkinson's Disease

Participants
Yun Jung Bae, MD, Seongnam, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To examine glymphatic function in Parkinson disease (PD) utilizing "Diffusion Tensor Image-Analysis aLong the Perivascular Space (DTI-ALPS)" method.*Methods and Materials This case-control study included 54 consecutive patients diagnosed with de novo PD between June 2017 and March 2019 who underwent DTI with 123I-2ß-carbomethoxy-3ß-(4-iodophenyl)-N-(3-fluoropropyl)-nortropane dopamine transporter imaging and 54 age-sex matched controls. The correlations of DTI-ALPS values with clinical motor and cognition scores and with dopamine transporter uptake were examined.*Results DTI-ALPS values reflecting glymphatic activity were significantly lower in PD group than in controls (Dxproj [×10-3mm2/s], 0.59±0.08 vs 0.65±0.08; ALPS-index, 1.51±0.22 vs 1.66±0.2; both, P<0.0001). Dxproj and the ALPS-index showed significant negative correlations with motor score, and positive correlations with cognition scores (all, P<0.01). There was no significant correlation with dopamine transporter uptake (P>0.05).*Conclusions Glymphatic dysfunction was revealed in patients with PD using DTI-ALPS, correlating with disease severity.*Clinical Relevance/Application DTI-ALPS method can reveal glymphatic dysfunction in patients with Parkinson's disease, which can be correlated with clinical symptom severity, but not with dopamine transporter uptake.

RESULTS

DTI-ALPS values reflecting glymphatic activity were significantly lower in PD group than in controls (Dxproj [×10-3mm2/s], 0.59±0.08 vs 0.65±0.08; ALPS-index, 1.51±0.22 vs 1.66±0.2; both, P<0.0001). Dxproj and the ALPS-index showed significant negative correlations with motor score, and positive correlations with cognition scores (all, P<0.01). There was no significant correlation with dopamine transporter uptake (P>0.05).

CLINICAL RELEVANCE/APPLICATION

DTI-ALPS method can reveal glymphatic dysfunction in patients with Parkinson's disease, which can be correlated with clinical symptom severity, but not with dopamine transporter uptake.

SDP-NR-50   Fast 3D Wheel, Compressed Sensing And Parallel Imaging: Compared Capabilities For Scan Time Reduction And Image Quality And Diagnostic Performance Improvements In Suspected Brain Metastasis Patients

Participants
Kazuhiro Murayama, MD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation

PURPOSE

To compare the capability for examination time reduction and image quality and diagnostic performance improvements among conventional parallel imaging (PI), compressed sensing (CS) and wheel encoding order (Fast 3D wheel: i.e. Fast 3Dw) methods on contrast-enhanced brain MR examination in suspected brain metastasis patients.*Methods and Materials 35 consecutive patients suspected with brain metastases underwent contrast-enhanced MRI by PI, CS and Fast 3Dw methods. Each examination time was also recorded. SNR of normal white matter and contrast ratio (CR) between lesion and normal white matter were assessed by ROI measurements. Moreover, overall image quality was assessed by a 5-point scale by consensus of two readers. To compare detection performance of brain metastasis on CE-T1WI among all methods, probability of lesion detection at each lesion was assessed by consensus of same readers. To compare examination time, Tukey's HSD test was performed To compare quantitative image quality improvements, SNR and CR were compared among three methods by Tukey's HSD test. To compare detection capability among all data sets, Jackknife alternative free-response receiver operating characteristic (JAFROC) analysis were performed. Finally, sensitivity (SE) and false-positive/case (FPR) was also compared among six data sets by McNemar's test.*Results Mean examination times of CS and Fast 3Dw were significantly shorter than that of PI (p<0.0001). SNR of Fast 3Dw was significantly higher than those of PI and CS (p<0.001). Moreover, SNR of CS was significantly higher than that of PI (p<0.001). Image quality index of Fast 3Dw was significantly higher than those of PI and CS (p<0.05). There were no significant differences of figure of merit among all methods (p>0.05). SE of Fast 3Dw (SE=0.79) had significantly higher than those of PI and CS (PI: SE=0.74, p<0.01; CS: SE=0.73, p<0.01). FPR of all methods had no significant difference (p>0.05).*Conclusions Fast 3Dw has potentials than PI and CS for examination time reduction and image quality and diagnostic performance improvements in suspected brain metastasis patients.*Clinical Relevance/Application Fast 3Dw has potentials than PI and CS for examination time reduction and image quality and diagnostic performance improvements in suspected brain metastasis patients.

RESULTS

Mean examination times of CS and Fast 3Dw were significantly shorter than that of PI (p<0.0001). SNR of Fast 3Dw was significantly higher than those of PI and CS (p<0.001). Moreover, SNR of CS was significantly higher than that of PI (p<0.001). Image quality index of Fast 3Dw was significantly higher than those of PI and CS (p<0.05). There were no significant differences of figure of merit among all methods (p>0.05). SE of Fast 3Dw (SE=0.79) had significantly higher than those of PI and CS (PI: SE=0.74, p<0.01; CS: SE=0.73, p<0.01). FPR of all methods had no significant difference (p>0.05).

SDP-NR-52 Fast Stroke Protocol Development And Validation For A New Point Of Care Low Field Strength MRI

Participants
Kathryn Wagner, Halifax, Nova Scotia (*Presenter*) Nothing to Disclose

PURPOSE

Stroke is a leading cause of death and disability worldwide and rapid imaging is required for an accurate diagnosis. Synaptive's new 0.5T MRI scanner can be used safely in a greater number of patients due to its low field and head only design. The aim of this study was to develop a fast MRI stroke protocol and to assess whether images are of diagnostic quality.*Methods and Materials The novel, head-only, 0.5T EvryTM system provides a unique opportunity to study the potential for point-of- care stroke imaging in low-field systems. The EvryTM is a small foot-print, cryogen free system designed for point of care use, therefore amenable to use in emergency medicine settings. It has high slew rate (400 T/m/s) high strength (100 mT/m) gradients and a 16 channel patient conformable head coil. We developed a stroke protocol containing the following sequences: DWI 1:40 min, T2 FSE 4:15 min, FLAIR 4:15 min, SWI 1:09 min, and optionally TOF MRA 7:38 min; total 11:19 min or 18:57 min. Next, 12 consecutive patients that had recently proven stroke on either CT or MR imaging were scanned. The 0.5T MRI scans were anonymized, after which a blinded, board certified neuroradiologist assessed them for evidence of acute stroke using confidence levels on a Likert scale (1-5, 1=0% confidence, 5=100% confidence).*Results 12 patients with acute ischemic strokes, median age 62, 50% (6/12) males were enrolled. All 0.5T MRI scans assessed confirmed presence of ischemic stroke: 3/12 (25%) patients had subacute strokes and 9/12 (75%) patients had acute strokes that were identified. The radiologist's confidence level was excellent for 9/12 (75%) cases and good in 3/12 (25%) cases.*Conclusions The newly developed sequences for the 0.5T MRI scanner show good to excellent visualization of acute strokes.*Clinical Relevance/Application This acquisition protocol needs further assessment for quality, and optimization for speed, but initial results are promising. Ongoing work examining undersampled acquisitions with deep learning reconstructions is underway, with the ultimate goal of defining a protocol that is "as fast as clinically useful". Doing so could help make MRI the modality of choice for triaging neurological issues in emergency medicine, increase patient throughput, and reduce the overall burden on hospital resources.

RESULTS

12 patients with acute ischemic strokes, median age 62, 50% (6/12) males were enrolled. All 0.5T MRI scans assessed confirmed presence of ischemic stroke: 3/12 (25%) patients had subacute strokes and 9/12 (75%) patients had acute strokes that were identified. The radiologist's confidence level was excellent for 9/12 (75%) cases and good in 3/12 (25%) cases.

CLINICAL RELEVANCE/APPLICATION

This acquisition protocol needs further assessment for quality, and optimization for speed, but initial results are promising. Ongoing work examining undersampled acquisitions with deep learning reconstructions is underway, with the ultimate goal of defining a protocol that is "as fast as clinically useful". Doing so could help make MRI the modality of choice for triaging neurological issues in emergency medicine, increase patient throughput, and reduce the overall burden on hospital resources.

SDP-NR-53 Diffusion Weighted Imaging With Background Suppression Of Tibial And Common Peroneal Nerves In Patients With Guillain-barre Syndrome

Participants
Cao Jinfeng, Zibo, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the feasibility of diffusion weighted imaging with background suppression (DWIBS) in evaluating the peripheral nerve disorders in patients with Guillain-Barre syndrome (GBS).*Methods and Materials 32 GBS patients and 32 sex- and age- matched healthy volunteers underwent DWIBS examination of tibial nerve (TN) and the common peroneal nerve (CPN). Two senior radiologists scored the coronal 3D volume images of TN and CPN after reconstruction by the four-grade scoring system. The value of motor nerve conduction velocity (MCV) and motor nerve conduction amplitude of GBS patients were recorded. Kappa statistic was used to calculate inter-observer agreement for visualization scores. One-way ANOVA method was used to compare the values of MCV and motor nerve conduction amplitude in different scoring groups of the TN and CPN of GBS patients. The Spearman correlation analysis was used to evaluate the correlation between the scores of DWIBS and MCV, motor nerve conduction amplitude of TN and CPN in GBS patients.*Results In the DWIBS images of 32 healthy volunteers, 64 TN and CPN showed clear, sharp edges, good signal intensity, uniformity, and the scores were all 4. The consistency between the two readers was good (Kappa value=1.0). In the 64 TN and CPN of 32 GBS patients, 57 TN and 55 CPN showed abnormal changes in varying degrees, including blurred edges, distortions, difficulty in recognition, and weakened signal strength. The score distributions of TN and CPN were 7 and 9 (score = 1), 20 and 22 (score = 2), 27 and 25 (score = 3), 10 and 8 (score = 4), respectively. The consistency between the two readers was good. The Kappa values of TN and CPN were 0.879 and 0.863, respectively. With the scores of TN and CPN in DWIBS sequence decrease, the MCV and motor nerve conduction amplitude values of TN and CPN of GBS patients decreased, and the differences between the score groups were statistically significant (P<0.05). The scores of TN and CPN in DWIBS were positively correlated with MCV (r=0.83 and 0.84, respectively. P<0.05), motor nerve conduction amplitude (r=0.81 and 0.79, respectively. P<0.05).*Conclusions DWIBS could provide a three dimensional visualization of TN and CPN, and evaluate the disorders of peripheral nerves in patients with GBS. There was a moderate correlation between the scores of TN and CPN in DWIBS and electrophysiology parameters.*Clinical Relevance/Application Although electrophysiological examination can assess the peripheral nerve injury of GBS to a certain extent, it is difficult to provide morphological information to fully evaluate nerve injury and can result in inappropriate treatment.

RESULTS

In the DWIBS images of 32 healthy volunteers, 64 TN and CPN showed clear, sharp edges, good signal intensity, uniformity, and the scores were all 4. The consistency between the two readers was good (Kappa value=1.0). In the 64 TN and CPN of 32 GBS patients, 57 TN and 55 CPN showed abnormal changes in varying degrees, including blurred edges, distortions, difficulty in recognition, and weakened signal strength. The score distributions of TN and CPN were 7 and 9 (score = 1), 20 and 22 (score = 2), 27 and 25 (score = 3), 10 and 8 (score = 4), respectively. The consistency between the two readers was good. The Kappa values of TN and CPN were 0.879 and 0.863, respectively. With the scores of TN and CPN in DWIBS sequence decrease, the MCV and

motor nerve conduction amplitude values of TN and CPN of GBS patients decreased, and the differences between the score groups were statistically significant (P<0.05). The scores of TN and CPN in DWIBS were positively correlated with MCV (r=0.83 and 0.84, respectively. P<0.05), motor nerve conduction amplitude (r=0.81 and 0.79, respectively. P<0.05).

CLINICAL RELEVANCE/APPLICATION

Although electrophysiological examination can assess the peripheral nerve injury of GBS to a certain extent, it is difficult to provide morphological information to fully evaluate nerve injury and can result in inappropriate treatment.

SDP-NR-54 Value Of Adopting Fast Brain MRI Techniques For Outpatient Brain MRI: Proof Of Principle And Operational Impact

Participants
Min Lang, MD, Cambridge, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Clinical validation studies have demonstrated the ability of accelerated MRI sequences to decrease acquisition time and motion artifact while preserving image quality. The operational benefits, however, have been less explored. Here, we report our initial clinical experience in implementing fast MRI techniques across a variety of brain MRI protocols for outpatient imaging during the COVID-19 pandemic.*Methods and Materials In the first half of 2020, our tertiary-care academic medical center implemented fast MRI sequences into the clinical brain MRI protocols on two 3T and one 1.5T outpatient MR scanners to allow for increased time for room sanitization and social distancing. Aggregate acquisition times were extracted from the medical record on consecutive imaging examinations performed during matched pre-implementation (7/1/2019-12/31/2019) and post-implementation periods (7/1/2020-12/31/2020). Expected acquisition time reduction for each MRI protocol was calculated through manual collection of acquisition times for the conventional and accelerated sequences performed during the pre- and post-implementation periods. Aggregate and expected acquisition times were compared for five of the most frequently performed brain MRI protocols: brain without contrast (BR-), brain with and without contrast (BR+), multiple sclerosis (MS), memory loss (MML), and epilepsy (EPL).*Results The average acquisition time reduction for 2D sequences (DWI, T1, FLAIR) was 1.9 min. The average acquisition time reduction for 3D sequences (SWI, SPACE FLAIR, and MPRAGE) was approximately 3 min. The expected time reductions for BR-, BR+, MS, MML, and EPL protocols were 6.6 min, 11.9 min, 14 min, 10.8 min, and 14.1 min, respectively. The overall median aggregate acquisition time was 31.00 [25.00, 36.00] min for the pre-implementation period and 18.00 [15.00, 22.00] min for the post-implementation period, with a difference of 13 min (42%). The median acquisition time was reduced by 5.5 min (20%) for BR-, 14.0 min (44%) for BR+, 13.5 min (37%) for MS, 11 min (52%) for MML, and 16 min (35%) for EPL.*Conclusions The implementation of fast brain MRI sequences significantly reduced the acquisition times for outpatient brain MRI protocols. *Clinical Relevance/Application The real-world implementation of fast brain MRI sequences significantly reduced acquisition times for the most performed brain MRI protocols. The projected benefits to the clinical workflow and patient care are substantial, and include increased imaging volume throughput, improved patient access for valuable MRI resources, increased departmental revenue, and improved patient and healthcare worker safety during the COVID-19 pandemic.

RESULTS

The average acquisition time reduction for 2D sequences (DWI, T1, FLAIR) was 1.9 min. The average acquisition time reduction for 3D sequences (SWI, SPACE FLAIR, and MPRAGE) was approximately 3 min. The expected time reductions for BR-, BR+, MS, MML, and EPL protocols were 6.6 min, 11.9 min, 14 min, 10.8 min, and 14.1 min, respectively. The overall median aggregate acquisition time was 31.00 [25.00, 36.00] min for the pre-implementation period and 18.00 [15.00, 22.00] min for the post-implementation period, with a difference of 13 min (42%). The median acquisition time was reduced by 5.5 min (20%) for BR-, 14.0 min (44%) for BR+, 13.5 min (37%) for MS, 11 min (52%) for MML, and 16 min (35%) for EPL.

CLINICAL RELEVANCE/APPLICATION

The real-world implementation of fast brain MRI sequences significantly reduced acquisition times for the most performed brain MRI protocols. The projected benefits to the clinical workflow and patient care are substantial, and include increased imaging volume throughput, improved patient access for valuable MRI resources, increased departmental revenue, and improved patient and healthcare worker safety during the COVID-19 pandemic.

SDP-NR-55 Efficacy Of Deep Learning Reconstruction For High-resolution Three-dimensional MR Cisternography In Evaluation Of Cerebellopontine Angle Tumors

Participants
Masamichi Hokamura, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning reconstruction (DLR) can reduce image noise and increase the signal-to-noise ratio (SNR) of MR images. We aimed to evaluate the efficacy of DLR for high-spatial resolution (HR) three-dimensional (3D) MR cisternography in the evaluation of cerebellopontine angle (CPA) tumors.*Methods and Materials This study included consecutive 13 patients (5 men, 8 women; age range 35-77 years; mean age 54 years) who preoperatively underwent HR 3D isotropic T2-weighted fast asymmetric spin-echo (FASE) imaging (HR MR cisternography) using a 3T MRI scanner with a 32-channel head coil. The CPA tumors were 11 schwannomas and 2 meningiomas. The reconstruction voxel size of HR MR cisternography was 0.23 × 0.23 × 0.5 mm and the scan time 5 min 40 s. The HR MR cisternography was reconstructed with or without DLR. Contrast-to-noise ratio (CNR) between the tumor and trigeminal nerve and between the cerebrospinal fluid and trigeminal nerve were compared between the images with and without DLR. Identification and demarcation of the cranial nerves V-XII contralateral to the tumor were independently rated using a 4-point grading scale on HR MR cisternography with and without DLR. Visualization of the cranial nerves VII/VIII around the tumor on HR MR cisternography were assessed with reference to intraoperatative findings.*Results The mean CNR between the tumor and trigeminal nerve and between the cerebrospinal fluid and trigeminal nerve were significantly higher with DLR than without DLR (16.4 ± 9.3 vs. 12.0 ± 6.7, P < 0.001, 76.1 ± 21.8 vs. 57.6 ± 20.6, P < 0.001). In the identification of lower cranial nerves XI, X, and XI and the demarcation of the cranial nerves VI-XII, the mean score was significantly higher with DLR than without DLR (P < 0.05). The cranial nerves VII/VIII around the tumor were clearly visualized in 4 of 13 (31%) cases on HR MR cisternography with DLR, but in 2 of 13 (15%) without DLR.*Conclusions HR MR cisternography using DLR may improve cranial nerve identification and help detect nerves around CPA tumors.*Clinical Relevance/Application HR MR cisternography using DLR is a promising non-invasive imaging tool for assessing cerebellopontine angle tumors.

RESULTS

The mean CNR between the tumor and trigeminal nerve and between the cerebrospinal fluid and trigeminal nerve were significantly higher with DLR than without DLR (16.4 ± 9.3 vs. 12.0 ± 6.7, P < 0.001, 76.1 ± 21.8 vs. 57.6 ± 20.6, P < 0.001). In the identification of lower cranial nerves XI, X, and XI and the demarcation of the cranial nerves VI-XII, the mean score was significantly higher with DLR than without DLR (P < 0.05). The cranial nerves VII/VIII around the tumor were clearly visualized in 4 of 13 (31%) cases on HR MR cisternography with DLR, but in 2 of 13 (15%) without DLR.

CLINICAL RELEVANCE/APPLICATION

HR MR cisternography using DLR is a promising non-invasive imaging tool for assessing cerebellopontine angle tumors.

SDP-NR-56   Fully Automated Radiomics-based Machine Learning Models For Multiclass Classification Among Glioblastoma, Primary Central Nervous System Lymphoma, And Single Brain Metastasis

Participants
Bio Joo, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance and generalizability of fully automated traditional machine learning and deep learning models for multiclass classification of an untreated single brain mass among glioblastoma, primary central nervous system lymphoma, and brain metastasis using radiomics.*Methods and Materials The training and external validation cohorts were comprised of 538 cases with an untreated single brain lesion (300 glioblastomas, 73 lymphomas, and 165 metastases) and 169 cases (101 glioblastomas, 29 lymphomas, and 39 metastases), respectively. All cases were histopathologically-proven. A total of 372 radiomic features extracted on contrast-enhanced T1-weighted images and T2-weighted images based on both enhancing masks and non-enhancing T2 hyperintense masks using a fully automated segmentation method were analyzed. By using a sequential feature selection method with five traditional machine learning classifiers, the optimal classifiers and number of features were chosen. A deep neural network (DNN) model was also trained on the radiomic features. Hyperparameters of each model were optimized through fivefold cross-validation in the training cohort. The diagnostic performance of the optimized models was tested in the external validation cohort.*Results After the feature selection and model optimization, LASSO model and XGBoost model with 15 selected features were chosen. In the external validation, the LASSO model, XGBoost model, and DNN model showed an accuracy of 0.769 (95% CI, 0.698-0.831), 0.710 (95% CI, 0.642-0.778), and 0.716 (95% CI, 0.648-0.784), respectively.*Conclusions Our results revealed that the fully automated traditional machine learning and deep learning models based on radiomic features can serve a generalizable multiclass classification task for differentiation of an untreated single brain mass among glioblastoma, primary central nervous system lymphoma, and brain metastasis.*Clinical Relevance/Application Fully automated radiomics-based models can serve a generalizable multiclass classification task for an untreated single brain mass.

RESULTS

After the feature selection and model optimization, LASSO model and XGBoost model with 15 selected features were chosen. In the external validation, the LASSO model, XGBoost model, and DNN model showed an accuracy of 0.769 (95% CI, 0.698-0.831), 0.710 (95% CI, 0.642-0.778), and 0.716 (95% CI, 0.648-0.784), respectively.

CLINICAL RELEVANCE/APPLICATION

Fully automated radiomics-based models can serve a generalizable multiclass classification task for an untreated single brain mass.

SDP-NR-57   Development And Validation Of Visual Grading System For Intracranial Arterial Stenosis On Time-of-flight Magnetic Resonance Angiography

Participants
Byungjun Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Although overestimation problem of time-of-flight magnetic resonance angiography (TOF-MRA) applying the warfarin-aspirin symptomatic intracranial disease (WASID) method to assess intracranial arterial stenosis has been suggested, no pertinent grading system for TOF-MRA has been developed. We aimed to develop and evaluate the performance of a visual grading system for intracranial arterial stenosis on TOF-MRA (MRAVICAST).*Methods and Materials This single-center cohort study analyzed prospective observational registry data from a comprehensive stroke center between January 2014 and February 2020. Patients with confirmed stenosis of the intracranial large arteries who underwent confirmative digital subtraction angiography (DSA) were included; a four-point grading system was developed based on physical characteristics of TOF-MRA. The overall diagnostic accuracies of MRAVICAST for each grade, interobserver reproducibility, and positive predictive values for >50% and >70% stenoses were evaluated.*Results We analyzed 132 segments with intracranial atherosclerotic stenosis from 71 patients (34 men and 37 women; mean age, 61.0±15.25 years; range, 21-89 years). The overall diagnostic accuracy of MRAVICAST (93.9%, 124/132) was higher than that of MRAWASID (50.8%, 67/132) for each grade. The degree of stenosis did not differ significantly between MRAVICAST and DSAWASID (P=.849). Regarding reproducibility, MRAVICAST demonstrated excellent interobserver agreement (ICC, 0.989; 95% CI, 0.979-0.999). The positive predictive values of MRAVICAST for the diagnosis of >50% and >70% stenoses were 97.3% and 100.0%, respectively.*Conclusions The new intuitive grading system accurately and reliably determined the degree of stenosis in intracranial arterial atherosclerosis patients.*Clinical Relevance/Application In the era of medical treatment for intracranial atherosclerotic stenosis, MRAVICAST could be a versatile alternative method to MRAWASID for evaluating intracranial arterial stenosis.

RESULTS

We analyzed 132 segments with intracranial atherosclerotic stenosis from 71 patients (34 men and 37 women; mean age, 61.0±15.25 years; range, 21-89 years). The overall diagnostic accuracy of MRAVICAST (93.9%, 124/132) was higher than that of MRAWASID (50.8%, 67/132) for each grade. The degree of stenosis did not differ significantly between MRAVICAST and DSAWASID (P=.849). Regarding reproducibility, MRAVICAST demonstrated excellent interobserver agreement (ICC, 0.989; 95% CI, 0.979-0.999). The positive predictive values of MRAVICAST for the diagnosis of >50% and >70% stenoses were 97.3% and 100.0%, respectively.

CLINICAL RELEVANCE/APPLICATION

In the era of medical treatment for intracranial atherosclerotic stenosis, MRAVICAST could be a versatile alternative method to

MRAWASID for evaluating intracranial arterial stenosis.

SDP-NR-58 Measuring Adherence To Tripod Of Artificial Intelligence Papers In The Glioma Segmentation

Participants
Niklas Tillmanns, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

Generalizability, reproducibility and objectivity are critical elements that need to be considered when translating machine learning models into clinical practice. While a large body of literature has been published on machine learning methods for segmentation of brain tumors, a systematic evaluation of paper quality and reproducibility has not been done. We investigated the use of "Transparent Reporting of studies on prediction models for Individual Prognosis Or Diagnosis" (TRIPOD) items, which are similar to the CLAIM checklist, among papers published in this relatively new and growing field.*Methods and Materials According to the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) a literature review was performed on four databases, Ovid Embase, Ovid MEDLINE, Cochrane trials (CENTRAL) and Web of science core-collection first in October 2020 and a second time in February 2021. Keywords and controlled vocabulary included artificial intelligence, machine learning, deep learning, radiomics, magnetic resonance imaging, glioma, and glioblastoma. The publications were assessed in order to the TRIPOD items.*Results 37 publications from our database search were screened in TRIPOD and yielded an average score of 12.08 with the maximum score being 16 and the minimum score 7. The best scoring item was interpretation (item 19) where all papers scored a point. The lowest scoring items were the title, the abstract, risk groups and the model performance (items number 1, 2, 11 and 16), where no paper scored a point. Less than 1% of the papers discussed the problem of missing data (item 9) and the funding for research (item 22).*Conclusions TRIPOD analysis was applied to machine learning papers that described novel approaches to brain tumor segmentation and showed that majority of the papers do not score high on critical elements that allow reproducibility, translation, and objectivity of research. An average score of 12.08 (40%) indicates that the publications usually achieve a relatively low score. The categories that were consistently poorly described include the ML network description, measuring model performance, title details, and inclusion of information into the abstract.*Clinical Relevance/Application A Systematic adherence-scoring-system enhances objectivity and ensures consistent measurement of adherence to a reporting guideline. This allows reproducibility of data and translation of algorithms into clinical practice.

RESULTS

37 publications from our database search were screened in TRIPOD and yielded an average score of 12.08 with the maximum score being 16 and the minimum score 7. The best scoring item was interpretation (item 19) where all papers scored a point. The lowest scoring items were the title, the abstract, risk groups and the model performance (items number 1, 2, 11 and 16), where no paper scored a point. Less than 1% of the papers discussed the problem of missing data (item 9) and the funding for research (item 22).

CLINICAL RELEVANCE/APPLICATION

A Systematic adherence-scoring-system enhances objectivity and ensures consistent measurement of adherence to a reporting guideline. This allows reproducibility of data and translation of algorithms into clinical practice.

SDP-NR-59 Identifying Clinically Applicable Machine Learning Algorithms For Glioma Segmentation Using A Systematic Literature Review

Participants
Niklas Tillmanns, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

Machine learning (ML) algorithms are commonly used for segmentation of gliomas, but which algorithms provide the most accurate method for implementation into clinical practice has not fully been identified. We performed a systematic review of the literature to characterize the methods used for glioma segmentation and their accuracy.*Methods and Materials In accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA), a literature review was performed on four databases, Ovid Embase, Ovid MEDLINE, Cochrane trials (CENTRAL) and Web of science core-collection first in October 2020 and in February 2021. Keywords and controlled vocabulary included artificial intelligence, machine learning, deep learning, radiomics, magnetic resonance imaging, glioma, and glioblastoma. Publications were screened in Covidence and the bias analysis was done in agreement with Transparent Reporting of studies on prediction models for Individual Prognosis Or Diagnosis (TRIPOD).*Results The search identified 11,727 candidate articles, 1,135 articles underwent full text review, and 66 articles were used for data extraction. BRATS and TCIA datasets were used in 36.6% of all studies, with average number of patients being 141 (range: 1 to 622). ML methods represented 45.3% of studies, with deep learning used in 54.7%; Dice score for the tumor core ranged from 0.72 to 0.95. The most common algorithm used in the machine learning papers was support vector machines (SVM) and for deep learning papers, it was Convolutional Neural Networks (CNN). Preliminary TRIPOD analysis yielded an average score from 12 (range: 7-16) with the majority of papers demonstrating deficiencies in description of the ML algorithm, funding role, data acquisition and measures of model performance.*Conclusions In the last years, many articles were published on segmentation of gliomas using machine learning, thus establishing this method for tumor segmentation with high accuracy. However, the major limitations for clinically applicable use of ML in glioma segmentation include more than one-third of publications use the same datasets, thus limiting generalizability, increase the likelihood of overfitting, show and lack of ML network description and standardization in accuracy reporting.*Clinical Relevance/Application We present a systematic review on ML approaches, that provide insights on clinically applicable algorithm for segmentation of brain tumors.

RESULTS

The search identified 11,727 candidate articles, 1,135 articles underwent full text review, and 66 articles were used for data extraction. BRATS and TCIA datasets were used in 36.6% of all studies, with average number of patients being 141 (range: 1 to 622). ML methods represented 45.3% of studies, with deep learning used in 54.7%; Dice score for the tumor core ranged from 0.72 to 0.95. The most common algorithm used in the machine learning papers was support vector machines (SVM) and for deep learning papers, it was Convolutional Neural Networks (CNN). Preliminary TRIPOD analysis yielded an average score from 12 (range: 7-16) with the majority of papers demonstrating deficiencies in description of the ML algorithm, funding role, data acquisition and measures of model performance.

CLINICAL RELEVANCE/APPLICATION

We present a systematic review on ML approaches, that provide insights on clinically applicable algorithm for segmentation of brain tumors.

SDP-NR-60 Discrimination Of Intracerebral Tumorous Hemorrhage From Pure Hemorrhage Using CT Texture Analysis

Participants
Kyung-Min Lee, MD, Gyeonggi-do, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Detection of underlying tumor in patients with acute intracerebral hemorrhage (ICH) is critical in initial treatment planning and following prognosis. The purpose of our study was to investigate the diagnostic value of CT texture analysis for discriminating tumorous hemorrhage from pure ICH*Methods and Materials This retrospective study included 50 patients with tumorous hemorrhage and 50 patients with pure ICH who underwent non-enhanced CT scan within 24 hours after symptom onset. CT texture analysis were performed using commercially available TexRAD software. Differences between tumorous hemorrhage and pure ICH were analyzed using ?2 test and independent t-test. ROC curve analysis was performed for discriminating tumorous hemorrhage with texture parameters. Diagnostic performance of texture parameters were compared with those of radiologists who have variable degree of experience in neuroradiology using McNemar test.*Results The location (p=0.583) and size (p=0.545) of ICH were not significantly different between tumorous and pure hemorrhage. All histogram texture features (mean, SD, entropy, skewness, and kurtosis) were significantly different between two groups of ICH. Among 20 second order gray-level co-occurrence matrix (GLCM) features, 19 features of tumorous hemorrhage were significantly different from those of pure ICH. The mean and entropy showed highest AUC, 0.985 with cutoff of 67.98 and 0.916 with cutoff of 3.43, respectively. Diagnostic accuracy of mean (94.0%) and entropy (89.9%) were similar to those of radiologists (88.0~93.0%). When combining the mean and entropy, the accuracy increased to the 100%, although it was not statistically different from those of radiologist (p=0.424, 0.053, 0.077).*Conclusions Texture parameters from non-enhanced CT scan is helpful for differentiating tumorous hemorrhage from pure ICH and the diagnostic performance is not different from that of radiologist.*Clinical Relevance/Application CT texture analysis might be useful for detecting underlying tumor when a patient presents acute intracerebral hemorrhage.

RESULTS

The location (p=0.583) and size (p=0.545) of ICH were not significantly different between tumorous and pure hemorrhage. All histogram texture features (mean, SD, entropy, skewness, and kurtosis) were significantly different between two groups of ICH. Among 20 second order gray-level co-occurrence matrix (GLCM) features, 19 features of tumorous hemorrhage were significantly different from those of pure ICH. The mean and entropy showed highest AUC, 0.985 with cutoff of 67.98 and 0.916 with cutoff of 3.43, respectively. Diagnostic accuracy of mean (94.0%) and entropy (89.9%) were similar to those of radiologists (88.0~93.0%). When combining the mean and entropy, the accuracy increased to the 100%, although it was not statistically different from those of radiologist (p=0.424, 0.053, 0.077).

CLINICAL RELEVANCE/APPLICATION

CT texture analysis might be useful for detecting underlying tumor when a patient presents acute intracerebral hemorrhage.

SDP-NR-61 Glymphatic System Evaluation Using Diffusion Tensor Imaging In Patients With Traumatic Brain Injury

Participants
Sung Hyun An, Sunwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The activity of the glymphatic system is known to be impaired in animal models of traumatic brain injury (TBI). We evaluated the activity of the human glymphatic system using a non-invasive method called "Diffusion Tensor Image Analysis along the Perivascular Space (DTI-ALPS)" in patients with traumatic brain injury (TBI).*Methods and Materials From June 2018 to May 2020, patients with TBI (n=89) and age- and sex-matched control subjects (n=34) were included. All MRIs were obtained using a 3T scanner with DTI (32 directions of gradients) and MRIs were scanned within 7 to 28 days after the date of injury in TBI patients. Clinical classification of TBI severity was performed based on the electronic medical records (EMR) including the Glasgow Coma Scale (GCS). The presence of diffuse axonal injury (DAI) was evaluated based on the MRI by a neuro-radiologist. DTI-ALPS method was adopted and the index called "ALPS-index" was calculated to quantify the glymphatic system activity along the perivascular space. The independent t-test was used to compare ALPS-index between TBI/control subjects and DAI/no DAI patients. A one-way analysis of variance (ANOVA) was used to determine whether there was a significant difference in ALPS-index between control/mild TBI/moderate to severe TBI patients.*Results ALPS-index was significantly lower in TBI patients (mean±SD, 1.32±0.19) than in normal control subjects (1.52±0.16, P<.001). There was a significant difference of ALPS-index between control subjects and patients with mild or moderate to severe TBI (ANOVA, P<.001; Tukey's test, P<0.05 for control vs. mild or moderate to severe TBI). ALPS-index was significantly lower in TBI patients with DAI than in patients without DAI (1.26±0.16 vs. 1.38±0.2, P=.003).*Conclusions The DTI-ALPS method can be used to assess glymphatic system impairment in patients with TBI.*Clinical Relevance/Application This is the first study to show human glymphatic system impairment in patients with traumatic brain injury. There may be a possible association between TBI-related brain injury and glymphatic dysfunction.

RESULTS

ALPS-index was significantly lower in TBI patients (mean±SD, 1.32±0.19) than in normal control subjects (1.52±0.16, P<.001). There was a significant difference of ALPS-index between control subjects and patients with mild or moderate to severe TBI (ANOVA, P<.001; Tukey's test, P<0.05 for control vs. mild or moderate to severe TBI). ALPS-index was significantly lower in TBI patients with DAI than in patients without DAI (1.26±0.16 vs. 1.38±0.2, P=.003).

CLINICAL RELEVANCE/APPLICATION

This is the first study to show human glymphatic system impairment in patients with traumatic brain injury. There may be a possible association between TBI-related brain injury and glymphatic dysfunction.

SDP-NR-62 Estimation Of R2 From Conventional Mr Images: A Deep Learning Approach

Participants
Dohoon Park, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Most clinical MRI were "weighted" for specific NMR properties, such as T1 or T2 relaxation times. While signal intensities were

Most clinical MRI were "weighted" for specific NMR properties, such as T1 or T2 relaxation times. While signal intensities were closely related to them, they are not quantitative enough, such as radiomics or other parametric approaches. Meanwhile, conventional relaxometry requires very long scan time, especially for R2, which is almost impossible in clinics. In this work we used a deep learning (DL) approach to disentangle the relationship between conventional MRI signals and R2 relaxation time, and explore the potential clinical values.*Methods and Materials We used 125 subjects, 179 MRI sets (training 161 , validation 18) with a MR protocol for demyelinating disease, which included multi-contrast structural images, as well as multi-echo spin echo images (mSE) for R2 mapping. To maximize the information regarding NMR relaxation into DL model, we added all T2-, T1-weighted and T2 FLAIR images as input channels. An exponentially estimated R2 map from mSE was used as the label. Due to limited scan time of clinical MRI, mSE was performed in narrow area of the brain, and training was done within the area with mSE data. Preprocessing steps including brain extraction, linear registration, and normalization. RandomFieldBias augmentation from the TorchIO library was used. We modified 2D U-net structures with axial image input, with about 3600 slices (training 3300, validation 300). The loss function was defined as the sum of L1 loss and 0.1*gradient loss. After training, estimation of whole brain R2 was performed, in and out of the labeled area (matched to mSE data). Evaluation of estimated R2 map was done including correlation coefficient of R2 to reference data according to the brain tissue classes.*Results After 500 epoch of training, DL-based estimated R2 showed good correlation to reference R2 estimation, as well as map quality improvement. Especially, this correlation was excellent in gray and white matters (correlation coefficient > 0.98), as compared to CSF (=0.90). Interestingly, estimation was excellent at the brain area out of the mSE area which was not have training data. Whole brain R2 were well matched known range of the R2, and there were smooth continuation between area with labels and without labels.*Conclusions Using proposed approach, whole brain R2 map can be estimated successfully from a combination of clinically available 'weighted' images.*Clinical Relevance/Application From this approach, estimation of whole brain R2 relaxation time, which is in general very time-consuming, can be obtained from combination of clinically acquired T1 and T2 weighted images and deep learning. It can be used for objective imaging analysis, as well as further image processing, such as radiomics or other parametric mappings.

RESULTS

After 500 epoch of training, DL-based estimated R2 showed good correlation to reference R2 estimation, as well as map quality improvement. Especially, this correlation was excellent in gray and white matters (correlation coefficient > 0.98), as compared to CSF (=0.90). Interestingly, estimation was excellent at the brain area out of the mSE area which was not have training data. Whole brain R2 were well matched known range of the R2, and there were smooth continuation between area with labels and without labels.

CLINICAL RELEVANCE/APPLICATION

From this approach, estimation of whole brain R2 relaxation time, which is in general very time-consuming, can be obtained from combination of clinically acquired T1 and T2 weighted images and deep learning. It can be used for objective imaging analysis, as well as further image processing, such as radiomics or other parametric mappings.

SDP-NR-64 Deoxyhemoglobin Perfusion MRI In Patients With Steno-Occlusive Vascular Disease

Participants
Ece Su Sayin, BSC, Toronto, Ontario (*Presenter*) Contract, Thornhill Research Inc

PURPOSE

The magnetic properties of hemoglobin depend directly on its oxygenation state. The ability to rapidly control blood oxygenation could therefore be used to generate paramagnetic deoxyhemoglobin (dHb) in the form of a bolus for perfusion imaging. Generating rapid changes in lung PO2 could therefore be applied to control hemoglobin (Hb) oxygen saturation in pulmonary veins thus delivering dHb to the tissues for use as an endogenous paramagnetic contrast agent to acquire maps of CBF metrics.*Methods and Materials 6 healthy controls and 15 patients with steno-occlusive disease were studied. A computer-controlled gas blender was used to control end-tidal gas values using sequential gas delivery. BOLD MRI was acquired on a 3T GE Signa HDx system. The PO2 change was modulated in ranged from 95 mmHg to 40 mmHg. An arterial input function (AIF) was selected using a single voxel with the greatest signal change corresponding to known arterial anatomy. A linear regression of the BOLD signal (S) against the SaO2 calculated from PO2 was used to calculate %BOLD, correlation and time delay (TD) maps. Maps of relative CBF, CBV, and MTT were generated. The mean transit time (MTT) was calculated as $S(t)=(rCBV/MTT)SaO2(t)? e^{(-t/MTT)}$, where the limits were set between 0-8s. The relative CBV (rCBV) was calculated as the area under the curve. The relative CBF (rCBF) was calculated as rCBF = rCBV/MTT.*Results The MTT, rCBF and rCBF showed expected differences in gray matter and white matter in controls while showing longer MTT, increased rCBV, and thereby reduced rCBF in patients.*Conclusions The dHb bolus method has the potential to provide diagnostic quality rCBV, rCBF and MTT maps without using intra-venous contrast. Limited interrupted exposure to 75% SaO2 provides safety (Bickler et al., 2017).*Clinical Relevance/Application Testing in patients shows promise in identifying the effects of steno-occlusive disease on cerebral perfusion. Advantages of this "needle-free" approach include: absence of contrast reactions and toxicities, unlimited repeatability, no recirculation and no extra-vascular leakage from the circulation thus improving measurement of perfusion metrics when the BBB is disrupted.

RESULTS

The MTT, rCBF and rCBF showed expected differences in gray matter and white matter in controls while showing longer MTT, increased rCBV, and thereby reduced rCBF in patients.

CLINICAL RELEVANCE/APPLICATION

Testing in patients shows promise in identifying the effects of steno-occlusive disease on cerebral perfusion. Advantages of this "needle-free" approach include: absence of contrast reactions and toxicities, unlimited repeatability, no recirculation and no extra-vascular leakage from the circulation thus improving measurement of perfusion metrics when the BBB is disrupted.

SDP-NR-65 Error Quantification Analysis On CT Perfusion Thresholds And Parameters Approaching To Predict Infarct Core Volumes Using Different Commercial Software: Short-interval DWI Follow-up From Initial CT Perfusion

Participants
Chuluunbaatar Otgonbaatar, MD, Ulaanbaatar, Mongolia (*Presenter*) Nothing to Disclose

PURPOSE

Although CTP is widely used practically in the selection of patients and guides decision-making in acute ischemic stroke, still there is a no clear standardization of optimal thresholds and parameters. Nowadays, infarct core volume with rCBF<30% threshold is

commonly used. Several studies were performed in assessing the volumetric agreement of the infarct core volume between CTP and follow-up DWI within 24 hours. Therefore, in this study, we aimed to assess the volumetric agreement of estimated infarct core using different threshold and parameters with commercial software including VITREA and RAPID on CTP and final infarct volume on DWI in patients with short interval times (less than 60 minutes) from CTP to DWI.*Methods and Materials 39 acute ischemic stroke patients with occlusion of a large artery in the anterior circulation were included. The CT perfusion maps were processed with two different CT perfusion software including singular value decomposition plus (SVD+) in VITREA (Vital Images, MN, USA) and RAPID (iSchema View, Menlo Park, CA). The RAPID identifies infarct as tissue with rCBF<20%-42% while CBV reduction of 29%, 35%, 38% and 41% on VITREA. Olea Sphere was used to measure the infarct volume on DWI.*Results The CTP was performed before DWI in all patients and the median time between CTP and DWI was 38 minutes (IQR 21 - 44). The median final infarct volume was 19.75 ml (IQR 7.68 - 73.97) with DWI. The CBV reduction of 29% (mean infarct volume difference 1.68±32.63) for VITREA and rCBF < 38% (mean infarct volume difference 13.62±26.12) for RAPID predicted final infarct volume with the lowest mean infarct volume difference for each software (Table 1 and Figure 1). Compared to default settings of each CTP software, the limits of agreement were smallest with RAPID rCBF < 38% 5.32 to 21.72 ml and VITREA CBV reduction of 29% -8.56 to 11.92 (Figure 2-3). The representative case is shown in Figure 4.*Conclusions The CBV threshold was non-inferior in the estimation of infarct core volume compared to CBF threshold. rCBF<38% proved to estimate infarct core volume more accurately than rCBF<30% while CBV reduction of 29% performed more accurately than the reduction of 41% by lower mean infarct core volume differences.*Clinical Relevance/Application The underestimation and overestimation measurement by different parameters and thresholds could exclude or select the patient for endovascular treatment differently and directly associated with the clinical outcome of the patient.

RESULTS

The CTP was performed before DWI in all patients and the median time between CTP and DWI was 38 minutes (IQR 21 - 44). The median final infarct volume was 19.75 ml (IQR 7.68 - 73.97) with DWI. The CBV reduction of 29% (mean infarct volume difference 1.68±32.63) for VITREA and rCBF < 38% (mean infarct volume difference 13.62±26.12) for RAPID predicted final infarct volume with the lowest mean infarct volume difference for each software (Table 1 and Figure 1). Compared to default settings of each CTP software, the limits of agreement were smallest with RAPID rCBF < 38% 5.32 to 21.72 ml and VITREA CBV reduction of 29% -8.56 to 11.92 (Figure 2-3). The representative case is shown in Figure 4.

CLINICAL RELEVANCE/APPLICATION

The underestimation and overestimation measurement by different parameters and thresholds could exclude or select the patient for endovascular treatment differently and directly associated with the clinical outcome of the patient.

SDP-NR-8   A Novel Method To Visualize Ischemic Cores By Employing Contrast Differences Between Virtual Monoenergetic Images

Participants
Tomomi Omura, Akita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to propose a novel method to visualize the ischemic core using the contrast difference of brain tissue between virtual monoenergetic images (VMIs).*Methods and Materials Twenty-eight patients who underwent non-enhanced dual-energy CT (NE-DECT) on suspicion of AIS were scanned using a dual-source DECT (SOMATOM Drive, Siemens Healthineers, Forchheim, Germany). The NE-DECT images were acquired at a kV-pair of 80 kV and 140 kV with tin-filtration at about 70 mGy using automatic exposure control. Mixed-120 kV images were synthesized by compositing both kV images. The native VMIs were generated at 40, 70, 100, 130, 160, and 190 keV using a CT vendor's workstation. The proposed contrast change rate ischemic core (CCI) image, which reflected the contrast difference of brain tissue, was generated by dividing the 130 keV image by the corresponding 40 keV image. The CCI image, all native VMIs, mixed-120 kV images, and DWIs were transformed to the standard brain map using SPM (Wellcome Department of Cognitive Neurology, Institute of Neurology, London, U.K.) and applied the ASPECTS 10-ROIs template to measure pixel values. The ischemic core for CT images was found in the region where its ROI value in the normal hemisphere was higher than the corresponding ROI in the ischemic hemisphere. The ischemic core for DWI was found in the region with the highest signal. Finally, sensitivity and specificity for the CCI image, all keV of the VMIs, and the mixed-120 kV images were calculated by comparing with DWIs.*Results Both the sensitivity and the specificity of the CCI image resulted the highest scores among all images (The CCI image; 0.591/0.609, mixed-120 keV; 0.583/0.296, VMI-40 keV; 0.557/0.365, VMI-70 keV; 0.559/0.346, VMI-100 keV; 0.564/0.309, VMI-130 keV; 0.571/0.306, VMI-160 keV; 0.572/0.301, VMI-190 keV 0.571/0.296). Notably, the specificity was significantly higher in the CCI image.*Conclusions Our proposed method to visualize the ischemic core using the contrast difference of brain tissue between VMIs was able to detect the ischemic core accurately.*Clinical Relevance/Application The higher the VMI in energy (keV), the greater the change in tissue contrast between the lower VMI. Imaging the difference in contrast change is useful for detecting the ischemic core.

RESULTS

Both the sensitivity and the specificity of the CCI image resulted the highest scores among all images (The CCI image; 0.591/0.609, mixed-120 keV; 0.583/0.296, VMI-40 keV; 0.557/0.365, VMI-70 keV; 0.559/0.346, VMI-100 keV; 0.564/0.309, VMI-130 keV; 0.571/0.306, VMI-160 keV; 0.572/0.301, VMI-190 keV 0.571/0.296). Notably, the specificity was significantly higher in the CCI image.

CLINICAL RELEVANCE/APPLICATION

The higher the VMI in energy (keV), the greater the change in tissue contrast between the lower VMI. Imaging the difference in contrast change is useful for detecting the ischemic core.

SDP-NR-9   Assessment Of The Degree Of Arterial Stenosis In Intracranial Atherosclerosis Using 3D High-resolution MRI: Comparison With Time-of-flight MRA, Contrast-enhanced MRA And DSA

Participants
Deng-Ling Zhao, Nanjing, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the accuracy of 3D high-resolution MRI (HR-MRI), time-of-flight magnetic resonance angiography (TOF-MRA), contrast-enhanced magnetic resonance angiography (CE-MRA) and digital subtraction angiography (DSA) in measuring the degree of stenosis in intracranial atherosclerosis.*Methods and Materials All patients with intracranial artery ischemic events underwent HR-MRI, TOF-MRA, and CE-MRA analysis, and some of these patients underwent DSA examination. The correlation between

different methods for measuring the degree of lumen stenosis was analyzed. The accuracy of HR-MRI, TOF-MRA and CE-MRA was evaluated and compared with that of DSA.*Results A total of 189 arterial stenoses were identified in 93 patients. Of them, 72 patients with 142 arterial stenoses underwent DSA examination. A very strong correlation between HR-MRI and CE-MRA measurements was shown (r=0.839). The correlation between HR-MRI and TOF-MRA measurements was strong (r=0.720). A very strong correlation between HR-MRI and DSA measurements was found (r=0.864), and a similar correlation was observed between CE-MRA and DSA measurements (r=0.843). The correlation between TOF-MRA and DSA measurements was strong (r=0.686). There was substantial agreement between HR-MRI and DSA measurements (K=0.772) and between CE-MRA and DSA measurements (K=0.734) that was slightly higher than the agreement between TOF-MRA and DSA measurements (K=0.625).*Conclusions 3D HR-MRI can accurately measure stenosis (especially for moderate and severe stenosis) in intracranial atherosclerosis by direct visualization of the vessel lumen and steno-occlusive plaque.*Clinical Relevance/Application 3D HR-MRI can be used to access the multiple intracranial atherosclerotic arteries. And it is promising to be a reliable and comprehensive clinical assessment method for ischemic stroke risk prediction.

RESULTS

A total of 189 arterial stenoses were identified in 93 patients. Of them, 72 patients with 142 arterial stenoses underwent DSA examination. A very strong correlation between HR-MRI and CE-MRA measurements was shown (r=0.839). The correlation between HR-MRI and TOF-MRA measurements was strong (r=0.720). A very strong correlation between HR-MRI and DSA measurements was found (r=0.864), and a similar correlation was observed between CE-MRA and DSA measurements (r=0.843). The correlation between TOF-MRA and DSA measurements was strong (r=0.686). There was substantial agreement between HR-MRI and DSA measurements (K=0.772) and between CE-MRA and DSA measurements (K=0.734) that was slightly higher than the agreement between TOF-MRA and DSA measurements (K=0.625).

CLINICAL RELEVANCE/APPLICATION

3D HR-MRI can be used to access the multiple intracranial atherosclerotic arteries. And it is promising to be a reliable and comprehensive clinical assessment method for ischemic stroke risk prediction.

NR03-C1   Multi-phase CTA For The Diagnosis Of ICA Pseudo-occlusion

Participants

Gerald Riccardello, MD, Providence, Rhode Island (*Presenter*) Nothing to Disclose

PURPOSE

Pseudo-occlusion (PO) of the cervical internal carotid artery (cICA) are common and have been shown to have poor outcome after mechanical thrombectomy. Prompt diagnosis and differentiation between ICA POs and true cICA occlusion are thus important. We investigated the diagnostic utility of multiphase CTA for the evaluation of cICA POs.*Methods and Materials We retrospectively reviewed all patients who underwent multiphase CTA and subsequent diagnostic cerebral angiography (DCA) between 1-1-2018 and 12-2019. Results of the DCA were reviewed to determine cICA POs and true cICA occlusion, with PO being defined as complete lack of opacification of any portion of the cICA on CTA without complete occlusion of the cICA on DCA. The Fisher exact test was used in data analysis.*Results 98 patients were found to have complete lack of opacification of the cICA on arterial phase of multiphase CTA and subsequently underwent DCA, and were included in the study. 38 patients were found to have true cICA occlusion on DCA with 0/38 (0%) demonstrating late filling of the ICA on delayed phases of the CTA, while 39 demonstrated cICA PO on DCA with 20/39 (51%) demonstrating late filling of the ICA on delated phases of the CTA (p<0.0001)*Conclusions Multiphase CTA has utility in the diagnosis and differentiation of cICA PO and true cICA occlusion.*Clinical Relevance/Application Multiphase CTA is a readily available and non-invasive test that has the ability to differentiation between cICA PO and true cICA occlusion, which has implications in patient selection and treatment preparation in stroke therapy.

RESULTS

98 patients were found to have complete lack of opacification of the cICA on arterial phase of multiphase CTA and subsequently underwent DCA, and were included in the study. 38 patients were found to have true cICA occlusion on DCA with 0/38 (0%) demonstrating late filling of the ICA on delayed phases of the CTA, while 39 demonstrated cICA PO on DCA with 20/39 (51%) demonstrating late filling of the ICA on delated phases of the CTA (p<0.0001)

CLINICAL RELEVANCE/APPLICATION

Multiphase CTA is a readily available and non-invasive test that has the ability to differentiation between cICA PO and true cICA occlusion, which has implications in patient selection and treatment preparation in stroke therapy.

NR03-C3   Automated Assessment Of Aneurysm Volume And Size In Subarachnoid Hemorrhage Using Deep Learning: Comparison With Manual Segmentation And Manual Measurement Of Aneurysm Diameters

Participants

Lenhard Pennig, MD, Cologne, Germany (*Presenter*) Speakers Bureau, Koninklijke Philips NV;Institutional Grant, Koninklijke Philips NV

PURPOSE

The selection of the most suitable method of aneurysm embolization in subarachnoid hemorrhage (SAH) depends on various factors including aneurysm location, shape, and size. The purpose of this study was to compare aneurysm volume and size in SAH on computed tomography angiography as determined by I) manual segmentation (reference standard, RS), II) fully automated segmentation by a deep learning model (DLM), and III) approximation from manually measured aneurysm diameters.*Methods and Materials Three DLMs were trained for fully automated 3D voxel-wise segmentation of aneurysms (68 patients, 79 aneurysms) with their outputs being combined using ensemble learning (DLM-Ens). The DLM-Ens was evaluated on an independent test set (104 patients, 126 aneurysms). Manual aneurysm segmentations by two radiologists using 3D voxel-wise regional thresholding in consensus served as the RS. The largest diameters in three dimensions (length, height, and width) of the aneurysms in the test set were manually measured by two radiologists with four (R1) and two years (R2) of experience in diagnostic neuroradiology. The aneurysm volume was estimated using the formula $V=4/3*p*(length/2)*(height/2)*(width/2)$. Pearson's correlation coefficient (r) was used to assess the correlation of aneurysm volume and maximum diameter between the three approaches.*Results In the test set, the DLM-Ens detected and segmented 108 of 126 aneurysms (sensitivity of 85.7%). For these, the maximum aneurysm diameter obtained by the DLM (6.2±5.4 mm, r=0.835, p=0.01) and the readers (R1: 6.6±2.5 mm, r=0.842, p<0.01; R2: 6.4±2.6 mm, r=0.828, p<0.01) correlated strongly with the RS (manual segmentation: 6.4±5.7 mm). Aneurysm volume obtained by the DLM (124.6±182.9 mm3, r=0.916, p<0.01) and the readers (R1: 134.7±194.8 mm3, r=0.959, p<0.01; R2: 132.1±186.8 mm3, r=0.949, p<0.01) correlated even stronger with manual segmentations (138.6±197.4 mm3).*Conclusions Automated delineation of aneurysm volume and diameter strongly correlates with the results from manual segmentations and the approximation from manual aneurysm diameters. Therefore, the DLM has the potential to assist the physician in evaluating intracranial aneurysms while providing 3D geometrical characterization.*Clinical Relevance/Application By delineation of aneurysm volume and maximum diameter, the proposed DLM provides geometrical characterization of aneurysms and can support the physicians in charge for treatment of aneurysms in aSAH.

RESULTS

In the test set, the DLM-Ens detected and segmented 108 of 126 aneurysms (sensitivity of 85.7%). For these, the maximum

aneurysm diameter obtained by the DLM (6.2±5.4 mm, r=0.835, p=0.01) and the readers (R1: 6.6±2.5 mm, r=0.842, p<0.01; R2: 6.4±2.6 mm, r=0.828, p<0.01) correlated strongly with the RS (manual segmentation: 6.4±5.7 mm). Aneurysm volume obtained by the DLM (124.6±182.9 mm3, r=0.916, p<0.01) and the readers (R1: 134.7±194.8 mm3, r=0.959, p<0.01; R2: 132.1±186.8 mm3, r=0.949, p<0.01) correlated even stronger with manual segmentations (138.6±197.4 mm3).

CLINICAL RELEVANCE/APPLICATION

By delineation of aneurysm volume and maximum diameter, the proposed DLM provides geometrical characterization of aneurysms and can support the physicians in charge for treatment of aneurysms in aSAH.

NR03-C6 Resting State Functional Connectivity Patterns Associated With Simple Partial And Complex Partial Seizure Types In Temporal Lobe Epilepsy

Participants
Mashaal Syed, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Since focal epilepsy has been shown to impact neural regions beyond the epileptogenic zone, investigating the underlying functional connectivity patterns of individuals with Temporal Lobe Epilepsy (TLE) with Mesial Temporal Sclerosis (MTS) can improve understanding of this disease's neural connections. In particular those with a pre-operative history of simple partial seizures (SP) and those with a pre-operative history of complex partial seizures (CP) were evaluated to determine associations between resting state functional (rsf) brain connectivity and these seizure types.*Methods and Materials The rsf-MRIs of 17 controls (NC) (aged 21 - 35 years), 10 left-sided TLE-MTS CP (aged 24 - 66 years), and 13 left-sided TLE-MTS SP (aged 24 - 68 years), were compared to determine unique functional connectivity patterns with respect to these seizure types. This regions of interest (ROI)-to-ROI connectivity analysis included a total of 171 ROIs, and accounted for age and duration of epileptic activity. Significant correlations were determined via two-sample t-tests and bonferroni correction with an alpha value of 0.05.*Results Between CP and SP, significant correlation was observed between the contralateral (CL) anterior cingulate gyrus, subgenual region and the CL cerebellum, lobule III (P value = 2.26e-4, mean z-score = -0.05 (SD 0.28), T = -4.23). Comparing NC with SP depicted significant correlation between the CL reuniens nucleus and CL substantia nigra pars compacta (P value = 6.9e-5, mean z-score = 0.08 (SD 0.18), T = -4.64), as well as between the CL hippocampus and the CL cerebellum, lobule X (P value = 1.77e-4, mean z-score = 0.05 (SD 0.17), T = -4.30). Comparison of NC with CP revealed significant correlation between the ipsilateral (IL) parahippocampal gyrus and the CL supplementary motor area (P-value = 5.1e-5, mean z-score = -0.14 (SD 0.15), T = 4.75), the IL nucleus accumbens and the IL medial geniculate nucleus (P value = 1.53e-4, mean z-score = -0.04 (SD 0.18), T = 4.35), and the CL pallidum with the CL inferior temporal gyrus (P value = 1.58e-4, mean z-score = -0.009 (SD 0.15), T = 4.34).*Conclusions Aside from the widespread network disruptions in the limbic and cerebellar networks - in which SP experienced hyperactivity, in comparison to CP and NC - notable alterations were found in the basal ganglia. Furthermore, while both unilateral and bilateral changes were observed in CP, the SP group experienced exclusively unilateral changes of their functional connectivity patterns.*Clinical Relevance/Application Differences in functional connectivity patterns associated with these seizure types further supports the understanding of widespread network disruptions in TLE, and thus, could provide new avenues for pharmaceutical or surgical interventions.

RESULTS

Between CP and SP, significant correlation was observed between the contralateral (CL) anterior cingulate gyrus, subgenual region and the CL cerebellum, lobule III (P value = 2.26e-4, mean z-score = -0.05 (SD 0.28), T = -4.23). Comparing NC with SP depicted significant correlation between the CL reuniens nucleus and CL substantia nigra pars compacta (P value = 6.9e-5, mean z-score = 0.08 (SD 0.18), T = -4.64), as well as between the CL hippocampus and the CL cerebellum, lobule X (P value = 1.77e-4, mean z-score = 0.05 (SD 0.17), T = -4.30). Comparison of NC with CP revealed significant correlation between the ipsilateral (IL) parahippocampal gyrus and the CL supplementary motor area (P-value = 5.1e-5, mean z-score = -0.14 (SD 0.15), T = 4.75), the IL nucleus accumbens and the IL medial geniculate nucleus (P value = 1.53e-4, mean z-score = -0.04 (SD 0.18), T = 4.35), and the CL pallidum with the CL inferior temporal gyrus (P value = 1.58e-4, mean z-score = -0.009 (SD 0.15), T = 4.34).

CLINICAL RELEVANCE/APPLICATION

Differences in functional connectivity patterns associated with these seizure types further supports the understanding of widespread network disruptions in TLE, and thus, could provide new avenues for pharmaceutical or surgical interventions.

NR03-C8 Introduction Of MRI-based AI Model In Prediction Of MCI Conversion To Dementia: Could It Be A Key To Early Diagnosis Of Alzheimer's Disease?

Participants
Eun Kyoung Hong, MD, Gwangmyeong-Si, Korea, Republic Of (*Presenter*) Research Consultant, VUNO Inc

PURPOSE

Mild cognitive impairment (MCI), often recognized as a prodrome of dementia, possesses a 10-15% of risk of converting to Alzheimer's disease (AD). Hence, predicting the conversion of MCI to dementia using various subtle changes of the brain, in association with clinical symptoms and disease progression, is clinically important. The aim of this study is to investigate the prediction performance of a deep learning algorithm in predicting conversion of MCI to dementia.*Methods and Materials This retrospective study included 284 MCI patients (144 early MCI (EMCI) and 140 late MCI (LMCI) patients) who underwent 3D T1-weighted MRI. Among them, 52 MCI patients went through conversion from MCI to AD within 3 years from being diagnosed with MCI. A previously developed deep learning-based AD prediction model (A model trained with 1100 MRI scans of AD and cognitively normal subjects using Inception-v4 architecture) was utilized for the analysis of structural MRI. The output of the model was presented as an AD probability score. AD probability scores from the deep learning model were compared between EMCI vs. LMCI patients and patients who converted to AD vs. those who did not. Thereafter, the performance of AD probability score in predicting conversion of MCI to dementia was analyzed and compared with that of amyloid ß PET.*Results The average of the AD probability scores were 0.38 for EMCI and 0.60 for LMCI (p < 0.001) and 0.69 for patients who converted to AD and 0.41 for patients who did not (p < 0.001). When a cut-off of 0.38 was applied for AD probability score, Accuracies and AUC were 0.83 and 0.77 for AD probability score and 0.92 and 0.82 for amyloid ß PET in predicting dementia conversion from MCI (p = 0.140 and 0.270 for difference). Accuracies of AD probability score and amyloid ß PET were 0.73 and 0.91 for EMCI (p = 0.280), 0.85 and 0.93 for LMCI(p = 0.292). There was no statistically significant difference in prediction performance between the two modalities.*Conclusions A deep learning-based AD prediction model using MRI showed comparable performance in predicting conversion of MCI to dementia in both EMCI and LMCI patients to amyloid ß PET.*Clinical Relevance/Application We found a

comparable performance of a deep learning-based AD prediction model using MRI for predicting MCI patients' risk for AD conversion to amyloid ß PET. The findings of this study suggest that the deep learning-based model potentially can be utilized as a convenient and efficient solution in clinical practices for the early diagnosis of AD.

RESULTS

The average of the AD probability scores were 0.38 for EMCI and 0.60 for LMCI (p < 0.001) and 0.69 for patients who converted to AD and 0.41 for patients who did not (p < 0.001). When a cut-off of 0.38 was applied for AD probability score, Accuracies and AUC were 0.83 and 0.77 for AD probability score and 0.92 and 0.82 for amyloid ß PET in predicting dementia conversion from MCI (p = 0.140 and 0.270 for difference). Accuracies of AD probability score and amyloid ß PET were 0.73 and 0.91 for EMCI (p = 0.280), 0.85 and 0.93 for LMCI(p = 0.292). There was no statistically significant difference in prediction performance between the two modalities.

CLINICAL RELEVANCE/APPLICATION

We found a comparable performance of a deep learning-based AD prediction model using MRI for predicting MCI patients' risk for AD conversion to amyloid ß PET. The findings of this study suggest that the deep learning-based model potentially can be utilized as a convenient and efficient solution in clinical practices for the early diagnosis of AD.

NR03-C9   Rethinking Intravenous Alteplase For Stroke Patients With Large Vessel Occlusions Undergoing Endovascular Treatment - The DEBATE Survey

Participants
Johanna Ospel, MD, Basel, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

Current guidelines recommend that eligible acute ischemic stroke (AIS) patients receive intravenous alteplase (IVT) prior to endovascular treatment (EVT). Four randomized controlled trials recently sought to determine the risks and value of administering IVT prior to EVT. It is unclear whether and how the results of these trials will change guidelines. With the DEBATE survey, we aimed to assess the influence of the recent trials on treatment strategies with respect to IVT for large vessel occlusions (LVO).*Methods and Materials Participants were provided with 15 cases of patients with AIS due to LVO and asked whether they would treat with IVT+EVT or EVT alone, before and after publication of the trials. All cases were within a mothership scenario. Multivariable logistic regression clustered by respondent and scenario was performed to assess factors influencing the decision to adopt an EVT alone paradigm.*Results Overall, 291 participants (48 women, 16.5%) from 37 countries provided 4365 responses. 13.4% (586/4365) changed from an IVT+EVT strategy to EVT alone. Interventional neuroradiologists (incidence-rate ratio [IRR] 1.3, 95%CI:1.05-1.58) were more likely to adopt an EVT alone strategy, in contrast to neurosurgeons (IRR 0.69, 95%CI:0.51-0.93). Those with 16-19 years of interventional experience (IRR 0.79, 95%CI:0.60-1.03), and from Europe and Asia were less likely to change (IRR 0.66, 95%CI:0.55-0.81 and IRR 0.70, 95%CI:0.57-0.86, respectively). Scenario characteristics associated with a preference for EVT alone were higher Alberta Stroke Program Early CT score (IRR 1.09, 95%CI:1.00-1.19), higher age (IRR 1.01, 95%CI:1.00-1.02), intracranial internal carotid artery occlusions (IRR 1.8, 95%CI:1.17-2.71), and dominant M2 segment occlusions (0.49, 95%CI:0.38-0.64).*Conclusions In light of the recent trials, a proportion of stroke physicians appear to be rethinking IVT treatment strategies of EVT-eligible patients with AIS due to LVO.*Clinical Relevance/Application This survey provides insight on how randomized trials can change clinical practice.

RESULTS

Overall, 291 participants (48 women, 16.5%) from 37 countries provided 4365 responses. 13.4% (586/4365) changed from an IVT+EVT strategy to EVT alone. Interventional neuroradiologists (incidence-rate ratio [IRR] 1.3, 95%CI:1.05-1.58) were more likely to adopt an EVT alone strategy, in contrast to neurosurgeons (IRR 0.69, 95%CI:0.51-0.93). Those with 16-19 years of interventional experience (IRR 0.79, 95%CI:0.60-1.03), and from Europe and Asia were less likely to change (IRR 0.66, 95%CI:0.55-0.81 and IRR 0.70, 95%CI:0.57-0.86, respectively). Scenario characteristics associated with a preference for EVT alone were higher Alberta Stroke Program Early CT score (IRR 1.09, 95%CI:1.00-1.19), higher age (IRR 1.01, 95%CI:1.00-1.02), intracranial internal carotid artery occlusions (IRR 1.8, 95%CI:1.17-2.71), and dominant M2 segment occlusions (0.49, 95%CI:0.38-0.64).

CLINICAL RELEVANCE/APPLICATION

This survey provides insight on how randomized trials can change clinical practice.

MK03-D2 **Comparison Of A Novel MRI Technique That Produces Superior Bone Contrast With 2D CT For The Assessment Of Glenoid Bone Loss**

Participants
Hamza Alizai, MD, Valley Stream, New York (*Presenter*) Nothing to Disclose

PURPOSE

FRACTURE (FFE Resembling A CT Using Restricted Echo-spacing), a 3D gradient echo pulse sequence with restricted echo-spacing combined with an automated post-processing is a technical innovation which provides superior cortical and trabecular bone contrast on MRI. The objective of this study is to validate this technique in a cadaveric glenoid bone loss model using 2DCT as the reference standard*Methods and Materials Glenoid fractures of varying sizes were arthroscopically created in 10 cadaveric shoulders. 2D-CT and MRI FRACTURE (on 3T Philips Ingenia; Philips Healthcare, Best, Netherlands) were performed on all 10 shoulders. The CT and MRI were presented in a blinded fashion to an experienced musculoskeletal radiologist for measurement of the glenoid fracture height and width. Paired t-tests were performed to compare the measurements obtained on CT with those obtained on the MR FRACTURE images.*Results There was no statistically significant difference between CT and MRI in terms of the measured glenoid fracture height (P-value=0.54). The mean height measured on CT was 23.40mm (SD=6.87) and on MRI was 22.50mm (SD=7.28). Additionally, there was no statistically significant difference between CT and MR in terms of the measured glenoid fracture width (P-value=0.86). The mean width on CT measured 7.50mm (SD=3.57) and on MRI measured 7.60mm (SD=3.50).*Conclusions Measurements of glenoid fracture height and width on CT were comparable with measurements obtained using the MR FRACTURE technique.*Clinical Relevance/Application The technique may obviate preoperative CT in patients with anterior shoulder instability.

RESULTS

There was no statistically significant difference between CT and MRI in terms of the measured glenoid fracture height (P-value=0.54). The mean height measured on CT was 23.40mm (SD=6.87) and on MRI was 22.50mm (SD=7.28). Additionally, there was no statistically significant difference between CT and MR in terms of the measured glenoid fracture width (P-value=0.86). The mean width on CT measured 7.50mm (SD=3.57) and on MRI measured 7.60mm (SD=3.50).

CLINICAL RELEVANCE/APPLICATION

The technique may obviate preoperative CT in patients with anterior shoulder instability.

MK03-D4 **Relative Fat Fraction Of Malignant Bone Lesions In Breast Cancer, Prostate And Myeloma Shows Good Inter Observer Agreement And May Aid Disease Detection.**

Participants
Francesca Castagnoli, MD, London, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

The objective of this study was to compare the relative fat fraction (rFF) of active bone lesions from breast, prostate and myeloma malignancies and normal bone marrow; and to assess its inter-reader agreement.*Methods and Materials Patients with breast cancer (n=26), myeloma (n=32) and prostate cancer (n=52) were retrospectively evaluated. 110 baseline axial rFF maps from whole-body MRI (including Dixon T1 weighted and DWI from skull base to mid-thigh) were reviewed by two radiologists. The rFF maps were calculated by (fat-only image)/(fat-only image + water-only image) x 100%. Regions of interest (ROIs) for up to four focal active bone lesions was drawn on rFF maps, one each at the cervicothoracic spine, lumbosacral spine, pelvis and extremity. The mean and standard deviation of rFF (%) were recorded. The rFF of normal marrow was measured in patients without diffuse pelvic disease (n=88). We compared the rFF of bone lesions and normal marrow using Mann-Whitney test. Interobserver agreement was assessed by interclass correlation (ICC).*Results Malignant bone lesions showed significantly lower median rFF (13.87%) compared with normal bone marrow (89.76%) with little overlap (P<0.0001). There was no significant difference in the median rFF of malignant bone lesions from breast cancer (14.46%), myeloma (13.12%) and prostate cancer (13.67%) (p>0.017, Bonferroni correction). There was also no significant difference in the median rFF of bone disease according to their anatomical locations (p>0.008, Bonferroni correction). There was excellent interobserver agreement of rFF measurements between readers (0.976).*Conclusions The low rFF of active bone lesions in breast cancer, myeloma and prostate cancer, provides high image contrast relative to normal marrow that can enhance disease detection. Furthermore, the rFF also has excellent inter-reader agreement, which could be useful for assessing the treatment response of bone metastases.*Clinical Relevance/Application Relative Fat fraction quantification has the potential to be an important diagnostic and response biomarker for the assessment of malignant bone disease.

RESULTS

Malignant bone lesions showed significantly lower median rFF (13.87%) compared with normal bone marrow (89.76%) with little overlap (P<0.0001). There was no significant difference in the median rFF of malignant bone lesions from breast cancer (14.46%),

myeloma (13.12%) and prostate cancer (13.67%) (p>0.017, Bonferroni correction). There was also no significant difference in the median rFF of bone disease according to their anatomical locations (p>0.008, Bonferroni correction). There was excellent interobserver agreement of rFF measurements between readers (0.976).

CLINICAL RELEVANCE/APPLICATION

Relative Fat fraction quantification has the potential to be an important diagnostic and response biomarker for the assessment of malignant bone disease.

HN04-A2   DWI And PWI Assessment Of Hereditary And Non-hereditary Paragangliomas In The Head And Neck

Participants
Yoshiaki Ota, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

This study is aimed to assess the clinical usefulness of diffusion-weighted imaging and dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) in differentiating hereditary and non-hereditary paragangliomas in the head and neck.*Methods and Materials From June 2016 to June 2020, 27 patients (mean age, 48.2 ± 17.2 years; 7 females) pathologically diagnosed with paragangliomas underwent pre-treatment DCE-MRI with conventional MRI in a single center. The genetic testing was performed by the PGLNext panel, which is designed and validated to detect >99.9% of SDH mutations noted above. The variables of apparent diffusion coefficient (ADC) values, DCE-MRI parameters, and tumor characteristics were compared between paragangliomas' mutation status by t-test, Mann-Whitney U test, and Fisher's exact test, as appropriate. For values that showed a statistically significant difference, the optimal cut-off values in ROC analysis were determined by the Youden index, and the diagnostic performances were calculated. Inter-reader agreement for tumor characteristics was assessed by the kappa coefficient.*Results 10 SDH mutation-positive paragangliomas (SDHA: 1, SDHB: 8, SDHC: 2, SDHD: 6) and 17 mutation-negative paragangliomas constituted this study. The patients with SDH mutation-positive paragangliomas were younger than the patients with SDH mutation-negative paragangliomas (mean age: 43.1 ± 17.7 vs 56.8 ± 12.9 years, P = 0.043). As for tumor characteristics, there was no significant difference in other tumor characteristics. As for ADC values, mean ADC and normalized mean ADC were significantly lower in SDH mutation-positive paragangliomas than in SDH mutation-negative paragangliomas (mean ADC: 0.99 ± 0.18 vs 1.27 ± 0.18 × 10-3 mm2/s, P = .0012, normalized mean ADC: 1.25 ± 0.21 vs 1.73 ± 0.32, P < .001, respectively). The diagnostic performances of mean ADC and normalized mean ADC were 0.88 and 0.92 AUCs with the cut-off values of 1.14 × 10-3 mm2/s and 1.52, respectively. As for DCE-MRI dynamic data, there were no parameters that showed statistical significance.*Conclusions Age was lower in SDH mutation-positive paragangliomas than in SDH mutation-negative paragangliomas. Mean and normalized mean ADC values were able to differentiate SDH mutation-positive and SDH mutation-negative paragangliomas with AUCs of 0.88 and 0.92, while DCE-MRI parameters were not.*Clinical Relevance/Application ADC values can be promising as a noninvasive imaging biomarker to predict SDH mutation in head and neck paragangliomas.

RESULTS

10 SDH mutation-positive paragangliomas (SDHA: 1, SDHB: 8, SDHC: 2, SDHD: 6) and 17 mutation-negative paragangliomas constituted this study. The patients with SDH mutation-positive paragangliomas were younger than the patients with SDH mutation-negative paragangliomas (mean age: 43.1 ± 17.7 vs 56.8 ± 12.9 years, P = 0.043). As for tumor characteristics, there was no significant difference in other tumor characteristics. As for ADC values, mean ADC and normalized mean ADC were significantly lower in SDH mutation-positive paragangliomas than in SDH mutation-negative paragangliomas (mean ADC: 0.99 ± 0.18 vs 1.27 ± 0.18 × 10-3 mm2/s, P = .0012, normalized mean ADC: 1.25 ± 0.21 vs 1.73 ± 0.32, P < .001, respectively). The diagnostic performances of mean ADC and normalized mean ADC were 0.88 and 0.92 AUCs with the cut-off values of 1.14 × 10-3 mm2/s and 1.52, respectively. As for DCE-MRI dynamic data, there were no parameters that showed statistical significance.

CLINICAL RELEVANCE/APPLICATION

ADC values can be promising as a noninvasive imaging biomarker to predict SDH mutation in head and neck paragangliomas.

GI05-A1   **Hydro-MDCT For Gastric Adenocarcinoma Staging. Comparative Study With Surgical And Histopathological Follow-up To Select Patients For Echo-endoscopy**

Participants
Marco Di Girolamo, MD, Rome, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the accuracy of hydro-MDCT in the evaluation of gastric adenocarcinoma with subsequent surgical and histo-pathological specimen and to identify when this technique has the least sensitivity, specificity and diagnostic accuracy in the evaluation of T and N parameter, to select cases for echo-endoscopy.*Methods and Materials 65 patients with gastric adenocarcinoma diagnosed by endoscopy and biopsy, underwent hydro-MDCT (64 detectors). The distension of the gastric lumen was obtained after the oral administration of 500ml of water and i.v. injection of spasmolytic agent. The dynamic study was performed during arterial and portal phase. Sensitivity, specificity and diagnostica accuracy were calculated for T, N and M parameter.*Results Contrast-enhanced Hydro-MDCT always detected the gastric cancer as a focal or diffuse gastric wall thickening with or without abnormal enhancement. The tumor was pre-operatively classified as T1 stage in 11 cases, T2 in 21, T3 in 25 and T4 stage in 8 cases. In 49/65 patients the assessment of local tumor extension on hydro-MDCT was identical to the histopathological results in defining the T category according TNM classification, with overall accuracy of 75%. We found overstaging in 12 and understaging in 4 cases. Local enlarged lymphnodes were always identified but MDCT results in the N stage were in agreement with histo-pathological samples in 69% of cases. For the evaluation of metastatic disease hydro-MDCT had an accuracy of 99%. Hydro-MDCT has proven to be more reliable diagnostic technique in evaluating T3 and T4 stage in comparison with T1 and T2 stage: in the definition of T2 stage we found the highest number of staging errors, equal to 37% of cases.*Conclusions Hydro-MDCT is a reliable technique in the preoperative staging of gastric adenocarcinoma. Echo-endoscopy could be particularly useful in doubtful MDCT cases to evaluate the muscularis propria infiltration (T1 vs T2) and to characterize peri-gastric lymph nodes, as they are fundamental for subsequent therapeutical path.*Clinical Relevance/Application Hydro-MDCT is a reliable technique in preoperative staging of gastric adenocarcinoma. Echo-endoscopy could be proposed to differentiate T1 vs T2 and to characterize peri-gastric lymphnodes where CT has a minor diagnostic accuracy.

RESULTS

Contrast-enhanced Hydro-MDCT always detected the gastric cancer as a focal or diffuse gastric wall thickening with or without abnormal enhancement. The tumor was pre-operatively classified as T1 stage in 11 cases, T2 in 21, T3 in 25 and T4 stage in 8 cases. In 49/65 patients the assessment of local tumor extension on hydro-MDCT was identical to the histopathological results in defining the T category according TNM classification, with overall accuracy of 75%. We found overstaging in 12 and understaging in 4 cases. Local enlarged lymphnodes were always identified but MDCT results in the N stage were in agreement with histo-pathological samples in 69% of cases. For the evaluation of metastatic disease hydro-MDCT had an accuracy of 99%. Hydro-MDCT has proven to be more reliable diagnostic technique in evaluating T3 and T4 stage in comparison with T1 and T2 stage: in the definition of T2 stage we found the highest number of staging errors, equal to 37% of cases.

CLINICAL RELEVANCE/APPLICATION

Hydro-MDCT is a reliable technique in preoperative staging of gastric adenocarcinoma. Echo-endoscopy could be proposed to differentiate T1 vs T2 and to characterize peri-gastric lymphnodes where CT has a minor diagnostic accuracy.

GI05-A10   **Fully Automated Segmentation And Volumetry Of Couinaud'S Liver Segment At CT Prior To Major Hepatectomy Using Deep Learning**

Participants
Tingting Xie JR, MD, Shenzhen, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop a deep learning model for automated segmentation and volumetry of Couinaud's liver segment at CT and to apply it for preoperative volumetric assessment of major hepatectomy.*Methods and Materials A three-dimensional U-Nets model was developed for automated segmentation of the Couinaud's liver segment on contrast enhanced portovenous phase (PVP) CT scans. Images were obtained from patients undergoing CT scans for the upper abdomen from May 2016 to March 2019. A total of 110 PVP images from 110 patients (61 with normal findings and 49 with hepatic steatosis) were recruited. The Couinaud's segmentations were annotated by 2 experienced radiologists. A 3D U-Net model was trained with the images randomly divided into the dataset of the train (n=86), validate (n=12), and test (n=12). The 12 images in the test dataset were used to assess the accuracy of segmentation by using Dice scores. Quantitative volumetry for evaluation of respectability in major hepatectomy was compared between automated and manual segmentation by using Pearson correlation and Bland-Altman analysis.*Results Dice scores in the test dataset for Segment I to VIII ranged from 0.84 ± 0.09 to 0.90 ± 0.04 with an average of 0.88 ± 0.06. Total liver volume and future liver remnant (FLR) % for four types of major hepatectomy measured with manual and automated segmentation agreed closely (95 % limits of agreement: -7.02 mL to 39.08 mL and -3.00 % to 5.34 %, -1.46 % to 1.79 %, -5.32 % to 2.97 %, -5.76 % to 3.13 %). In the qualitative analysis, the consistency between the model and surgeon on the permission of four types of major

hepatectomy was more than 95.83 %.*Conclusions Fully automated segmentation and volumetric analysis of Couinaud's liver segment at CT prior to major hepatectomy are accurate and applicable by using deep learning.*Clinical Relevance/Application This study developed a DL method for automated segmentation and volumetric analysis of Couinaud's liver segment prior to major hepatectomy.

RESULTS

Dice scores in the test dataset for Segment I to VIII ranged from 0.84 ± 0.09 to 0.90 ± 0.04 with an average of 0.88 ± 0.06. Total liver volume and future liver remnant (FLR) % for four types of major hepatectomy measured with manual and automated segmentation agreed closely (95 % limits of agreement: -7.02 mL to 39.08 mL and -3.00 % to 5.34 %, -1.46 % to 1.79 %, -5.32 % to 2.97 %, -5.76 % to 3.13 %). In the qualitative analysis, the consistency between the model and surgeon on the permission of four types of major hepatectomy was more than 95.83 %.

CLINICAL RELEVANCE/APPLICATION

This study developed a DL method for automated segmentation and volumetric analysis of Couinaud's liver segment prior to major hepatectomy.

GI05-A2   Evaluation Oflauren Types Of Gastric Cancer Using Spectral CT Quantitative Parameters

Participants
Zhang Min, Jinan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the feasibility of spectral CT quantitative Parameters in distinguishing expression of non-intestinal type gastric cancer.*Methods and Materials 68 patients confirmed of gastric cancer with gastroscopy were preoperatively examined spectral CT and curative gastrectomy. The enrolled patients were divided into intestinal type group and non-intestinal type group according to Lauren type. spectral CT quantitative Parameters, volume iodine content and Slope of energy spectrum curve in every phases were calculated. The differences of parameters in 2 groups were calculated with One-way analysis of variance (ANOVA). A receiver operating characteristic (ROC) analysis was applied to evaluate the diagnostic performance of meaningful spectral CT quantitative parameters.*Results volume iodine content in arterial phase and Slope of energy spectrum curve in artery phases of intestinal type group and non-intestinal type group were 12.44±0.40 (100 μ g / mL),1.68±0.082 ,respectively. The above parameters were significantly different between the two groups.(p<0.05)Areas under the ROC curve for the diagnosis of non-intestinal type gastric cancer by volume iodine content and Slope of energy spectrum curve in artery phases was 0.872(sensitivity, 96.6%; specificity, 70%) ,0.779 (sensitivity, 69.3%; specificity, 88.2%),with the cut-off value of 11.63(100 μ g / mL) and 1.92.*Conclusions Spectrum enhanced CT can accurately evaluate the non-intestinal type gastric cancer with certain quantitative parameters.*Clinical Relevance/Application Spectrum enhanced CT quantitative parameters are potential in the diagnosis of non-intestinal type gastric cancer.

RESULTS

volume iodine content in arterial phase and Slope of energy spectrum curve in artery phases of intestinal type group and non-intestinal type group were 12.44±0.40 (100 μ g / mL),1.68±0.082 ,respectively. The above parameters were significantly different between the two groups.(p<0.05)Areas under the ROC curve for the diagnosis of non-intestinal type gastric cancer by volume iodine content and Slope of energy spectrum curve in artery phases was 0.872(sensitivity, 96.6%; specificity, 70%) ,0.779 (sensitivity, 69.3%; specificity, 88.2%),with the cut-off value of 11.63(100 μ g / mL) and 1.92.

CLINICAL RELEVANCE/APPLICATION

Spectrum enhanced CT quantitative parameters are potential in the diagnosis of non-intestinal type gastric cancer.

GI05-A3   Quantified Small Bowel Motility As A Marker Of Treatment Response In Crohn's Disease: An Audit Of Initial Experience And Comparison To A Validated Activity Index In A Real World Setting

Participants
Safi Rahman, MBBS, London, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

Commercial software is now available to quantify small bowel motility in Crohn's Disease (CD) from magnetic resonance enterography (MRE) (Menys et al 2018; Plumb et al 2015).Our aim was to compare this against a validated simplified magnetic resonance activity index of CD - sMaRIA (Ordas et al 2019)*Methods and Materials Patients with CD undergoing therapy who had MRE (Jan2020-Jan2021) with motility imaging at two time points were selected. Motility index (arbitrary units, a.u.) derived from 'cine' images using commercially available software (GIQuant®, Motilent, London, UK) was compared with the change in sMaRIA score at the site of most severe disease. Patients were categorised as improving disease (reducing sMaRIA) or no improvement (static/increasing sMaRIA) and the difference in change in the motility index between groups compared using the Mann-Whitney test. Note was made of time taken and processes to calculate both the motility index and the sMaRIA. All results are presented as proportions or median (range).*Results 23 patients (61%M), age 32y (14 to 65) were identified with an interval of 469 (133 to 699) days between MRE. The most severe disease site was the terminal ileum in 19 patients (3 ileum, 1 no disease). 16 (70%) patients had no improvement whilst 9 (30%) had improving disease according to the change in sMaRIA. Motility index increased by 95 a.u. (54 to 113) in patients with improving disease compared to -1.5 a.u. (-58 to 39) in patients with static or worsening disease (p<0.001)The processes and time taken to acquire the motility index and the sMaRIA scores were comparable. The sMaRIA score required an increased number of subjective assessments in comparison to obtaining the motility index.*Conclusions Our results show that the change in motility index acquired using software analysis of cine imaging correlates with a validated MRE disease response assessment (sMaRIA). The process of obtaining the motility index is comparable to sMaRIA scoring with the added advantage of a fewer subjective judgements.*Clinical Relevance/Application Clinical relevance statement: Motility index (GIQuant®, Motilent, London, UK) offers a comparable and less subjective quantification of disease response assessment in patients with CD in comparison to other indices such as sMaRIA.

RESULTS

23 patients (61%M), age 32y (14 to 65) were identified with an interval of 469 (133 to 699) days between MRE. The most severe disease site was the terminal ileum in 19 patients (3 ileum, 1 no disease). 16 (70%) patients had no improvement whilst 9 (30%) had improving disease according to the change in sMaRIA. Motility index increased by 95 a.u. (54 to 113) in patients with improving

disease compared to -1.5 a.u. (-58 to 39) in patients with static or worsening disease (p<0.001)The processes and time taken to acquire the motility index and the sMaRIA scores were comparable. The sMaRIA score required an increased number of subjective assessments in comparison to obtaining the motility index.

CLINICAL RELEVANCE/APPLICATION

Clinical relevance statement: Motility index (GIQuant®, Motilent, London, UK) offers a comparable and less subjective quantification of disease response assessment in patients with CD in comparison to other indices such as sMaRIA.

GI05-A5   MRI Evaluation Of The Tumor Microenvironment In Pancreatic Ductal Adenocarcinoma

Participants
Donghoon Lee, PhD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the tumor microenvironment in pancreatic ductal adenocarcinoma using multi-parametric MRI and correlate the MRI results to histopathology findings.*Methods and Materials We used the KPC genetic mouse model of pancreatic ductal adenocarcinoma (PDA). The KPC mouse model recapitulates the clinical manifestations, histopathology, and genetic progression of the human PDA from inception to invasion and metastasis. KPC mice (n = 22) were enrolled in the study when a mouse had a tumor mass > 250 mm3, which was confirmed by ultrasound imaging. Animals were then scanned on a preclinical 14 tesla (T) MRI system. Multi-parametric MRI was conducted to acquire relaxation times T1 and T2, magnetization transfer ratio (MTR), diffusion parameters, and glycosaminoglycan-chemical exchange saturation transfer (Gag-CEST) response. After completing MRI scans, mice were euthanized for tissue harvest for histopathology including hematoxylin and eosin (H&E), Masson's trichrome, hyaluronic acid (HA) binding protein, Ki67, and CD31 staining.*Results Several MRI parameters showed some correlation with tumor volume and histological measurements. T2 was negatively correlated with the tumor volume (r = -0.64, p = 0.002) while MTR was positively correlated with the tumor volume (r = 0.58, p = 0.005). For diffusion, a negative correlation was found for the low-b ADC versus the tumor volume (r = -0.44, p = 0.02) and a positive correlation was observed for the high-b apparent diffusion coefficient (ADC) versus the tumor volume (r = 0.64, p = 0.002). There was an increase in Gag-CEST values with the tumor volume (r = 0.54, p = 0.01). There were several correlations between some MRI parameters and fibrosis quantified by Masson's trichrome stained images. There was a significant correlation between Gag-CEST values and HA staining (r = 0.81).*Conclusions T2 relaxation, MTR, Gag-CEST, and ADC demonstrated good correlations with histology and may be effective MRI parameters to monitor the tumor microenvironment of PDA.*Clinical Relevance/Application Multi-parametric MRI may be used to non-invasively monitor the tumor microenvironment for patients with PDA.

RESULTS

Several MRI parameters showed some correlation with tumor volume and histological measurements. T2 was negatively correlated with the tumor volume (r = -0.64, p = 0.002) while MTR was positively correlated with the tumor volume (r = 0.58, p = 0.005). For diffusion, a negative correlation was found for the low-b ADC versus the tumor volume (r = -0.44, p = 0.02) and a positive correlation was observed for the high-b apparent diffusion coefficient (ADC) versus the tumor volume (r = 0.64, p = 0.002). There was an increase in Gag-CEST values with the tumor volume (r = 0.54, p = 0.01). There were several correlations between some MRI parameters and fibrosis quantified by Masson's trichrome stained images. There was a significant correlation between Gag-CEST values and HA staining (r = 0.81).

CLINICAL RELEVANCE/APPLICATION

Multi-parametric MRI may be used to non-invasively monitor the tumor microenvironment for patients with PDA.

GI05-A6   A Novel Deep Learning-based Iodine Contrast Boosting Algorithm Of Liver CT For Improvement Of Image Quality And Lesion Conspicuity In Patients At High Risk For HCC

Participants
Jae Hyun Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To assess the feasibility of applying a deep learning-based iodine contrast boosting algorithm to liver computed tomography (CT) for improving image quality and hepatocellular carcinoma (HCC) conspicuity in high-risk patients.*Methods and Materials We retrospectively enrolled 90 high-risk patients who underwent contrast-enhanced liver CT, including 70 consecutive patients without evidence of HCC in January 2010 and 20 consecutive patients with pathologically confirmed single HCC between January 2010 and April 2010. We developed a deep learning-based denoising and iodine contrast boosting algorithm, which was an upgraded version of our previous denoising algorithm (ClariCT.AI, ClariPI). The arterial phase images with algorithm applied and original arterial phase images of 90 patients were prepared. Two abdominal radiologists blindly assessed the two CT data sets for extrahepatic artery clarity, intrahepatic artery clarity, overall image quality, lesion conspicuity, and level of confidence in HCC diagnosis (1-4 Likert scales) in consensus. The Wilcoxon signed-rank test and McNemar test were used for statistical analysis.*Results The proposed deep learning-based algorithm yielded significant improvements of extrahepatic artery clarity (mean 2.89 vs. 3.87, P <0.0001), intrahepatic artery clarity (mean 2.49 vs. 3.47, P<0.0001), overall image quality (mean 2.97 vs. 3.23, P < 0.0001), lesion conspicuity (mean 2.38 vs. 3.48, P = 0.0003), and level of confidence in HCC diagnosis (mean 2.81 vs. 3.78, P = 0.0002). There were no significant differences in sensitivity (100% vs. 100%) and specificity (97.1% vs. 94.3%, P = 0.50) of HCC detection between dataset before and after applying the algorithm.*Conclusions With the proposed deep learning-based iodine contrast boosting algorithm, we can improve the image quality, hepatic vessel clarity, and HCC conspicuity of liver CT images in high-risk patients.*Clinical Relevance/Application The proposed deep learning-based algorithm could help radiologists or clinicians diagnose HCC and identify hepatic artery variation before surgery in contrast-enhanced liver CT.

RESULTS

The proposed deep learning-based algorithm yielded significant improvements of extrahepatic artery clarity (mean 2.89 vs. 3.87, P <0.0001), intrahepatic artery clarity (mean 2.49 vs. 3.47, P<0.0001), overall image quality (mean 2.97 vs. 3.23, P < 0.0001), lesion conspicuity (mean 2.38 vs. 3.48, P = 0.0003), and level of confidence in HCC diagnosis (mean 2.81 vs. 3.78, P = 0.0002). There were no significant differences in sensitivity (100% vs. 100%) and specificity (97.1% vs. 94.3%, P = 0.50) of HCC detection between dataset before and after applying the algorithm.

CLINICAL RELEVANCE/APPLICATION

The proposed deep learning-based algorithm could help radiologists or clinicians diagnose HCC and identify hepatic artery variation

The proposed deep learning-based algorithm could help radiologists or clinicians diagnose HCC and identify hepatic artery variation before surgery in contrast-enhanced liver CT.

GI05-A7 Characterisation Of Abnormalities In The Biliary System By Quantitative MRCP Imaging: A Repeatability And Reproducibility Study

Participants
Andrea Dennis, Oxford, United Kingdom (*Presenter*) Employee, Perspectum Diagnostics Ltd;

PURPOSE

Magnetic resonance cholangiopancreatography (MRCP) is an important tool for the non-invasive diagnosis and monitoring of biliary diseases. However, the assessment of MRCPs is subjective and dependent on radiologist experience, resulting in high intra- and inter- observer variation. A novel MRCP post-processing method, MRCP+, models the biliary tree in 3D, allowing for quantification of the biliary tree volume, local duct diameters, and dilated/strictured regions. We investigated the robustness of biliary stricture/dilatation-related metrics derived from MRCP+ across different MRI scanner models and field strengths.*Methods and Materials Twenty healthy subjects and 20 patients with liver disease (n=10 biliary disease, n=10 parenchymal disease) underwent heavily T2-weighted 3D MRCP scans on Siemens Prisma 3T and Avanto-fit 1.5T. Two acquisition repeats were conducted for each scanner with 15 min breaks between scans. Participants were scanned on different scanner models and field strengths in pseudorandomised order with up to 1 week between scans. Following processing with MRCP+ by two independent operators, 40 biliary stricture/dilation-related metrics were derived. Bland-Altman analysis was performed, and bias, 95% of the limits of agreement (LoA), the intraclass correlation coefficient (ICC) and its confidence intervals (CI) were calculated.*Results Results from 5 MRCP+ metrics with high clinical relevance [Cheng et al. 2020] are summarised below. ICCs from the repeatability test ranged from 0.77 - 0.92, indicating both scanners had excellent repeatability, with the reference scanner (Siemens Prisma 3T) (ICC: 0.87 - 0.92) slightly higher than 1.5T Avanto-fit (0.77 - 0.88). Differences between the two scanners can be attributed to the variation in image contrast due to different field strengths. Moreover, MRCP+ metrics had excellent reproducibility between both scanners, e.g., total length of strictures & dilatations (bias: 13.9 mm, 95% LoA of -86.4 to 114.3 mm, ICC: 0.77), and the number of ducts with dilatations (bias: 0.78, 95% LoA of -6 to 8, ICC: 0.88). In the reproducibility test bias is positive but not significant for the five metrics, indicating Avanto-fit has slightly higher values than Prisma but the differences are not significant (p-value > 0.05).*Conclusions MRCP+ reliably quantifies biliary strictures/dilatations independent of scanner model and field strength (1.5T or 3T), and therefore has potential applications in biliary disease diagnosis, stratification, and monitoring.*Clinical Relevance/Application High scan/rescan repeatability and cross-scanner reproducibility in quantitative MRCP allows for reduced subjectivity in the assessment of biliary tree strictures/dilatations.

RESULTS

Results from 5 MRCP+ metrics with high clinical relevance [Cheng et al. 2020] are summarised below. ICCs from the repeatability test ranged from 0.77 - 0.92, indicating both scanners had excellent repeatability, with the reference scanner (Siemens Prisma 3T) (ICC: 0.87 - 0.92) slightly higher than 1.5T Avanto-fit (0.77 - 0.88). Differences between the two scanners can be attributed to the variation in image contrast due to different field strengths. Moreover, MRCP+ metrics had excellent reproducibility between both scanners, e.g., total length of strictures & dilatations (bias: 13.9 mm, 95% LoA of -86.4 to 114.3 mm, ICC: 0.77), and the number of ducts with dilatations (bias: 0.78, 95% LoA of -6 to 8, ICC: 0.88). In the reproducibility test bias is positive but not significant for the five metrics, indicating Avanto-fit has slightly higher values than Prisma but the differences are not significant (p-value > 0.05).

CLINICAL RELEVANCE/APPLICATION

High scan/rescan repeatability and cross-scanner reproducibility in quantitative MRCP allows for reduced subjectivity in the assessment of biliary tree strictures/dilatations.

GI05-A9 Performance Of Machine Learning And Texture Analysis With 3T MRI In Predicting Response To Neoadjuvant Chemo-Radiotherapy In Locally Advanced Rectal Cancer

Participants
Elena Orlando, MD, Curinga, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To determine the performance of texture analysis (TA) in the prediction of response to neoadjuvant chemo-radio-therapy (CRT) in patients affected by locally advanced rectal cancer (LARC), using machine learning (ML) algorithms in order to improve diagnostic accuracy.*Methods and Materials Forty patients affected by LARC, who underwent pre- and post-CRT 3T MRI examination, were prospectively enrolled. TA was performed on axial T2 weighted images in order to extract texture parameters (skewness, kurtosis, entropy, and mean of positive pixels). After CRT, all patients underwent complete surgical resection and the surgical specimen served as the reference standard. ROC curve analysis was performed to assess the discriminatory power of each quantitative parameter to predict complete response. Artificial Intelligence software was used to evaluate the impact of machine learning algorithms aimed to combine all texture parameters in order to improve diagnostic accuracy.*Results Entropy, kurtosis and MPP showed significant differences before and after CRT in complete responders (CR); partial responders (PR)/non-responders (NR) entropy and skewness showed significant differences before and after CRT (all p<0.05). Absolute changes of entropy, kurtosis, and MPP before and after CRT showed significant differences (0.31±0.35, in CR, -0.02 ± 1.28 in PR/NR, (p=0.04); 1.87 ± 2.19, in CR, -0.06 ± 3.78 in PR/NR(p=0.0005); 107.91 ± 274.40, in CR, -28.33 ± 202.91 in PR/NR, (p=0.004), respectively). ROC curves showed the optimal cut-off value for pre-treatment kurtosis, the best parameter, =3.29, resulting in a sensitivity and specificity for pCR prediction of 81.5% and 61.5%, respectively. A decisional map was defined combining all texture parameters.*Conclusions TA on T2WI can potentially have an important role as imaging biomarker of response to neoadjuvant CRT in LARC. Machine learning software can be applied to combine efficiently all texture parameters with the aim of improving diagnostic accuracy.*Clinical Relevance/Application T2WI analazyed through TA and ML algorithms could play an important role in evaluating response to neoadjuvant CRT in patients affected by LARC.

RESULTS

Entropy, kurtosis and MPP showed significant differences before and after CRT in complete responders (CR); partial responders (PR)/non-responders (NR) entropy and skewness showed significant differences before and after CRT (all p<0.05). Absolute changes of entropy, kurtosis, and MPP before and after CRT showed significant differences (0.31±0.35, in CR, -0.02 ± 1.28 in PR/NR, (p=0.04); 1.87 ± 2.19, in CR, -0.06 ± 3.78 in PR/NR(p=0.0005); 107.91 ± 274.40, in CR, -28.33 ± 202.91 in PR/NR, (p=0.004), respectively). ROC curves showed the optimal cut-off value for pre-treatment kurtosis, the best parameter, =3.29, resulting in a sensitivity and specificity for pCR prediction of 81.5% and 61.5%, respectively. A decisional map was defined

combining all texture parameters.

CLINICAL RELEVANCE/APPLICATION

T2WI analazyed through TA and ML algorithms could play an important role in evaluating response to neoadjuvant CRT in patients affected by LARC.

NMMI04-B1 The Clinical Performance Of Artificial Intelligence Based Fdg Pet Denoising On A Digital Pet/ct

Participants
Kathleen Weyts, Caen, France (*Presenter*) Nothing to Disclose

PURPOSE

In the context of an increasing PET/CT demand, we aimed to investigate the performance of an artificial intelligence (AI) based PET denoising while simulating a 50% FDG PET acquisition time reduction.*Methods and Materials 194 consecutive patients referred for a FDG PET/CT were prospectively included in january-february 2021. The original FDG PET studies (3MBq/kg, 90 sec/bed position, 3D-OSEM + PSF reconstruction-VEREOS SiPM PET/CT) were reconstructed on half of the acquisition time data (45 sec/bed position) and subsequently denoised by Subtle PET® (50% denoised PET), a FDA approved software based on deep learning with deep convolutional neural networks. Five nuclear medicine physicians compared side to side the masked original gold-standard and 50% denoised PET, displayed in a random order. The visual detectability and semi-quantitative parameters of lesions/ foci with increased FDG uptake (malignant or benign), and of the liver as a reference, were collected. For each PET serie a 3-scale global image quality score (IQ) per patient was given (1: bad to 3: good).*Results Of 194 PET examinations, 33 were normal on both PET series. In the remaining 161, 857 FDG avid lesions/foci were visually detected in either of both series. The concordance rate was 98%. There were seven false negative lesions in six patients on the 50% denoised PET, leading to a 99.2% lesion-based sensitivity. False negative lesions showed a small lesion size on CT (median and maximum long axis 5 and 9mm vs 15 and 130mm for true-positive lesions, p=0.009) and low SUL on original PET (median SULpeak 1.5 vs 2.7g/ml, p=0.0008). The per-patient and per-lesion false positive rate on 50% denoised PET was 5% and 1.5%, respectively. Thirteen false positives were found in the liver (n=10), bone (n=2) and spleen (n=1) corresponding to small, indeterminate lesions. Standard and harmonized EARL-1 lesional SULmax , SULpeak, MTV, hepatic SULmean were not significantly different and highly correlated (intraclass correlation coefficients-ICC of at least 0,863 (for MTV) up to 0,996 (for standard and EARL-1 SULpeak and EARL-1 SULmax) between original and 50% denoised PET. Also, the mean visual IQ was similar in the original and 50% denoised PET, 2.94 vs 2.91.*Conclusions This prospective study demonstrates similar performances of 50% denoised and original FDG PET in a digital PET/CT. These data may allow reducing PET acquisition time by half in clinical practice.*Clinical Relevance/Application The use of arteficial intelligence may improve PET image quality and allow an acquisition time reduction while keeping a similar clinical performance.This can lead to a better patient comfort and facilitate the organisation while reducing the patients' delay for having the PET examination.

RESULTS

Of 194 PET examinations, 33 were normal on both PET series. In the remaining 161, 857 FDG avid lesions/foci were visually detected in either of both series. The concordance rate was 98%. There were seven false negative lesions in six patients on the 50% denoised PET, leading to a 99.2% lesion-based sensitivity. False negative lesions showed a small lesion size on CT (median and maximum long axis 5 and 9mm vs 15 and 130mm for true-positive lesions, p=0.009) and low SUL on original PET (median SULpeak 1.5 vs 2.7g/ml, p=0.0008). The per-patient and per-lesion false positive rate on 50% denoised PET was 5% and 1.5%, respectively. Thirteen false positives were found in the liver (n=10), bone (n=2) and spleen (n=1) corresponding to small, indeterminate lesions. Standard and harmonized EARL-1 lesional SULmax , SULpeak, MTV, hepatic SULmean were not significantly different and highly correlated (intraclass correlation coefficients-ICC of at least 0,863 (for MTV) up to 0,996 (for standard and EARL-1 SULpeak and EARL-1 SULmax) between original and 50% denoised PET. Also, the mean visual IQ was similar in the original and 50% denoised PET, 2.94 vs 2.91.

CLINICAL RELEVANCE/APPLICATION

The use of arteficial intelligence may improve PET image quality and allow an acquisition time reduction while keeping a similar clinical performance.This can lead to a better patient comfort and facilitate the organisation while reducing the patients' delay for having the PET examination.

NMMI04-B4 Prospective Evaluation Of 18F-DCFPyL PET/CT In Biochemically Recurrent Prostate Cancer: Analysis Of 18F-DCFPyL Uptake In Possible Extra-pelvic Oligometastases

Participants
Hong Song, MD, Stanford, California (*Presenter*) Nothing to Disclose

PURPOSE

We prospectively evaluated a PET agent targeting prostate specific membrane antigen (PSMA), 18F-DCFPyL, in a single center study for detecting recurrent lesions in prostate cancer patients with biochemical recurrence (BCR).*Methods and Materials We prospectively enrolled 223 men (49-91 years old, mean ± SD: 69.8±8.1) with biochemical recurrence (PSA median 2.0 ng/mL, range 0.12 to 698.4) after primary definitive treatment with prostatectomy (72%), radiotherapy (28%) or both (25%). The 18F-DCFPyL positive lesions compatible with prostate cancer were evaluated by two independent readers. Patients with possible extra-pelvic oligometastases (1-3 lesions with 18F-DCFPyL uptake) were identified. The maximum standardized uptake values (SUV max) of 18F-DCFPyL in these lesions were measured and used to categorize lesions into high uptake (SUV max = parotid gland SUV mean), moderate uptake (parotid gland SUV mean > SUV max = liver SUV mean) and mild uptake (liver SUV mean > SUV max = blood pool

SUV mean).*Results 18F-DCFPyL PET/CT had an overall positivity rate of 84% (172 scans), which increased with higher prostate specific antigen (PSA) levels (ng/mL): 62% (PSA<0.5), 77% (0.5=PSA<1), 90% (1=PSA<2), 92% (2=PSA<5) and 96% (PSA=5), respectively. In the cohort who underwent prostatectomy, 18F-DCFPyL PET/CT had a higher positivity rate in patients with shorter PSA doubling time (PSAdt) (93% in PSAdt 0-3 months vs. 63% in PSAdt > 12 months, P<0.01). Higher positivity rate was also observed in prostatectomy patients with high Gleason score (GS) (92% in GS 8-10 vs 71% in 72% in GS 6-7, P < 0.01). No difference of 18F-DCFPyL positivity rate was observed in post-radiation patients with different PSAdt or GS. We identified 62 patients (28%) with a total of 109 possible extra-pelvic oligometastases. Among them, there are 60 osseous lesions (8 high, 16 moderate and 36 mild uptake), 40 lymph nodes (9 high, 13 moderate and 18 mild uptake) and 9 other lesions such as lung nodules (6 high, 2 moderate and 1 mild uptake). 27 out of the 62 patients (44%) received locally targeted therapy for these lesions (radiation therapy or surgery) with or without androgen deprivation therapy.*Conclusions 18F-DCFPyL PET/CT holds great potential to be a "one-stop shop" diagnostic tool in the work-up of BCR prostate cancer to identify possible extra-pelvic oligometastases for locally targeted therapy.*Clinical Relevance/Application Improve understanding and clinical application of 18F-DCFPyL PET/CT in management of prostate cancer biochemical recurrence.

RESULTS

18F-DCFPyL PET/CT had an overall positivity rate of 84% (172 scans), which increased with higher prostate specific antigen (PSA) levels (ng/mL): 62% (PSA<0.5), 77% (0.5=PSA<1), 90% (1=PSA<2), 92% (2=PSA<5) and 96% (PSA=5), respectively. In the cohort who underwent prostatectomy, 18F-DCFPyL PET/CT had a higher positivity rate in patients with shorter PSA doubling time (PSAdt) (93% in PSAdt 0-3 months vs. 63% in PSAdt > 12 months, P<0.01). Higher positivity rate was also observed in prostatectomy patients with high Gleason score (GS) (92% in GS 8-10 vs 71% in 72% in GS 6-7, P < 0.01). No difference of 18F-DCFPyL positivity rate was observed in post-radiation patients with different PSAdt or GS. We identified 62 patients (28%) with a total of 109 possible extra-pelvic oligometastases. Among them, there are 60 osseous lesions (8 high, 16 moderate and 36 mild uptake), 40 lymph nodes (9 high, 13 moderate and 18 mild uptake) and 9 other lesions such as lung nodules (6 high, 2 moderate and 1 mild uptake). 27 out of the 62 patients (44%) received locally targeted therapy for these lesions (radiation therapy or surgery) with or without androgen deprivation therapy.

CLINICAL RELEVANCE/APPLICATION

Improve understanding and clinical application of 18F-DCFPyL PET/CT in management of prostate cancer biochemical recurrence.

NPM04-A1   Shaping The Future Of Teaching In Radiology - Results Of An International Study.

Participants
Fabian Stoehr, Mainz, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Due to the outbreak of the coronavirus disease 2019 (COVID-19), it proved necessary to rapidly change medical education from on-site to online teaching. In the wake of the crisis, medical educators were forced to rethink the purpose of teaching and the best form of transmission of knowledge. In cooperation with the European Society of Radiology (ESR), this study investigated the attitudes of radiologists in Europe and North America towards innovative online teaching concepts.*Methods and Materials In total, 224 radiologists from 31 different countries participated in our cross-sectional, web-based survey study. On a 7-point Likert-scale, participants were asked to answer 27 questions about the online teaching situation before and during the pandemic, technical and social aspects of online teaching and the future role of online teaching in radiology.*Results An overwhelming majority stated that radiology is particularly well-suited for online teaching (91%), that online teaching should play a more prominent role even after the pandemic (73%) and that lecturers should be familiar with online teaching techniques (89%). Difficulties include a higher workload in preparing online courses (59%), issues with motivating students to follow online courses (56%) and the risk of social isolation (71%). Before the pandemic, only 12% of teaching was provided online; for the future our participants deemed a balanced ratio of approximately 50% online vs. on-site teaching appropriate (Figure 1).*Conclusions Our participants are open-minded about online teaching in radiology. As the best way of transferring knowledge in medical education is still unclear, online teaching offers potential for innovation in radiology education. To support online teaching development, a structured, framework-based "online curriculum" should be established.*Clinical Relevance/Application We believe that the lessons learned during the pandemic might stimulate beneficial changes in teaching. The future challenge will be to further develop and integrate novel online teaching concepts.

RESULTS

An overwhelming majority stated that radiology is particularly well-suited for online teaching (91%), that online teaching should play a more prominent role even after the pandemic (73%) and that lecturers should be familiar with online teaching techniques (89%). Difficulties include a higher workload in preparing online courses (59%), issues with motivating students to follow online courses (56%) and the risk of social isolation (71%). Before the pandemic, only 12% of teaching was provided online; for the future our participants deemed a balanced ratio of approximately 50% online vs. on-site teaching appropriate (Figure 1).

CLINICAL RELEVANCE/APPLICATION

We believe that the lessons learned during the pandemic might stimulate beneficial changes in teaching. The future challenge will be to further develop and integrate novel online teaching concepts.

NPM04-A2   Current Status Of Clinical And Academic Productivity Bonus Proportions

Participants
Sanaz Ameli, MD, Little Rock, Arkansas (*Presenter*) Nothing to Disclose

PURPOSE

Many radiology practices incentivize clinical productivity. However, studies have shown less widespread incentives dedicated to academic productivity even in university-based settings. We investigated the current state of incentive plans in academic radiology practices.*Methods and Materials A questionnaire was designed based on the literature describing measures of clinical and academic productivity. The electronic survey was emailed to the directors of Diagnostic Radiology (DR, N=189) and Neuroradiology (NR, N=87) programs. The survey queried the proportion of salary appropriated to bonuses, changes in distribution ratio in the past years, and satisfaction levels with the incentive plans.*Results Response rate was 21% for DR and 19.5% for NR to date. Among these, 80% (DR) and 76.5% (NR) reported the presence of an incentive plan. The factors which were incentivized (more than one could apply for each program) were clinical productivity (52.5% DR, 52.9% NR), academic productivity (27.5% DR, 29.4% NR), other factors (35.0% DR, 29.4% NR), or none (20.0% DR, 23.5% NR). From the total incentive budget, 50.5±32.1 (DR) and 48.2±31.6% (NR) were dedicated to clinical productivity, 25.0±22.9% (DR) and 48.8±32.5% (NR) to academic productivity (DR P<0.05), and 24.5±36.8% (DR) and 3.0±6.7% (NR) to other factors. The trend of ratio of the bonus devoted to each category in the past 10 years was reported as below: Clinical productivity (DR & NR): 47.8% & 33.3% increased; 26.1% & 8.3% decreased; 26.1% & 58.3% not changed, respectively. Academic productivity (DR & NR): 20.0% & 9.1% increased; 25.0% & 36.4% decreased; 55% & 54.5% not changed, respectively. For DR & NR, 56.25% & 38.46%, 12.5% & 7.69%, and 31.25% & 53.85% of the directors were satisfied, neutral, or dissatisfied with their current incentive plans, respectively.*Conclusions Less than 30% of the programs incentivize academic productivity. The total budget dedicated to academic productivity is significantly less than clinical productivity by more than 50% in DR programs (P<0.5). In the past 10 years, the incentives dedicated to clinical productivity have mainly increased, while either not changed or decreased for academic productivity.*Clinical Relevance/Application The fact that 1/3 of the programs incentivize academic productivity, and even in those, significantly less money is set aside for academic bonus, raises an alarm for the future of academic radiology.

RESULTS

Response rate was 21% for DR and 19.5% for NR to date. Among these, 80% (DR) and 76.5% (NR) reported the presence of an incentive plan. The factors which were incentivized (more than one could apply for each program) were clinical productivity (52.5% DR, 52.9% NR), academic productivity (27.5% DR, 29.4% NR), other factors (35.0% DR, 29.4% NR), or none (20.0% DR, 23.5% NR). From the total incentive budget, 50.5±32.1 (DR) and 48.2±31.6% (NR) were dedicated to clinical productivity, 25.0±22.9% (DR) and 48.8±32.5% (NR) to academic productivity (DR $P<0.05$), and 24.5±36.8% (DR) and 3.0±6.7% (NR) to other factors. The trend of ratio of the bonus devoted to each category in the past 10 years was reported as below: Clinical productivity (DR & NR): 47.8% & 33.3% increased; 26.1% & 8.3% decreased; 26.1% & 58.3% not changed, respectively. Academic productivity (DR & NR): 20.0% & 9.1% increased; 25.0% & 36.4% decreased; 55% & 54.5% not changed, respectively. For DR & NR, 56.25% & 38.46%, 12.5% & 7.69%, and 31.25% & 53.85% of the directors were satisfied, neutral, or dissatisfied with their current incentive plans, respectively.

CLINICAL RELEVANCE/APPLICATION

The fact that 1/3 of the programs incentivize academic productivity, and even in those, significantly less money is set aside for academic bonus, raises an alarm for the future of academic radiology.

SDP-RO-1   Effects Of P53 Status Of Tumor Cells, 10B Delivery Agent Type And Concentration At The Time Of Administration On The Biological Effectiveness For Boron Neutron Capture Therapy

Participants
Shinichiro Masunaga, MD, Osaka, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To examine the effect of p53 status of tumor cells, including the type and the concentration of 10B delivery agents at the time of administration on the values of compound biological effectiveness (CBE) in boron neutron capture therapy.*Methods and Materials After subcutaneous administration of a 10B delivery agent, boronophenylalanine-10B (BPA) or sodium mercaptododecaborate-10B (BSH), at 2 separate concentrations, the 10B concentrations in implanted p53-wild (SAS/neo) or mutated type (SAS/mp53) tumors were measured using ?-ray spectrometry. The tumor-bearing mice received 5-bromo-2'-deoxyuridine (BrdU) continuously to label all intratumor proliferating (P) tumor cells, then were treated with BPA or BSH. Right after reactor neutron beam irradiation to the tumor, during which intratumor 10B concentrations were kept at levels similar to each other, cells from the tumors were isolated and incubated with a cytokinesis blocker. The responses of tumor cells were assessed based on the frequencies of micronucleation.*Results In both SAS/neo and SAS/mp53 tumors, the CBE values were higher in quiescent (Q) cells and in the use of BPA than total (P+Q) cells and BSH, respectively. The higher the administered concentrations were, the smaller the CBE values became, with a clearer tendency in the use of BPA and SAS/neo tumors than BSH and SAS/mp53 tumors, respectively. The values for 10B delivery agents that deliver into solid tumors more dependently on uptake capacity of cells became more changeable.*Conclusions Tumor characteristics, such as tumor micro-environmental heterogeneity, influence on the CBE value. The CBE value itself can be regarded as the index showing the level of intratumor heterogeneity.*Clinical Relevance/Application The CBE factor for each tissue and tumor, shown to be highly dependent on the degree of ability of distributing 10B from 10B-carriers, may be one of the promising candidates for the index to estimate tumor heterogeneity.

RESULTS

In both SAS/neo and SAS/mp53 tumors, the CBE values were higher in quiescent (Q) cells and in the use of BPA than total (P+Q) cells and BSH, respectively. The higher the administered concentrations were, the smaller the CBE values became, with a clearer tendency in the use of BPA and SAS/neo tumors than BSH and SAS/mp53 tumors, respectively. The values for 10B delivery agents that deliver into solid tumors more dependently on uptake capacity of cells became more changeable.

CLINICAL RELEVANCE/APPLICATION

The CBE factor for each tissue and tumor, shown to be highly dependent on the degree of ability of distributing 10B from 10B-carriers, may be one of the promising candidates for the index to estimate tumor heterogeneity.

SDP-RO-2   Differential Diagnosis Of Inflammatory And Lymphoma And Metastatic Cervical Lymph Nodes By Dual-energy Computed Tomography

Participants
Ronghua Wang, Taiyuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the utility of dual-source dual-energy CT (DECT)-derived imaging in the differential diagnosis between inflammatory, lymphoma and metastatic cervical lymph nodes .*Methods and Materials A retrospective analysis of DECT images of 19 patients with cervical inflammatory lymph node (43 lymph nodes), 21 patients with cervical lymphoma (56 lymph nodes), and 25 patients with cervical lymph node metastases (46 lymph nodes) from a single institution was performed. The iodine map, monochromatic energy images (40-190 keV), and DECT-derived iodine quantitative parameters in the arterial and venous phases of the lymph node lesions were measured and compared. Receiver operating characteristics (ROC) were obtained to evaluate the diagnostic effectiveness of DECT-derived iodine quantitative parameters in differentiating the three groups and calculate the optimal threshold.*Results The iodine overlay values, iodine concentration, and normalized iodine concentrations among inflammatory cervical lymph node, cervical lymphoma, and metastatic cervical lymph node were statistically significantly different (p< 0.01). The values obtained for all iodine parameters of the inflammatory group were higher than those of the other two groups, with the values of the metastatic group being the lowest. Pairwise comparisons demonstrated significant differences in all iodine parameters of inflammatory versus metastatic groups and lymphoma versus metastatic groups. The inflammatory versus lymphoma group displayed a significant difference in the iodine parameters only in the venous phase. Differences in the properties of the tissues were also detectable based on the CT overlay value in the venous phase(CTV) of lymph nodes derived from the monochromatic energy images (p < 0.05) and the slope of the energy-attenuation curves (p < 0.05). ROC curves indicated the iodine concentration in the venous phase (ICVP) displayed better diagnostic efficiency for distinguishing metastatic lymph node from lymphoma (AUC=0.914) and inflammatory lymph nodes (AUC=0.977). The CTV had the highest AUC between lymphoma and inflammatory lymph nodes (AUC=0.876).*Conclusions Dual-source DECT imaging is a promising tool for the differential diagnosis of inflammatory and metastatic cervical lymph nodes and cervical lymphoma. thereby enhancing non-invasive diagnostic capabilities.*Clinical Relevance/Application Scanning at the venous phase is recommended to potentially make a differential diagnosis.

RESULTS

The iodine overlay values, iodine concentration, and normalized iodine concentrations among inflammatory cervical lymph node, cervical lymphoma, and metastatic cervical lymph node were statistically significantly different ($p < 0.01$). The values obtained for all iodine parameters of the inflammatory group were higher than those of the other two groups, with the values of the metastatic group being the lowest. Pairwise comparisons demonstrated significant differences in all iodine parameters of inflammatory versus metastatic groups and lymphoma versus metastatic groups. The inflammatory versus lymphoma group displayed a significant difference in the iodine parameters only in the venous phase. Differences in the properties of the tissues were also detectable based on the CT overlay value in the venous phase(CTV) of lymph nodes derived from the monochromatic energy images ($p < 0.05$) and the slope of the energy-attenuation curves ($p < 0.05$). ROC curves indicated the iodine concentration in the venous phase (ICVP) displayed better diagnostic efficiency for distinguishing metastatic lymph node from lymphoma (AUC=0.914) and inflammatory lymph nodes (AUC=0.977). The CTV had the highest AUC between lymphoma and inflammatory lymph nodes (AUC=0.876).

CLINICAL RELEVANCE/APPLICATION

Scanning at the venous phase is recommended to potentially make a differential diagnosis.

PD03-C2   Intra-and Interobserver Agreement In Evaluation Of Image-defined Risk Factors In Pediatric Neuroblastomas: A Multireader Study

Participants
Yaw Amoako-Tuffour, MD, Halifax, Nova Scotia (*Presenter*) Nothing to Disclose

PURPOSE

International-Neuroblastoma-Risk-Group-Staging System (INRGSS) is the latest staging system for pediatric neuroblastomas. INRGSS depends on the presence or absence of image-defined risk factors (IDRFs) on pretreatment imaging. IDRFs were introduced to provide a consensus approach for pretreatment risk stratification and facilitate comparisons across imaging studies. Despite its wide use, no radiological study has validated the reproducibility of IDFRs across radiologists. We aimed to determine the intra and interreader agreement of IDRFs on CT between pediatric radiologists with varying levels of career experience.*Methods and Materials CT scans of 31 children (mean age 3.1 years, male=21) with neuroblastomas who were imaged at our institution between 2006 and 2020, were retrospectively assessed by 7 pediatric radiologists in two rounds. Following an educational session on IDRFs and consensus readings of few cases, radiologists were provided anonymized CTs of patients for assessment. Each CT was accompanied by a customized survey to indicate the presence or absence of IDRFs for each patient. A 3-week period between rounds, as well as randomization and relabeling of the CT studies, was implemented to minimize recall bias. Fleiss' Kappa analysis was used and values less than 0.20 were interpreted as poor, 0.21-0.40 as fair, 0.41-0.60 as moderate, 0.61-0.80 as substantial, and 0.81-1.00 as excellent agreement.*Results In total 559 potentials IDRFs were assessed. Inter-reader agreement among radiologists was 0.65; 95% CI (0.60, 0.69) for the 1st round, 0.62(0.58, 0.66) for the 2nd round and 0.63(0.60, 0.662) for overall reading. Intra-reader agreement for each radiologist ranged from 0.67 (0.60,0.70) to 0.86 (0.82,0.90). IDRF with the highest agreement was "Tumor compressing principal bronchi" [1.0 (1.0-1.0)] and the one with negligible agreement was "Tumor encasing vertebral artery" [-0.077(-0.19-0.04)].*Conclusions Staging of pediatric neuroblastoma using IDRFs yields reproducible and substantial agreement among pediatric radiologists with varying levels of experience. This increases confidence in the use of the INRGSS as a prognostic and clinical decision-making tool.*Clinical Relevance/Application We present an independent external validation for the use of IDRFs in staging of neuroblastoma to confirm reproducibility across pediatric radiologists, which supports its generalizability across different centers.

RESULTS

In total 559 potentials IDRFs were assessed. Inter-reader agreement among radiologists was 0.65; 95% CI (0.60, 0.69) for the 1st round, 0.62(0.58, 0.66) for the 2nd round and 0.63(0.60, 0.662) for overall reading. Intra-reader agreement for each radiologist ranged from 0.67 (0.60,0.70) to 0.86 (0.82,0.90). IDRF with the highest agreement was "Tumor compressing principal bronchi" [1.0 (1.0-1.0)] and the one with negligible agreement was "Tumor encasing vertebral artery" [-0.077(-0.19-0.04)].

CLINICAL RELEVANCE/APPLICATION

We present an independent external validation for the use of IDRFs in staging of neuroblastoma to confirm reproducibility across pediatric radiologists, which supports its generalizability across different centers.

MK04-A2 Hip-Spine Syndrome: Lumbosacral Spine Transitional Vertebral Anomalies Are Frequent In Adult Acetabular Dysplasia;#8211;A Cross;#8211;sectional Evaluation Of A Prospective Hip Registry Cohort

Participants
Joshua Sun, Flower Mound, Texas (*Presenter*) Nothing to Disclose

PURPOSE

A subset of patients presenting with hip pain and instability who are found to have acetabular dysplasia (AD) do not experience resolution of symptoms after surgical management. Hip-spine syndrome is a possible underlying cause. We hypothesized that there is increased frequency of radiographic spine anomalies in patients with AD. A secondary aim was to assess between radiographic severity of AD and frequency of spine anomalies.*Methods and Materials This was a cross-sectional analysis of 122 hips in 122 patients who presented with hip pain and had the final diagnosis of AD. Two readers analyzed hip and spine variables using standard hip radiographic series. Frequency of lumbosacral transitional vertebra (LSTV) along with associated Castellvi grade, pars interarticularis defect, and spinal morphological measurements were recorded and correlated with radiographic severity of AD.*Results Out of 122 patients, 110 were females and 12 were males. We analyzed 122 hip radiographic series, 59 from patients with symptoms in the left hip and 63 from patients with symptoms in the right hip. Average age at time of presentation was 34.2 +/- 11.2 years. Frequency of LSTV was high (39-43%), compared to historic records from the general population, with Castellvi type 3b being the most common (60-63%). Patients with AD have increased L4 and L5 interpedicular distance (IPD) compared to published values. Frequency of pars interarticularis defect was 4%. Intraclass correlation coefficient (ICC) for hip and spine variables assessed ranged from good (0.60 - 0.75) to excellent (0.75 - 1.00). Severity of AD did not demonstrate statistically significant correlation with frequency of radiographic spine anomalies.*Conclusions Patients with AD have increased frequency of spinal anomalies seen on standard hip radiographs. However, there exists no correlation between radiographic severity of AD and frequency of spine anomalies.*Clinical Relevance/Application In managing AD patients, clinicians should also assess spinal anomalies that are easily found on standard hip radiographs.

RESULTS

Out of 122 patients, 110 were females and 12 were males. We analyzed 122 hip radiographic series, 59 from patients with symptoms in the left hip and 63 from patients with symptoms in the right hip. Average age at time of presentation was 34.2 +/- 11.2 years. Frequency of LSTV was high (39-43%), compared to historic records from the general population, with Castellvi type 3b being the most common (60-63%). Patients with AD have increased L4 and L5 interpedicular distance (IPD) compared to published values. Frequency of pars interarticularis defect was 4%. Intraclass correlation coefficient (ICC) for hip and spine variables assessed ranged from good (0.60 - 0.75) to excellent (0.75 - 1.00). Severity of AD did not demonstrate statistically significant correlation with frequency of radiographic spine anomalies.

CLINICAL RELEVANCE/APPLICATION

In managing AD patients, clinicians should also assess spinal anomalies that are easily found on standard hip radiographs.

MK04-A3 The Wedged Hip Aspiration Technique: A Primer On A Highly Successful Modified Approach

Participants
Roman Shrestha, MD, Phoenix, Arizona (*Presenter*) Nothing to Disclose

PURPOSE

To describe a wedged hip aspiration technique and compare its success to more standard approaches.*Methods and Materials Our pilot study includes a retrospective chart review of patients over a 2-year period, who underwent a hip aspiration performed by a specific attending. The attending's technique places the patient into a wedged oblique position, accessing proximal to the greater trochanter, and targeting the dependent joint space along the superolateral aspect of the femoral head/neck junction. Evaluation included aspiration success, aspirate volume, culture results, and needle gauge.*Results There were 34 females and 33 males in the pilot study, with an average age of 65 (range of 29-86). A prosthesis was the target for 61 of the procedures. For the purposes of the study, a "dry tap" was considered to be a volume of <1 mL of synovial aspirate. Overall success (=1 mL of aspirate) was found to be 94%, with an average volume of 17.2 mL withdrawn. The most common needle gauge utilized was 20 (range of 18-22) for 94% of the procedures.*Conclusions The wedged hip aspiration technique is highly successful in clinical practice with great reproducibility across all patients. Its success demonstrates great promise compared to more standard approach success rates of 32-49%.*Clinical Relevance/Application The hip is the second most commonly aspirated joint. Creating awareness of this modified technique will hopefully aid other radiologists in a procedure which typically carries a high "dry tap" rate. This approach is also greatly beneficial to many anatomical barriers, such as body habitus, and further reduces risk of injuring the major femoral neurovascular structures. Current plans include expanding the study retrospectively over 10 years.

RESULTS

There were 34 females and 33 males in the pilot study, with an average age of 65 (range of 29-86). A prosthesis was the target for

There were 54 females and 68 males in the pilot study, with an average age of 65 (range of 29-88). A prosthesis was the target for 61 of the procedures. For the purposes of the study, a "dry tap" was considered to be a volume of <1 mL of synovial aspirate. Overall success (≥1 mL of aspirate) was found to be 94%, with an average volume of 17.2 mL withdrawn. The most common needle gauge utilized was 20 (range of 18-22) for 94% of the procedures.

CLINICAL RELEVANCE/APPLICATION

The hip is the second most commonly aspirated joint. Creating awareness of this modified technique will hopefully aid other radiologists in a procedure which typically carries a high "dry tap" rate. MK04-A4   Cartilage Damage Interpretation At MRI: How To Most Accurately Match Findings At Arthroscopy

Awards
Identified for RadioGraphics
Certificate of Merit

Participants
Brian K. Markhardt, MD, Madison, Wisconsin (*Presenter*) Nothing to Disclose

TEACHING POINTS

(1) A gold standard for cartilage assessment does not exist, with both MRI and arthroscopy providing different insights into the disease. (2) Distinction between partial-thickness and full-thickness cartilage lesions is often more accurate and clinically important than distinction between grades of partial-thickness lesions. (3) Osteochondral unit appearance is dependent on MRI parameters and articular surface angle. (4) Understanding the true margin of the subchondral bone plate is important for determining cartilage lesion depth. (5) Hyperintense and hypointense lesions often represent partial-thickness cartilage degeneration at arthroscopy. (6) Subchondral reactive changes increase the likelihood and depth of cartilage damage at arthroscopy. (7) Central osteophytes are associated with cartilage damage but are usually not visualized at arthroscopy. (8) Damaged cartilage in one compartment of the knee may cause marginal osteophytes at another compartment with intact cartilage.

TABLE OF CONTENTS/OUTLINE

(1) Introduction (2) Osteochondral unit anatomy a. Diagrams - zone anatomy and fibril organization b. MRI - anisotropy and dependence on sequence parameters c. CT arthrogram - normal subchondral bone plate thickness d. Histology - columnar organization, vascular and nerve supply (3) Signal abnormality lesions at MRI with arthroscopic correlation (4) Morphologic lesions at MRI with CT and arthroscopic correlation (5) Preferred terminology and synonyms (6) Subchondral bone (7) Osteophytes (8) Synovitis (9) Conclusion

HN02-A2   Automatic GTV Segmentation Using Versatile DCNN Framework With Multi-modality Support

Participants
Kanchan Ghimire, Arlington, Virginia (*Presenter*) Nothing to Disclose

PURPOSE

The recent development in deep convolutional neural networks (DCNN) have led to accurate segmentation of single-modality medical images; however, there are challenges in effectively utilizing information from multiple modalities. The purpose of this study is to develop a versatile DCNN framework for head and neck (H&N) gross tumor volume (GTV) segmentation with either single-modality or multi-modality 3D images.*Methods and Materials To segment H&N GTV, pre-processing was performed by normalizing the voxel spacing and intensity and fusing the complementary CT and PET scans. Then patch-based 3D U-Nets were trained using channel dropout and conventional vs dilated convolutions, and then finally ensemble modeling was performed to produce the final GTV segmentation. The dataset was provided by MICCAI 2020 'HECKTOR' Challenge, with 201 H&N scans (CT and PET) and annotated GTVs. Channel dropout was used during training to emulate the variance of input modalities and train a single network that supports different combinations of input modalities in deployment.*Results The proposed method using channel dropout yield a Dice Similarity Coefficient (DSC) of 0.777 when tested on combined modalities (CT and PET), DSC of 0.596 on CT and DSC of 0.743 on PET. The results are comparable to models trained and tested on single modality (DSC 0.620 for CT and DSC 0.743 for PET). Finally, ensemble of conventional and dilated convolutions trained with channel dropout yield DSC of 0.803.*Conclusions The proposed DCNN method demonstrated good performance on automatic segmentation of H&N GTV on CT and PET scans. While the fusion of CT and PET scans yield superior result, the channel dropout method allowed for versatile approach in leveraging either single-modality or multi-modality scans. This method has the potential to be applied to real-world clinical practice for accurate, fast and reproducible delineation of GTVs.*Clinical Relevance/Application Automatic segmentation of head and neck (H&N) gross tumor volume (GTV) plays a pivotal role in disease characterization and cancer staging by reducing human efforts and inter-observer variability.

RESULTS

The proposed method using channel dropout yield a Dice Similarity Coefficient (DSC) of 0.777 when tested on combined modalities (CT and PET), DSC of 0.596 on CT and DSC of 0.743 on PET. The results are comparable to models trained and tested on single modality (DSC 0.620 for CT and DSC 0.743 for PET). Finally, ensemble of conventional and dilated convolutions trained with channel dropout yield DSC of 0.803.

CLINICAL RELEVANCE/APPLICATION

Automatic segmentation of head and neck (H&N) gross tumor volume (GTV) plays a pivotal role in disease characterization and cancer staging by reducing human efforts and inter-observer variability.

HN02-A4   The Last Decade Of The Neuroimaging Signs

Participants
Melih Akyuz, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. A large number of journal articles are published each year describing new imaging signs. The most impactful of these transition into radiology textbooks and help in expanding our knowledge base. 2. The clinical utility of a sign published in a journal is determined by its accuracy. Articles describing the most accurate signs invariably accrue the most citations. 3. For this exhibit, we did a comprehensive search of the top neuroimaging journals including the American Journal of Neuroradiology and Neuroradiology. We also searched allied journals from other specialties Neurosurgery, Neurology, Spine, and Otolaryngology. 4. A list of the top 10 articles from the last decade was compiled based on the overall accuracy of the sign and the citations received. Our experience working with that imaging sign is also added.

TABLE OF CONTENTS/OUTLINE

1. Case-based imaging review of the top 10 radiologic signs from the last decade. 2. Description of the imaging sign and its pathophysiological or histopathological basis. 3. Our experience of the applicability of the imaging sign.

Abstract Archives of the RSNA, 2021

NPM04-B1   Understanding Compliance With Recommendations For Additional Imaging

Participants
Jack Renfrew, MD, phoenix, Arizona (*Presenter*) Nothing to Disclose

PURPOSE

To measure the rate of compliance for recommended additional imaging (RAI) based on whether the recommendation was for immediate or delayed follow-up and whether there was communication of recommendations to the ordering provider.*Methods and Materials We evaluated radiology reports generated over a twelve-month period by a community practice radiology group. We compared whether the recommendations were followed when the RAI was for immediate or delayed imaging and whether the radiologist called the ordering provider with the recommendation that imaging should be performed.*Results We reviewed 237,917 consecutive radiology reports and identified 3,558 (1.50%) reports in which at least one RAI was made. 3,444 of these were analyzed (the others had recommendations beyond the time frame of this report). For the 1,648 reports recommending immediate further imaging, 778 (47.3%) were performed and for the 1,798 reports recommending delayed further imaging, 600 (33.4%) were performed (p<.01). For the 268 reports where the ordering physician was called, 172 (64.2%) were performed and for the 3,176 reports where the ordering physician was not called 1,206 (38.0%) were performed (p<.01). Reports recommending immediate imaging were called much more frequently (14.8%) than reports recommending delayed imaging (3.4%) (p<.01).*Conclusions Recommendations for immediate imaging were followed more frequently than recommendations calling for delayed imaging. Calling the ordering provider with RAI was associated with increased likelihood of the imaging being performed.*Clinical Relevance/Application When constructing follow-up assurance apparatuses, it is important to know which follow-up exams have a high chance of not being performed. Further, the act of physician-to-physician communication helps increase appropriate follow-up completion rate.

RESULTS

We reviewed 237,917 consecutive radiology reports and identified 3,558 (1.50%) reports in which at least one RAI was made. 3,444 of these were analyzed (the others had recommendations beyond the time frame of this report). For the 1,648 reports recommending immediate further imaging, 778 (47.3%) were performed and for the 1,798 reports recommending delayed further imaging, 600 (33.4%) were performed (p<.01). For the 268 reports where the ordering physician was called, 172 (64.2%) were performed and for the 3,176 reports where the ordering physician was not called 1,206 (38.0%) were performed (p<.01). Reports recommending immediate imaging were called much more frequently (14.8%) than reports recommending delayed imaging (3.4%) (p<.01).

CLINICAL RELEVANCE/APPLICATION

When constructing follow-up assurance apparatuses, it is important to know which follow-up exams have a high chance of not being performed. Further, the act of physician-to-physician communication helps increase appropriate follow-up completion rate.

NPM04-B2   Pathway To The C-Suite: An Analysis Of Radiology's Representation In Hospital Leadership Roles In New York State

Participants
Zachary Chung, BS, Elmont, New York (*Presenter*) Nothing to Disclose

PURPOSE

This study analyzes organizational information of academic medical institutions and teaching affiliates in New York State to identify factors associated with ascent to clinical and non-clinical senior leadership hospital roles.*Methods and Materials NY State teaching hospitals and affiliates identified in the 2020 Texas STAR Database and the AMA's ACGME Fellowship & Residency Programs Database Institution Directory were included in the data set. Home health agencies, hospice institutions, rehabilitation centers, stand-alone diagnostic/interventional practices and most ambulatory care facilities were excluded from the data set. Physicians without complete background information on DocInfo tool, AMA DocFinder, the NYS Office of the Professions Verification Search Tool, and, physician self-reports via Doximity and LinkedIn were excluded. Physicians were stratified based on medical and surgical specialties. Leadership designations and roles were subcategorized on the basis of clinical (Chief Medical Officer, Chief Quality Officer, Physician-in-Chief), nonclinical (Chief Executive Officer, Chief Financial Officer) and hybrid (clinical and nonclinical components) responsibilities.*Results 197 physicians were identified in senior hospital leadership positions in New York State. Physician leaders were mostly US medical school graduates with additional degrees and training in the medical specialties.*Conclusions Early data analysis suggests that specialty, US medical school training, and additional degrees beyond the medical degree may influence the likelihood of promotion into senior hospital leadership roles.*Clinical Relevance/Application A critical analysis of the potential etiologies of the disparate representation between radiologists and other specialties/subspecialties will allow modifications to existing radiology graduate medical education and organizational structure to facilitate more robust and comprehensive resident and junior attending leadership education and training.

RESULTS

197 physicians were identified in senior hospital leadership positions in New York State. Physician leaders were mostly US medical school graduates with additional degrees and training in the medical specialties.

CLINICAL RELEVANCE/APPLICATION

A critical analysis of the potential etiologies of the disparate representation between radiologists and other specialties/subspecialties will allow modifications to existing radiology graduate medical education and organizational structure to facilitate more robust and comprehensive resident and junior attending leadership education and training.

CA04-A2   The Influence Of Artificial Intelligence Assistance On The Diagnostic Performance Of Ccta In Coronary Stenosis In Radiologists With Different Levels Of Experience

Participants
Xianjun Han, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to investigate radiologists with different levels of experience and whether the diagnostic performance and time efficiency of coronary computed tomography angiography (CCTA) could be improved by the use of CCTA-artificial intelligence (CCTA-AI) assistance.*Methods and Materials This was a single-centre retrospective analysis that included 200 patients (125 men (62.5%), average age: 63.8 ± 8.8) with complete CCTA and invasive coronary angiography (ICA) data, and ICA results were used as the gold standard. Eighteen radiologists with different levels of experience were divided into three groups (novice, junior and senior), and then the three groups were divided into Group A (without AI-assisted, Group 1 to Group 3) and Group B (with AI-assisted, Group 4 to Group 6) by stratified random sampling, totalling 6 groups (avoided readers' recall bias). CCTA-AI and each radiologist interpreted the degree of stenosis in 200 CCTA cases. The average sensitivity, specificity, negative predictive value (NPV), positive predictive value (PPV), and accuracy, as measured by the area under the receiver operating characteristic curve (AUC), were reported for the 6 groups on patient-based, vessel-based and segment-based. The interpretation time for each radiologist in Group A and Group B was recorded.*Results Compared to without CCTA-AI, the novice group with CCTA-AI had improved sensitivity (75.0% vs. 83.0% on patient-based, p=0.003). AI assistance could identify more segments and vessels in novices. In the seniors, the specificity was better with CCTA-AI assistance than without. There was no significant improvement in CCTA-AI assistance in juniors. The median interpretation times for Group A and Group B were 615 seconds and 413 seconds, respectively, and the difference was statistically significant (p <0.001).*Conclusions CCTA-AI could assist in and improve the diagnostic performance of radiologists with different levels of experience, with novices exhibiting improved sensitivity while seniors exhibiting improved specificity. Use of CCTA-AI assistance could shorten the training time for radiologists.*Clinical Relevance/Application CCTA-AI could assist in and improve the diagnostic performance of inexperienced radiologists. Use of CCTA-AI assistance could shorten the training time for radiologists.

RESULTS

Compared to without CCTA-AI, the novice group with CCTA-AI had improved sensitivity (75.0% vs. 83.0% on patient-based, p=0.003). AI assistance could identify more segments and vessels in novices. In the seniors, the specificity was better with CCTA-AI assistance than without. There was no significant improvement in CCTA-AI assistance in juniors. The median interpretation times for Group A and Group B were 615 seconds and 413 seconds, respectively, and the difference was statistically significant (p <0.001).

CLINICAL RELEVANCE/APPLICATION

CCTA-AI could assist in and improve the diagnostic performance of inexperienced radiologists. Use of CCTA-AI assistance could shorten the training time for radiologists.

CA04-A3   Photon-Counting CT For Coronary Stent Imaging: A Phantom Study

Participants
Bernhard Petritsch, Wuerzburg, Germany (*Presenter*) Research Consultant, Siemens AG

PURPOSE

To assess in-stent lumen visibility and quantitative image characteristics of different coronary stents using a clinical photon-counting detector (PCD) CT system in comparison to a conventional energy-integrating detector (EID) CT system.*Methods and Materials In this phantom study 18 different coronary stents in 7 different sizes (2.25 mm to 4.5 mm diameter) were expanded into plastic vessel phantom filled with contrast agent. Stent-containing vessel phantoms were positioned in an anthropomorphic phantom (QRM) simulating a medium-sized patient. CT scans were acquired parallel to the scanners z-axis using a novel clinical cadmium-telluride (CdTe) based PCD CT system (SOMATOM CountPlus, Siemens Healthineers) with sub-pixels of 0.275x0.322 mm size. Examinations were performed with two different scan-modes (standard-resolution [SR mode - 2x2 binning] and ultra-high-resolution [UHR mode- subpixels readout separately]). A state of the art EID CT system from the same vendor served as reference standard (SOMATOM Force, Siemens Healthineers). CTDIvol matched images were reconstructed with matched convolution kernels and identical reconstruction parameters. In-stent lumen visibility (in %) and image noise (in HU) were measured. Differences were tested using Wilcoxon signed-rank test.*Results The PCD-UHR mode achieved best in-stent lumen visibility while the PCD-SR mode provided lowest noise levels. In-stent lumen visibility was significantly higher (p < 0.001) with PCD in both, SR mode (66.7%, interquartile range [IQR] 63.3-72.3) and UHR mode (68.9%, IQR 64.4-74.4) when compared to conventional EID (65.4%, IQR 62.2-70.4). Image noise was significantly lower (p <0.001) for PCD in SR mode (21 HU, IQR 21-21) compared to conventional EID images (25 HU, IQR 24-25.0). The difference in image noise was also significant between PCD-SR mode and PCD-UHR mode (p < 0.001).*Conclusions In an in vitro setting, the clinical PCD CT system provides superior in-stent lumen visibility and lowered image noise when compared to state-of-the-art EID CT technology of the same vendor.*Clinical Relevance/Application Clinical PCD CT has

the potential to allow for improved assessment of coronary artery stents and in-stent restenosis in particular, respectively. At the same time it offers possibilities for substantial dose reduction.

RESULTS

The PCD-UHR mode achieved best in-stent lumen visibility while the PCD-SR mode provided lowest noise levels. In-stent lumen visibility was significantly higher (p < 0.001) with PCD in both, SR mode (66.7%, interquartile range [IQR] 63.3-72.3) and UHR mode (68.9%, IQR 64.4-74.4) when compared to conventional EID (65.4%, IQR 62.2-70.4). Image noise was significantly lower (p <0.001) for PCD in SR mode (21 HU, IQR 21-21) compared to conventional EID images (25 HU, IQR 24-25.0). The difference in image noise was also significant between PCD-SR mode and PCD-UHR mode (p < 0.001).

CLINICAL RELEVANCE/APPLICATION

Clinical PCD CT has the potential to allow for improved assessment of coronary artery stents and in-stent restenosis in particular, respectively. At the same time it offers possibilities for substantial dose reduction.

PH04-B10   Evaluation Of Dose And Image Quality For Two Cardiovascular Fluoroscopy Systems

Participants
Gregory Anthony, BA, Indianapolis, Indiana (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate two cardiovascular interventional fluoroscopy systems based on dose, image noise, and spatial and temporal resolution.*Methods and Materials Two interventional fluoroscopy systems, Artis Q with Pure/Care+Clear (Siemens Healthineers, Erlangen, Germany) and Azurion with ClarityIQ (Philips Healthcare, Best, Netherlands) were evaluated. The most clinically-used cardiovascular protocol (7.5 f/s at maximum source-to-image distance), on each system was applied. Dose rate was measured at the IEC reference point to test AEC performance for a range of patient thicknesses, simulated with PMMA slabs and copper sheets. Image noise was assessed via SNR measurements in flat field images. Limiting spatial resolution and spatial-temporal resolution were observed with a line pair phantom and rotating spoke phantom, respectively.*Results Air kerma rates were comparable for both systems' low-dose settings. The Artis Q normal mode gave approximately 2-3x higher dose than the low-dose mode. Dose efficiency (defined as SNR divided by square root of dose) for the Artis Q system was generally 2-3x greater than that of the Azurion system. The Artis Q low-dose mode also increased dose efficiency over normal mode for small and intermediate patient sizes. Limiting spatial resolution was comparable for both systems, but Artis Q low-dose images exhibited some loss of spatial resolution. At similar dose levels, Azurion images were visually sharper than Artis Q images. The thinnest resolvable spoke in cineradiography images was identical for both systems. Cineradiography images from the Azurion system appeared to have less uniform noise properties, while Artis Q images had more noticeable edge enhancement artifacts. The measured beam half-value layer was consistently greater for Artis Q.*Conclusions When low-dose settings are selected, both systems can be expected to produce similar patient entrance dose rates. However, Artis Q images had markedly reduced noise, and thus higher dose efficiency. This is likely related to stronger image smoothing or frame averaging, combined with harder beam filtration employed in the Artis Q. The data suggests these two systems have different approaches in AEC function (different Cu filters) and image post-processing. Further study is underway to include task-specific image quality evaluation.*Clinical Relevance/Application Due to the two systems' similar dose rates, electing to use one over another will likely depend on image quality preferences. Images produced by the two systems are very different in their noise and, to some extent, sharpness. Image quality is highly dependent upon post-processing and AEC function, the default settings of which can often be adjusted as per user preference.

RESULTS

Air kerma rates were comparable for both systems' low-dose settings. The Artis Q normal mode gave approximately 2-3x higher dose than the low-dose mode. Dose efficiency (defined as SNR divided by square root of dose) for the Artis Q system was generally 2-3x greater than that of the Azurion system. The Artis Q low-dose mode also increased dose efficiency over normal mode for small and intermediate patient sizes. Limiting spatial resolution was comparable for both systems, but Artis Q low-dose images exhibited some loss of spatial resolution. At similar dose levels, Azurion images were visually sharper than Artis Q images. The thinnest resolvable spoke in cineradiography images was identical for both systems. Cineradiography images from the Azurion system appeared to have less uniform noise properties, while Artis Q images had more noticeable edge enhancement artifacts. The measured beam half-value layer was consistently greater for Artis Q.

CLINICAL RELEVANCE/APPLICATION

Due to the two systems' similar dose rates, electing to use one over another will likely depend on image quality preferences. Images produced by the two systems are very different in their noise and, to some extent, sharpness. Image quality is highly dependent upon post-processing and AEC function, the default settings of which can often be adjusted as per user preference.

PH04-B11   Radiopathomic Correlation Model For Differentiation Of Invasive And Pre-invasive Lung Cancer With LDCT Images

Participants
Chuan Zhou, PhD, Ann Arbor, Michigan (*Presenter*) Scientific Advisory Board, Perception Vision Medical Technology Co., Ltd

PURPOSE

To investigate the feasibility of building radiopathomics correlation maps to improve the classification of pathologic invasive and pre-invasive lung nodules with low dose CT (LDCT) images.*Methods and Materials Previously we developed two support vector machine (SVM) models to differentiate invasive from pre-invasive lung nodules by quantitative analysis of pathologic images (SVM-p) and LDCT images (SVM-ct). With least absolute shrinkage and selection operator (LASSO) method, 11 pathologic and 10 CT image features were identified to be informative features for SVM-p and SVM-ct, respectively. With permission from the National Lung Screening Trial (NLST) project, a data set of 52 cases having both LDCT and pathologic images was used. Among 85 biopsied nodules, 50 and 35 nodules were pathologically diagnosed as invasive and pre-invasive. To establish correlation maps between pathomic and radiomic features, those 11 pathologic and 10 CT features were separately extracted from the corresponding pathologic and LDCT images for each nodule. We then built 11 new SVM models with LASSO method that used the 10 CT radiomic features as the input variables to predict each pathologic feature. We referred to the new set of pathologic features that were

mapped to the CT radiomic features guided by machine learning as radiopathomic features. Finally, a new radiopathomic model was built with the radiopathomic features as the input for classifying invasive and pre-invasive nodules in LDCT images. The performances of the SVM-p, SVM-ct and the radiopathomic models were evaluated using leave-one-case-out cross-validation and the area under the receiver operating characteristic (ROC) curve (AUC).*Results Our radiopathomic model achieved a test AUC of 0.869±0.04. For comparison, the SVM-p and SVM-ct alone achieved a test AUC of 0.915±0.03 and 0.772±0.05, respectively. The differences between pairs of the three models were statistically significant (P<0.05).*Conclusions Our results demonstrated the feasibility of building radiopathomics correlation maps that could translate each pathomic feature to radiomic features and effectively classify invasive and pre-invasive nodules, facilitating the use of CT images for "virtual biopsy".*Clinical Relevance/Application The histopathologic features may be correlated with CT radiomic features to facilitate non-invasive image-based stratification of invasive and indolent lung nodules for guiding management decisions.

RESULTS

Our radiopathomic model achieved a test AUC of 0.869±0.04. For comparison, the SVM-p and SVM-ct alone achieved a test AUC of 0.915±0.03 and 0.772±0.05, respectively. The differences between pairs of the three models were statistically significant (P<0.05).

CLINICAL RELEVANCE/APPLICATION

The histopathologic features may be correlated with CT radiomic features to facilitate non-invasive image-based stratification of invasive and indolent lung nodules for guiding management decisions.

PH04-B4   Exploring The Optimal Monochromatic Energy Level On The Detection Efficiency Of Pulmonary Nodules Using Deep Learning Assisted Lung Nodule Detection System

Participants
Yu Ziting, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the optimal monochromatic energy level on the detection efficiency of pulmonary nodules using deep learning assisted lung nodule detection system.*Methods and Materials Twenty patients underwent chest enhanced CT scans were prospectively enrolled from March to April in 2019 with approval from the ethics committee. All patients signed informed consent before CT examinations. A 256-slice CT was used (Revolution, GE Healthcare) with Pre-ASIR-V weight of 50% and reconstruction slice thickness of 1.25mm. Monochromatic energy levels reconstructed at 50keV,60keV,70keV,80keV and 90keV were selected. Deep learning based AI lung nodule detection system (InferRead CT Lung Research, Infervision, Beijing) was used to analyze the lung nodule detection efficiency for each monochromatic energy levels. Two senior radiologists read the 120kV image with the help of AI to confirm the gold standard nodules by consensus. The number of true and false positive nodules diagnosed by AI in each keV group were recorded by comparing with the gold standard nodules. The lung nodule true positive rate and false positive rate of each monochromatic energy level group were calculated accordingly.*Results A total of 134 nodules were identified in 20 patients as gold standard. AI detected 101, 113, 123, 130 and 129 nodules in 50keV, 60keV, 70keV, 80keV and 90keV energy levels, with 67(51.15%), 87(66.41%), 91(69.47%), 94(71.76%) and 85(64.89%) true positive nodules and 34 (25.95%), 29(22.14%), 32(24.43%), 35(26.72%) and 32(24.43%) false positive nodules. The false positive rate in different keV group tend to be stable with no statistically significant difference. The true positive rate gradually increases from 50 keV to 80 keV while decreases from 80 keV to 90 keV and the maximum true positive value was found at 80keV (71.76%).*Conclusions The optimal monochromatic level for lung nodule detection is 80 keV because it could detect the maximum number of true positive nodules as compared to 50keV, 60 keV, 70 keV and 90keV while false positive rate uncompromised.*Clinical Relevance/Application It is recommended to choose 80 keV as optimal dual energy monochromatic energy level to achieve the highest lung nodule detection rate using deep learning assisted lung nodule detection system.

RESULTS

A total of 134 nodules were identified in 20 patients as gold standard. AI detected 101, 113, 123, 130 and 129 nodules in 50keV, 60keV, 70keV, 80keV and 90keV energy levels, with 67(51.15%), 87(66.41%), 91(69.47%), 94(71.76%) and 85(64.89%) true positive nodules and 34 (25.95%), 29(22.14%), 32(24.43%), 35(26.72%) and 32(24.43%) false positive nodules. The false positive rate in different keV group tend to be stable with no statistically significant difference. The true positive rate gradually increases from 50 keV to 80 keV while decreases from 80 keV to 90 keV and the maximum true positive value was found at 80keV (71.76%).

CLINICAL RELEVANCE/APPLICATION

It is recommended to choose 80 keV as optimal dual energy monochromatic energy level to achieve the highest lung nodule detection rate using deep learning assisted lung nodule detection system.

PH04-B6   Performance Evaluation Of A Super Resolution Deep Learning Reconstruction Algorithm Trained Using Data From A Commercial High Resolution CT System

Participants
Kirsten Lee Boedeker, PHD, Los Angeles, California (*Presenter*) Employee, Canon Medical Systems Corporation

PURPOSE

To evaluate image quality performance of a Super Resolution Deep Learning Reconstruction (SR-DLR) algorithm trained using a commercial High Resolution Computed Tomography (CT) scanner.*Methods and Materials A 20cm Catphan was scanned on a wide volume CT scanner (Canon Aquilion ONE Prism) with a standard cardiac protocol and reconstructed with a prototype SR-DLR which outputs a 1024 matrix and slice width less than the 0.5mm acquisition slice thickness. The raw data was also reconstructed with hybrid iterative reconstruction (AIDR Enhanced), model-based iterative reconstruction (FIRST), and Filtered Backprojection (FBP). A 160mm FOV was used. The SR-DLR uses high-dose CT data acquired on a commercial high resolution CT system (Aquilion Precision) as the training target. The Precision CT system used for training acquires data with a 0.25 mm detector element size at isocenter, both in-plane and longitudinal. Simulated low-dose normal resolution data was used as the training input. The modulation transfer function (MTF), Noise Power Spectra (NPS), and Noise Equivalent Quanta (NEQ) were determined via Fourier analysis. The NEQ was applied to Low Contrast Detectability (LCD) and size differentiation tasks. LCD with a spatial domain model observer was also evaluated as well as the longitudinal noise and spatial resolution for all algorithms.*Results High contrast 10% MTF improved with SR-DLR vs AIDR, FBP, and FIRST, by 4.6lp/cm, 6.0 lp/cm, and 2.8lp/cm, respectively, while maintaining equivalent or improved LCD. The SR-DLR reduced noise vs AIDR, FBP, and FIRST by 14%, 20%, and 54%, respectively, while maintaining good noise texture. NEQ increased across all frequencies. NEQ applied to a ?1mm size discrimination task yielded an 54%, 86%, and 132% increase in detectability for SR-DLR vs AIDR, FBP, and FIRST. Longitudinal resolution significantly improved vs other reconstruction

methods.*Conclusions SR-DLR significantly improves spatial resolution, both in-plane and longitudinal, for a standard cardiac protocol, while maintaining equivalent or improved LCD and other image quality properties, relative to the other reconstruction methods.*Clinical Relevance/Application SR-DLR offers a significant improvement in spatial resolution for Cardiac CT, while maintaining LCD, offering the potential for improved diagnosis and quantification of biomarkers.

RESULTS

High contrast 10% MTF improved with SR-DLR vs AIDR, FBP, and FIRST, by 4.6lp/cm, 6.0 lp/cm, and 2.8lp/cm, respectively, while maintaining equivalent or improved LCD. The SR-DLR reduced noise vs AIDR, FBP, and FIRST by 14%, 20%, and 54%, respectively, while maintaining good noise texture. NEQ increased across all frequencies. NEQ applied to a ?1mm size discrimination task yielded an 54%, 86%, and 132% increase in detectability for SR-DLR vs AIDR, FBP, and FIRST. Longitudinal resolution significantly improved vs other reconstruction methods.

CLINICAL RELEVANCE/APPLICATION

SR-DLR offers a significant improvement in spatial resolution for Cardiac CT, while maintaining LCD, offering the potential for improved diagnosis and quantification of biomarkers.

PH04-B9   Improving Daily CT Quality Control By Identifying Ring Artifacts Using Convolutional Neural Networks: A Proof-of-Concept Simulation Study

Participants
Muhannad Fadhel, MD, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

Identifying artifacts in CT phantom images is one of the daily quality control (QC) tasks performed by CT technologists. CT scanners are prone to detector miss-calibrations that result in generation of ring artifacts. Identifying this type of artifact is crucial to avoid repeat exams or potential miss-diagnosis. Given the relatively higher doses associated with CT, this becomes particularly important in pediatric imaging. Due to the random occurrence of ring artifacts of varying magnitude, differing technologist subjectivity & the time constraints associated with the daily QC tasks, image artifacts may be missed. The goal of this project was to create a neural network (NN) model that may be able to identify ring artifacts allowing more robust detection of scanner anomalies, independent of factors discussed.*Methods and Materials 10,000 images of a 32 cm diameter CT uniformity phantom were simulated using Matlab. Half of the simulated images contain three ring artifacts randomly distributed in each phantom image with thicknesses randomly varying between 0.2 cm and 1.0 cm. The ring artifacts were implemented in the sinogram domain for 360 radial projections. The artifactual CT images were computed by filtered back-projection reconstruction technique. Both types of images were randomly displayed and examined just before feeding them in to the convolutional neural network (CNN). A CNN with four convolutional layers followed by a dense layer were trained using Keras in Python with 75% of the images and tested using the rest of the data set. CNN was trained using the RMSProp optimizer. Binary cross entropy loss function was used given the two class classification problem. In the output layer, sigmoid squashing function was employed that maps any predicted value between 0 and 1. We arrived at the employed learning rate based on the accuracy results of the CNN.*Results An optimal learning rate of 0.0001 was arrived at, by repeat trials of the CNN. The results demonstrate a highly reproducible CNN model with an accuracy of more than 99.9% & a loss of 0.3 within 10 epochs.*Conclusions Machine learning algorithms have the potential to effectively assist CT technologists in their daily quality control activities.*Clinical Relevance/Application Quality control of CT scanners is a critical component of a successful clinical CT service, whether it is a stand-alone imaging facility or a large scale health care system like ours. Assessing images for artifactual anomalies on a daily basis is required by accreditation bodies such as ACR, as a part of their CT accreditation program. Our work is a successful first step in an effort to improve outcomes associated with such quality control initiatives, by incorporating state of the art artificial intelligence tools in to daily clinical work flow.

RESULTS

An optimal learning rate of 0.0001 was arrived at, by repeat trials of the CNN. The results demonstrate a highly reproducible CNN model with an accuracy of more than 99.9% & a loss of 0.3 within 10 epochs.

CLINICAL RELEVANCE/APPLICATION

Quality control of CT scanners is a critical component of a successful clinical CT service, whether it is a stand-alone imaging facility or a large scale health care system like ours. Assessing images for artifactual anomalies on a daily basis is required by accreditation bodies such as ACR, as a part of their CT accreditation program. Our work is a successful first step in an effort to improve outcomes associated with such quality control initiatives, by incorporating state of the art artificial intelligence tools in to daily clinical work flow.

MK01-A1   Are NSAIDs In Suspected Axial Spondyloarthropathy Patients Reducing The Yield Of MRI Imaging?

Participants
Prasanna Partha Sarathy, MBChB,BMedSc, Swansea, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

Early diagnosis of Axial Spondyloarthropathy (AxSpA) is essential and hinges on HLA-B27 testing and MRI imaging. Patients suspected to have AxSpA are often started on non-steroidal anti-inflammatory drugs (NSAIDs) for symptomatic relief prior to MRI imaging. Evidence suggests that NSAIDs can lead to improvement in MRI appearances. We aimed to assess the use of MRI in patients with suspected AxSpA and the effect of NSAID on diagnostic yield of MRI scanning.*Methods and Materials A multicentre retrospective cohort study was conducted over 6 months including all patients referred for MRI spine for suspected AxSpA. We collected demographic, clinical, and biochemical data. Patients were asked about NSAID use at the time of MRI. MRI results were collated to assess for evidence of active inflammation. Chi-squared and logistic regression adjusting for age and gender were performed.*Results 74 patients met the inclusion criteria. MRI showed signs compatible with AxSpA in 16 patients (22%). Patients not using NSAIDs at the time of the scan were more likely to have MRI proven inflammation (p=0.017). In the adjusted regression analysis, patients not taking NSAIDs were more likely to have MRI proven inflammation compared to patients taking NSAIDs (OR=8.3; 95% CI: 1.9 to 36; p=0.005). This was mainly driven by the no NSAID vs regular use subgroups (OR=14; 95% CI: 2.1 to 97; p=0.006). The subgroup analysis of patients taking no NSAIDs vs as required NSAIDs and patients taking as required vs regular NSAIDs were not statistically significant (p=0.12 and p=0.289 respectively).*Conclusions This study suggests suspected AxSpA patients not taking NSAIDs were more likely to have MRI proven inflammation compared to patients taking NSAIDs especially those on regular NSAIDs. It is possible that NSAID use at the time of scanning reduces the diagnostic yield of MRI scanning. Further prospective research is warranted to explore this further.*Clinical Relevance/Application Undiagnosed AxSpA can have significant impact on patients' physical and mental health but also their quality of life and livelihood. It is essential that barriers to early and accurate diagnosis such as NSAID use pre-MRI scan be explored and addressed.

RESULTS

74 patients met the inclusion criteria. MRI showed signs compatible with AxSpA in 16 patients (22%). Patients not using NSAIDs at the time of the scan were more likely to have MRI proven inflammation (p=0.017). In the adjusted regression analysis, patients not taking NSAIDs were more likely to have MRI proven inflammation compared to patients taking NSAIDs (OR=8.3; 95% CI: 1.9 to 36; p=0.005). This was mainly driven by the no NSAID vs regular use subgroups (OR=14; 95% CI: 2.1 to 97; p=0.006). The subgroup analysis of patients taking no NSAIDs vs as required NSAIDs and patients taking as required vs regular NSAIDs were not statistically significant (p=0.12 and p=0.289 respectively).

CLINICAL RELEVANCE/APPLICATION

Undiagnosed AxSpA can have significant impact on patients' physical and mental health but also their quality of life and livelihood. It is essential that barriers to early and accurate diagnosis such as NSAID use pre-MRI scan be explored and addressed.

MK01-A2   The Sonographic Quantitative Assessment Of The Deltoid Muscle To Detect Type 2 Diabetes Mellitus: A Potential Noninvasive And Sensitive Screening Method?

Participants
Steven B. Soliman, DO, Ann Arbor, Michigan (*Presenter*) Consultant, General Electric Company;Speaker, General Electric Company

PURPOSE

To evaluate if the sonographic quantitative assessment of the deltoid muscle can be used to detect type 2 diabetes (T2DM).*Methods and Materials Deltoid muscle ultrasound images from 124 patients were stored: 31 obese T2DM, 31 non-obese T2DM, 31 obese non-T2DM, and 31 non-obese non-T2DM. Images were independently reviewed by 3 musculoskeletal radiologists, blinded to the patient's category. Each measured the grayscale pixel intensity of the deltoid muscle and humeral cortex to calculate a muscle/bone ratio for each patient. Following 3 weeks, the 3 radiologists independently repeated measurements on a random 40 subjects. Age, gender, race, body mass index, insulin usage and hemoglobin A1c level were analyzed. The difference among the 4 groups was compared using ANOVA or chi-square tests. Both univariate and multivariate linear mixed models were performed. Multivariate mixed-effects regression models were used, adjusting for demographic and clinical variables. Post hoc comparisons were done with Bonferroni adjustments to identify any differences between groups. The sample size achieved 90% power. Sensitivity and specificity were calculated based on a set ratio threshold. Both inter- and intra-radiologist variability or agreement were assessed.*Results A statistically significant difference in muscle/bone ratios between the groups was identified with the average ratios as follows: obese T2DM, 0.54 (P < 0.001); non-obese T2DM, 0.48 (P < 0.001); obese non-T2DM, 0.42 (P = 0.03); and non-obese non-T2DM, 0.35. There was excellent inter-observer agreement (ICC 0.87) and excellent intra-observer agreements (ICC 0.92, 0.95, and 0.94). Using threshold ratios, the sensitivity for detecting T2DM was 80% with a specificity of 63%.*Conclusions The quantitative assessment of the deltoid muscle by ultrasound is sensitive and accurate for the detection of T2DM. Following further studies, this process could translate into a dedicated, simple and noninvasive screening method to detect T2DM with the hope of identifying some of the 232 million undiagnosed persons globally and could prove especially beneficial in

screening of underserved and underrepresented communities.*Clinical Relevance/Application Quantitative deltoid muscle ultrasound can detect type 2 diabetes with the potential for a highly sensitive noninvasive screening method for identifying some of the 232 million undiagnosed worldwide.

RESULTS

A statistically significant difference in muscle/bone ratios between the groups was identified with the average ratios as follows: obese T2DM, 0.54 ($P < 0.001$); non-obese T2DM, 0.48 ($P < 0.001$); obese non-T2DM, 0.42 ($P = 0.03$); and non-obese non-T2DM, 0.35. There was excellent inter-observer agreement (ICC 0.87) and excellent intra-observer agreements (ICC 0.92, 0.95, and 0.94). Using threshold ratios, the sensitivity for detecting T2DM was 80% with a specificity of 63%.

CLINICAL RELEVANCE/APPLICATION

Quantitative deltoid muscle ultrasound can detect type 2 diabetes with the potential for a highly sensitive noninvasive screening method for identifying some of the 232 million undiagnosed worldwide.

NPM04-C2   X-ray And Radiomania

Participants
Priya Dave, BA, Greenwood, Indiana (*Presenter*) Nothing to Disclose

PURPOSE

To discuss the advent of the X-ray and its lasting effects on the public's perception of science, technology, and race. To use a historical perspective to elicit how novel medical and radiologic technologies are accepted by groups of power and the public.*Methods and Materials Analysis of historical documents was conducted through multiple online databases. Documents were also obtained from the National Library of Medicine and the Mount Sinai Medical Archives.*Results Soon after the invention of the X-ray in 1895, it captivated the minds of the public and its advent played a lasting role in the public's perception of medical technology. For a short period at the turn of the century, when its danger remained largely unknown, X-ray devices were pervasive and became a household item. By the 1930s, the X-ray also became a cornerstone of hospital medicine. Records from the Pennsylvania hospital show upwards of one in four admitted patients would undergo imaging. The "Radiomania" settled when the public finally became aware of the X-ray's carcinogenic properties. Upon its advent, the X-ray also played a role in race relations. The ability to see skin-deep challenged preconceived notions about racial superiority and groups in power feared its role as an equalizer.*Conclusions Given its delayed toxicity, the X-ray was one of the first devices warning the public to be cautious towards the long-term effects of technology on the human body. Further, the X-ray allowed the public, for the first time, to see skin deep and has contributed to our modern-day understanding of race relations.*Clinical Relevance/Application As the field of radiology continues to pioneer new technology this presentation discusses how the X-ray, one of the first medical technologies, became integrated into society. Understanding the excitement, followed by distrust, then trust of the device can be a model to understand the degree to which new medical technology might be accepted by groups of power and the public at large.

RESULTS

PD01-B1   **Quantifying Cobb Angle Measurement Error For Scoliosis Patients Due To Magnification Effect In Biplane EOS Systems**

Participants
Danielle Beaulieu, MS, Stoughton, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To quantify the effect of magnification along the lateral axis on Cobb angle measurements for scoliosis patients due to incorrect patient positioning and/or reference point selection while using low-dose biplanar EOS system frontal images.*Methods and Materials Two methods of quantifying magnification effects were implemented. In the first method, a long steel pipe with outer diameter 1.86 cm was leaned at a known angle against the frontal detector along the center line. The pipe was then scanned using both the frontal and lateral detectors simultaneously, with the patient reference position within the EOS system set to zero (centered along both planes). The lateral image was used to confirm both the diameter and angle of the pipe along the center line, while the frontal image was used to measure the pipe diameter at multiple locations. Linear and polynomial fits were then applied to approximate the magnification factor as a function of displacement from the frontal detector. In the second method, a radiopaque ruler was placed parallel to the frontal detector at the center of the EOS scanner (0 cm reference position) and was then scanned five times with the reference position set to 0, 5, 10, 15, and 20 cm. The ruler was then moved to the 20 cm reference position and scanned again with each reference position set. Lateral magnification of the ruler was measured along 10 cm of the ruler for each image, and the relationship between magnification error and selected reference point was calculated for the ruler at each of the two locations. Theoretical Cobb angle error was calculated for nominal Cobb angles between 0 and 45 degrees at maximum displacement from the reference point.*Results Analysis of the steel pipe images gave a linear approximation of 2.3 mm of lateral magnification for every 10 cm of displacement from the system-set reference point. Magnification errors ranging from -16.9 to 20.2% were measured using the radiopaque ruler across reference points. Error in Cobb angle measurements due to these magnification effects were shown to be between -2.52 and 1.68 degrees for a 10 degree nominal Cobb angle, -6.65 and 4.44 degrees for a 25 degree nominal Cobb angle, and -14.04 and 9.46 degrees for a 45 degree nominal Cobb angle.*Conclusions Incorrect patient placement with respect to the selected reference point caused substantial magnification effects, leading to Cobb angle measurement discrepancies of up to -14.04 degrees.*Clinical Relevance/Application The discrepancies in Cobb angle can change clinical outcomes for scoliosis patients and methods for image correction should be explored in future works.

RESULTS

Analysis of the steel pipe images gave a linear approximation of 2.3 mm of lateral magnification for every 10 cm of displacement from the system-set reference point. Magnification errors ranging from -16.9 to 20.2% were measured using the radiopaque ruler across reference points. Error in Cobb angle measurements due to these magnification effects were shown to be between -2.52 and 1.68 degrees for a 10 degree nominal Cobb angle, -6.65 and 4.44 degrees for a 25 degree nominal Cobb angle, and -14.04 and 9.46 degrees for a 45 degree nominal Cobb angle.

CLINICAL RELEVANCE/APPLICATION

The discrepancies in Cobb angle can change clinical outcomes for scoliosis patients and methods for image correction should be explored in future works.

PD01-B2   **Does Vascular Injury Affect Immature Cartilage Defects Repair?**

Participants
Ali Rashidi, MD, Stanford, California (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the effect of vascular injury of premature cartilage on the outcome of cartilage repair with matrix-associated stem cell implants (MASI) in Göttingen minipigs.*Methods and Materials We created full-thickness defects in the vascularized cartilage of the distal femur of immature pigs (n= 12 defects in 6 knee joints of 3 immature pigs; age, 3.5-4 months) or the avascular cartilage of mature pigs (n= 4 defects in 2 knee joints of 1 mature control pig; age, 21 months). Porcine bone marrow stromal stem cells (BMSCs) were implanted into the sixteen cartilage defects (5 mm ø), followed by magnetic resonance imaging (MRI) at 2, 4, 12 (n=16 defects), and 24 weeks (n=8 defects) after MASI. One reviewer evaluated the cartilage repair according to the MR observation of subchondral edema and cartilage repair tissue (MOCART) score. After the last MRI, animals were sacrificed, knee joints explanted and stained with Hematoxylin & Eosin (H+E), Van Giessen, and Mallory stain stains. Cartilage repair was graded according to the Pineda score. Semiquantitative scores for subchondral edema at 2 weeks were correlated with MOCART scores at 12 weeks and Pineda scores at the end of the study.*Results Immature joints demonstrated increasing subchondral edema and increasing subchondral bone defect over time, while mature joints demonstrated progressive healing of cartilage defects: The MOCART score at 12 weeks was significantly higher for mature joints (87.5 ± 2.88) compared to immature joints (30 ± 10) (p < 0.001). Histopathology confirmed microvessel injury in immature cartilage, which presumably led to the subchondral edema and bone defects observed on MRI. The quantitative scores for subchondral edema at 2 weeks demonstrated a negative correlation with MOCART scores at 12 weeks (r=-0.843) and a positive correlation with Pineda scores at the end of the study

(r=0.716).*Conclusions Vascular injury in immature epiphyses negatively affects MASI-mediated cartilage repair due to localized ischemia and subchondral bone defects.*Clinical Relevance/Application MASI is useful in the treatment of cartilage defects, while the effect of vascular injury in immature epiphyses should be considered in the outcome prediction of young patients with full-thickness cartilage defects.

RESULTS

Immature joints demonstrated increasing subchondral edema and increasing subchondral bone defect over time, while mature joints demonstrated progressive healing of cartilage defects: The MOCART score at 12 weeks was significantly higher for mature joints (87.5 ± 2.88) compared to immature joints (30 ± 10) ($p < 0.001$). Histopathology confirmed microvessel injury in immature cartilage, which presumably led to the subchondral edema and bone defects observed on MRI. The quantitative scores for subchondral edema at 2 weeks demonstrated a negative correlation with MOCART scores at 12 weeks ($r=-0.843$) and a positive correlation with Pineda scores at the end of the study ($r=0.716$).

CLINICAL RELEVANCE/APPLICATION

MASI is useful in the treatment of cartilage defects, while the effect of vascular injury in immature epiphyses should be considered in the outcome prediction of young patients with full-thickness cartilage defects.

GU03-C1　Effect of PI-RADS Minimum Technical Standards Adherence In PI-RADS 3 Vs PI-RADS 4/5 Lesion Designation

Participants
James Ryan, BMedSc,MRCPI, Brookline, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

PI-RADS v2.0 provides a standardized framework for multi-parametric prostate MRI acquisition/reporting. PI-RADS Minimum Technical Standards (MTS) are the recommended mpMRI parameters. PI-RADS lesions are categorized in order of increasing likelihood of clinically significant prostate cancer (csPCa). PI-RADS 3 lesions (P3) have an intermediate risk for csPCa. Most large studies advise biopsy of P3 lesions. We aimed to determine if MTS adherence impacts PI-RADS 3 vs PI-RADS 4/5 (P4/5) designation.*Methods and Materials A retrospective review of the electronic medical record was conducted at 2 academic institutions from July 1, 2014-August 22, 2019. All MRIs containing >/= P3 lesions were included. Patients with a pre-existing diagnosis of csPCa or prior PCa treatment were excluded. Demographic, technical acquisition and MTS data were collected. Groups were compared using logistic regression and conditional odds ratios.*Results The initial cohort was 3238 MRIs, after accounting for eligibility criteria the final cohort was 355 MRIs reported by 41 different radiologists across 2 institutions, with 183 P3 lesions and 172 P4/5s. Overall, 76% of lesions were in the peripheral zone (PZ) and 24% in the transitional zone (TZ). There were 282 (79.4%) MRIs from institution A and 69 (19.4%) from institution B. The median patient age was 66 yrs, median PSA was 6.37ng/mL, and median PSA density was 0.12. Endorectal coils were used in 132 (37.18%) MRIs. Increasing age (OR 0.9, p<0.001), PSA (OR 0.48, p=0.007) and PSA density (OR 0.68, p=0.02) decreased the odds of P3 designation in the PZ whereas institution A (OR 2.2, p=0.019) and endorectal coil use (OR 2.02, p=0.05) increased the odds. The average annual MTS adherence ranged from 71-80%. Regarding T2 weighted sequence (T2WS) MTS adherence; frequency in-plane resolution (0%), phase in-plane resolution (22%) and field of view (63%) were most poorly adhered to over 5-years. For DWI, phase in-plane resolution (54.2%), and DWI field of view (64.8%) were least adhered to.*Conclusions Adherence to MTS did not affect the odds of P3 vs P4/5 designation. Elderly patients with higher PSA values were less likely to have a P3 lesion. MTS compliance is of concern particularly in the T2WS limiting analysis of TZ lesions. There was significant institutional variance in the odds of P3 designation. Endorectal coil use increased the odds of P3 designation. Correlation with histology is needed in the endorectal coil group to determine if coil use affected diagnostic accuracy.*Clinical Relevance/Application Knowledge of patient demographics prior to mpMRI interpretation likely impacts PI-RADS assessment. Improved MTS compliance and standardization of acquisition technique across institutions is needed to optimize lesion assessment.

RESULTS

The initial cohort was 3238 MRIs, after accounting for eligibility criteria the final cohort was 355 MRIs reported by 41 different radiologists across 2 institutions, with 183 P3 lesions and 172 P4/5s. Overall, 76% of lesions were in the peripheral zone (PZ) and 24% in the transitional zone (TZ). There were 282 (79.4%) MRIs from institution A and 69 (19.4%) from institution B. The median patient age was 66 yrs, median PSA was 6.37ng/mL, and median PSA density was 0.12. Endorectal coils were used in 132 (37.18%) MRIs. Increasing age (OR 0.9, p<0.001), PSA (OR 0.48, p=0.007) and PSA density (OR 0.68, p=0.02) decreased the odds of P3 designation in the PZ whereas institution A (OR 2.2, p=0.019) and endorectal coil use (OR 2.02, p=0.05) increased the odds. The average annual MTS adherence ranged from 71-80%. Regarding T2 weighted sequence (T2WS) MTS adherence; frequency in-plane resolution (0%), phase in-plane resolution (22%) and field of view (63%) were most poorly adhered to over 5-years. For DWI, phase in-plane resolution (54.2%), and DWI field of view (64.8%) were least adhered to.

CLINICAL RELEVANCE/APPLICATION

Knowledge of patient demographics prior to mpMRI interpretation likely impacts PI-RADS assessment. Improved MTS compliance and standardization of acquisition technique across institutions is needed to optimize lesion assessment.

GU03-C2　Diagnostic Value Of Synthetic Magnetic Resonance Imaging For Biparametric Evaluation Of Primary Prostate Cancer.

Participants
Yuki Arita, MD, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Recently, the utility of biparametric magnetic resonance imaging (bpMRI), which avoids the costs and potential side-effects of gadolinium-based contrast agents including nephrogenic systemic fibrosis and gadolinium deposition in the brain, has been proposed for screening significant prostate cancer. The aim of the study was to investigate the utility of synthetic MRI for bpMRI-based evaluation of primary prostate cancer.*Methods and Materials One-hundred five prostate cancer-suspected patients who underwent multiparametric MRI and synthetic MRI prior to prostate biopsy were prospectively included. Six radiologists (three expert and three basic prostate radiologists according to the ESUR/ESUI consensus statements) assessed the diagnostic performance of the following datasets for clinically significant prostate cancer (International Society of Urological Pathology grade group =2 according to the Prostate Imaging and Reporting and Data System [PI-RADS] version 2.1): Conventional bpMRI (axial

diffusion-weighted imaging [DWI] scans with a b-value of 2,000 s/mm2 + axial conventional T2-weighted imaging [T2WI] scans) and Synthetic bpMRI (axial DWI scans with a b-value of 2,000 s/mm2 + synthetic T2WI scans). Furthermore, the diagnostic performance of relaxometry measurements from synthetic MRI (T1, T2, and proton density [PD]) was compared with that of the dynamic contrast-enhanced MRI (DCE-MRI) PI-RADS score for PI-RADS category 3 lesions. Radical prostatectomy or systemic biopsy was used as the reference standard.*Results Four-hundred eight lesions (88 clinically significant prostate cancer + 14 clinically insignificant prostate cancer + 306 non-cancerous lesions) in 102 patients were eligible for analysis. The sensitivity and specificity of conventional bpMRI (80.7-87.5% and 81.3-89.1%) were not significantly different from those of synthetic bpMRI (77.3-85.2% and 80.0-87.2%) for all the six radiologists (p =0.35 and 0.24, respectively). There also was no significant difference in the sensitivity and specificity between relaxometry measurements (T1+T2+PD) (84.0-88.0% and 75.4-78.0%) and DCE-MRI (72.0-80.0% and 85.2-86.0%, p = 0.32, 0.16, respectively) for PI-RADS category 3 lesions.*Conclusions The diagnostic performance of synthetic bpMRI was comparable to that of conventional bpMRI for primary prostate cancer evaluation. Moreover, the diagnostic performance of relaxometry measurements from synthetic MRI was similar to that of DCE-MRI for clinically significant prostate cancer diagnosis for PI-RADS category 3 lesions.*Clinical Relevance/Application BpMRI with relaxometry measurements derived from synthetic MRI shows great potential as a contrast agent-free method for primary prostate cancer evaluation.

RESULTS

Four-hundred eight lesions (88 clinically significant prostate cancer + 14 clinically insignificant prostate cancer + 306 non-cancerous lesions) in 102 patients were eligible for analysis. The sensitivity and specificity of conventional bpMRI (80.7-87.5% and 81.3-89.1%) were not significantly different from those of synthetic bpMRI (77.3-85.2% and 80.0-87.2%) for all the six radiologists (p =0.35 and 0.24, respectively). There also was no significant difference in the sensitivity and specificity between relaxometry measurements (T1+T2+PD) (84.0-88.0% and 75.4-78.0%) and DCE-MRI (72.0-80.0% and 85.2-86.0%, p = 0.32, 0.16, respectively) for PI-RADS category 3 lesions.

CLINICAL RELEVANCE/APPLICATION

BpMRI with relaxometry measurements derived from synthetic MRI shows great potential as a contrast agent-free method for primary prostate cancer evaluation.

MK03-C3   **Adaptable Multi-view Model For Fracture Detection In Hand Radiographs Using Convolutional Neural Network**

Participants
Jin-Kyeong Sung, MD, Seoul, Korea, Republic Of (*Presenter*) Employee, VUNO Inc

PURPOSE

Musculoskeletal radiographs are often taken with a variable combination of views and radiologists interpret images using all views in clinical practice not to miss subtle fractures. However, most deep learning-based models are trained with an image of one view. In this study, we aimed to develop and evaluate an adaptable multi-view model for fracture detection in hand radiographs using convolutional neural network.*Methods and Materials This study included retrospectively collected 5561 hand and wrist radiographs from 902 patients and then 2281 multi view sets (Anteroposterior(AP) + Lateral(Lat): 1334 sets, AP+Lat+Oblique(Obl): 947) using images from the same body parts were constructed. Twelve board-certified radiologists labeled the radiographs as normal or abnormal and annotated the location of each fracture. In this study we propose an approach based on feature aggregation using adaptive pooling layer. Instead of passing a fixed number of images as input, we use a model that receives an adaptable number of input images and then aggregates them through pooling at the feature level. We use ResNext50 encoder with ImageNet pretrained weight and training model with four different combinations of data set: AP only, Lat only, AP with Lat, and AP with Lat and Obl. We evaluated the performance of each model with 5-fold cross validation. In addition, we selected 371 (normal: 216, abnormal: 155) wrist radiographs with various views from MURA (musculoskeletal radiographs) public dataset for external validation. To assess the model performances, we compared the area under the receiver operating characteristic (AUROC), sensitivity, and specitivity among the models with different data sets.*Results When using only AP view image as a training set, the sensitivity, specificity, and AUROC(patient-level) were 92.3%, 85%, and 0.956, respectively. The model trained with AP, Lat view pair showed 93.6%, 96.6% and 0.979. Models using all view position sets (AP, Lat, Obl) showed the best performance at 97.1%, 95.0% and 0.983. External validation results of the best model using the MURA test set (single view image) show 99.6%, 61.1%, and 0.966*Conclusions The deep learning model with multi view inputs showed improved performance in finding fractures compared to the model with single input, and robust performance for the external validation set.*Clinical Relevance/Application The deep learning model with adaptable multi view inputs can be readily used for clinical practice using variable combination of radiographic views.

RESULTS

When using only AP view image as a training set, the sensitivity, specificity, and AUROC(patient-level) were 92.3%, 85%, and 0.956, respectively. The model trained with AP, Lat view pair showed 93.6%, 96.6% and 0.979. Models using all view position sets (AP, Lat, Obl) showed the best performance at 97.1%, 95.0% and 0.983. External validation results of the best model using the MURA test set (single view image) show 99.6%, 61.1%, and 0.966

CLINICAL RELEVANCE/APPLICATION

The deep learning model with adaptable multi view inputs can be readily used for clinical practice using variable combination of radiographic views.

NR05-A1   **Trends In Development Of Novel Machine Learning Methods For Identification Of Gliomas In Datasets That Include Non-glioma Images: A Systematic Review**

Participants
Harry Subramanian, MD, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

Machine learning (ML), has been applied to the diagnostic imaging of gliomas to augment classification, prognostication, segmentation, and treatment planning. A systematic literature review was performed to identify how machine learning has been applied to identify gliomas in datasets which include non-glioma images thereby simulating normal clinical practice.*Methods and Materials Four databases were searched by a medical librarian and confirmed by a second librarian for all articles published prior to February 1, 2021: Ovid Embase, Ovid MEDLINE, Cochrane trials (CENTRAL), Web of Science-Core Collection. The search strategy included both keywords and controlled vocabulary combining the terms for: artificial intelligence, machine learning, deep learning, radiomics, magnetic resonance imaging, glioma, as well as related terms. Two independent reviewers performed abstract screening, full text screening, data extraction, and TRIPOD bias assessment.*Results A total of 11,727 candidate articles were identified, of which 13 articles were included in the final analysis. Methodology of sample size is mixed, as some studies report the number of individual images (median 390, 10 studies) while others report the number of patients used (median 280, 7 studies). The articles included both high- and low-grade gliomas as well as non-neoplastic neurologic diseases. The datasets used most frequently were BRATS (31%), single institutional dataset (31%), and TCIA (15%). Neural networks were the most common type of algorithm, used in 85% of studies. The accuracy of algorithms ranged from 0.82 to 1.00 (median 0.98, 11 studies). The DICE coefficient ranged from 0.86 to 0.98 (median 0.92, 3 studies). Assessment of the quality of the studies using TRIPOD criteria yielded a median score of 21 (range 10-31, maximum possible score of 35).*Conclusions Systematic review identified 13 articles investigating the differentiation of glioma from non-glioma images. Most articles used neural network algorithms. While most studies used already established databases, the sample sizes were low. TRIPOD criteria scoring indicates that the quality of these studies is lacking in multiple domains.*Clinical Relevance/Application Automatic identification of gliomas in a dataset of normal studies or other pathologies simulates clinical practice and identifies ML algorithms that would be most suitable for clinical translation.

RESULTS

A total of 11,727 candidate articles were identified, of which 13 articles were included in the final analysis. Methodology of sample size is mixed, as some studies report the number of individual images (median 390, 10 studies) while others report the number of patients used (median 280, 7 studies). The articles included both high- and low-grade gliomas as well as non-neoplastic neurologic diseases. The datasets used most frequently were BRATS (31%), single institutional dataset (31%), and TCIA (15%). Neural networks were the most common type of algorithm, used in 85% of studies. The accuracy of algorithms ranged from 0.82 to 1.00 (median 0.98, 11 studies). The DICE coefficient ranged from 0.86 to 0.98 (median 0.92, 3 studies). Assessment of the quality of the studies using TRIPOD criteria yielded a median score of 21 (range 10-31, maximum possible score of 35).

CLINICAL RELEVANCE/APPLICATION

Automatic identification of gliomas in a dataset of normal studies or other pathologies simulates clinical practice and identifies ML algorithms that would be most suitable for clinical translation.

NR05-A4   **Guided Brain Tissue Segmentation: Deep Learning-based Segmentation Using Flair MRI Exclusively**

Participants
ZunHyan Rieu, BS, Seoul, Korea, Republic Of (*Presenter*) Employee, NEUROPHET, Inc

PURPOSE

White matter hyperintensity (WMH) is a primary marker for small vessel disease and may play a role in the brain functional decline in later life. For the detailed WMH study, multi-modal approach, including T1-weighted (T1w) and T2- Fluid Attenuated Inversion Recovery (FLAIR) MRI, is desired to identify normal white matter (WM), deep grey matter (DGM), and WMH. That is because WM and DGM are visible in T1w MRI while WMH noticeable in T2-FLAIR. It is, however, common that only T2-FLAIR available in clinical settings. We thus propose Guided Brain Tissue Segmentation that separate brain tissues, WM, DGM, and WMH, only using FLAIR MRI.*Methods and Materials A total of 100 subjects with paired T1w and FLAIR MRI was utilized from the Catholic Aging Brain Imaging (CABI) database of St. Mary's Hospital, the Catholic University of Korea. Our in-house multi-label brain tissue segmentation tool was applied to obtain the initial 98 segmentations from T1w MRI. Then 98 labels merged into 9 labels: cerebral WM, left and right hemisphere of cerebral GM, DGM, ventricles, left and right hemisphere of cerebellum WM, and left and right hemisphere of cerebellum GM. As for the alignment between T1 MRI into FLAIR MRI, we applied the co-registration using a rigid transform. Finally, we used U-Net based segmentation architecture to train the T1w brain tissue labels into FLAIR MRI. For the segmentation, we distributed the dataset into train and validation with a ratio of 9:1. To increase the robustness of segmentation, we applied augmentation using Rescale-Intensity, and Z-Normalization. We computed the dice score coefficients (DSC) score and relative volume difference between labels from T1w to FLAIR for the performance evaluation.*Results For brain segmentation using FLAIR exclusively, we achieved the average DSC of 0.81±0.08 on the validation. The average relative volume difference between the T1w

and the FLAIR MRI resulted with 5.12%.*Conclusions Guided Brain Tissue Segmentation using FLAIR MRI exclusively was developed, and we demonstrated the feasibility of brain tissue segmentation on FLAIR MRI exclusively.*Clinical Relevance/Application We believe the brain tissue segmentation on FLAIR MRI can provide easy access to the detailed WMH study.

RESULTS

For brain segmentation using FLAIR exclusively, we achieved the average DSC of 0.81±0.08 on the validation. The average relative volume difference between the T1w and the FLAIR MRI resulted with 5.12%.

CLINICAL RELEVANCE/APPLICATION

We believe the brain tissue segmentation on FLAIR MRI can provide easy access to the detailed WMH study.

Thomas Weikert, MD, Basel, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To develop, evaluate and deploy a PET/CT processing pipeline based on a Retina-U-Net for detection of malignant lesions in primary lung cancer.*Methods and Materials A total of 364 patients with histologically confirmed lung cancer that underwent FDG-PET/CT between 01/2010-06/2016 were included. The dataset comprised tumors of all stages (according to the 8th edition of TNM in Lung Cancer). To establish a standard of reference, all lung tumors (T), lymphatic metastases (N) and distant metastases (M) were manually segmented as 3D volumes using the transverse, fused whole-body PET/CT series. The dataset was split into a training (n=216), validation (n=74) and testing dataset (n=74). A Retina-U-Net using both CT and PET component as input was trained on all lesion types (T,N,M). Detection performance for all lesion subtypes was assessed using area under the ROC-curves (AUROC). Furthermore, reasons of false-positive findings were visually assessed by a radiology resident (PGY-5). The algorithm was deployed on a clinic-near radiology viewer enabling swift processing of PET/CTs.*Results General performance was good, e.g. the AUROC for all T-lesions was 0.89. AUC for T1 was good (0.81), but excellent for T2 (0.94), T3 (0.98) and T4 (0.89). We found promising sensitivities of more than 90% for T3 and T4 lesions at low false-positive rates per case of 1. Detection rates of N- and M-lesions were slightly worse. Important reasons for false-positive detections were the normal metabolic signal of bone marrow (16.5%), pulmonary vessels (7.8%) and the myocardium (3.8%).*Conclusions The algorithm presented in this study enables an automated detection of T-, N- and M-lesions in PET/CTs at good performance levels. However, it is not performant enough to enable fully automated reading of PET/CTs without human interaction.*Clinical Relevance/Application The Retina-U-Net presented in this study is a foundation for a tool assisting nuclear medicine physicians with the analysis of PET-CTs. In combination with an intuitive interface allowing for swift approval or modification of automatically generated findings, it can help to improve routine reading workflows.

RESULTS

General performance was good, e.g. the AUROC for all T-lesions was 0.89. AUC for T1 was good (0.81), but excellent for T2 (0.94), T3 (0.98) and T4 (0.89). We found promising sensitivities of more than 90% for T3 and T4 lesions at low false-positive rates per case of 1. Detection rates of N- and M-lesions were slightly worse. Important reasons for false-positive detections were the normal metabolic signal of bone marrow (16.5%), pulmonary vessels (7.8%) and the myocardium (3.8%).

CLINICAL RELEVANCE/APPLICATION

The Retina-U-Net presented in this study is a foundation for a tool assisting nuclear medicine physicians with the analysis of PET-CTs. In combination with an intuitive interface allowing for swift approval or modification of automatically generated findings, it can help to improve routine reading workflows.

NMMI05-A3 18F-fluciclovine Pet/ct-based Salvage Radiotherapy In Patients With Very Low Psa (<=0.3 Ng/ml) Post-radical Prostatectomy.

Participants
Olayinka Abiodun-Ojo, MD,MPH, Atlanta, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

We evaluated the effect of 18F-fluciclovine PET/CT on detection of recurrent prostate cancer (PCa) and treatment decisions in men with prostate-specific antigen (PSA) =0.3 ng/mL after radical prostatectomy (RP).*Methods and Materials Between 2012 and 2019, 165 patients with rising PSA and negative extrapelvic findings on conventional imaging post-RP were randomized to undergo either salvage radiotherapy (XRT) planning based on conventional imaging (MR or CT) alone or XRT based on the addition of fluciclovine PET/CT. In the fluciclovine arm (n=83), initial prospective documented XRT plans 1) to offer XRT and 2) XRT fields were based on conventional imaging, while final treatment plans were based on fluciclovine PET findings. We conducted a post hoc subgroup analysis of patients with PSA =0.3 ng/mL. Fluciclovine positivity rate for detection of recurrence was determined. PSA at PET and Gleason score were compared between patients with positive and negative PET scans using t-test and Fisher's exact test. Initial and final XRT decisions were compared and changes in management decisions noted.*Results Thirty-six patients with mean PSA at PET of 0.17 ng/mL (standard deviation 0.08; median 0.17 ng/mL; interquartile range 0.12-0.23 ng/mL) were analyzed. Fluciclovine PET was positive in 27/36 (75.0%) patients: 21/27 (77.8%) had local recurrence, while 6/27 (22.2%) had pelvic lymph node involvement ± prostate bed (PB) uptake. No extrapelvic nodal, osseous or soft tissue lesion was detected on PET. There was no significant difference in PSA at PET (p = 0.15) and Gleason score (p = 0.45) between patients with positive and negative fluciclovine PET scans. For initial treatment decision, all patients were planned for salvage XRT: 26/36 (72.2%) for XRT of PB only and 10/36 (27.8%) for XRT of PB and pelvic lymph nodes. Although there was no change in the decision to offer XRT, 7/36 (19.4%) patients had a change in radiotherapy fields: 6/27 (22.2%) PET positive and 1/9 (11.1%) PET negative patients. Radiotherapy field decision was altered from PB only to PB and pelvis in 4 patients and from PB and pelvis to PB only in 3 patients.*Conclusions In our

patient cohort with PSA levels =0.3 ng/mL postprostatectomy, fluciclovine PET/CT detects recurrent disease and can guide targeted therapy. Our findings suggest that fluciclovine PET/CT is useful in the management of PCa patients with early biochemical recurrence postprostatectomy even at very low PSA levels.Research support: NIH (R01CA169188), NCT 01666808, Blue Earth Diagnostics, Ltd.*Clinical Relevance/Application Fluciclovine PET was positive in 75.0% of patients and resulted in 19.4% change in salvage radiotherapy planning in patients with early biochemical recurrence and very low PSA levels (=0.3 ng/mL) postprostatectomy.

RESULTS

Thirty-six patients with mean PSA at PET of 0.17 ng/mL (standard deviation 0.08; median 0.17 ng/mL; interquartile range 0.12-0.23 ng/mL) were analyzed. Fluciclovine PET was positive in 27/36 (75.0%) patients: 21/27 (77.8%) had local recurrence, while 6/27 (22.2%) had pelvic lymph node involvement ± prostate bed (PB) uptake. No extrapelvic nodal, osseous or soft tissue lesion was detected on PET. There was no significant difference in PSA at PET (p = 0.15) and Gleason score (p = 0.45) between patients with positive and negative fluciclovine PET scans. For initial treatment decision, all patients were planned for salvage XRT: 26/36 (72.2%) for XRT of PB only and 10/36 (27.8%) for XRT of PB and pelvic lymph nodes. Although there was no change in the decision to offer XRT, 7/36 (19.4%) patients had a change in radiotherapy fields: 6/27 (22.2%) PET positive and 1/9 (11.1%) PET negative patients. Radiotherapy field decision was altered from PB only to PB and pelvis in 4 patients and from PB and pelvis to PB only in 3 patients.

CLINICAL RELEVANCE/APPLICATION

Fluciclovine PET was positive in 75.0% of patients and resulted in 19.4% change in salvage radiotherapy planning in patients with early biochemical recurrence and very low PSA levels (=0.3 ng/mL) postprostatectomy.

NMMI05-A4 C-11-pk11195 Positron Emission Tomography Evaluation Of Neuroinflammation And Its Clinical Correlation In Patients With Relapsing Remitting Multiple Sclerosis

Participants
Ajay Kumar, MD, PhD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the relationships of neuroinflammatory changes with clinical disability in patients with relapsing remitting multiple sclerosis (MS).*Methods and Materials Thirteen MS patients were recruited in this pilot study who underwent Expanded Disability Status Scale (EDSS) and Multiple Sclerosis Functional Composite (MSFC) scoring with its three-components (timed 25-foot walk test (T25FWT), 9-Hole Peg Test (9-HPT) on dominant (9-HPT-D) and non-dominant (9-HPT-ND) hands, Paced Auditory Serial Addition Test (PASAT), followed by whole brain dynamic C-11-PK-11195 (PK) PET scan. Based on a simplified reference region model, regional binding potential (BP), reflecting PK binding to TSPO receptor expressed by activated microglia, was calculated for: normal appearing white matter (NAWM), frontal cortex, parietal cortex, temporal cortex, occipital cortex, whole neocortex, thalamus, caudate nucleus and lentiform nucleus in each hemisphere. The associations between clinical assessments and neuroinflammation, expressed as BP values in various brain regions, were analyzed using multivariate linear regression.*Results Age was positively correlated to BP values in NAWM (age coefficient(B)=0.005, p=0.003), temporal cortex (age B=0.003, p=0.047), neocortex (age B=0.002, p=0.045), thalamus (age B=0.007, p=0.018), caudate nucleus (age B=0.007, p=0.009) and lentiform nucleus (age B=0.005, p=0.008). After adjusting for age, EDSS was positively correlated to BP values in thalamus (EDSS B=0.029, p=0.045), and also showed trends frontal cortex (EDSS B=0.014, p=0.086) and caudate nucleus (EDSS B=0.013, p=0.091). After adjusting for age, T25FWT showed trends in correlations with BP values in NAWM (T25FWT B=0.010, p=0.094) and thalamus (T25FWT B=0.019, p=0.053), while 9HPT-D was positively correlated with BP value in thalamus (9HPT-D B=0.009, p=0.016), and showed trends in correlations with BP values in NAWM (9HPT-D B=0.004, p=0.073), frontal cortex (9HPT-D B=0.004, p=0.090) and lentiform nucleus (9HPT-D B=0.005, p=0.056). PASAT inversely correlated with thalamic BP values (PASAT B=-0.004, p=0.0042) without adjusting for age.*Conclusions Our study revealed neuroinflammatory changes in various brain regions in patients with relapsing remitting multiple sclerosis, and regional extent of neuroinflammation, particularly in the thalamus, maybe a useful biomarker to define motor, cognitive and dexterity impairment and may predict disability in MS.*Clinical Relevance/Application C-11-PK11195 PET scan can be potentially used as an in-vivo neuroinflammatory biomarker to evaluate, prognosticate and monitor patients with relapsing remitting multiple sclerosis.

RESULTS

Age was positively correlated to BP values in NAWM (age coefficient(B)=0.005, p=0.003), temporal cortex (age B=0.003, p=0.047), neocortex (age B=0.002, p=0.045), thalamus (age B=0.007, p=0.018), caudate nucleus (age B=0.007, p=0.009) and lentiform nucleus (age B=0.005, p=0.008). After adjusting for age, EDSS was positively correlated to BP values in thalamus (EDSS B=0.029, p=0.045), and also showed trends frontal cortex (EDSS B=0.014, p=0.086) and caudate nucleus (EDSS B=0.013, p=0.091). After adjusting for age, T25FWT showed trends in correlations with BP values in NAWM (T25FWT B=0.010, p=0.094) and thalamus (T25FWT B=0.019, p=0.053), while 9HPT-D was positively correlated with BP value in thalamus (9HPT-D B=0.009, p=0.016), and showed trends in correlations with BP values in NAWM (9HPT-D B=0.004, p=0.073), frontal cortex (9HPT-D B=0.004, p=0.090) and lentiform nucleus (9HPT-D B=0.005, p=0.056). PASAT inversely correlated with thalamic BP values (PASAT B=-0.004, p=0.0042) without adjusting for age.

CLINICAL RELEVANCE/APPLICATION

C-11-PK11195 PET scan can be potentially used as an in-vivo neuroinflammatory biomarker to evaluate, prognosticate and monitor patients with relapsing remitting multiple sclerosis.

NPM03-A1   Perceptions Of US Medical Students Towards Radiology Education: A National Survey

Participants
Scott Rohren, Houston, Texas (*Presenter*) Nothing to Disclose

PURPOSE

Radiology and medical imaging are an important yet often underrepresented facet of medical education. Notably, radiologists are concerned that students do not receive enough radiology exposure and struggle with medical imaging upon entering residency. Therefore, the purpose of this survey was to identify how undergraduate medical students perceive the radiology curriculum and to determine gaps in delivery.*Methods and Materials This study was a multicenter national survey distributed to medical schools throughout the United States. Questions focused on demographic information, student's exposure to Radiology, teaching methods in the curriculum, and their perceptions towards medical imaging. Objective parameters were measured as percentage correct, while subjective parameters used a 4-point Likert scale.*Results A total of 472 medical students across 31 medical schools completed the surveys. Responses represented all class years within medical schools and showed equal distribution amongst future career plans. The majority of respondents (96%) indicated that their preclinical curriculum included medical imaging. X-ray and ultrasonography were the most commonly encountered imaging modalities. Fluoroscopy and PET were the least seen. Additionally, 87% of students responded that they did not feel they had adequate exposure to radiology during medical school. Clerkship students rated themselves as more confident in image interpretation than preclerkship students.*Conclusions This national survey demonstrates that students value radiology in their curriculum and feel like they do not receive adequate exposure. This survey identifies areas that can be addressed to promote further radiology education, such as increased interaction with radiologists during clinics as well as fostering students' confidence in image interpretation.*Clinical Relevance/Application This information can be used by educators to address learning gaps and promote radiology within the medical school curricula.

RESULTS

A total of 472 medical students across 31 medical schools completed the surveys. Responses represented all class years within medical schools and showed equal distribution amongst future career plans. The majority of respondents (96%) indicated that their preclinical curriculum included medical imaging. X-ray and ultrasonography were the most commonly encountered imaging modalities. Fluoroscopy and PET were the least seen. Additionally, 87% of students responded that they did not feel they had adequate exposure to radiology during medical school. Clerkship students rated themselves as more confident in image interpretation than preclerkship students.

CLINICAL RELEVANCE/APPLICATION

This information can be used by educators to address learning gaps and promote radiology within the medical school curricula.

NPM03-A2   Online Patient Portals Widen Health Disparities In Radiology: Analysis Of Patient Characteristics Of Self-scheduled Online Patient Portal Screening Mammography:

Participants
Patricia Balthazar, MD, Atlanta, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

Patient portals can increase patient access and engagement but can create potential new barriers to care and widen the digital divide. We aimed to identify potential sociodemographic disparities in utilization of an online patient portal to self-schedule screening mammograms (SM) as opposed to a traditional scheduling pathway (scheduler phone call and referral system). We hypothesized patients with limited English proficiency (LEP), racial/ethnic minorities, and low socioeconomic status would be less likely to utilize an online self-scheduling pathway.*Methods and Materials This was a HIPAA-compliant, IRB approved retrospective cohort study at an urban quaternary-care academic medical center with patient portal access to EMR. All female patients undergoing SM from 1/1/2019 to 12/31/2019 were included. Institutional data warehouse was queried to extract these variables: patient scheduling pathway (online self-scheduled vs. traditional), age, language, race, health insurance provider, and zip code. Patient's zip code was linked to Census data to extract the following demographic information: internet access, median household income, education level. Multivariable logistic regression was used to identify independent factors associated with utilizing online self-scheduling pathways for screening mammography.*Results 46,268 patients were included in the study; only 302 (0.7%) used the online self-scheduling pathway. Patients utilizing the self-scheduling pathway had higher odds of being younger (OR for age in year: 0.94; 95% CI: 0.93-0.96), English-speakers (21.6, 3.0-156.5), White (1.7, 1.2-2.5), have private insurance (1.5, 1.0-2.1), to live in zip code areas with higher percentage of access to broadband internet (1.2, 1.1-1.3). Patients living in zip code areas with higher median household income, education level, or with any type of internet access were not significantly associated with the online self-scheduling pathway.*Conclusions Racial ethnic minorities, patients with low socioeconomic status, lower access to broadband internet, and LEP were less likely to use a patient-portal self-scheduling pathway for SM.*Clinical Relevance/Application Understanding the factors associated with patient use of technology and patient portals for access to care can guide interventions to bridge the existing digital divide and promote health equity in radiology.

RESULTS

46,268 patients were included in the study; only 302 (0.7%) used the online self-scheduling pathway. Patients utilizing the self-scheduling pathway had higher odds of being younger (OR for age in year: 0.94; 95% CI: 0.93-0.96), English-speakers (21.6, 3.0-156.5), White (1.7, 1.2-2.5), have private insurance (1.5, 1.0-2.1), to live in zip code areas with higher percentage of access to broadband internet (1.2, 1.1-1.3). Patients living in zip code areas with higher median household income, education level, or with any type of internet access were not significantly associated with the online self-scheduling pathway.

CLINICAL RELEVANCE/APPLICATION

Understanding the factors associated with patient use of technology and patient portals for access to care can guide interventions to bridge the existing digital divide and promote health equity in radiology.

NPM03-A3   FDA - Cleared AI Algorithms: Trends, Strengths, And Limitations Of Validation Studies

Participants
Shadi Ebrahimian, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

The ACR Data Science Institute (DSI) Editorial Board compiles relevant information on the U.S. Food Drug Administration (FDA)-cleared imaging-based artificial intelligence (AI) algorithm including details of body areas, algorithm performance and validation studies. The purpose of our ACR DSI Editorial Board initiative was to assess keys trends, strengths, and gaps in validation studies of FDA-cleared AI algorithms in radiology.*Methods and Materials Our work audited publicly available details of FDA-cleared AI algorithms in imaging from 2008 until 2020. We reviewed 107 AI algorithms to classify information related to their parent company, subspecialty, body area and specific anatomy type, imaging modality, date of FDA clearance, indications for use, target pathology (such as trauma) and findings (such as fracture), CAD technique (triage, detection, characterization, quality, and quantification), product performance, presence, type, strength and available data of clinical validation for each AI algorithm. Pertaining to validation data, where available, we recorded the number of datasets evaluated, and available statistics (such as accuracy, ROC AUC). Two radiologists reviewed and classified types of AI algorithms (detection, quantitative, characterization, etc). Data were analyzed with pivot tables for descriptive statistics.*Results Over one-half of FDA-cleared AI algorithms (60/107) posted no validation claims or data. Al Just 9/107 reviewed AI algorithms had a validation dataset sizes of over 1000, 2/107 algorithms with >5000. The most common type of AI algorithms included detection (CADe; n= 27) and quantitative algorithms (n= 34). Nearly all CADe and CADt (triage) targeted specific radiology finding (one per algorithm). Breast (mammography), chest (chest radiography and CT), and brain (CT and MR) dominated the targeted body regions of interest. Among 33 CADe cleared algorithm, there were no datasets for 14 (42%), while 2/3 CADx (characterization) had either 0 or 50 validation datasets.*Conclusions Insufficient validation datasets in several FDA-cleared AI algorithms makes it difficult to assess generalizability and predict bias in clinical implementation.*Clinical Relevance/Application Insufficient validation datasets in AI algorithms necessitate need for a cautious implementation into clinical routine.

RESULTS

Over one-half of FDA-cleared AI algorithms (60/107) posted no validation claims or data. Al Just 9/107 reviewed AI algorithms had a validation dataset sizes of over 1000, 2/107 algorithms with >5000. The most common type of AI algorithms included detection (CADe; n= 27) and quantitative algorithms (n= 34). Nearly all CADe and CADt (triage) targeted specific radiology finding (one per algorithm). Breast (mammography), chest (chest radiography and CT), and brain (CT and MR) dominated the targeted body regions of interest. Among 33 CADe cleared algorithm, there were no datasets for 14 (42%), while 2/3 CADx (characterization) had either 0 or 50 validation datasets.

CLINICAL RELEVANCE/APPLICATION

Insufficient validation datasets in AI algorithms necessitate need for a cautious implementation into clinical routine.

CA01-A4   Clinical Significance Of An Anomalous Right Coronary Artery Found By Angiography In An Adult

Participants
Aishwarya Gulati, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Anomalous right coronary artery (RCA), the second most common coronary anomaly, is often identified on computed tomography angiography (CTA) in association with atherosclerotic disease, but treatment guidelines are not universally accepted. We evaluated a population with an interarterial course (IAC) of an anomalous right coronary artery (RCA) arising from the left coronary sinus to determine whether this population benefits from bypass surgery.*Methods and Materials Our retrospective review of conventional angiography and CTA studies identified 191 patients over the age of 35 years, including 93 patients with an anomalous RCA and an IAC, and 98 patients with an anomalous left circumflex (LCx) artery with a retro-aortic course; the anomalous LCx population, an accepted benign anomaly, was chosen as our control population. Clinical outcomes for these patients were available with a mean follow-up time of 6 years. Hard outcomes were compared between the two populations, including MI, cardiac death, unstable angina, and all-cause mortality.*Results The demographic distribution of our cases and controls was similar. Hard outcomes were identified among 20 cases and 30 controls. There was no significant difference in hard outcomes (p=0.15), non-fatal hard outcomes (p=0.07), all-cause mortality (p=0.09), and cardiac death (p=0.29) between case and control groups. Using a Cox Proportional Hazard Model, only age (p< 0.02) and coronary artery disease (p<0.01) were significant predictors of hard outcomes and all-cause mortality.*Conclusions There is no significant difference in hard outcomes or overall survival between adults with an anomalous RCA with an IAC versus those with an anomalous LCx. Only age and coronary artery disease burden predict outcomes. Our findings suggest that management of adult patients with an anomalous RCA can be based on atherosclerotic disease burden alone without considering the IAC as an added risk.*Clinical Relevance/Application Given the increasing identification of anomalous coronary arteries on cCTA, evidence-based treatment guidelines are needed. Analysis of clinical outcomes can define appropriate management strategies.

RESULTS

The demographic distribution of our cases and controls was similar. Hard outcomes were identified among 20 cases and 30 controls. There was no significant difference in hard outcomes (p=0.15), non-fatal hard outcomes (p=0.07), all-cause mortality (p=0.09), and cardiac death (p=0.29) between case and control groups. Using a Cox Proportional Hazard Model, only age (p< 0.02) and coronary artery disease (p<0.01) were significant predictors of hard outcomes and all-cause mortality.

CLINICAL RELEVANCE/APPLICATION

Given the increasing identification of anomalous coronary arteries on cCTA, evidence-based treatment guidelines are needed. Analysis of clinical outcomes can define appropriate management strategies.

GI04-D11   **Impact Of Celiac Trunk Calcification On Clinical Outcome In Patients Undergoing Liver Transplantation**

Participants
Robert Siepmann, MD, Aachen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Post-operative complications after liver transplantation (oLTx) contribute to a 90-day mortality rate of up to 11%. To improve post-operative outcomes, adequate arterial perfusion of the transplant is essential. Aim of this study is to investigate risk factors on pre-operative CT imaging of the celiac vessels and their impact on clinical outcome.*Methods and Materials Retrospective, monocentric study on patients undergoing oLTx between January 2015 and December 2019 who had undergone non-contrast-enhanced CT not longer than one year before surgery. Calcifications of the celiac artery (CA) and the visceral aorta (VA: aorta from aortic hiatus to superior mesenteric artery) were determined by using the Agatson method (cut-off values: CA >50 mm3, VA >100 mm3). Association between visceral calcification and overall survival or graft survival was evaluated using Kaplan-Meier estimator (p<0.05). Mann-Whitney U test (p<0.05) was used to investigate the association between visceral calcification and intraoperative fresh frozen plasma (FFP) units needed, intraoperative red blood cell (RBC) units needed, major complications (MC) (Clavien-Dindo =3b), length of ICU stay (ICUS), length of hospital stay (HS), Charlson Comorbidity Index (CCI) and cost prediction (CP).*Results 138 patients were included. 28/138 had relevant calcifications of the VA alone, 3/138 of the CA alone, and 10/138 of both. VA and CA calcification had no relevant impact on overall survival (p=0.089, p=0.310) or graft survival (p=0.347, p=0.421). However, patients with relevant CA calcification had a significantly higher risk of major complications (p=0.010) and needed significantly more FFPs intra-operatively (p=0.015). CA calcification was not significantly associated with ICUS, HS, CCI, CP or RBC. VA calcification was not significantly associated with any of the outcome metrics under investigation.*Conclusions Patients with relevant calcifications of the celiac artery undergoing liver transplantation face a significantly higher risk of complicated surgery or major postoperative complications.*Clinical Relevance/Application Evaluation of celiac artery calcifications on abdominal CT obtained prior to liver transplant surgery can help identify patients at high-risk of intra- and postoperative complications.

RESULTS

138 patients were included. 28/138 had relevant calcifications of the VA alone, 3/138 of the CA alone, and 10/138 of both. VA and CA calcification had no relevant impact on overall survival (p=0.089, p=0.310) or graft survival (p=0.347, p=0.421). However, patients with relevant CA calcification had a significantly higher risk of major complications (p=0.010) and needed significantly more FFPs intra-operatively (p=0.015). CA calcification was not significantly associated with ICUS, HS, CCI, CP or RBC. VA calcification was not significantly associated with any of the outcome metrics under investigation.

CLINICAL RELEVANCE/APPLICATION

Evaluation of celiac artery calcifications on abdominal CT obtained prior to liver transplant surgery can help identify patients at high-risk of intra- and postoperative complications.

GI04-D9   **Oportunistic Screening For Metabolic Syndrome And Osteoporosis In Non-enhanced Computer Tomography: A Deep Learning Approach**

Participants
Marcelo Takahashi, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

To develop an AI model capable of automatically extracting quantitative biomarkers that are predictors of metabolic syndrome and osteoporosis from non-enhanced abdominal CTs*Methods and Materials Ongoing retrospective study with IRB approval. An in-house developed deep learning algorithm, based on UNet architecture, was utilized for independent volumetric segmentation of liver, visceral fat, abdominal fat and anterior portion of lumbar vertebral bodies. Steatosis evaluation was based on mean attenuation from volumetric liver segmentation.Abdominal fat relation was calculated as the proportion of segmentation area of a single slice (umbilical level) of visceral/subcutaneous fat.Bone density was based on mean attenuation of segmented volume of the sum of all identified lumbar vertebrae.*Results Analysis was made in three distinct patient groups. Liver steatosis group: of 176 exams selected based on the presence/absence of steatosis in the report. With attenuation threshold of <40HU for steatosis and >60UH for normal algorithm 100% accuracy.Abdominal fat group: 39 exams with previous conventional manual single-slice segmentation of visceral and subcutaneous fat at umbilical level. Considering manual segmentation as ground truth algorithm demonstrated an excellent performance with mean absolute error of 1%.Bone density group: 65 pairs of exams of patients who underwent bone densitometry within 30 days of CT. Considering mean attenuation of 158HU as threshold algorithm achieved: 83% accuracy, 76% PPV and 89% NPV.*Conclusions We successfully developed an AI model capable of extracting relevant data from abdominal CT which correlates well to both manual segmentation and bone densitometry results.*Clinical Relevance/Application If integrated to radiologic workflow our models can assist radiologists and/or referring physicians in prospectively detecting patients at risk for metabolic syndrome and osteoporosis/osteopenia through regular non-enhanced abdominal CTs automatic analysis. Retrospective analysis can also be done, as either screening method or as to generate and collect large amounts of population data.

RESULTS

Analysis was made in three distinct patient groups. Liver steatosis group: of 176 exams selected based on the presence/absence of steatosis in the report. With attenuation threshold of <40HU for steatosis and >60UH for normal algorithm 100% accuracy.Abdominal fat group: 39 exams with previous conventional manual single-slice segmentation of visceral and subcutaneous fat at umbilical level. NPM02-B1   **Educational Impact Of The Abrupt Conversion Of A Core Medical Student Radiology Clerkship To Remote Learning Secondary To The COVID-19 Pandemic**

Participants
Jonathan Martin, MD, Durham, North Carolina (*Presenter*) Speakers Bureau, Inari Medical, Inc

PURPOSE

Second-year medical students at a single institution undergo a required 4-week clerkship in Radiology. Historically, this course is entirely in-person with approximately 40 lecture hours and 140 clinical hours. In the setting of the COVID-19 pandemic a new hybrid model was created in academic year (AY) 2020-21, consisting of 15 live videoconference lecture hours, 25 prerecorded lecture hours, and approximately 40 in-person clinical hours and 100 remote clinical hours (videoconference readouts), the breakdown of which varied by clinical division. Here we examine if the conversion of an entirely in-person clinical curriculum to a hybrid model resulted in a significant change in student performance or student satisfaction.*Methods and Materials A standardized written exam has been administered at the end of each clerkship block since 2016. Given the propensity for general medical knowledge to increase across the clinical year, exam scores from the 6 completed blocks of AY 2020-21 were compared to results from the first 6 blocks of AY 2016-2020. Student final grades (Satisfactory/Unsatisfactory), lecture evaluation scores and student satisfaction scores on a 5-point Likert scale were also compared. Student suggestions for improvement were compiled.*Results There has been no significant change in mean exam scores pre- and post-curriculum-change (AY 2016-20: mean 89.0, std dev 4.8; AY 2020-21: mean 88.6, std dev 5.1; p=0.26). No students in AY 2020-21 had a failing exam score or received an Unsatisfactory grade. Lecture ratings for AY 2020-21 saw a significant decrease in average score (4.2 vs 4.5, p<0.001). Clinical divisions which had majority in-person clinical hours saw an increase in student satisfaction scores (77.3% favorable or very favorable pre-change, 93.6% post), while divisions with a majority remote clinical hours saw a decrease (77.1% pre; 69.8% post). Additionally, 73% of student suggestions for improvement were centered around remote readouts.*Conclusions With the conversion to a hybrid curriculum, metrics of student performance have remained stable. However, student satisfaction with remote clinical work and evaluations of remote lectures were both decreased compared to in-person learning.*Clinical Relevance/Application While these findings suggest that a hybrid remote and in-person curriculum can maintain student performance, the significant decrease in student satisfaction related to remote clinical work indicates that a return to safe in-person learning should be prioritized.

RESULTS

There has been no significant change in mean exam scores pre- and post-curriculum-change (AY 2016-20: mean 89.0, std dev 4.8; AY 2020-21: mean 88.6, std dev 5.1; p=0.26). No students in AY 2020-21 had a failing exam score or received an Unsatisfactory grade. Lecture ratings for AY 2020-21 saw a significant decrease in average score (4.2 vs 4.5, p<0.001). Clinical divisions which had majority in-person clinical hours saw an increase in student satisfaction scores (77.3% favorable or very favorable pre-change, 93.6% post), while divisions with a majority remote clinical hours saw a decrease (77.1% pre; 69.8% post). Additionally, 73% of student suggestions for improvement were centered around remote readouts.

CLINICAL RELEVANCE/APPLICATION

While these findings suggest that a hybrid remote and in-person curriculum can maintain student performance, the significant decrease in student satisfaction related to remote clinical work indicates that a return to safe in-person learning should be prioritized.

GI01-A10   Prediction Of KRAS Mutations In Rectal Cancer Based On Clinical Data, Dual-energy Spectral CT Parameters And ADC Values

Participants
Xiaoqiang Lin, Lanzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the value of combined clinical information, dual-energy spectral CT (DESCT) and ADC parameters in predicting KRAS mutations in rectal cancer.*Methods and Materials Forty-nine patients with rectal cancer underwent DWI and triple-phase enhanced DESCT were retrospectively collected and divided into two groups: group A (wild-type) and group B (mutation). Clinical baseline characteristics included age, gender, tumor location and serum tumor markers. A radiologist delineated the regions of interest (ROIs) on the layer of maximum tumor diameter and the nearest upper and lower layers in axial enhanced images and calculated the average value. Effective atomic number (Eff-Z), iodine concentration (IC) of tumor and artery were acquired to calculate normalized iodine concentration (NIC, NIC = ICtumor / ICartery). The apparent diffusion coefficient (ADC) value including minimum ADC (mADC) value, average ADC (aADC) value and relative ADC (rADC) value (rADC = aADCtumor / aADCgluteus) were obtained by drawing ROIs referred to T2 map. The differences of clinical baseline characteristics between groups were checked by ?2 test. The t test or Mann Whitney U test is used for continuous data. Univariate and multivariable logistic regression analysis were used to determine the independent factors of KRAS mutation status. Before the construction of a multivariate model, collinearity diagnostics were performed. Receiver operating characteristic (ROC) curves were generated to assess the predictive performance.*Results The mutation rate of KRAS in superior segment was significantly higher than that in middle and low rectal cancer ($P < 0.05$). The Eff-Z and NIC in venous phase (VP) of group B were significantly higher than group A (both $P < 0.05$), while the aADC and rADC value of group B was significantly lower (both $P < 0.05$). Univariate logistic regression showed that tumor location ($P = 0.031$) and NIC in VP ($P = 0.019$) were risk factors for KRAS mutation, while rADC value was protective factor for KRAS mutation ($P = 0.036$), further multivariate logistic regression analysis of combined tumor location showed that rADC was an independent predictor of KRAS mutation ($P < 0.05$, OR = 0.228). Three significant factors (tumor location, NICVP and rADC) were combined to determine the predictive value for KRAS mutations with the AUC value of 0.806.*Conclusions Tumor location, Eff-Z, NIC in VP, aADC and rADC values of rectal cancer have moderate predictive efficacy for KRAS mutation. Moreover, rADC is an independent predictor of KRAS mutation. Combined model has higher value for predicting KRAS mutation in rectal cancer.*Clinical Relevance/Application Regression models based on tumor segmentation, DSECT and ADC parameters are helpful for preoperative treatment strategy selection.

RESULTS

The mutation rate of KRAS in superior segment was significantly higher than that in middle and low rectal cancer ($P < 0.05$). The Eff-Z and NIC in venous phase (VP) of group B were significantly higher than group A (both $P < 0.05$), while the aADC and rADC value of group B was significantly lower (both $P < 0.05$). Univariate logistic regression showed that tumor location ($P = 0.031$) and NIC in VP ($P = 0.019$) were risk factors for KRAS mutation, while rADC value was protective factor for KRAS mutation ($P = 0.036$), further multivariate logistic regression analysis of combined tumor location showed that rADC was an independent predictor of KRAS mutation ($P < 0.05$, OR = 0.228). Three significant factors (tumor location, NICVP and rADC) were combined to determine the predictive value for KRAS mutations with the AUC value of 0.806.

CLINICAL RELEVANCE/APPLICATION

Regression models based on tumor segmentation, DSECT and ADC parameters are helpful for preoperative treatment strategy selection.

GI01-A12   Detection Of Early-stage Hcc By Abbreviated Mri: Multicenter Validation Against Surgical Pathology

Participants
Takeshi Yokoo, MD, PhD, Dallas, Texas (*Presenter*) Nothing to Disclose

PURPOSE

Evaluate early-stage detection of dynamic contrast enhanced abbreviated MRI (dynamic AMRI) in cirrhosis, against surgical pathology as reference standard.*Methods and Materials We conducted a multi-center retrospective case-control study at 3 U.S. liver transplantation centers on cirrhosis patients who underwent liver resection or transplant during 2009-2019 and had full dynamic contrast-enhanced liver MRI within 3 months of surgery. Patients were excluded if they had: any cancer therapy prior to surgery, hepatobiliary contrast for MRI, tumor beyond Milan criteria on pathology, or HCC size <1 cm.Dynamic AMRI exam was simulated from the pre-surgical full MRI by retaining only the localizing coronal T2-weighted and dynamic contrast enhanced T1-weighted sequences (pre-contrast, arterial, portal venous, and delayed phases), and omitting most non-contrast sequences. Two abdominal radiologists at each center independently reviewed AMRI images using 2018 Liver Imaging Reporting and Data System (LI-RADS), blinded to all clinical, pathological, and prior imaging data. Patients with liver observations categorized as LI-RADS 4, 5, or M were recorded as "positive" for HCC detection, and "negative" otherwise.Patients with pathologically-confirmed HCC were classified as HCC+, and those without HCC on pathology as HCC-. Patients with pathologically-confirmed non-HCC mass were

classified as HCC-. Early-stage status was pathologically confirmed by applying Milan criteria.Patient-level sensitivity and specificity for early-stage HCC detection were calculated in the HCC+ and HCC- groups, respectively, for each reader as well as for the average reader.*Results We enrolled 166 patients with early-stage HCC and 139 patients without HCC. The most common etiology of cirrhosis was hepatitis C among HCC+ (67.5%) and alcohol-related among controls (55.4%). Most HCC cases had Child Pugh A cirrhosis (89.4%) and treated with resection (79.4%). Most HCC were unifocal (89.4%) and median diameter was 2.4 cm. Pooled sensitivity and specificity of dynamic AMRI for early-stage HCC were 0.888 (95%CI 0.841-0.931) and 0.892% (0.842-0.935), respectively (Table 1). There was variation in performance across readers, sites, and type of surgery (resection vs. transplant). Notably, the sensitivity of AMRI was significantly higher for patients undergoing resection than those undergoing transplantation (95.7% vs. 62.1%).*Conclusions Using surgical pathology as the reference standard, AMRI had sensitivity and specificity of ~90% for detection of early-stage HCC in cirrhosis.*Clinical Relevance/Application Using rigorous reference standard (surgical resection), our data further support the use of abbreviated MRI for early detection of cirrhosis-associated HCC.

RESULTS

We enrolled 166 patients with early-stage HCC and 139 patients without HCC. The most common etiology of cirrhosis was hepatitis C among HCC+ (67.5%) and alcohol-related among controls (55.4%). Most HCC cases had Child Pugh A cirrhosis (89.4%) and treated with resection (79.4%). Most HCC were unifocal (89.4%) and median diameter was 2.4 cm. Pooled sensitivity and specificity of dynamic AMRI for early-stage HCC were 0.888 (95%CI 0.841-0.931) and 0.892% (0.842-0.935), respectively (Table 1). There was variation in performance across readers, sites, and type of surgery (resection vs. transplant). Notably, the sensitivity of AMRI was significantly higher for patients undergoing resection than those undergoing transplantation (95.7% vs. 62.1%).

CLINICAL RELEVANCE/APPLICATION

Using rigorous reference standard (surgical resection), our data further support the use of abbreviated MRI for early detection of cirrhosis-associated HCC.

GI01-A13   An Interactive CT-based Series Of Gastric Pathology

Participants
Edward Lawrence, MD, PhD, Madison, Wisconsin (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Localizing extraluminal fluid/air can help find the location of perforation. 2. Features that suggest true gastric wall thickening include altered wall enhancement, asymmetric thickening, adjacent stranding, or local adenopathy 3. Lower attenuation (edema) or mural stratification favors benign. Higher attenuation/enhancement is suspicious for infiltrative tumor. 4. The most challenging neoplastic mimics are lymphoma and adenocarcinoma (including linitis plastica)

TABLE OF CONTENTS/OUTLINE

1. 'How to' interact with web-based cases 2. Case based teaching a. Highlight key imaging findings, including companion cases b. Emphasize differentiating inflammatory from malignant etiologies 3. Case examples: a. Gastritis; b. Peptic ulcers (including perforated); c. Emphysematous gastritis; d. Gastric volvulus; e. Gastric adenocarcinoma; f. Gastric lymphoma; g. Gastric GIST; h. Linitis plastica (metastatic breast cancer); i. Gastric neuroendocrine tumor; j. Gastric schwanomma; k. Gastric pseudocysts; l. Ménétrier disease; m. Puetz Jeghers with gastric polyposis; n. Gastric varices

GI01-A3   Diagnostic Performance Of Multiparametric Mr Imaging In Detecting Pathologic Complete Response After Neoadjuvant Therapy In Esophageal Squamous Cell Carcinoma

Participants
Jin Rong Qu, MD,PhD, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To determine the performance of multiparametric magnetic resonance (MR) imaging in evaluating response to neoadjuvant therapy in patients with esophageal squamous cell carcinoma (ESCC).*Methods and Materials Thirty-six ESCC patients with cT2-T4a/N0-N3/M0 stage were retrospectively reviewed utilizing a prospectively maintained database. Biopsy proven staging was performed according to the 7th edition of Union for International Cancer Control/American Joint Committee on Cancer TNM classification of esophageal cancer (EC). MRI was performed before and after neoadjuvant therapy (nT), followed by surgical resection. Lesions were analyzed for five MRI features (changes of size, signal on DWI, ADC map, T2-weighted TSE BLADE and degree of enhancement) and response was assessed by using tumor regression grade (TRG). Chi-square test or Fisher exact test was used, and sensitivity, specificity, positive predictive value, negative predictive value and C-Index were calculated.*Results Five MR features after nT showed strong positive correlations with TRG 0 (r = 0.7432; P<.001). All 10 cases with TRG 0 showed either complete disappearance of the mass or decreased mass with minimal residual thickening of the esophageal wall, iso- or decreased-intensity on DWI, iso- or increased-intensity on ADC map, iso- or decreased-intensity on T2-weighted TSE BLADE, or homogeneous enhancement on high-resolution delayed StarVIBE. These features were different from all the TRG 2-3 in 20 cases. ADC map had the highest performance in distinguishing TRG 0 from non-TRG 0 with the sensitivity of 96.1%, specificity of 76.5%, negative predictive value (NPV) of 74.7%, and positive predictive value (PPV) of 91.6%*Conclusions Multiparametic MR features provide useful diagnostic information of pCR among patients with ESCC who undergo neoadjuvant therapy.*Clinical Relevance/ApplicationMR assessment of changes in tumor size, signal on DWI, ADC map, T2-weighted TSE BLADE, and enhancement pattern may distinguish between biopsy proven TRG 0 and non-TRG 0 in patients with ESCC.

RESULTS

Five MR features after nT showed strong positive correlations with TRG 0 (r = 0.7432; P<.001). All 10 cases with TRG 0 showed either complete disappearance of the mass or decreased mass with minimal residual thickening of the esophageal wall, iso- or decreased-intensity on DWI, iso- or increased-intensity on ADC map, iso- or decreased-intensity on T2-weighted TSE BLADE, or homogeneous enhancement on high-resolution delayed StarVIBE. These features were different from all the TRG 2-3 in 20 cases. ADC map had the highest performance in distinguishing TRG 0 from non-TRG 0 with the sensitivity of 96.1%, specificity of 76.5%, negative predictive value (NPV) of 74.7%, and positive predictive value (PPV) of 91.6%

CLINICAL RELEVANCE/APPLICATION

MR assessment of changes in tumor size, signal on DWI, ADC map, T2-weighted TSE BLADE, and enhancement pattern may

distinguish between biopsy proven TRG 0 and non-TRG 0 in patients with ESCC.

GI01-A4   Gadoxetic Acid-enhanced MR Imaging Predictors Of Mortality And Hepatic Decompensation In Chronic Liver Disease

Participants
Lucian Beer, MD,PhD, Vienna, Austria (*Presenter*) Nothing to Disclose

PURPOSE

The Functional Liver Imaging Score (FLIS), derived from hepatobiliary phase MRI, was associated with graft survival in patients who underwent liver transplantation and linked to a first hepatic decompensation and transplant-free survival (TFS) in patients with advanced chronic liver disease (ACLD). The aim of this study was to investigate the accuracy of the FLIS in combination with the spleen craniocaudal diameter (SCCD) for the prediction of hepatic decompensation and TFS in patients with CLD.*Methods and Materials There were 397 patients with CLD who had undergone gadoxetic acid-enhanced liver MRI included. A FLIS was assigned based on the sum of three hepatobiliary-phase features, each scored on an ordinal 0-2 scale: hepatic enhancement; biliary excretion; and the signal intensity in the portal vein. The SCCD was measured. Patients were stratified into three groups according to the Fibrosis-4 score (FIB-4) and present or past hepatic decompensation: non-advanced CLD; compensated-advanced CLD (cACLD); and decompensated-advanced CLD (dACLD). The predictive value of SCCD and FLIS for a first or further hepatic decompensation and TFS was investigated using Kaplan-Meier analysis, log-rank tests, and Cox regression analysis.*Results We observed a strong positive correlation between the measured spleen volume and the SCCD (Spearman's rho = 0.887; P < 0.001). The inter-reader and intra-reader agreement for the SCCD was excellent, with ICC values of 0.982 (range: 0.973-0.955; n = 241) and 0.997 (range: 0.994-0.998; n = 41), respectively.In patients with ACLD, the FLIS was an independent risk factor for mortality (adjusted hazard ratio, [aHR]: 2.38, 95%CI: 1.51-43.76, P < .001). Allocating patients into three groups based on their FLIS and SCCD enabled further stratification of patients according to their risk for mortality (log-rank test: P<.001). The SCCD was further identified as an independent risk factor for a first and further hepatic decompensation in patients with ACLD (aHR: 1.10, 95%CI: 1.02-1.19, P = .01; aHR: 1.13, 95%CI: 1.05-1.22, P = .001).*Conclusions The functional liver imaging score, derived from gadoxetic acid-enhanced MRI in combination with the splenic craniocaudal diameter, identifies patients with advanced chronic liver disease who are at increased risk for hepatic decompensation and for mortality.*Clinical Relevance/Application Gadoxetic acid-enhanced MRI, in combination with the splenic craniocaudal diameter, can be used to identify patients with advanced chronic liver disease who are at increased risk for hepatic decompensation and for mortality.

RESULTS

We observed a strong positive correlation between the measured spleen volume and the SCCD (Spearman's rho = 0.887; P < 0.001). The inter-reader and intra-reader agreement for the SCCD was excellent, with ICC values of 0.982 (range: 0.973-0.955; n = 241) and 0.997 (range: 0.994-0.998; n = 41), respectively.In patients with ACLD, the FLIS was an independent risk factor for mortality (adjusted hazard ratio, [aHR]: 2.38, 95%CI: 1.51-43.76, P < .001). Allocating patients into three groups based on their FLIS and SCCD enabled further stratification of patients according to their risk for mortality (log-rank test: P<.001). The SCCD was further identified as an independent risk factor for a first and further hepatic decompensation in patients with ACLD (aHR: 1.10, 95%CI: 1.02-1.19, P = .01; aHR: 1.13, 95%CI: 1.05-1.22, P = .001).

CLINICAL RELEVANCE/APPLICATION

Gadoxetic acid-enhanced MRI, in combination with the splenic craniocaudal diameter, can be used to identify patients with advanced chronic liver disease who are at increased risk for hepatic decompensation and for mortality.

SDP-RI-1   A Clinical And Multimodal MRI-based Radiomics Model For Preoperatively Detecting Concurrent Endometrial Cancer From Atypical Endometrial Hyperplasia

Participants
Jieying Zhang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the capability of multimodal MRI-based radiomics for preoperatively detecting concurrent endometrial cancer (CEC) from atypical endometrial hyperplasia (AEH).*Methods and Materials A total of 87 patients (57 AEHs and 30 CECs) were retrospectively enrolled with preoperative MRI. The radiomics features were extracted basing on T2-weighted imaging (T2WI), diffusion-weighted imaging (DWI), and apparent diffusion coefficient (ADC) maps. A data reduction and feature selection process including the least absolute shrinkage and selection operator algorithm was performed. Single-modal and multimodal radiomics signatures, clinical model and clinical-radiomics model were built using logistic regression. Area under the receiver operating characteristic (ROC) curves (AUC) and calibration curves were used to assess these models. Model internal validations were performed using the enhanced bootstrap resampling method (n=1000). Subgroup analysis was performed according to preoperative endometrial biopsy results.*Results T2WI, DWI, ADC and the combined radiomics signatures all showed good discrimination abilities with an AUC of 0.887 (95%CI: 0.818-0.956), 0.785 (95%CI: 0.688-0.883), 0.833 (95%CI: 0.741-0.925) and 0.920 (95%CI: 0.865-0.974), respectively. The clinical-radiomics model consisted of multimodal radiomics features, endometrial thickness (>11mm), and nulliparity status, achieved the highest AUC of 0.932 (95% CI: 0.880-0.984) and bias-corrected AUC of 0.922. The subgroup analysis showed that this model also performed well in patients with preoperative endometrial biopsy consistent and inconsistent with postoperative pathology (consistent biopsy group, accuracy = 0.848; inconsistent biopsy group, accuracy = 0.905).*Conclusions The clinical- and multimodal MRI-based radiomics model has the potential to be used as a noninvasive imaging tool for preoperatively distinguishing CEC from AEH, especially in patients with under- or over-estimated preoperative endometrial biopsy.*Clinical Relevance/Application We developed a noninvasive, highly sensitive, and specific clinical- and multimodal MRI-based radiomics model for preoperatively detecting CEC from AEH with a supplementary value to endometrial biopsy.

RESULTS

T2WI, DWI, ADC and the combined radiomics signatures all showed good discrimination abilities with an AUC of 0.887 (95%CI: 0.818-0.956), 0.785 (95%CI: 0.688-0.883), 0.833 (95%CI: 0.741-0.925) and 0.920 (95%CI: 0.865-0.974), respectively. The clinical-radiomics model consisted of multimodal radiomics features, endometrial thickness (>11mm), and nulliparity status, achieved the highest AUC of 0.932 (95% CI: 0.880-0.984) and bias-corrected AUC of 0.922. The subgroup analysis showed that this model also performed well in patients with preoperative endometrial biopsy consistent and inconsistent with postoperative pathology (consistent biopsy group, accuracy = 0.848; inconsistent biopsy group, accuracy = 0.905).

CLINICAL RELEVANCE/APPLICATION

We developed a noninvasive, highly sensitive, and specific clinical- and multimodal MRI-based radiomics model for preoperatively detecting CEC from AEH with a supplementary value to endometrial biopsy.

SDP-RI-10   The Value Of IVIM-DWI Combined With DTI In Prediction Of Lymphovascular Space Invasion For Early Cervical Squamous Cell Carcinoma

Participants
Tingting Lin, Hefei, China (*Presenter*) Nothing to Disclose

PURPOSE

This study aims to investigate the prediction of lymphovascular space invasion (LVSI) through a combination of intravoxel incoherent motion diffusion-weighted (IVIM-DWI) with diffusion tensor imaging (DTI) in patients with early cervical squamous cell carcinoma.*Methods and Materials Eighty patients with pathologically confirmed early cervical squamous cell carcinoma underwent conventional MRI, IVIM-DWI and DTI pretreatment. The patients were divided into LVSI positive and LVSI negative groups according to surgical pathology findings. The parameters of IVIM-DWI (ADC, D, D* and f value) and DTI (DCavg and FA) were measured. One-way analysis of variance was performed to compare the differences of preoperative parameters between the two groups, and optimal cut-off values and predictive performance of parameters with statistical significance were estimated by drawing the receiver operator characteristic (ROC) curve.*Results There were 45 patients in LVSI positive and 35 in negative group. The positive group showed a lower D and FA value (all p < 0.05). The area under the ROC curve (AUC) of D and FA was 0.852 and 0.731 respectively, and the combination of D and FA exhibited a higher diagnostic performance compared with individual MRI parameters.*Conclusions Both D and FA value showed promising results for diagnosing LVSI in early cervical squamous cell carcinoma. A combination of D and FA might improve the predictive value.*Clinical Relevance/Application Choose individual treatment for patients with early cervical squamous cell carcinoma.

RESULTS

There were 45 patients in LVSI positive and 35 in negative group. The positive group showed a lower D and FA value (all p <

0.05). The area under the ROC curve (AUC) of D and FA was 0.852 and 0.731 respectively, and the combination of D and FA exhibited a higher diagnostic performance compared with individual MRI parameters.

CLINICAL RELEVANCE/APPLICATION

Choose individual treatment for patients with early cervical squamous cell carcinoma.

SDP-RI-11   **Assessing The Correlation Of Ultrasonographic Placental Thickness And Intraplacental Villous Artery (IPVA) Doppler In Normal Pregnancies And Pregnancies With Intrauterine Growth Restriction(IUGR)**

Participants
Nirali S. Mehta, MBBS, Vadodara, India (*Presenter*) Nothing to Disclose

PURPOSE

To assess the placental thickness in normal pregnancies and pregnancies with IUGR. To compare intraplacental villous artery (IPVA) and umbilical artery(UA) Doppler indices between normal and IUGR pregnancies. To evaluate the role of IPVA Doppler and placental thickness in early detection of IUGR.*Methods and Materials A quantitative prospective was conducted on pregnant females coming for antenatal ultrasound using low frequency (3 to 5 MHz) curvilinear transducer of Philips Affinitti 50G at the Radiology Department. Singleton uncomplicated pregnancies were included. Antenatal females with twin gestation, anomalous foetus, abnormal placentation and any systemic disease were excluded. A total of 124 pregnant females were enrolled and fetal biometric parameters, placental thickness, IPVA and UA Doppler were studied for 4 times between 16 to 20, 24 to 26, 30 to 32 and at 36 weeks of gestation. The data was analysed with standard statistical tests.*Results Out of 124 antenatal females included, 96 had normal pregnancy outcome, 22 developed IUGR and 6 were lost to follow up. There was a significant increase in mean placental thickness with advancing gestational age in normal uncomplicated and IUGR pregnancies (p < 0.001). Placental thickness was significantly lower in IUGR pregnancies as compared to normal uncomplicated pregnancies at all four visits (p < 0.05). There was significant decrease in IPVA and UA Doppler indices (PI, RI and S/D values) with advancing gestational age in normal uncomplicated pregnancies (p < .05). IPVA Doppler indices were significantly higher in IUGR foetuses as compared to normal foetuses (p <0.05) at all four consecutive scans where as there was no statistically significant difference in UA Doppler indices between the two groups as early as 16 to 20 weeks.*Conclusions IPVA resistance indices decrease and placental thickness increase as gestational age advances in normal uncomplicated pregnancies. Lack of decrease in IPVA resistance indices or increase in their values with advancing gestational age and lack of increase in placental thickness with advancing gestational age may be used for early prediction of IUGR.*Clinical Relevance/Application Subnormal placental thickness and raised IPVA Doppler indices can be used as early predictor of IUGR in contrast to the UA Doppler which reflects changes when 2/3rd of uteroplacental circulation is hampered.

RESULTS

Out of 124 antenatal females included, 96 had normal pregnancy outcome, 22 developed IUGR and 6 were lost to follow up. There was a significant increase in mean placental thickness with advancing gestational age in normal uncomplicated and IUGR pregnancies (p < 0.001). Placental thickness was significantly lower in IUGR pregnancies as compared to normal uncomplicated pregnancies at all four visits (p < 0.05). There was significant decrease in IPVA and UA Doppler indices (PI, RI and S/D values) with advancing gestational age in normal uncomplicated pregnancies (p < .05). IPVA Doppler indices were significantly higher in IUGR foetuses as compared to normal foetuses (p <0.05) at all four consecutive scans where as there was no statistically significant difference in UA Doppler indices between the two groups as early as 16 to 20 weeks.

CLINICAL RELEVANCE/APPLICATION

Subnormal placental thickness and raised IPVA Doppler indices can be used as early predictor of IUGR in contrast to the UA Doppler which reflects changes when 2/3rd of uteroplacental circulation is hampered.

SDP-RI-12   **Validating The Diagnostic Accuracy Of An MRI-based Scoring System For Differentiating Benign Uterine Leiomyomas From Leiomyosarcomas**

Participants
Maryam Al-Khouri, MD, Muscat, Oman (*Presenter*) Nothing to Disclose

PURPOSE

The purpose is to propose and validate the diagnostic accuracy of a multi-parametric MRI-based scoring system to differentiate between uterine leiomyomas, Smooth muscle Tumors of Unknown Malignant Potential (STUMP) and leiomyosarcomas.*Methods and Materials An ethics board approved retrospective study was performed at two tertiary care centres. All patients with a pathology-proven uterine mass who underwent a pre-operative pelvic MRI between January 2010-December 2019 were included. Initially, a scoring system was designed based on previously published worrisome MR imaging features of uterine leiomyosarcomas. Each feature was allocated a score according to the strength of association with malignancy and the degree of its overlap with benign masses. Subsequently, the MR images were blindly and independently reviewed by a fellowship-trained radiologist and a clinical fellow/senior resident. Each uterine mass was scored according to their imaging features. The scores were divided into 5 categories according to the sum of scores; I: 0, II: 1-3, III: 4-6, IV: 7-9 and V: >9. Category III and above were considered positive for malignancy or STUMP. Sensitivity, specificity, Positive Predictive Value (PPV) and Negative Predictive Value (NPV) were calculated.*Results A total of 244 women were included (age range 20-74 years, mean 40). Of these, 218 patients had a benign leiomyoma, 13 had a STUMP and 13 had a leiomyosarcoma. The sensitivity and specificity of the scoring system were 92.3% and 64.7%, respectively. The NPV was 98.6%. No leiomyosarcoma was missed using this scoring system. The presence of T2 hyperintensity, that is not cystic, or diffusion restriction in a uterine mass were the most sensitive signs of a uterine malignancy/STUMP.*Conclusions The proposed multi-parametric MRI-based scoring system is useful in differentiating benign uterine leiomyomas from STUMP tumors and leiomyosarcomas.*Clinical Relevance/Application To overcome the pre-operative pelvic MRI challenges in differentiating between benign leiomyoma and leiomyosarcoma, this proposed scoring system can be helpful; however, requires further validation.

RESULTS

A total of 244 women were included (age range 20-74 years, mean 40). Of these, 218 patients had a benign leiomyoma, 13 had a STUMP and 13 had a leiomyosarcoma. The sensitivity and specificity of the scoring system were 92.3% and 64.7%, respectively. The NPV was 98.6%. No leiomyosarcoma was missed using this scoring system. The presence of T2 hyperintensity, that is not cystic, or diffusion restriction in a uterine mass were the most sensitive signs of a uterine malignancy/STUMP.

CLINICAL RELEVANCE/APPLICATION

To overcome the pre-operative pelvic MRI challenges in differentiating between benign leiomyoma and leiomyosarcoma, this proposed scoring system can be helpful; however, requires further validation.

SDP-RI-13 Tumor Immune Evolution Determined By Dynamic PD-L1 Radiomics Signature (PD-L1-R) Is Prognostic In Glioblastoma Patients Treated With Postsurgical Radiochemotherapy

Participants
Francesco Sforazzini, Heidelberg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

We have recently devised a radiomics signature as surrogate for tumor tissue PD-L1 quantification (PD-L1-R) from post contrast agent MR images (T1ce) in Glioblastoma multiforme (GBM) with the PD-L1-R high group demonstrating a better prognosis. Dynamic immune monitoring is currently limited in GBM by the lack of repeated biopsies. We sought to utilize the non-invasive PD-L1-R score to study longitudinal evolution of PD-L1 and correlate its dynamic with clinical outcome.*Methods and Materials Among the 121 primary GBM subjects used to build PD-L1-R, 111 had at least one follow up (FU) time-point (range between 1 and 24, for a total of 557, median FU time: 46 months) after first surgery. T1ce images underwent standard pre-processing (bias field correction, brain extraction) and the features extracted from the gross tumor volumes were used to compute PD-L1-R scores (between 0-1, cutoff for PD-L1-R high (H) /low (L) groups: 0.5). For subjects from H (n=60, 49.6%), the time period to a group switch H to L was evaluated. Median observed time was used to split H based on their PD-L1-R dynamics: high-early h-e and high-late h-l and h-miss if the cutoff was not reached. A treebag model (PDL1R-Dyn) was trained on pre-surgery (TP0) image features to differentiate between h-e/h-miss and h-l (70%/30% training/validation, repeated LASSO on resampled data for robust feature selection). Cox-PH models were used for survival analysis.*Results In TP0, 49% of the tumors were assigned to PD-L1-R H. Post surgery and radiochemotherapy (RCHT) 65% switched from H to L. H was stratified based on the median time to switch (early h-e <3.5mo, n=18, late h-l >= 3.5mo). For n=20, the group threshold was not reached (h-miss) within median of 1.5 time points vs 7.5 and 6.5 for h-e and h-l. h-miss, h-e and h-l showed median OS of 16, 16 and 28mo. H-e and h-miss were merged based on similar survival to train PDL1R-Dyn which yielded an AUC of 84% (95%CI: 0.64-1). Univariate analysis of PDL1R-Dyn in the full cohort (n=121) yielded a hazard ratio (HR) of 1.71 (95 %CI: 1.09-2.66). Multivariate survival analysis (MV) of PD-L1-R and PDL1R-Dyn yielded an AIC of 711.4, slightly outperforming univariate survival models (AIC P-L1-R: 715.0, PDL1R-Dyn: 712.2). HR of PDL1R-Dyn in MV was 1.70 (95%CI: 1.09-2.65).*Conclusions We showed that longitudinal changes of the immune-surrogate PD-L1-R contain prognostic information and that these trajectories might help to discover novel GBM immune-subgroups. Tumors with high PD-L1-R postoperative and delayed switch after RCHT show a more favorable outcome.*Clinical Relevance/Application High PD-L1-R status and delayed switch to PD-L1-R low phenotype are associated with improved prognosis in GBM. MRI may allow deciphering the dynamic of tumor immune status and help in stratification.

RESULTS

In TP0, 49% of the tumors were assigned to PD-L1-R H. Post surgery and radiochemotherapy (RCHT) 65% switched from H to L. H was stratified based on the median time to switch (early h-e <3.5mo, n=18, late h-l >= 3.5mo). For n=20, the group threshold was not reached (h-miss) within median of 1.5 time points vs 7.5 and 6.5 for h-e and h-l. h-miss, h-e and h-l showed median OS of 16, 16 and 28mo. H-e and h-miss were merged based on similar survival to train PDL1R-Dyn which yielded an AUC of 84% (95%CI: 0.64-1). Univariate analysis of PDL1R-Dyn in the full cohort (n=121) yielded a hazard ratio (HR) of 1.71 (95 %CI: 1.09-2.66). Multivariate survival analysis (MV) of PD-L1-R and PDL1R-Dyn yielded an AIC of 711.4, slightly outperforming univariate survival models (AIC P-L1-R: 715.0, PDL1R-Dyn: 712.2). HR of PDL1R-Dyn in MV was 1.70 (95%CI: 1.09-2.65).

CLINICAL RELEVANCE/APPLICATION

High PD-L1-R status and delayed switch to PD-L1-R low phenotype are associated with improved prognosis in GBM. MRI may allow deciphering the dynamic of tumor immune status and help in stratification.

SDP-RI-2 The Predictive Value Of Conventional Mr Features Combined With Radiomics Features In Energy Efficiency Factor Of Hifu Ablation Uterine Fibroids

Participants
Chao Wei, Hefei, China (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to explore the additional value of radiomics features on conventional MRI further in predicting energy efficiency factor(EEF) of HIFU ablation uterine fibroids .*Methods and Materials A total of 216 symptomatic uterine &7;broids in 216 female patients were treated with HIFU therapy from October 2015 to March 2020. The baseline clinical and MR parameters before and after HIFU ablation were retrospectively analyzed. And the EEF was calculated according to the above results. Lesions segmented and features extracted were performed by ITK-SNAP and A.K. software on T2WI respectively.The minimum redundancy and maximum (mRMR) were used to select the radiomics features, and 20 features with high correlation but no redundancies with NPVR were retained. SPSS software was used to establish multiple linear regression models using the conventional MR features, conventional MRI and radiomics combined features, respectively. The NPVR related features of the two models were found out, and the prediction efficiency of the two models were compared, statistically. The validation of the predictive effectiveness of the final model was based on the correlation analysis between the predicted EEF value and the actual EEF value.*Results Conventional MRI and radiomics features combined model showed that wavelet _ HHH_ firstorder_ Skewness (X12), T1WI enhancement (X11: mild = 0, moderate = 1, marked = 2), T2WI signal intensity (X9: hyperintense signal = 0, iso-intensesignal = 1, hyperintense signal = 2) and DWI signal intensity (X10: hyporintense signal = 0, iso-intensesignal = 1, hyperintense signal = 2) had positive effect on EEF, original_shape_Maximum2DDiameterSlice(X13) had negative affect on EEF. The regression equation is: EEF = 14.901 + 58.177 X12 + 3.753 X11&3;0.26X13+ 3.089 X9 + 2.828 X10. The adjusted R2 of conventional MRI model and combined model were 0.144 and 0.297 respectively, and the two fitted model was statistically significant (P < 0.05). The Durbin Watson values of the two models were 2.007 and 1.958, respectively. The predicted EEF value of the combined model was 9.61 [3.60; 15.22] J / mm3, and the actual EEF value was 6.24 [3.40; 11.01] J / mm3, with the correlation coefficient r = 0.5.*Conclusions The prediction efficiency of the combined model is better than that of the conventional MRI model, and the radiomics parameters have important supplementary value for conventional MRI. There was moderate correlation between the predicted EEF of the combined prediction model and the actual EEF, which has a certain popularization value.*Clinical Relevance/Application Radiomics have important supplementary value for conventional MRI in predicting EEF of HIFU ablation uterine fibroids.

RESULTS

Conventional MRI and radiomics features combined model showed that wavelet _ HHH_ firstorder_ Skewness (X12), T1WI

enhancement (X11: mild = 0, moderate = 1, marked = 2), T2WI signal intensity (X9: hyporintense signal = 0, iso-intensesignal = 1, hyperintense signal = 2) and DWI signal intensity (X10: hyporintense signal = 0, iso-intensesignal = 1, hyperintense signal = 2) had positive effect on EEF, original_shape_Maximum2DDiameterSlice(X13) had negative affect on EEF. The regression equation is: EEF = 14.901 + 58.177 X12 + 3.753 X11&3;0.26X13+ 3.089 X9 + 2.828 X10. The adjusted R2 of conventional MRI model and combined model were 0.144 and 0.297 respectively, and the two fitted model was statistically significant (P < 0.05). The Durbin Watson values of the two models were 2.007 and 1.958, respectively. The predicted EEF value of the combined model was 9.61 [3.60; 15.22] J / mm3, and the actual EEF value was 6.24 [3.40; 11.01] J / mm3, with the correlation coefficient r = 0.5.

CLINICAL RELEVANCE/APPLICATION

Radiomics have important supplementary value for conventional MRI in predicting EEF of HIFU ablation uterine fibroids.

SDP-RI-3   Ultrasound-based Radiomics Score: A Potential Biomarker For The Prediction Of Progression-free Survival In Ovarian Epithelial Cancer

Participants
Yunjun Yang, Wenzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

More than eighty percent of the ovarian epithelial cancer (OEC) patients showed complete remissions after initial treatment but eventually experience recurrences of the disease. In this study, we aimed to develop a radiomics signature to found a new prognostic indicator based on preoperative ultrasound imaging.*Methods and Materials A total of 111 patients with OEC who underwent transvaginal ultrasound before surgery were included. Of these patients, 76 were divided into the training cohort and 35 to the test cohort. We defined the region of interest (ROI) of the tumor by manually drawing the tumor contour on the ultrasound image of the lesion. The radiomics features were extracted from ultrasound images. Constructing radiomics score (Rad-Score) was applied by Least absolute shrinkage and selection operator (LASSO) analysis and Cox regression. Combined with the ultrasound radiomics features, the significant clinical variables were also used to establish predictive models for 5-year progression-free survival (PFS) prediction. The efficiency of the models was evaluated by the area under the curve (AUC). Kaplan-Meier analysis was used to evaluate the association between the Rad-Score and PFS.*Results The combined model was superior to the clinical and Rad-Score models to estimate 5-year PFS, and achieved an AUC of 0.868 (95%CI: 0.766-0.971) in the training cohort. In the training and the test cohort, Rad-Score was negatively correlated with prognosis.*Conclusions The combined model which incorporated both clinical parameters and ultrasound radiomics features achieved a good performance for prognosis in patients with OEC.*Clinical Relevance/Application The combined model with clinical parameters and ultrasound radiomics features could aid in clinical decision-making.

RESULTS

The combined model was superior to the clinical and Rad-Score models to estimate 5-year PFS, and achieved an AUC of 0.868 (95%CI: 0.766-0.971) in the training cohort. In the training and the test cohort, Rad-Score was negatively correlated with prognosis.

CLINICAL RELEVANCE/APPLICATION

The combined model with clinical parameters and ultrasound radiomics features could aid in clinical decision-making.

SDP-RI-4   Ultrasound Image-based Radiomics To Predict Histologic Subtypes Of Epithelial Ovarian Cancer

Participants
Yunjun Yang, Wenzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Ovarian cancer is one of the most common causes of death in gynecological tumors, and epithelial ovarian cancer (EOC) is the most common category. In this study, we aimed to institute a radiomics signature based on the ultrasound images. And we would compare the performance of radiomics model, clinical model and combined model associating radiomics signature and clinical features in predicting histopathological types of EOC.*Methods and Materials A total of 265 patients with EOC who underwent transvaginal ultrasound before surgery were included. They were divided into a training cohort (n = 186) and a test cohort (n =79). We defined the region of interest (ROI) of the tumor by manually drawing the tumor contour on the ultrasound image of the lesion. The radiomics features were extracted from ultrasound images. Constructing radiomics score (Rad-Score) was applied by Least absolute shrinkage and selection operator (LASSO) analysis. clinical model was combined with the Rad-score model to establish a combined model. The efficiency of the models was evaluated by receiver operating characteristic curves (ROC), calibration curves and decision curve analysis (DCA).*Results The combined model was superior to the clinical and Rad-score models to predict histopathological types of EOC, and achieved an AUC of 0.83 (95%CI: 0.77-0.90) in the training cohort. And the calibration curve and DCA further confirmed the clinical usefulness of the combined model.*Conclusions The combined model which incorporated both clinical parameters and ultrasound radiomics features achieved a good performance in predicting histopathological types of EOC.*Clinical Relevance/Application The combined model with clinical features and ultrasound radiomics features might provide additional benefit to predict histopathological types of EOC.

RESULTS

The combined model was superior to the clinical and Rad-score models to predict histopathological types of EOC, and achieved an AUC of 0.83 (95%CI: 0.77-0.90) in the training cohort. And the calibration curve and DCA further confirmed the clinical usefulness of the combined model.

CLINICAL RELEVANCE/APPLICATION

The combined model with clinical features and ultrasound radiomics features might provide additional benefit to predict histopathological types of EOC.

SDP-RI-5   MRI Radiomics Analysis To Evaluate Clinical Risk For High-risk Patients With Placenta Accreta Spectrum

Participants
Caiting Chu, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the clinical risk assessment of MRI-radiomics based on sagittal FIESTA images in high-risk gravid patients suspected placenta accreta spectrum (PAS).*Methods and Materials From January 2013 and August 2019, a total of 131 patients suspected PAS, were included and data of them were analyzed retrospectively. The volume of interest (VOI) included suspected lesion in placenta and uterus was located and segmented on sagittal FIESTA-sequence. Image feature extraction and selection were performed via mRMR and LASSO. The radiomics model, clinical prediction model and clinical-radiomics combined model were respectively built via univariate or multivariate logistic regression analysis. A clinical-radiomics nomogram was built finally. Univariate associations of patient were analyzed by independent two-sample t test, chi-squared test via SPSS 23.0. Python was used to extract and select the radiomic features. Prediction model were performed with R software (version3.4.2, http://www.Rproject.org). Receiver operating characteristic (ROC) curve was performed to determine the performance of the model.*Results All the patients received cesarean delivery. There were 63 patients without PAS, 31 patients with placenta accreta (PA), 31 patients with Placenta increta (PI) and 6 patients with Placenta percreta (PP). Contrasted with a half of patients with PA needing manual removal placenta, all the patients with Placenta increta PI or PP needed manual removal placenta. In the group with patients of intraoperative hemorrhage (IPH)(=1000ml), the proportion of patients with PI (77.4%) or PP (100%) were more than the one of patients with PA (16.1%). The clinical model, radiomics model and clinical-radiomics combined model for predicting placenta stripping protocol and IPH were respectively built. According to ROC curve, the combined models for two predicting events were optimal. A clinical-radiomics nomogram was built with the selected clinical and radiomics features.*Conclusions The combined clinical-radiomics models can achieve a better performance for risk evaluation in high-risk patients of PAS.*Clinical Relevance/Application The clinical-radiomics nomogram as an individual and visualized tool can make the clinical benefit for high-risk patients of PAS.

RESULTS

All the patients received cesarean delivery. There were 63 patients without PAS, 31 patients with placenta accreta (PA), 31 patients with Placenta increta (PI) and 6 patients with Placenta percreta (PP). Contrasted with a half of patients with PA needing manual removal placenta, all the patients with Placenta increta PI or PP needed manual removal placenta. In the group with patients of intraoperative hemorrhage (IPH)(=1000ml), the proportion of patients with PI (77.4%) or PP (100%) were more than the one of patients with PA (16.1%). The clinical model, radiomics model and clinical-radiomics combined model for predicting placenta stripping protocol and IPH were respectively built. According to ROC curve, the combined models for two predicting events were optimal. A clinical-radiomics nomogram was built with the selected clinical and radiomics features.

CLINICAL RELEVANCE/APPLICATION

The clinical-radiomics nomogram as an individual and visualized tool can make the clinical benefit for high-risk patients of PAS.

SDP-RI-6   Evolution Of Early Post Therapy Apparent Diffusion Coefficient Values In Cervical Cancer: Opportunities For Image Guided Adaptive Radiotherapy

Participants
Megan Jacobsen, PhD, Houston, Texas (*Presenter*) Research Grant, Siemens AG

PURPOSE

Locally advanced cervical cancer poses therapeutic challenges due to potential inadequate tumor control for radiation resistant tumors and toxicity risks from combined chemoradiotherapy (CCRT). MR guided adaptive therapy may enable targeted dose escalation to radioresistant tumor subvolumes and dose de-escalation in responding tumors in the early treatment period. Quantitative biomarkers from diffusion weighted MR are advantageous for image guidance since acquisition does not require contrast agents, can be obtained rapidly, and is ubiquitous in routine patient exams. Prior work has correlated ADC values to tumor cellularity, grade and proliferation, with failure to increase tumor ADC after therapy associated with poor prognosis. The purpose of this study was to evaluate ADC histograms in patients undergoing CCRT prior to therapy and in the early treatment period, within the first 5 weeks of therapy.*Methods and Materials Ten cervical cancer patients who underwent definitive CCRT with MRI prior to and following external beam radiotherapy (EBRT) were retrospectively analyzed. Histogram features were calculated from volumes of interest (VOIs) contoured by an abdominal radiologist on ADC maps. Tumor volume and descriptive statistics for the ADC voxel data, including mean, median, standard deviation, quantiles, skewness, and kurtosis were compared using a paired t-test.*Results Post-CCRT scans were acquired an average of 40.6 days after baseline DWI. The average volume change was -48.8±50.2 cm3 (p = 0.01). Mean ADC was 1102.6±159.0 10-6 mm2/s and 1262.5±175.8 10-6 mm2/s (p = 0.03) pre-CCRT and post-CCRT, respectively. Skewness and kurtosis were 0.84±0.27 and 4.40±1.16 pre-CCRT and 0.34±0.38 and 3.69±0.50 post-CCRT (p = 0.005 and p = 0.03, respectively). All patient tumors decreased in volume, while the mean tumor ADC for three patients decreased.*Conclusions Cervical cancer CCRT results in statistically significant decreases in tumor volume and increases in mean ADC, ADC skewness and kurtosis within the first five weeks of therapy. Integration of tumor ADC segmentation into clinical workflow can facilitate future adaptive radiotherapy. Future work will evaluate ADC of viable tumor subvolumes over time and correlate histogram features with therapeutic response.*Clinical Relevance/Application The evolution of early post therapy ADC values in cervical cancer underscores the utility of DWI parameters in the development of individualized MRI guided adaptive radiotherapy regimens as evidenced by histogram profiling.

RESULTS

Post-CCRT scans were acquired an average of 40.6 days after baseline DWI. The average volume change was -48.8±50.2 cm3 (p = 0.01). Mean ADC was 1102.6±159.0 10-6 mm2/s and 1262.5±175.8 10-6 mm2/s (p = 0.03) pre-CCRT and post-CCRT, respectively. Skewness and kurtosis were 0.84±0.27 and 4.40±1.16 pre-CCRT and 0.34±0.38 and 3.69±0.50 post-CCRT (p = 0.005 and p = 0.03, respectively). All patient tumors decreased in volume, while the mean tumor ADC for three patients decreased.

CLINICAL RELEVANCE/APPLICATION

The evolution of early post therapy ADC values in cervical cancer underscores the utility of DWI parameters in the development of individualized MRI guided adaptive radiotherapy regimens as evidenced by histogram profiling.

SDP-RI-7   The Sonographic Appearance Of Endometrial Intraepithelial Neoplasia

Participants
Charlene Kwan, Los Angeles, California (*Presenter*) Nothing to Disclose

PURPOSE

Our goal is to describe US findings of EIN, a precursor of endometrial cancer.*Methods and Materials Cases were found by word search of pathology database 1/2013-6/2019. 176 patients who had US within 1 year prior to biopsy were included. Medical records were searched for patient data such as age, menopausal status, index ultrasound report, and quality of bleeding. Two radiologists independently and blindly classified images. Differences of opinion were decided by correlation with clinical interpretation. Univariate and multivariate analyses were performed.*Results Time between US and first sampling procedure was mean 49 days. Median age was 55 (range 28-85) years. Endometrial thickness ranged from 4-90 mm. Mean endometrial thickness was 12 + 6 mm in the noncancer group and 16 + 11 mm in the cancer group (p=.02). The endometrium was almost always heterogeneous 166/176 (94%). Cysts were almost always multiple (84/93, 90%) and >1 mm (71/93, 76%). Masses were most often > 5mm (52/101, 51%) or ill-defined (41/101, 41%). Vascularity was present in 92/106 patients (87%) and always associated with cysts and/or mass. Vascularity was most often single vessel (57/92, 62%). There were 93 cancers, 24 with invasion (including 4 with tumor extension into adenomyosis). In 48 cases the endometrial-myometrial interface was graded as ill-defined by one or both reviewers, 39 of whom had hysterectomy. There was macroscopic cancer in 10, microscopic cancer in 4, and invasive carcinoma in 13 patients (p for invasive cancer vs all other outcome = .02). EIN and/or endometrial cancer were confined to a polyp in 43 patients, with US findings similar to that of the cohort as a whole. Depth of invasion ranged from 10->95%, with 5 invasive cancers having depth of invasion of >50%. Multivariate analysis showed thickness, polyps, and type of bleeding as the best set of independent variables for cancer (AUC = .74). Replacing type of bleeding with age or menopausal status provides models with nearly identical performance. For invasive cancer with known outcome (hysterectomy), endometrial thickness and age are the best independent variables, with AUC of .79.*Conclusions EIN has a variety of sonographic appearances. It is associated with a thickened endometrium, even in postmenopausal women, with thickness ranging up to 90 mm. Cysts and masses are common. Ill-definition of the endometrial-myometrial interface is a poor prognostic finding.*Clinical Relevance/Application It is important for Radiologists to recognize the term EIN. In early stages it is focal, unlike simple hyperplasia. EIN has a variety of US appearances. Endometrial thickness and appearance of the endometrial-myometrial interface are important findings.

RESULTS

Time between US and first sampling procedure was mean 49 days. Median age was 55 (range 28-85) years. Endometrial thickness ranged from 4-90 mm. Mean endometrial thickness was 12 + 6 mm in the noncancer group and 16 + 11 mm in the cancer group (p=.02). The endometrium was almost always heterogeneous 166/176 (94%). Cysts were almost always multiple (84/93, 90%) and >1 mm (71/93, 76%). Masses were most often > 5mm (52/101, 51%) or ill-defined (41/101, 41%). Vascularity was present in 92/106 patients (87%) and always associated with cysts and/or mass. Vascularity was most often single vessel (57/92, 62%). There were 93 cancers, 24 with invasion (including 4 with tumor extension into adenomyosis). In 48 cases the endometrial-myometrial interface was graded as ill-defined by one or both reviewers, 39 of whom had hysterectomy. There was macroscopic cancer in 10, microscopic cancer in 4, and invasive carcinoma in 13 patients (p for invasive cancer vs all other outcome = .02). EIN and/or endometrial cancer were confined to a polyp in 43 patients, with US findings similar to that of the cohort as a whole. Depth of invasion ranged from 10->95%, with 5 invasive cancers having depth of invasion of >50%. Multivariate analysis showed thickness, polyps, and type of bleeding as the best set of independent variables for cancer (AUC = .74). Replacing type of bleeding with age or menopausal status provides models with nearly identical performance. For invasive cancer with known outcome (hysterectomy), endometrial thickness and age are the best independent variables, with AUC of .79.

CLINICAL RELEVANCE/APPLICATION

It is important for Radiologists to recognize the term EIN. In early stages it is focal, unlike simple hyperplasia. EIN has a variety of US appearances. Endometrial thickness and appearance of the endometrial-myometrial interface are important findings.

SDP-RI-8   Feasibility Of A Magnetic Resonance Imaging-based Radiomics Model For Predicting Deep Stromal Invasion In Patients With Early-stage Cervical Squamous Cell Carcinoma

Participants
Jing Ren, MD,MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the prediction value of a clinical-radiomics model based on T2-weighted magnetic resonance imaging (MRI) for predicting deep stromal invasion (DSI) in patients with early-stage cervical squamous cell carcinoma (CSCC).*Methods and Materials A total of 168 patients with IB1-IIA1 CSCC who underwent radical hysterectomy from January 2017 to February 2021 were enrolled and randomly divided into a training cohort (n = 135) and a validation cohort (n = 33). Radiomics features were extracted from preoperative sagittal T2-weighted images. Significance testing, Pearson's correlation analysis, and Least absolute shrinkage and selection operator was applied for key features selection. Significance testing and multivariate analysis were performed on the clinical parameters to determine the independent risk factors for DSI. A radiomics model and a clinical-radiomics model were developed by logistic regression. Nomogram was developed to facilitate ease of clinical application.*Results Four radiomics features and two clinical parameters (FIGO stage and preoperative squamous cell carcinoma antigen levels) were selected and used to develop models. In validation cohort, the radiomics model and clinical-radiomics model showed an area under the curve, sensitivity, and specificity of 0.793(95% CI: 0.633-0.954), 71.4%, and 84.2%, 0.820 (95% CI: 0.665-0.974), 85.7%, and 73.7%, respectively.*Conclusions The presented clinical-radiomics model can be used for preoperative prediction of DSI in patients with early-stage CSCC.*Clinical Relevance/Application The clinical-radiomics model, which could predict deep stromal invasion, may aid clinicians predict prognosis and select optimal therapies (radical surgery or definitive radiotherapy) for early-stage CSCC.

RESULTS

Four radiomics features and two clinical parameters (FIGO stage and preoperative squamous cell carcinoma antigen levels) were selected and used to develop models. In validation cohort, the radiomics model and clinical-radiomics model showed an area under the curve, sensitivity, and specificity of 0.793(95% CI: 0.633-0.954), 71.4%, and 84.2%, 0.820 (95% CI: 0.665-0.974), 85.7%, and 73.7%, respectively.

CLINICAL RELEVANCE/APPLICATION

The clinical-radiomics model, which could predict deep stromal invasion, may aid clinicians predict prognosis and select optimal therapies (radical surgery or definitive radiotherapy) for early-stage CSCC.

SDP-RI-9   Rethinking The Sonographic Assessment Of Endometrial Polyps

Participants
Cinthia Cruz, MD, Newton, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Determine the prevalence and associations of sonographic features accepted as conventional wisdom, in the diagnosis of endometrial polyps in premenopausal women.*Methods and Materials Consecutive pelvic ultrasounds performed in premenopausal and perimenopausal women between 2018 and 2020 in a single tertiary institution. Inclusion: LMP within the last year as well as hysteroscopy and/or two sonohysterography (SHG) within 1 year. Exclusion criteria: no ultrasound findings, instrumentation or pregnancy within 6 months, concurrent gynecologic or breast malignancy, hormonal replacement therapy, Tamoxifen usage and uterine fibroids. Polyps confirmed through biopsy or repeated visualization of a well-defined, polypoid lesion isoechoic to the endometrium or hyperechoic with attachment to the endometrial-myometrial interphase, on separate SHGs. After a literature review, the most frequent sonographic features in the diagnosis of polyps were identified as: a) Well defined focal avascular echogenic lesion b) Focal vascularity within the endometrium seen on 2 incidences, c) Myometrial-endometrial vessel and d) Heterogenous endometrium. Endometrial thickness was recorded. Statistical analysis used Fisher's exact test.*Results Of 108 patients, 27 were excluded (including 2 with malignant cells). Average age: 41±11 years. 54/81 patients (65.1%) had confirmed polyps and one or more of the features: 38/54 had myometrial-endometrial vessel (p for polyps vs. non-polyps=0.05); 33/54 had focal vascularity in the endometrium (p=0.81); 29/54 had focal avascular echogenic lesion (p=0.085) and 13/54 had heterogeneous endometrium (p=0.58). Average endometrial thickness was 9 mm, with higher thickness significantly associated with the presence of polyps, median of 9 mm with polyps vs 7 mm without (p=0.034).*Conclusions Focal vascularity confined to the endometrium is not a reliable characteristic for the diagnosis of polyps, contradicting accepted wisdom. Whereas myometrial-endometrial vessel is. Endometrial thickness is associated with the presence of polyps, however other endometrial lesions such as cancer were excluded from analysis and further analysis that accounts for menstrual phase is needed.*Clinical Relevance/Application Because of low incidence of cancer in premenopausal women, ultrasound enables triage of premenopausal women who have features suggestive of polyps to the appropriate means of endometrial sampling. Identifying US features that are most associated with polyps, particularly the difference between vascularity limited to the endometrium and that extending along the myometrial-endometrial interphase, is highly important to reduce unnecessary biopsies and overdiagnosis.

RESULTS

Of 108 patients, 27 were excluded (including 2 with malignant cells). Average age: 41±11 years. 54/81 patients (65.1%) had confirmed polyps and one or more of the features: 38/54 had myometrial-endometrial vessel (p for polyps vs. non-polyps=0.05); 33/54 had focal vascularity in the endometrium (p=0.81); 29/54 had focal avascular echogenic lesion (p=0.085) and 13/54 had heterogeneous endometrium (p=0.58). Average endometrial thickness was 9 mm, with higher thickness significantly associated with the presence of polyps, median of 9 mm with polyps vs 7 mm without (p=0.034).

CLINICAL RELEVANCE/APPLICATION

Because of low incidence of cancer in premenopausal women, ultrasound enables triage of premenopausal women who have features suggestive of polyps to the appropriate means of endometrial sampling. Identifying US features that are most associated with polyps, particularly the difference between vascularity limited to the endometrium and that extending along the myometrial-endometrial interphase, is highly important to reduce unnecessary biopsies and overdiagnosis.

CA03-A2   **Cardiac Imaging Findings In Rosai-Dorfman Disease: A Systematic Review**

Participants
Daniel Vargas-Zapata, MD, San Antonio, Texas (*Presenter*) Nothing to Disclose

PURPOSE

Rosai-Dorfman disease (RDD), also known as "Sinus Histiocytosis with Massive Histiocytosis", is an uncommon benign histiocytic lymphoproliferative disease of unknown etiology. This study aims to evaluate the clinical presentation and most typical cardiac imaging findings in patients with RDD collected from 2 participant medical centers along with those reported in the literature so far.*Methods and Materials A total of 5 cases of RDD with cardiac manifestations were collected across the 2 participant institutions. Imaging modalities included CT, MRI, PET/CT and echocardiogram. Additionally, a PubMed literature search provided 27 additional cases. The cardiac and extra-cardiac imaging findings as well as relevant clinical history were reviewed.*Results Of the 32 cases of RDD, distribution among males and females was 1:1 with ages ranging from 12 to 79 years (mean = 45.1). The most commonly involved structure was the Right atrium (n = 43.75%), followed by the Aorta (34.4%) and the Pulmonary artery (25%). Most cases demonstrated involvement of multiple cardiac structures (65.6%), however, only 37.5% showed synchronous extra-cardiac manifestations. No significant associated comorbidities were found (50% had no comorbidities).*Conclusions Aside from the usual manifestations of RDD with massive lymphadenopathy being the most frequent, the heart may also be involved in some cases. When present, the most common cardiac manifestation of RDD is that of a homogenously enhancing endoluminal infiltrative soft tissue mass, mostly found within either the Right atrium, Aorta, or Pulmonary artery. The latter, may mimic a Pulmonary artery angiosarcoma. Additionally, pericardial involvement can also be found in some cases manifesting as pericardial thickening and/or effusion.*Clinical Relevance/Application Although, cardiac involvement from RDD has been reported, to our understanding, this is the largest cohort of patients with cardiac manifestations of RDD in which imaging findings have been described up to the date. The data collected in this study contributes to a better understanding of the potential cardiac imaging characteristics in patients with this condition. Even though RDD tends to have a benign course, if severe involvement of vital organs such as the heart are present, fatal outcomes may be encountered. Thus, in these cases, a multidisciplinary approach is warranted for appropriate selection of management options with radiology playing a pivotal role on ruling out potential mimics and excluding involvement of adjacent vital strcutures.

RESULTS

Of the 32 cases of RDD, distribution among males and females was 1:1 with ages ranging from 12 to 79 years (mean = 45.1). The most commonly involved structure was the Right atrium (n = 43.75%), followed by the Aorta (34.4%) and the Pulmonary artery (25%). Most cases demonstrated involvement of multiple cardiac structures (65.6%), however, only 37.5% showed synchronous extra-cardiac manifestations. No significant associated comorbidities were found (50% had no comorbidities).

CLINICAL RELEVANCE/APPLICATION

Although, cardiac involvement from RDD has been reported, to our understanding, this is the largest cohort of patients with cardiac manifestations of RDD in which imaging findings have been described up to the date. The data collected in this study contributes to a better understanding of the potential cardiac imaging characteristics in patients with this condition. Even though RDD tends to have a benign course, if severe involvement of vital organs such as the heart are present, fatal outcomes may be encountered. Thus, in these cases, a multidisciplinary approach is warranted for appropriate selection of management options with radiology playing a pivotal role on ruling out potential mimics and excluding involvement of adjacent vital strcutures.

CA03-A4   **4D-flow MRI Is Knocking At More Doors:**
How To Properly Analyze 3D Blood Flow Dynamics In A Fast, Patient- And Technologist-friendly, Full-chest Sequence

Participants
Maurice Pradella, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

TEACHING POINTS

A proposed clinical 4D-Flow MRI sequence allows acquisition of the complete vasculature of the chest in a total of 10-15min scan time without respiratory navigation. This allows qualitative and quantitative evaluation of any larger thoracic vessel's blood flow dynamics post hoc using commercially available software (e.g., cvi42, Circle, Canada). This exhibit summarizes aspects to consider for successful clinically implementation with valid and reproducible results. Key topics include: 1) how to perform image acquisition, 2) how to prepare the 4D-Flow MRI dataset for analysis, 3) how to quantify the aortic and pulmonary blood flow, and 4) identify pitfalls in order to further avoid them.

TABLE OF CONTENTS/OUTLINE

This exhibit will demonstrate a suggested methodology for acquiring and analyzing a 4D-Flow dataset of the whole chest. It will include: 1) basic principles of an easy to use 4D-Flow MRI sequence covering the whole chest, 2) pre-processing the dataset

(noise reduction, Eddy current correction, anti-aliasing), 3) post-processing of the target vessels for dataset analysis (thresh holding, dataset clean up), 4) how to measure blood flow in a 4D dataset in the thoracic aorta, 6) and in the pulmonary artery, 7) pitfalls in data pre- and post-processing and 8) pitfalls 4D-Flow quantification (vortical flow, valve disease)

RO03-A1   **Magnetic Resonance Imaging-guided Focused Ultrasound Hyperthermia Sensitize Prostate Cancer To Radiation Therapy In Xenograft Mice Model**

Participants
Andreas Melzer, MD, DDS, Dundee, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

Focused ultrasound (FUS) has been used in clinic for ablation of uterine fibroids, prostate cancer and essential tremor under magnetic resonance (MR) imaging guidance. FUS-induced hyperthermia (FUS-HT) carries potential rto become adjuvant therapy to other treatment modalities. In this study, we investigated the sensitization effect of FUS-HT to radiation therapy (RT) in a xenograft model of prostate cancer using a new developed preclinical in vivo FUS system.*Methods and Materials A novel MR-compatible phased-array transducer (Fraunhofer IBMT) was developed and installed in a 7T preclinical MRI (Bruker, Pharmascan 7T). The xenograft model of prostate cancer was established by subcutaneous injection of PC-3 cells, tumor-bearing mice were anesthetized with 2% isoflurane before and during treatment. FUS-HT treatment was performed at 2MHz with adjusted power ($\sim$ 4.8W/cm2) to keep the temperature at 45°C for 30min. The real-time temperature was monitored by fiber optics (Luxtron) and MR-thermometry was visualized offline in MATLAB. RT was conducted with a single-dose X-ray at 10Gy (XStrahl Medical). Tumor growth, proliferation and apoptosis were evaluated by H&E staining, immunohistochemistry of ki67 and TUNEL assay with 40 days follow-up, respectively.*Results The combination of FUS-HT and RT leads to a reduction of the tumor nucleoli and increased survival compared to the untreated group without obvious damage to healthy organs. Decreased ki67-positive cells after FUS-HT+RT (7.85 %) treatment indicated inhibition of tumor proliferation in comparison to single RT (59.37 %). Apoptosis effect was enhanced in FUS-HT+RT group showing increased fluorescence surface area compared to single treatment.*Conclusions This study showed the feasibility of non-invasive FUS-HT interventions in a preclinical MR system. Histology results demonstrated that FUS-induced hyperthermia has an additive effect to RT in vivo.*Clinical Relevance/Application FUS ablation has been approved as a clinical treatment for prostate cancer, however, the application of FUS-hyperthermia is not sufficiently investigated yet. We provided the fundamental data in an in vivo study showing the potential of FUS-HT in future clinical applications.

RESULTS

The combination of FUS-HT and RT leads to a reduction of the tumor nucleoli and increased survival compared to the untreated group without obvious damage to healthy organs. Decreased ki67-positive cells after FUS-HT+RT (7.85 %) treatment indicated inhibition of tumor proliferation in comparison to single RT (59.37 %). Apoptosis effect was enhanced in FUS-HT+RT group showing increased fluorescence surface area compared to single treatment.

CLINICAL RELEVANCE/APPLICATION

FUS ablation has been approved as a clinical treatment for prostate cancer, however, the application of FUS-hyperthermia is not sufficiently investigated yet. We provided the fundamental data in an in vivo study showing the potential of FUS-HT in future clinical applications.

CH01-B1 Likelihood Ratios Of A Semantic Feature Library For Assessing The Risk Of Cancer In Pulmonary Nodules

Participants
Wei Wu, MD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

Likelihood ratios (LR) help interpret the significance of radiological findings. However, the likelihood ratio hierarchy of semantic features for malignancy in pulmonary nodules summarized 20 years ago has become outdated due to the CT technology development. Furthermore, semantic features including spiculation has not been formally defined, which leads to highly variable diagnostic accuracy in radiologists' actual recommendations. Our goal is to evaluate and compare the likelihood ratios for malignancy of a comprehensive list of well-defined semantic features.*Methods and Materials This retrospective study enrolled 498 patients from a lung cancer early detection and prevention program in our institution. Nodule malignancy was confirmed by histopathology while benignity was confirmed by histopathology, 2-year stability, or resolution. In total, 54 semantic features in 10 categories including nodule count, location, size, margin, density, invasiveness, lymphadenopathy, emphysema, fibrosis and asbestosis, were defined through consensus method by two radiologists. A thoracic radiologist blinded to clinical and histologic findings evaluated the presence or absence of these features, and the positive LR (LR+) of these features were computed.*Results There were 246 patients with malignant pulmonary nodules and 252 patients with benign nodules. The semantic features with the largest effects on the post-test probability of malignancy were: 'size of less than 6 mm' with LR+ of 0.02 (95%CI: 0.01-0.09), 'smooth margin' with LR+ of 0.04 (95%CI: 0.01-0.09), 'spiculation' with LR+ of 28.7 (95%CI: 7.1-116.3), 'corona radiata' with LR+ of 25.6 (95%CI: 3.5-187.5), 'invasion into pleura or fissure' with LR+ of 18.4 (95%CI: 5.8-58.2), 'pseudo-cavitation' with LR+ of 12.3 (95%CI: 1.6-93.8).*Conclusions The diagnostic value of semantic features in pulmonary nodule classification can be compared and easily understood by using the LR for malignancy to assist radiologists and providers with assessing patients' lung cancer risk.*Clinical Relevance/Application A standardized library of semantic feature LRs may assist with provider management of nodule cancer risk and predictive modeling.

RESULTS

There were 246 patients with malignant pulmonary nodules and 252 patients with benign nodules. The semantic features with the largest effects on the post-test probability of malignancy were: 'size of less than 6 mm' with LR+ of 0.02 (95%CI: 0.01-0.09), 'smooth margin' with LR+ of 0.04 (95%CI: 0.01-0.09), 'spiculation' with LR+ of 28.7 (95%CI: 7.1-116.3), 'corona radiata' with LR+ of 25.6 (95%CI: 3.5-187.5), 'invasion into pleura or fissure' with LR+ of 18.4 (95%CI: 5.8-58.2), 'pseudo-cavitation' with LR+ of 12.3 (95%CI: 1.6-93.8).

CLINICAL RELEVANCE/APPLICATION

A standardized library of semantic feature LRs may assist with provider management of nodule cancer risk and predictive modeling.

CH01-B2 AI-aided Diagnosis On The Performance Of Radiologists To Diagnose Lung Nodule Malignancy: A Sequential Reader Study

Participants
Eun Kyoung Hong, MD, Gwangmyeong-Si, Korea, Republic Of (*Presenter*) Research Consultant, VUNO Inc

PURPOSE

To evaluate whether an AI-aided diagnosis system can improve the performance of readers for the diagnosis of malignant lung nodules*Methods and Materials A total of 150 CT scans containing benign nodules and 50 CT scans containing malignant nodules were randomly selected from the NLST dataset. An AI system consisting of 1) characterization of lung nodules (diameter, volume, type, 4X findings) and 2) multivariate logistic regression model for prediction of nodule malignancy was used. The most suspicious malignant nodule was selected for each scan based on the automatically calculated Lung-RADS category from the AI system, and the coordinates were recorded. The system processed each nodule and the binary malignancy classification was performed prior to the reader study. Two experienced radiologists participated in the reader study. Each radiologist first diagnosed each representative nodule without the AI output. And immediately after, they again diagnosed the nodules with reference to AI output. The readers were asked to grade the malignancy probability of the nodule on a five-point scale. (1: mostly benign, 5: mostly malignant) The score was then binarized using the score 3 threshold to compare with binary AI output (less than 3: benign, otherwise malignant).*Results A total of 194 nodules were selected (49 malignant and 145 benign). Without AI as a reference, the performances of reader 1 and 2 were as follows; For reader 1, AUC, sensitivity, and specificity were 0.820, 0.986, and 0.653, respectively. And for reader 2, AUC, sensitivity, and specificity were 0.803, 0.993, and 0.769, respectively. With reference to AI output, the performance of reader 1 and reader 2 was as follows; For reader 1, AUC, sensitivity and specificity 0.891, 0.986, and 0.795. And for reader 2, AUC, sensitivity, and specificity were 0.857, 0.979, and 0.735. In the comparison of without and with AI as a reference, both readers demonstrated improvements in terms of AUC, however, only reader 1 showed statistical significance in AUC by 0.0714 (p = 0.005).*Conclusions From the reader study, readers with CADx output showed a promising improvement of performance on the diagnosis of lung nodule malignancy.*Clinical Relevance/Application The result implies that the computer-aided

diagnosis has the potential to improve the rate of correct diagnosis of malignancy without exaggerating patient harm from overdiagnosis.

RESULTS

A total of 194 nodules were selected (49 malignant and 145 benign). Without AI as a reference, the performances of reader 1 and 2 were as follows; For reader 1, AUC, sensitivity, and specificity were 0.820, 0.986, and 0.653, respectively. And for reader 2, AUC, sensitivity, and specificity were 0.803, 0.993, and 0.769, respectively. With reference to AI output, the performance of reader 1 and reader 2 was as follows; For reader 1, AUC, sensitivity and specificity 0.891, 0.986, and 0.795. And for reader 2, AUC, sensitivity, and specificity were 0.857, 0.979, and 0.735. In the comparison of without and with AI as a reference, both readers demonstrated improvements in terms of AUC, however, only reader 1 showed statistical significance in AUC by 0.0714 (p = 0.005).

CLINICAL RELEVANCE/APPLICATION

The result implies that the computer-aided diagnosis has the potential to improve the rate of correct diagnosis of malignancy without exaggerating patient harm from overdiagnosis.

CH01-B4 Automated Radiographic Quantification Of COVID-19 Pneumonia As A Prognostic Marker Of Outcomes - A One Year Experience

Participants
Abraham Noorbakhsh, MD,MPH, San Diego, California (*Presenter*) Nothing to Disclose

PURPOSE

Chest x-ray (CXR) emerged as an inexpensive and pervasive tool in the triage of COVID-19 patients with suspected lung involvement. We assessed the prognostic value of a deep learning algorithm to quantify pneumonia for patients with COVID-19 presenting to the Emergency Department (ED) over the first year of the pandemic.*Methods and Materials We retrospectively obtained CXRs and clinical data for patients positive for COVID-19 by RT-PCR who presented to the ED at our institution between March 2020 to January 2021. Using a previously developed convolutional neural network (CNN) algorithm, percentage of lung involvement was quantified for all patients who underwent CXR within five days before to one day after date of presentation, and stratified into four categories (0%, 1-25%, 26-50%, and >50%). Primary outcome was progression to severe COVID-19, defined as a composite of ICU admission, discharge to hospice, or death. Kaplan-Meier survival curves and multivariate Cox regression were used for analyses. Clinical factors included in models were age, gender, initial O2 saturation % and initial heart rate.*Results Of 1,682 confirmed COVID-19 positive patients presenting to the ED, 1,254 (75%) had an initial CXR and were included. Mean age was 54 years, 65% were admitted, and 23% developed severe COVID-19. The probability of progression to severe COVID-19 at 1 week, stratified by categories of percentage of lung involvement (0%, 1-25%, 26-50%, and >50%) on initial CXR was 6%, 12%, 15%, and 43% respectively (log-rank p<0.001). On adjusted analyses, the adjusted hazard ratios (HR) for severe outcome increased with increasing lung involvement: HR (95% confidence interval) 1.4 (0.9-2.3, p=0.128) for 1-25%, 2.1 (1.3-3.4, p=0.004) for 26-50%, and 5.4 (3.4-8.4, p<0.001) for >50%, relative to patients with no pneumonia.*Conclusions Automated deep learning quantification of pneumonia on initial CXR strongly prognosticates disease course in patients presenting to the ED with COVID-19.*Clinical Relevance/Application An automated deep learning algorithm can assess severity of lung involvement and prognosticate outcomes in patients with COVID-19, and may support rapid triage of patients presenting to the ED.

RESULTS

Of 1,682 confirmed COVID-19 positive patients presenting to the ED, 1,254 (75%) had an initial CXR and were included. Mean age was 54 years, 65% were admitted, and 23% developed severe COVID-19. The probability of progression to severe COVID-19 at 1 week, stratified by categories of percentage of lung involvement (0%, 1-25%, 26-50%, and >50%) on initial CXR was 6%, 12%, 15%, and 43% respectively (log-rank p<0.001). On adjusted analyses, the adjusted hazard ratios (HR) for severe outcome increased with increasing lung involvement: HR (95% confidence interval) 1.4 (0.9-2.3, p=0.128) for 1-25%, 2.1 (1.3-3.4, p=0.004) for 26-50%, and 5.4 (3.4-8.4, p<0.001) for >50%, relative to patients with no pneumonia.

CLINICAL RELEVANCE/APPLICATION

An automated deep learning algorithm can assess severity of lung involvement and prognosticate outcomes in patients with COVID-19, and may support rapid triage of patients presenting to the ED.

CH01-B5 External Validation Of CORADS-AI To Triage COVID-19 Patients Requiring Immediate Hospitalization In The Moscow Region

Participants
Steven Schalekamp, MD, Nijmegen, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

External validation of CORADS-AI to automatically flag patients with severe coronavirus disease (COVID-19) lung disease on CT for immediate hospitalization and comparison with human reading.*Methods and Materials In the Moscow region 1110 COVID-19 suspects in 42 outpatient clinics between March 1 and April 25 2020 received chest CT upon admission. Scans were scored prospectively for severity of COVID-19 induced pneumonia by the on-site physician and an expert radiologist using the following scoring system: 0 (normal), 1 (mild), 2 (moderate), 3 (severe), 4 (very severe). Cases with score 3 and 4 were immediately hospitalized. CORADS-AI, an artificial intelligence system developed in The Netherlands, was used to generate for each case of the full dataset the CT severity score (CTSS, range 0-25), reflecting the percentage of involved lung tissue in COVID-19 pneumonia. Two radiologists in The Netherlands and two radiologists in Moscow, Russia read a subset of the CT scans in a reader study, including all cases of score 3 (45) and score 4 (2) and randomly selected cases of score 0, 1, 2 (in total 133). Area under the receiver operating characteristics curve (AUC) with 95% confidence intervals (95%CI) was used to assess performance. AUC of radiologists were statistically compared with the AUC of the AI system using MedCalc Software Ltd (Ostend, Belgium; v14.8.1). P<0.05 were considered significant.*Results CORADS-AI achieved an AUC of 0.90 (95%CI 0.86-0.94) on the full dataset of 1110 CT scans. Optimal performance was achieved at a CTSS threshold of 5 giving a sensitivity of 77% and a specificity of 87%. In the reader study subset, CORADS-AI reached an AUC of 0.89 (95%CI 0.84-0.94), and was similar or significantly better than the participating radiologists that achieved an AUC of 0.78 (95%CI 0.72-0.84; p<0.001), 0.83 (95%CI 0.77-0.89; p=0.004), 0.87 (95%CI 0.84-0.94; p=0.02), 0.89 (95%CI 0.79-0.91; p=0.99).*Conclusions In a pandemic, CO-RADS-AI could be used for first-line screening of patients who require immediate hospitalization for severe COVID-19 lung disease.*Clinical Relevance/Application CO-RADS AI can be a helpful tool in clinical decision making on hospitalization of patients with COVID-19 based on chest CT upon admission.

RESULTS

CORADS-AI achieved an AUC of 0.90 (95%CI 0.86-0.94) on the full dataset of 1110 CT scans. Optimal performance was achieved at a CTSS threshold of 5 giving a sensitivity of 77% and a specificity of 87%. In the reader study subset, CORADS-AI reached an AUC of 0.89 (95%CI 0.84-0.94), and was similar or significantly better than the participating radiologists that achieved an AUC of 0.78 (95%CI 0.72-0.84; p<0.001), 0.83 (95%CI 0.77-0.89; p=0.004), 0.87 (95%CI 0.84-0.94; p=0.02), 0.89 (95%CI 0.79-0.91; p=0.99).

CLINICAL RELEVANCE/APPLICATION

CO-RADS AI can be a helpful tool in clinical decision making on hospitalization of patients with COVID-19 based on chest CT upon admission.

IR05-B1   Utility Of The 2-hour Radiograph In The Prevention Of Delayed Post-Discharge Pneumothorax Following Lung Biopsy

Participants
Elton Law, MD, Hamilton, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

Post-biopsy pneumothorax is a clinically concerning complication of image-guided lung biopsies. In our institution, all patients receive a chest radiograph 1 hour post-lung biopsy to exclude a significant pneumothorax. The purpose of this study is to evaluate the utility of an additional radiograph performed 2 hours post-biopsy following resumption of normal activity for the prevention of delayed post-discharge pneumothorax.*Methods and Materials All CT-guided lung biopsies performed at our institution from January 1, 2017 - April 30, 2020 were reviewed. Cases were excluded if a pneumothorax was detected on intra-procedural imaging. All included patients received a 1 hour post-biopsy radiograph (1HR). Some patients received 2 hour a radiograph (2HR) if they had a negative 1HR study.*Results A total of 900 cases were included in the analysis. The 1HR group had 782 cases, while the 2HR group had 118 cases. A post-biopsy pneumothorax was detected in 81 cases, 74 (91%) were detected in the 1HR group, 31 of which required a chest tube. Seven (9%) cases of pneumothorax were seen only in the 2HR group, with 4 (57%) requiring a chest tube. Nine post-discharge pneumothoraces occurred in the 1HR group; these were detected a median of 86 hours (range 23-193) post-discharge. Of these, 5 (56%) required a chest tube. No post-discharge pneumothorax was found in the 2HR group.The baseline characteristics significantly associated with the development of a pneumothorax were age > 60 (p < 0.01), presence of emphysema in the same lobe as the lesion (p <0.01), lesion location in the upper lobes (p < 0.01), and lesion distance > 3 cm from the pleura (p<0.01).*Conclusions An additional radiograph at 2 hours post-lung biopsy, following an hour of normal activity, identified additional pneumothoraces and prevented delayed post-discharge pneumothoraces.*Clinical Relevance/Application Currently, there is a relative paucity of data with regards to post-lung biopsy imaging in the detection of pneumothoraces. Our findings can be used to help craft a more standardized post-lung biopsy patient care protocol to reduce the risk of a delayed pneumothorax and improve patient safety.

RESULTS

A total of 900 cases were included in the analysis. The 1HR group had 782 cases, while the 2HR group had 118 cases. A post-biopsy pneumothorax was detected in 81 cases, 74 (91%) were detected in the 1HR group, 31 of which required a chest tube. Seven (9%) cases of pneumothorax were seen only in the 2HR group, with 4 (57%) requiring a chest tube. Nine post-discharge pneumothoraces occurred in the 1HR group; these were detected a median of 86 hours (range 23-193) post-discharge. Of these, 5 (56%) required a chest tube. No post-discharge pneumothorax was found in the 2HR group.The baseline characteristics significantly associated with the development of a pneumothorax were age > 60 (p < 0.01), presence of emphysema in the same lobe as the lesion (p <0.01), lesion location in the upper lobes (p < 0.01), and lesion distance > 3 cm from the pleura (p<0.01).

CLINICAL RELEVANCE/APPLICATION

Currently, there is a relative paucity of data with regards to post-lung biopsy imaging in the detection of pneumothoraces. Our findings can be used to help craft a more standardized post-lung biopsy patient care protocol to reduce the risk of a delayed pneumothorax and improve patient safety.

IR05-B4   Safety And Efficacy Of Rotational Thrombectomy For Treatment Infrarenal Arterial Occlusions In A Large Single-center Cohort.

Participants
Christoph Artzner, Tuebingen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the safety and efficacy of rotational thrombectomy (RT) for treatment infrarenal arterial occlusions in a large single center-cohort.*Methods and Materials This HIPPA-compliant, IRB-approved, retrospective study included 397 consecutive interventions in 294 patients between April 2010 and December 2019. All patients underwent RT (Rotarex®S, Straub Medical AG) for infrarenal occlusions of native arteries, arterial stents, and/or bypass grafts. Complications, clinical success, and technical success were assessed by the clinical documentation system. P-values <0.05 were regarded significant.*Results Symptoms were acute, subacute, and chronic in 47.5%, 22.2%, and 30.3% or patients, respectively. Rutherford categories three (23.5%) and four (32.1%) were most prevalent. Target lesions were in the pelvic 7.1%, pelvic/femoral 5%; femoral 59.4%, femoral / below-the-knee (BTK) 27%, and BTK arteries 1.5%. Target lesion characteristics were: length >20 cm 61.5%, after bypass surgery 14.9%, and previous stenting 41.4%. RT device size was 6F 88.6% and 8F 11.4%. Additional lysis after RT was necessary in 24.2% of cases. Subsequent plain balloon or drug-coated balloon angioplasty was performed in 89.5% of cases. Technical and clinical success rates were 90.9% and 90.4%, respectively, with an improvement of ankle-brachial-index from 0.33±0.29 to 0.81±0.25 (p<0.01). Symptom-free walking distance of more than 200m was reported in 78.1% of cases after treatment. Complications occurred in 38.8% of cases with peripheral embolization being most common at 22.4%, of which 65.2% required further treatment. Dissections and perforations occurred less frequently in 9.6% and 2.7% of cases, respectively. RT demonstrated an over-all complication rate

of 6.8%. Of note, dissections that occurred while recanalizing chronic total occlusions were also classified as complication though it might be inevitable.*Conclusions Rotational thrombectomy is a safe and efficacious procedure for the treatment of acute, subacute, and chronic thrombotic occlusion of native arteries, arterial stents, and/or bypass grafts.*Clinical Relevance/Application Rotational thrombectomy is an important/bail-out treatment strategy for a patient with contraindication for lysis. Rotational thrombectomy shows excellent value for acute, subacute, and chronic occlusions. Our data show a good safety profile for rotational thrombectomy in a large cohort.

RESULTS

Symptoms were acute, subacute, and chronic in 47.5%, 22.2%, and 30.3% or patients, respectively. Rutherford categories three (23.5%) and four (32.1%) were most prevalent. Target lesions were in the pelvic 7.1%, pelvic/femoral 5%; femoral 59.4%, femoral / below-the-knee (BTK) 27%, and BTK arteries 1.5%. Target lesion characteristics were: length >20 cm 61.5%, after bypass surgery 14.9%, and previous stenting 41.4%. RT device size was 6F 88.6% and 8F 11.4%. Additional lysis after RT was necessary in 24.2% of cases. Subsequent plain balloon or drug-coated balloon angioplasty was performed in 89.5% of cases. Technical and clinical success rates were 90.9% and 90.4%, respectively, with an improvement of ankle-brachial-index from 0.33±0.29 to 0.81±0.25 (p<0.01). Symptom-free walking distance of more than 200m was reported in 78.1% of cases after treatment. Complications occurred in 38.8% of cases with peripheral embolization being most common at 22.4%, of which 65.2% required further treatment. Dissections and perforations occurred less frequently in 9.6% and 2.7% of cases, respectively. RT demonstrated an over-all complication rate of 6.8%. Of note, dissections that occurred while recanalizing chronic total occlusions were also classified as complication though it might be inevitable.

CLINICAL RELEVANCE/APPLICATION

Rotational thrombectomy is an important/bail-out treatment strategy for a patient with contraindication for lysis. Rotational thrombectomy shows excellent value for acute, subacute, and chronic occlusions. Our data show a good safety profile for rotational thrombectomy in a large cohort.

IR05-B5   **Immunonutritive Scoring In Patients With Hepatocellular Carcinoma Undergoing Transarterial Chemoembolisation: Prognostic Nutritional Index Or Controlling Nutritional Status Score?**

Participants
Lukas Mueller, MD, Mainz, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Both immunonutritive scoring systems, the Prognostic Nutritional Index (PNI) and the Controlling Nutritional Status (CONUT) score, proved their predictive ability in various cancer entities, including hepatocellular carcinoma (HCC). This study aimed to perform the first evaluation of the CONUT score for patients undergoing transarterial chemoembolisation (TACE) and to compare both scores in their ability to predict median overall survival (OS).*Methods and Materials Between 2010 and 2020, we retrospectively identified 237 treatment naïve patients with HCC who underwent initial TACE at our institution. Both scores comprise the albumin level and total lymphocyte count. The CONUT additionally includes the cholesterol level. Both scores were compared with established risk factors using multivariate regression analyses regarding median OS. Furthermore, subgroup analysis was performed on recommended TACE (BCLC A & B) candidates.*Results CONUT score and PNI were associated with an impaired median OS (high vs low CONUT: 8.7 vs 22.3 months, p<0.001; low vs high PNI: 6.8 vs 20.1 months, p<0.001) (Figure 1). In multivariate analysis only the PNI remained an independent prognostic predictor (p=0.003), while the CONUT score lost its predictive ability (p=0.201). For recommended TACE candidates both, CONUT and PNI were able to stratify patients regarding their median OS (10.2 vs 24.0 months, p<0.001 respectively 6.6 vs 19.4 months, p<0.001) (Figure 2). However, only the PNI was an independent prognostic factor (p=0.012).*Conclusions In general, immunonutritive scoring is promising for patients with HCC undergoing TACE. Both the PNI and CONUT score were able to stratify patients according to their median OS. However, taking into account additional established risk factors, only the PNI remained an independent prognostic factor; the CONUT score lost its predictive performance.*Clinical Relevance/Application PNI should be preferred when evaluating the nutritional status of patients undergoing TACE.

RESULTS

CONUT score and PNI were associated with an impaired median OS (high vs low CONUT: 8.7 vs 22.3 months, p<0.001; low vs high PNI: 6.8 vs 20.1 months, p<0.001) (Figure 1). In multivariate analysis only the PNI remained an independent prognostic predictor (p=0.003), while the CONUT score lost its predictive ability (p=0.201). For recommended TACE candidates both, CONUT and PNI were able to stratify patients regarding their median OS (10.2 vs 24.0 months, p<0.001 respectively 6.6 vs 19.4 months, p<0.001) (Figure 2). However, only the PNI was an independent prognostic factor (p=0.012).

CLINICAL RELEVANCE/APPLICATION

PNI should be preferred when evaluating the nutritional status of patients undergoing TACE.

GU03-D1   Assessment Of Diagnostic Performance With 18F-DCFPYL-PET/CT In Men With Suspected Recurrence Of Prostate Cancer: A Condor Study Subanalysis Comparing Central And Local Reader Results

Participants
Kenneth L. Gage, MD, PhD, Wesley Chapel, Florida (*Presenter*) Institutional Research Grant, Lantheus Holdings;

PURPOSE

PSMA PET improves the ability to detect prostate cancer (PCa) in patients with biochemical recurrence (BCR). In the phase 3 CONDOR study of PET/CT with 18F-DCFPyL (PyL), a novel PSMA-targeted PET imaging agent, central readers had a correct localization rate (CLR) of approximately 85% in men with BCR. In this subanalysis, the agreement between local and central reader interpretations of PyL scans was assessed.*Methods and Materials Patients with rising PSA after definitive therapy for histologically confirmed PCa and negative or equivocal conventional imaging were administered PyL (~9 mCi (333 MBq)) followed by a whole-body PET/CT scan 1-2 hours later. CLR was defined as the percentage of patients with 1:1 correspondence of at least one lesion identified on PyL-PET/CT and a composite standard of truth. PyL-PET/CT scans were initially reviewed by local readers then centrally reviewed by three blinded independent experts. For local interpretation of PyL-PET/CT, readers were not blinded to clinical or other local imaging results.*Results CLR was determined separately for both PyL-PET/CT central and local readers' interpretations. Local readers reported positive PyL scans in 69.2% (144/208) of patients. Locally determined CLR was 80.3% (95% CI: 72.3% - 86.8%) and the true positive detection rate (DR) was 49.0% (95% CI: 42.2% - 55.8%) compared to CLR of 84.8% to 87.0% (lower bound of 95% CI: 77.8%-80.4%) and a DR of 40.4% to 42.8% for the central readers. Central readers were 75.5% (Fleiss' kappa 0.65 [95% CI 0.58, 0.73]) in agreement regarding the reading of PyL-PET/CT scans. Concordance between each central reader and local reader was 83.2% to 83.7%.*Conclusions The diagnostic performance of 18F-DCFPyL-PET/CT was maintained whether the CLR was determined using the adjudications of three independent central readers or the interpretation of the local readers at each study institution. These data suggest concordance between local and central read results of 18F-DCFPyL PET/CT as an imaging agent in BCR PCa patients. NCT03739684*Clinical Relevance/Application Agreement between local readers and a panel of three independent central readers suggests the data as read locally are concordant, and real-world experience can be relied upon rather than central reads.

RESULTS

CLR was determined separately for both PyL-PET/CT central and local readers' interpretations. Local readers reported positive PyL scans in 69.2% (144/208) of patients. Locally determined CLR was 80.3% (95% CI: 72.3% - 86.8%) and the true positive detection rate (DR) was 49.0% (95% CI: 42.2% - 55.8%) compared to CLR of 84.8% to 87.0% (lower bound of 95% CI: 77.8%-80.4%) and a DR of 40.4% to 42.8% for the central readers. Central readers were 75.5% (Fleiss' kappa 0.65 [95% CI 0.58, 0.73]) in agreement regarding the reading of PyL-PET/CT scans. Concordance between each central reader and local reader was 83.2% to 83.7%.

CLINICAL RELEVANCE/APPLICATION

Agreement between local readers and a panel of three independent central readers suggests the data as read locally are concordant, and real-world experience can be relied upon rather than central reads.

GU03-D2   Follow-up MRI Of Patients Within PI-RADS Category 3: Analysis Of Safety And An Advisable Control Interval

Participants
Tim Ullrich, Duesseldorf, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To analyze follow-up MRI scans of patients with initial PI-RADS 3 including evaluation of safety and of the optimal control interval to exclude significant prostate cancer development.*Methods and Materials This retrospective study includes consecutive patients with PI-RADS category 3 and one or more follow up mpMRI between 2012 and 2018. MRI-targeted and systematic TRUS-guided biopsy was used as histological reference standard. Follow-up mpMRI was evaluated by two readers blinded towards histopathologic results. PI-RADS classification, PSAD, PSA, and prostate volume during follow-up MRIs were assessed in the context of histopathologic results.*Results 89 patients (median PSA 6.6 ng/ml; PSAD 0.13 ng/ml/ml) were included with a follow-up period of 31±18 months. PCA was detected in 19 cases (median PSA 6.0 ng/ml; PSAD 0.13 ng/ml/ml) and csPCA in 5 cases (median PSA 5.5 ng/ml; PSAD 0.13 ng/ml/ml). The median PI-RADS category in follow-up scans was significantly higher in patients with csPCA (4) with a significant upgrade after 12 to 24 months than in healthy controls (3; p<0.001) which had a significant downgrade after 36 to 48 months. Neither PSA nor PSAD, or prostate volume showed a significant difference in follow-up scans.*Conclusions Patients in PI-RADS category 3 and stable PSAD can safely be followed-up using mpMRI after 12-24 months without missing csPCA. There seems to be no benefit of follow-up MRI earlier than 36 months after the first scan in patients with negative biopsy. This may facilitate a reduction of follow-up scans and possible overtreatment.*Clinical Relevance/Application Patients in PI-RADS category 3 and stable PSAD may receive follow-up mpMRI after 12-24 months instead of prompt biopsy without missing csPCA. Patients in PI-RADS category 3 with negative biopsy do not need follow-up mpMRI earlier than 36 months after the first scan.

RESULTS

89 patients (median PSA 6.6 ng/ml; PSAD 0.13 ng/ml/ml) were included with a follow-up period of 31±18 months. PCA was detected in 19 cases (median PSA 6.0 ng/ml; PSAD 0.13 ng/ml/ml) and csPCA in 5 cases (median PSA 5.5 ng/ml; PSAD 0.13 ng/ml/ml). The median PI-RADS category in follow-up scans was significantly higher in patients with csPCA (4) with a significant upgrade after 12 to 24 months than in healthy controls (3; p<0.001) which had a significant downgrade after 36 to 48 months. Neither PSA nor PSAD, or prostate volume showed a significant difference in follow-up scans.

CLINICAL RELEVANCE/APPLICATION

Patients in PI-RADS category 3 and stable PSAD may receive follow-up mpMRI after 12-24 months instead of prompt biopsy without missing csPCA. Patients in PI-RADS category 3 with negative biopsy do not need follow-up mpMRI earlier than 36 months after the first scan.

MK03-B3   **Comparison Of 3D Automated Ultrasound Tomography With Standard Handheld Ultrasound For The Visualization Of The Hands - Clinical Proof Of Concept**

Participants
Jonas Getzmann, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To assess the technical functioning of a 3D ultrasound (US) tomography prototype (Aison Pro; Aison Technologies AG, Winterthur, Switzerland) and its ability to visualize joint structures healthy hands as well as detect degenerative changes in singular cadaver cases.*Methods and Materials 12 individuals (6 males, 6 females, age 43.5 ± 17.8 years (mean ± SD)) without any known joint disease to the hands were prospectively recruited. Each participant underwent four scans with the Aison Pro (right and left hand, dorsal and palmar, respectively) followed by automated stitching of scan volumes as well as four sets of standard handheld US of predefined anatomic regions of the hands. The 3D US tomographic images and the standard handheld US images were independently assessed by two radiologists more than four weeks after image acquisition with regard to visibility of bone contour, joint capsule and space, and tendons. In addition, three cadaveric hands were scanned with the Aison Pro and MDCT to compare the ability to detect erosions or osteophytes. Standard statistical tests were used for the quantitative analysis. Cohen's kappa (k) was used to assess interreader and intermodality agreement.*Results Mean scan time for both hands was significantly faster with the standard handheld US (10min 30s ± 95s (mean ± SD)) compared to the Aison Pro (32min 9s ± 6s (mean ± SD); P < 0.05). Interreader and intermodality agreement were substantial (0.6 < k = 0.8) to almost perfect (0.8 < k) depending on the underlying qualitative parameter. Overall visibility of bone and joint structures was comparable between the modalities (P > 0.05) with better depiction at the level of the finger joints as opposed to the thumb or wrist in the Aison Pro. In addition, the Aison Pro was able to detect erosions and osteophytes in cadaveric hands which were confirmed by MDCT.*Conclusions The 3D US tomographic images of the Aison Pro are adequately able to visualize joint structures in healthy hands as well as singular erosions and osteophytes in cadaveric hands. Further technical improvements are necessary to shorten scan times and improve automated scanning of the thumb and wrist.*Clinical Relevance/Application The Aison Pro is able to perform quantitative ultrasound with standardized pressure, angle and patient position which could be used for tracking the evolution of rheumatic pathologies or injuries in the future.

RESULTS

Mean scan time for both hands was significantly faster with the standard handheld US (10min 30s ± 95s (mean ± SD)) compared to the Aison Pro (32min 9s ± 6s (mean ± SD); P < 0.05). Interreader and intermodality agreement were substantial (0.6 < k = 0.8) to almost perfect (0.8 < k) depending on the underlying qualitative parameter. Overall visibility of bone and joint structures was comparable between the modalities (P > 0.05) with better depiction at the level of the finger joints as opposed to the thumb or wrist in the Aison Pro. In addition, the Aison Pro was able to detect erosions and osteophytes in cadaveric hands which were confirmed by MDCT.

CLINICAL RELEVANCE/APPLICATION

The Aison Pro is able to perform quantitative ultrasound with standardized pressure, angle and patient position which could be used for tracking the evolution of rheumatic pathologies or injuries in the future.

BR05-A3   Outcomes Of COVID-19 Vaccination Related Adenopathy In A Population At High Risk For Breast Cancer

Participants
Samantha Zuckerman, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

COVID-19 vaccinations are associated with ipsilateral axillary adenopathy. We evaluate the management of post-vaccination adenopathy in patients who underwent high risk, staging, and abbreviated breast MRI.*Methods and Materials This retrospective study is HIPAA compliant and IRB exempt. Breast MRI reports from initiation of COVID-19 vaccinations, 12/14/2020, to 4/11/2021 at a single institution were queried for vaccine-related adenopathy. Study indication, date, site and type of vaccine, BI-RADS final assessment, and outcomes were recorded. Change in BI-RADS 0 and BI-RADS 3 before and after FDA COVID vaccination approval were assessed using two-sided Fisher's exact test with analysis in Stata v14.2.*Results Of 1899 MRIs performed from 12/14/2020-4/11/2021, 3.5% (66/1899) included comments on vaccine-related adenopathy compared to 0.02% (1/5326, influenza) from the comparison year. Of those, 64 were from COVID-19 vaccinations, 1 from a Shingles vaccination, and 1 from a Pneumovax vaccination. Adenopathy-specific recommendations were as follows: 65% (43/66) BI-RADS category 0 or 3, 27% (18/66) BI-RADS category 1 or 2, and 8% (5/66) BI-RADS category 4. Overall BI-RADS 3 (9.3%, 176/1899) and BI-RADS 0 assessments (1.7%, 33/1899) increased post-vaccination compared to the prior year (BIRADS 3 - 6.5% (346/5326), BI-RADS 0 - 0.8%, (45/5326)), P= <0.0001. Adenopathy thought to be related to vaccination represented 17% of BI-RADS 3 (30/176) and 24% of BI-RADS 0 outcomes (8/33). Adenopathy was evident 5-30 days after the 1st and 1-66 days after the 2nd dose, with 4 exams demonstrating adenopathy >6 weeks after a second dose. 20 women have had follow-up imaging - 55% (11/20) deemed normal or benign, 40% (8/20) recommending additional follow-up, and 1 recommending biopsy. The average time from final vaccination to follow-up exam was 47.6 days (2-78). 3/3 women who underwent nodal biopsy had benign results (1 with prior lymphoma and 2 with new breast cancer diagnoses).*Conclusions MRI-detected axillary adenopathy in the setting of recent COVID-19 vaccination may present management challenges. Adenopathy may be present longer than 6 weeks after 2nd vaccination. Biopsy should be reserved for patients with loss of fatty hila on ultrasound, suspicious breast imaging findings, or with concurrent cancer diagnoses.*Clinical Relevance/Application COVID-19 vaccination related adenopathy results in more false positive breast MRI exams. Our data demonstrates that in women without a cancer diagnosis or suspicious breast findings, biopsy can be deferred and additional imaging may not be necessary.

RESULTS

Of 1899 MRIs performed from 12/14/2020-4/11/2021, 3.5% (66/1899) included comments on vaccine-related adenopathy compared to 0.02% (1/5326, influenza) from the comparison year. Of those, 64 were from COVID-19 vaccinations, 1 from a Shingles vaccination, and 1 from a Pneumovax vaccination. Adenopathy-specific recommendations were as follows: 65% (43/66) BI-RADS category 0 or 3, 27% (18/66) BI-RADS category 1 or 2, and 8% (5/66) BI-RADS category 4. Overall BI-RADS 3 (9.3%, 176/1899) and BI-RADS 0 assessments (1.7%, 33/1899) increased post-vaccination compared to the prior year (BIRADS 3 - 6.5% (346/5326), BI-RADS 0 - 0.8%, (45/5326)), P= <0.0001. Adenopathy thought to be related to vaccination represented 17% of BI-RADS 3 (30/176) and 24% of BI-RADS 0 outcomes (8/33). Adenopathy was evident 5-30 days after the 1st and 1-66 days after the 2nd dose, with 4 exams demonstrating adenopathy >6 weeks after a second dose. 20 women have had follow-up imaging - 55% (11/20) deemed normal or benign, 40% (8/20) recommending additional follow-up, and 1 recommending biopsy. The average time from final vaccination to follow-up exam was 47.6 days (2-78). 3/3 women who underwent nodal biopsy had benign results (1 with prior lymphoma and 2 with new breast cancer diagnoses).

CLINICAL RELEVANCE/APPLICATION

COVID-19 vaccination related adenopathy results in more false positive breast MRI exams. Our data demonstrates that in women without a cancer diagnosis or suspicious breast findings, biopsy can be deferred and additional imaging may not be necessary.

BR05-A5   Comparison Of False Positive Versus True Positive Contrast Enhanced Digital Mammography

Participants
Maxine S. Jochelson, MD, New York, New York (*Presenter*) Speaker, General Electric Company

PURPOSE

To compare false positive (FP) contrast enhanced digital mammograms (CEDM) to true positive (TP) CEDM.*Methods and Materials All baseline screening CEDM performed between 1/2013 and 12/2018 with an American College of Radiology Breast Imaging Reporting and Data System (BI-RADS) category assessment of incomplete, probably benign, suspicious or highly suspicious (BI-RADS 0, 3, 4, 5) were reviewed. Breast density, background parenchymal enhancement (BPE), contrast finding (focus, mass, nonmass enhancement), lesion detection on iodine images and/or 2D images, and on one or two mammographic (MG) projection(s) were recorded. Additional necessary MG views and/or ultrasound (US) was performed at the time of CEDM. Breast MRI was obtained in patients with enhancement on CEDM without a MG or US correlate. FP was defined as an exam in which biopsy (bx) yielded benign pathology or in which MRI and two-year MG follow-up was negative. TP was defined as an exam in which bx yielded

malignancy. A univariate logistic regression analysis was done in the generalized estimating equation (GEE) framework to account for intra-patient correlation. Type I error rate was set to 0.05 (a).*Results 184 baseline screening CEDM met BI-RADS criteria. 27 patients were lost to follow up. 157 patients were included in analysis. 23 patients had TP exams with 26 total TP lesions. 134 patients had FP exams with 144 total FP lesions. Lesions seen on both the 2D and iodine images were more likely to be a TP while lesions seen on iodine only images were more likely to be FP (p=0.007). Lesions with an US or MRI correlate were more likely to be TP (p<0.001, p=0.012). Breast density, BPE, type of contrast finding, and visibility on one or two MG views was not statistically significant in predicting a FP or TP lesion.*Conclusions Findings seen on both low energy and iodine images are more likely to be a TP, as are those with an US or MR correlate. Such findings may help push the radiologist toward bx. Finding type and visibility on one or two views is not significantly associated with a TP or FP and suggests these factors shouldn't sway the radiologist's interpretation of a lesion.*Clinical Relevance/Application Understanding characteristics of TP compared with FP CEDM findings may help improve interpretation accuracy. To our knowledge, no study has been published assessing TP versus FP CEDM.

RESULTS

184 baseline screening CEDM met BI-RADS criteria. 27 patients were lost to follow up. 157 patients were included in analysis. 23 patients had TP exams with 26 total TP lesions. 134 patients had FP exams with 144 total FP lesions. Lesions seen on both the 2D and iodine images were more likely to be a TP while lesions seen on iodine only images were more likely to be FP (p=0.007). Lesions with an US or MRI correlate were more likely to be TP (p<0.001, p=0.012). Breast density, BPE, type of contrast finding, and visibility on one or two MG views was not statistically significant in predicting a FP or TP lesion.

CLINICAL RELEVANCE/APPLICATION

Understanding characteristics of TP compared with FP CEDM findings may help improve interpretation accuracy. To our knowledge, no study has been published assessing TP versus FP CEDM.

BR05-A6 Evaluating Response To Neoadjuvant Chemotherapy In Breast Cancer. A Radiopathological Correlation.

Participants
Sofía Ventura- Diaz, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the ability of Magnetic Resonance Imaging (MRI) to predict pathological complete response (pCR) in locally advanced breast cancers after neoadjuvant chemotherapy (NAC).*Methods and Materials This study retrospectively analyzed patients with locally advanced breast cancers collected from January 2014 to December 2019. Demographic, clinic, radiological and pathological findings were collected in an anomymized database. The imaging response was classified in five patterns according to the Union for International Cancer Control. Histopathological response was measured using two classifications: Miller and Payne (M&P) and residual cancer burden (RCB). A descriptive analysis was performed, subdiving the sample in molecular subtypes. Differents subgroups were compared using Student's t test, ANOVA test or X2 test, when appropriate.*Results 193 patients were included in our study (55,13 ± 12 years). 25,9% were triple negative (TN), 23,8% luminal B HER2+, 23,3% luminal B, 15% pure HER 2 + and 11,9 % luminal A. The most common histological subtype was the infiltrative ductal carcinoma (95,3 %). The highest nuclear degree and Ki67 level were found in TN subtype (p <0,001). The most frequent radiological finding was a nodule (89,1%). Non-masslike enhancement was present in 16,1%. The median size was 34 mm, IQR 24-50 mm. In 64,8% patients the tumor was unique, 28% multifocal, 21,2% multicentric and 4,1% bilateral. The highest rate of multicentricity was found in pure HER 2 +(44,8%, p=0,019). 44% patients had a radiological complete response (rCR). The molecular subtype with the greatest level of rCR was Luminal B HER2+ (13,5%), followed by TN (10,9%). The concentric response was the most common type in all molecular subtypes (33,2%). (M&P): 38,3% patients showed a pathological complete response (pCR), being TN the most responder (13%), followed by HER2+ (12,4%). The higher rates of no response to chemotherapy were seen in Luminal B (17,4%, p<0,001). RBC. 32,6% patients had a complete response. RBC agrees with M&P in TN being the most responder (12,4%), followed by HER 2+ (10,9%). We did not find a good radiopathological correlation being the overall kappa index low (0,25). Kappa index was better in HER2+ subtype (0,62).*Conclusions In 44% patients there is a rCR, mostly refered to Luminal B HER2+. The pathological analysis disagrees, both M&P and RBC say pCR in 32,6% -38,3%, being TN the best responder. Kappa index gets better in HER2+ subgroup.*Clinical Relevance/Application MRI does not accurately predict pCR after NAC but it still is the most accurate preoperative imaging method for assessing the therapeutic efficacy. More tools (such as diffusion) need to be introduced and validated to provide more accuracy in predicting pCR.

RESULTS

193 patients were included in our study (55,13 ± 12 years). 25,9% were triple negative (TN), 23,8% luminal B HER2+, 23,3% luminal B, 15% pure HER 2 + and 11,9 % luminal A. The most common histological subtype was the infiltrative ductal carcinoma (95,3 %). The highest nuclear degree and Ki67 level were found in TN subtype (p <0,001). The most frequent radiological finding was a nodule (89,1%). Non-masslike enhacement was present in 16,1%. The median size was 34 mm, IQR 24-50 mm. In 64,8% patients the tumor was unique, 28% multifocal, 21,2% multicentric and 4,1% bilateral. The highest rate of multicentricity was found in pure HER 2 +(44,8%, p=0,019). 44% patients had a radiological complete response (rCR). The molecular subtype with the greatest level of rCR was Luminal B HER2+ (13,5%), followed by TN (10,9%). The concentric response was the most common type in all molecular subtypes (33,2%). (M&P): 38,3% patients showed a pathological complete response (pCR), being TN the most responder (13%), followed by HER2+(12,4%). The higher rates of no response to chemotherapy were seen in Luminal B (17,4%, p<0,001). RBC. 32,6% patients had a complete response. RBC agrees with M&P in TN being the most responder (12,4%), followed by HER 2+ (10,9%). We did not find a good radiopathological correlation being the overall kappa index low (0,25). Kappa index was better in HER2+ subtype (0,62).

CLINICAL RELEVANCE/APPLICATION

MRI does not accurately predict pCR after NAC but it still is the most accurate preoperative imaging method for assessing the therapeutic efficacy. More tools (such as diffusion) need to be introduced and validated to provide more accuracy in predicting pCR.

BR05-A7 How Long To Wait? Follow-up Imaging Outcomes For Suspected COVID-19 Vaccine Induced Axillary Adenopathy

Participants
Shabnam Mortazavi, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

PURPOSE

The optimal time interval for normalization of COVID-19 vaccine axillary adenopathy is unknown. The purpose of this study was to assess the follow-up imaging outcomes of axillary adenopathy caused by COVID-19 vaccination.*Methods and Materials Data from women with suspected COVID-19 vaccine-induced axillary adenopathy detected in breast imaging (screening or diagnostic mammogram, ultrasound and MRI) who received a BI-RADS category 3 were retrospectively reviewed from December 2020 to May 2021. Imaging follow-up recommendations adhered to the Society of Breast Imaging (SBI) guidelines of 4-12 weeks. Age, type of vaccine (when available), vaccine administration dates and imaging dates were reviewed.*Results Imaging follow-up with ultrasound (BI-RADS 3) was recommend in 128 women with presumed COVID-19 vaccine-induced axillary adenopathy. Of the 34 follow-up exams performed to date, 26 had normalization of the axillary adenopathy in the recommended follow-up imaging, while 8 had persistent adenopathy for which additional short-term imaging follow-up was recommended. Thirty three percent had persistent adenopathy when imaging follow-up was done 4 weeks after the second dose of the vaccine compared to 22% when imaging follow-up was done at 9 weeks.*Conclusions Lengthening the follow-up imaging recommendation to 9 or more weeks after the second dose of vaccination may minimize the need for additional follow-up and optimize patient care.*Clinical Relevance/Application Understanding the optimal length of follow-up for suspected COVID-19 vaccine-induced axillary lymphadenopathy is important to minimize use of healthcare resources and optimize patient care.

RESULTS

Imaging follow-up with ultrasound (BI-RADS 3) was recommend in 128 women with presumed COVID-19 vaccine-induced axillary adenopathy. Of the 34 follow-up exams performed to date, 26 had normalization of the axillary adenopathy in the recommended follow-up imaging, while 8 had persistent adenopathy for which additional short-term imaging follow-up was recommended. Thirty three percent had persistent adenopathy when imaging follow-up was done 4 weeks after the second dose of the vaccine compared to 22% when imaging follow-up was done at 9 weeks.

CLINICAL RELEVANCE/APPLICATION

Understanding the optimal length of follow-up for suspected COVID-19 vaccine-induced axillary lymphadenopathy is important to minimize use of healthcare resources and optimize patient care.

BR05-A8   Axillary Lymphadenopathy (LAD) On Breast Imaging After COVID-19 Vaccine

Participants
Stacey Wolfson, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate findings of axillary LAD after COVID-19 vaccination.*Methods and Materials We retrospectively reviewed breast imaging reports from 12/1/19 through 4/12/21 for patients who received the COVID-19 vaccine. Seven radiologists extracted patient demographics, vaccine information, imaging findings, and recommendations. Statistics were calculated in Excel and Mann-Whitney U tests in SPSS.*Results Of the 1217 patients that received the COVID-19 vaccine and had breast imaging, 537 patients (44%) had LAD on at least one exam. 323 patients had mammogram and ultrasound (US) on the same day: 8.0% had LAD identified on mammography alone, 61.0% on US alone, and 31.0% on both exams. Patients had LAD as early as 1 day after the first dose of vaccine and as late as 71 days after the second dose. The timing was significantly different between the groups with and without LAD seen on imaging; LAD was more likely to be seen within 14 days after vaccination and was rare after 50 days after the 2nd dose. Patients with LAD were more likely to have received Moderna (51.8%) and the patients without LAD were more likely to have received Pfizer (55.2%) (p=0.007).21 patients underwent lymph node (LN) biopsy; 52% had a history of current or prior breast cancer. 14 biopsies yielded benign results. 4 patients were diagnosed with breast cancer metastatic to the axilla; all had concurrent imaging findings in the breast and were diagnosed with breast cancer. 3 patients were diagnosed with lymphoma, none of whom had unilateral LAD identified on screening. 38 patients had initial imaging with US and follow up (F/U) US performed after 0.5-13 weeks. 15 patients had decreased LN size at 1.5 to 9 week F/U, 7 of which had F/U </= 4 weeks. 23 patients had no change in LN size on 0.5 to 13 week F/U. Three patients demonstrated stable lymph nodes at F/U intervals of 10, 11, and 13 weeks.*Conclusions A minority of patients with LAD ipsilateral to COVID-19 vaccine underwent biopsy, most frequently in patients with history of breast cancer (52% of biopsies). Patients had stable LAD at 10-13 weeks; therefore, F/U US should be recommended no sooner than three months. In patients with combined mammogram/US exams, evaluating the axilla with US contributed to 61% of the BIRADS 0 and 3 exams; thus, performing breast-only screening US (excluding the axilla) could result in fewer false positive recall and F/U exams.*Clinical Relevance/Application The management of incidental vaccine-related LAD must be elucidated for breast imagers in order to avoid unnecessary follow up exams and biopsies.

RESULTS

Of the 1217 patients that received the COVID-19 vaccine and had breast imaging, 537 patients (44%) had LAD on at least one exam. 323 patients had mammogram and ultrasound (US) on the same day: 8.0% had LAD identified on mammography alone, 61.0% on US alone, and 31.0% on both exams. Patients had LAD as early as 1 day after the first dose of vaccine and as late as 71 days after the second dose. The timing was significantly different between the groups with and without LAD seen on imaging; LAD was more likely to be seen within 14 days after vaccination and was rare after 50 days after the 2nd dose. Patients with LAD were more likely to have received Moderna (51.8%) and the patients without LAD were more likely to have received Pfizer (55.2%) (p=0.007).21 patients underwent lymph node (LN) biopsy; 52% had a history of current or prior breast cancer. 14 biopsies yielded benign results. 4 patients were diagnosed with breast cancer metastatic to the axilla; all had concurrent imaging findings in the breast and were diagnosed with breast cancer. 3 patients were diagnosed with lymphoma, none of whom had unilateral LAD identified on screening. 38 patients had initial imaging with US and follow up (F/U) US performed after 0.5-13 weeks. 15 patients had decreased LN size at 1.5 to 9 week F/U, 7 of which had F/U </= 4 weeks. 23 patients had no change in LN size on 0.5 to 13 week F/U. Three patients demonstrated stable lymph nodes at F/U intervals of 10, 11, and 13 weeks.

CLINICAL RELEVANCE/APPLICATION

The management of incidental vaccine-related LAD must be elucidated for breast imagers in order to avoid unnecessary follow up exams and biopsies.

BR05-A9   Quantitative Analysis Enhancement Characteristics Of Contrast Enhanced Spectral Mammography In Indistinguishing Malignant And Benign Breast Masses

Participants
Huizhi Cao, PhD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To retrospectively analyze the roles of quantitative variables and kinetic enhancement patterns between different imaging acquisition phases in distinguishing the pathologically confirmed malignant breast masses from benign ones using contrast-enhanced spectral mammography (CESM).*Methods and Materials Pathologically confirmed breast masses from patients who underwent CESM were retrospectively analyzed, including 30 benign and 84 malignant ones. Contrast-based mammography performed with different energy exposures were taken after i.v. injection of contrast agent for less than 2min (early phase), between 3 to 6 min (second phase), and between 7 to 8 min (late phase), respectively. The differential enhancement of benign and malignant masses in the early, second, and late phases were analyzed; the lesion signal, signal noise ratio (SNR), the difference of enhancing lesion signal between different phases (% RS) were measured for each lesion. The kinetic enhancement pattern was assessed based on SNR and % RS changes across all these three phases.*Results The enhancement was statistically stronger in malignancies compared with benign lesions. The lesion signal and SNR for breast cancer and benign lesions were significantly different at the early phase (p < 0.05); the accuracy of lesion signal- and SNR-based analysis was 75.4% and 80.7%, respectively, at the early phase. No statistically significant differences were found at the second or late phase (p > 0.05). Analyzing based on the % RS, the enhancement pattern between the early and second phase and the kinetic enhancement pattern (changes across all three phases) were found to be statistically significant for the breast cancer and benign lesions (p<0.05); Regarding the kinetic enhancement patterns, 71.40% (60/84) breast cancer and 50.00% (15/30) benign lesions presented a depressed-depressed pattern based on RS% changes; while an elevated-elevated pattern was only found in the breast benign lesions (3/30,10.00%). In particular, 46.40% (39/84) breast cancers presented in depress-depress pattern and 25.00% (21/84) showed an elevated-depressed pattern; while the elevated-elevated pattern was found most for benign lesions with an incident rate of 33.30% (10/30).*Conclusions Quantitative variables and kinetic enhancement pattern analysis of breast lesions on CESM may be useful in distinguishing breast cancers and benign masses.*Clinical Relevance/Application The intensity and patterns of enhancement on CESM may contribute to the differential diagnosis of benign and malignant lesions.

RESULTS

The enhancement was statistically stronger in malignancies compared with benign lesions. The lesion signal and SNR for breast cancer and benign lesions were significantly different at the early phase (p < 0.05); the accuracy of lesion signal- and SNR-based analysis was 75.4% and 80.7%, respectively, at the early phase. No statistically significant differences were found at the second or late phase (p > 0.05). Analyzing based on the % RS, the enhancement pattern between the early and second phase and the kinetic enhancement pattern (changes across all three phases) were found to be statistically significant for the breast cancer and benign lesions (p<0.05); Regarding the kinetic enhancement patterns, 71.40% (60/84) breast cancer and 50.00% (15/30) benign lesions presented a depressed-depressed pattern based on RS% changes; while an elevated-elevated pattern was only found in the breast benign lesions (3/30,10.00%). In particular, 46.40% (39/84) breast cancers presented in depress-depress pattern and 25.00% (21/84) showed an elevated-depressed pattern; while the elevated-elevated pattern was found most for benign lesions with an incident rate of 33.30% (10/30).

CLINICAL RELEVANCE/APPLICATION

The intensity and patterns of enhancement on CESM may contribute to the differential diagnosis of benign and malignant lesions.

BR03-B1   Association Of Automated Breast Positioning Assessment With Technical Repeats And Recalls In The Nationalized U.K. Screening Program

Participants
Brian Drohan, PhD, Waltham, Massachusetts (*Presenter*) Employee, Volpara Health Technologies Limited

PURPOSE

This study investigated the association between images repeated due to inadequate positioning and automated scoring for breast positioning, based on a PGMI (Perfect, Good, Moderate, Inadequate) quality classification system.*Methods and Materials A retrospective dataset of negative, four-view mammographic screening exams were identified from the OPTIMAM database (screening mammograms from two sites in the UK NHS Breast Screening Programme between 2012-2015) from among those without any repeated views and among those with image retakes due to inadequate positioning. This comprised of 1340 accepted exams with no repeated views (AE), 2134 "technical repeats" which included a single, same-day repeated view (TP) and 144 "technical recalls" which included =1 repeated view on a later exam date (TR). Volpara algorithms (Volpara Health Ltd, NZ) were used to evaluate breast volume (BV), volumetric breast density (VBD) and breast positioning, assessing images as passing or failing a set of positioning metrics and assigning an image PGMI score. Univariate statistical analyses were used to investigate the associations between the PGMI system and TP, TR and AE image features.*Results Compared to women with TP, median age (58 vs 60 years) and BV (663 vs 775 cm3) were lower and VBD higher (8.1 vs 6.3%) for women with TR (p<0.01). TP had a significantly higher proportion of medio-lateral oblique (MLO) images than TR (83 vs 76%, p<0.01). Comparing TP/TR as a combined group to AE, there were significantly different (p<0.001) proportions of images which failed all positioning metrics except cranio-caudal (CC) nipple in profile. Comparing TP and TR, MLO TP had significantly more tissue cut off (7 vs 3%, p<0.05) and CC TR had more images where the CC posterior nipple line (PNL) was more than 1cm shorter than the corresponding MLO PNL (90 vs 64%, p<0.001). Comparing image PGMI score for TR to AE there were significantly more inadequate MLOs (48 vs 3%) and less perfect views (MLO; 3 vs 13%, CC; 2 vs 21%), all p<0.001. Comparing TP to AE there were significantly more inadequate views (MLO; 47 vs 3%, CC; 8 vs 2%) and less perfect views (MLO;1 vs 13%, CC; 9 vs 21%), all p<0.001.*Conclusions Automated breast positioning assessment showed significant differences in PGMI scores between groups of TP, TR and AE views. Between-group proportion differences identified specific positioning metrics that may be more difficult for technologists to identify at the time of the exam, thus, having timely automated feedback has the potential to reduce TR.*Clinical Relevance/Application Automated image quality assessment algorithms can help provide objective and timely feedback to technologists to aid continual monitoring to facilitate quality improvement of breast positioning to meet MQSA standards.

RESULTS

Compared to women with TP, median age (58 vs 60 years) and BV (663 vs 775 cm3) were lower and VBD higher (8.1 vs 6.3%) for women with TR (p<0.01). TP had a significantly higher proportion of medio-lateral oblique (MLO) images than TR (83 vs 76%, p<0.01). Comparing TP/TR as a combined group to AE, there were significantly different (p<0.001) proportions of images which failed all positioning metrics except cranio-caudal (CC) nipple in profile. Comparing TP and TR, MLO TP had significantly more tissue cut off (7 vs 3%, p<0.05) and CC TR had more images where the CC posterior nipple line (PNL) was more than 1cm shorter than the corresponding MLO PNL (90 vs 64%, p<0.001). Comparing image PGMI score for TR to AE there were significantly more inadequate MLOs (48 vs 3%) and less perfect views (MLO; 3 vs 13%, CC; 2 vs 21%), all p<0.001. Comparing TP to AE there were significantly more inadequate views (MLO; 47 vs 3%, CC; 8 vs 2%) and less perfect views (MLO;1 vs 13%, CC; 9 vs 21%), all p<0.001.

CLINICAL RELEVANCE/APPLICATION

Automated image quality assessment algorithms can help provide objective and timely feedback to technologists to aid continual monitoring to facilitate quality improvement of breast positioning to meet MQSA standards.

BR03-B3   Tomosynthesis-driven AI-derived Breast Cancer Scoring Among A Racially Diverse Cohort Of Women Undergoing Screening: Potential For Triage And Precision Cancer Screening

Participants
Emily F. Conant, MD, Philadelphia, Pennsylvania (*Presenter*) Research Grant, Hologic, Inc;Advisory Panel, Hologic, Inc;Research Grant, OM1, Inc;Research Grant, iCad, Inc;Advisory Panel, iCad, Inc;Speaker, Medscape, LLC

PURPOSE

To evaluate the impact of race on the performance of a deep convolutional neural network artificial intelligence (AI) software to identify digital breast tomosynthesis (DBT) screening exams with low-likelihood of cancer towards triaging workload and aiding in precision screening*Methods and Materials This IRB-approved, HIPAA-compliant observational study included consecutive DBT screening exams performed from 2/4/2020 to 1/3/2021 at a single academic site and processed with an FDA-approved, DBT AI-CAD software (ProFound AI 2.0, iCAD, Inc.). The distribution of AI-derived case-score deciles for the entire population, as well as for the two largest racial subgroups (White and Black), were determined separately for controls and breast cancer cases, including true positive (TP) cancer detections and false negatives (FN). In addition, the performance of the AI algorithm as a standalone interpretation was calculated via area under the ROC curve (AUC). All FNs were reviewed at consensus to determine if they were

"detectable" or not at index imaging.*Results Of 9,113 women screened, 41.0% were White, 52.4% Black, and 6.7% were "other" races. Ages ranged from 24-96 years (median = 59 years). Of the entire cohort, 717 were recalled (7.9%) with 58 cancers detected (CDR/1000 screened = 6.4 overall) and 659 false positives (FP). Of women with at least 1 year follow-up, there were 7 FNs, with case scores of 6, 18, 25, 26, 46, 62, and 75; 2 in White and 5 in Black women. The three lowest case score FNs were deemed non-detectable at index imaging (2 in Black women, 1 in a White woman). AI case-score distribution varied by race for controls (chi-square test, p < 0.001), but not for cases (p = 0.12). In addition, the AI algorithm demonstrated high standalone performance, which however, varied slightly by race (AUC for all women = 0.83 95% CIs [0.77, 0.87] (cases=65, controls=9,048); for White = 0.84 [0.77, 0.89] (cases=29, controls=3,705); for Black = 0.80 [0.70, 0.88] (cases=27, controls=4,745). There were 9 TP cases in race "Other".*Conclusions Preliminary data across a racially diverse screening population suggests there may be differences in the distribution of case scores and performance of a DBT-AI algorithm based on race.*Clinical Relevance/Application Artificial intelligence algorithms for CAD-driven triaging and precision breast cancer screening paradigms may require incorporation of racial data for further refinement of prediction models.

RESULTS

Of 9,113 women screened, 41.0% were White, 52.4% Black, and 6.7% were "other" races. Ages ranged from 24-96 years (median = 59 years). Of the entire cohort, 717 were recalled (7.9%) with 58 cancers detected (CDR/1000 screened = 6.4 overall) and 659 false positives (FP). Of women with at least 1 year follow-up, there were 7 FNs, with case scores of 6, 18, 25, 26, 46, 62, and 75; 2 in White and 5 in Black women. The three lowest case score FNs were deemed non-detectable at index imaging (2 in Black women, 1 in a White woman). AI case-score distribution varied by race for controls (chi-square test, p < 0.001), but not for cases (p = 0.12). In addition, the AI algorithm demonstrated high standalone performance, which however, varied slightly by race (AUC for all women = 0.83 95% CIs [0.77, 0.87] (cases=65, controls=9,048); for White = 0.84 [0.77, 0.89] (cases=29, controls=3,705); for Black = 0.80 [0.70, 0.88] (cases=27, controls=4,745). There were 9 TP cases in race "Other".

CLINICAL RELEVANCE/APPLICATION

Artificial intelligence algorithms for CAD-driven triaging and precision breast cancer screening paradigms may require incorporation of racial data for further refinement of prediction models.

BR03-B5   AI Algorithm Performs Better On DBT Than 2D Mammography

Participants
Abdul Rahman Diab, Cambridge, Massachusetts (*Presenter*) Employee, RadNet, Inc

PURPOSE

To assess AI performance on DBT compared to 2D mammography (FFDM and 2D synthetics).*Methods and Materials Screening FFDM and DBT mammograms were retrospectively collected from different women at 7 clinical sites under an IRB-approved protocol. Two types of exams were collected: negative exams, defined as BIRADS 1 or 2 screening mammograms followed by a BIRADS 1 or 2 negative screening mammogram 24+ months later, and cancer exams, defined as screening mammograms with malignant pathology confirmation within the 3 months following the exam. The FFDM data consisted of 832 negative exams and 501 cancer exams (1333 total), and the DBT data consisted of 850 negative exams and 469 cancer exams (1319 total). Two MQSA-qualified radiologists reviewed each collected case to ensure that it met the inclusion criteria specified in the case type definitions. An AI model generated predictions on the exams, and the model's performance was assessed using the area under the ROC curve (AUC). P-values for comparing AUC results were computed using bootstrapping with 10,000 samples, and confidence intervals were computed using the DeLong method. The AI algorithm contains two core AI models: one trained to evaluate 2D images, and one trained to evaluate 3D images. The algorithm combines model outputs into a single case-level score. DBT results were computed in two ways: 1) using all available images in the study and 2) using only synthetic 2D images. FFDM results were computed using all available images for each study.*Results The highest performance (AUC=0.987, CI: 0.982,0.992) was achieved when using all available images from DBT exams. Performance was lower when using only synthetic 2D images from the same DBT exams (AUC=0.962, CI: [0.951, 0.973], p < 0.0001) and when using FFDM exams (AUC=0.966, CI: [0.957, 0.975], p < 0.0001). At a specificity of 88.9% (BCSC mean radiologist specificity [Lehman et. al 2017]), sensitivity on DBT exams using all images was 0.968, sensitivity on DBT exams using only synthetic 2D images was 0.904, and sensitivity on FFDM exams was 0.912.*Conclusions AI performs well across all tested image types, and incorporating 3D information present in DBT exams leads to higher performance compared to using FFDM exams or only using 2D synthetics from DBT exams.*Clinical Relevance/Application The results indicate that AI can effectively utilize DBT data to improve performance over 2D mammography, reinforcing clinical experience that DBT is an invaluable mammographic tool.

RESULTS

The highest performance (AUC=0.987, CI: 0.982,0.992) was achieved when using all available images from DBT exams. Performance was lower when using only synthetic 2D images from the same DBT exams (AUC=0.962, CI: [0.951, 0.973], p < 0.0001) and when using FFDM exams (AUC=0.966, CI: [0.957, 0.975], p < 0.0001). At a specificity of 88.9% (BCSC mean radiologist specificity [Lehman et. al 2017]), sensitivity on DBT exams using all images was 0.968, sensitivity on DBT exams using only synthetic 2D images was 0.904, and sensitivity on FFDM exams was 0.912.

CLINICAL RELEVANCE/APPLICATION

The results indicate that AI can effectively utilize DBT data to improve performance over 2D mammography, reinforcing clinical experience that DBT is an invaluable mammographic tool.

BR03-B6   Demographic And Socioeconomic Risk Factors For Granulomatous Mastitis: A Case-control Study

Participants
Nina Capiro, MD, Culver City, California (*Presenter*) Nothing to Disclose

PURPOSE

To identify demographic and socioeconomic factors associated with granulomatous mastitis (GM).*Methods and Materials A retrospective case-control study was performed of 62 female patients with biopsy-proven GM at our institution from 11/2015 to 10/2020. Two age-matched controls per case were selected from patients presenting for diagnostic breast imaging. Demographic and socioeconomic characteristics were collected. Data were analyzed using univariable (odds ratio (OR) and 95% confidence interval (CI)) and multivariable conditional logistic regressions, and p<0.05 is statistically significant.*Results The mean (SD) age was 38.1 (8.9) and 38.1 (8.8) years for cases and controls respectively. When compared to age-matched controls, GM patients were more likely to identify as Hispanic/Latina (OR=5.7, CI=1.9, 16.6), to list Spanish as their preferred language (OR=5.5, CI=2.4,

12.7), and to be born in Mexico (OR=4.8, CI=1.6, 14.2). Cases were more likely to have no designated primary care provider (PCP) (OR=5.1, CI=2.2, 11.8) and to use Emergency Medi-Cal, a subset of California's Medicaid program for undocumented adults (OR=3.2, CI=1.6, 6.3). Although not statistically significant, there was a trend towards cases living in communities with slightly higher levels of poverty (cases 34% vs. controls 31% of population in home zip code living below 150% of the federal poverty level, p=0.06). These factors were not independently associated with GM in a multivariable model.*Conclusions Risk factors for GM include being Hispanic/Latina, having Spanish as a preferred language, being born in Mexico, and having limited healthcare access. Although most patients had government-assisted health insurance, cases were more likely to use Emergency Medi-Cal, suggesting that being undocumented is a risk factor for GM. These risk factors suggest that environmental and/or genetic factors are likely involved in the diagnosis of GM.*Clinical Relevance/Application GM is a benign inflammatory breast disease that can have an extended clinical course impacting quality of life and resulting in breast disfigurement. Diagnosis is often made by core-needle biopsy, and current treatment recommendations are controversial in the United States. Prior studies in the U.S. report GM predominantly affecting Hispanic/Latina patients, however we present the first study to further describe these patients as having Spanish as their preferred language, being born in Mexico, having poor healthcare access and being undocumented. Our institution provides care to an underserved community, however the cohort of GM patients proves to be uniquely underserved. By bringing to light such healthcare disparities, we hope to encourage further research to determine more effective treatments.

RESULTS

The mean (SD) age was 38.1 (8.9) and 38.1 (8.8) years for cases and controls respectively. When compared to age-matched controls, GM patients were more likely to identify as Hispanic/Latina (OR=5.7, CI=1.9, 16.6), to list Spanish as their preferred language (OR=5.5, CI=2.4, 12.7), and to be born in Mexico (OR=4.8, CI=1.6, 14.2). Cases were more likely to have no designated primary care provider (PCP) (OR=5.1, CI=2.2, 11.8) and to use Emergency Medi-Cal, a subset of California's Medicaid program for undocumented adults (OR=3.2, CI=1.6, 6.3). Although not statistically significant, there was a trend towards cases living in communities with slightly higher levels of poverty (cases 34% vs. controls 31% of population in home zip code living below 150% of the federal poverty level, p=0.06). These factors were not independently associated with GM in a multivariable model.

CLINICAL RELEVANCE/APPLICATION

GM is a benign inflammatory breast disease that can have an extended clinical course impacting quality of life and resulting in breast disfigurement. Diagnosis is often made by core-needle biopsy, and current treatment recommendations are controversial in the United States. Prior studies in the U.S. report GM predominantly affecting Hispanic/Latina patients, however we present the first study to further describe these patients as having Spanish as their preferred language, being born in Mexico, having poor healthcare access and being undocumented. Our institution provides care to an underserved community, however the cohort of GM patients proves to be uniquely underserved. By bringing to light such healthcare disparities, we hope to encourage further research to determine more effective treatments.

BR03-B7   Parenchymal Field Effect Analysis For Breast Cancer Risk Assessment: Evaluation Of FFDM Similarity Using Deep Learning Features

Participants
Natalie Baughan, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

In women with biopsy-proven breast cancer, histologically normal areas of the parenchyma and the tumor have shown molecular similarity, supporting the hypothesis of a cancer field effect. The purpose of this work was to further investigate a potential field effect in mammographic parenchymal patterns in multiple regions across the breast.*Methods and Materials The study included 103 FFDMs with at least one identified malignant tumor. All images (12-bit quantization, 70-micron pixels) were acquired with a Hologic Lorad Selenia system. Regions of interest (ROI) of 128x128 pixels were selected within the identified tumor, adjacent to the tumor, distant from the tumor, and behind the nipple in the contralateral breast within the craniocaudal projection. 1472 deep learning features were extracted using a VGG19 architecture. Features with low variance were excluded and principal component analysis was used to reduce dimensionality. The Kolmogorov-Smirnov (KS) test was used to assess similarity between the distributions of the first 20 principal components (86.5% of the total variance) for each ROI region, taken to be pseudo-features. Using the KS test statistic and a 95% confidence interval (CI) calculated using 2000 bootstrap iterations, compared distributions were claimed to be statistically equivalent if the CI fell below a critical value calculated at the p=0.05 threshold. Euclidean distance between the geometric means of each ROI region plotted using the first two principal components was also used to examine relationships between ROI regions.*Results KS test results indicated that 90.5% of feature distributions across all ROI regions achieved statistical equivalence. Distance between the tumor cluster geometric mean and the near, distant, and contralateral ROI cluster geometric means was 0.165, 0.219, and 0.197, respectively, with the tumor cluster showing more overlap with features from the near ROI region.*Conclusions Results indicate broad similarity across tumor and non-tumor regions in mammographic parenchymal patterns, while features extracted from ROIs closer to the tumor tend to show more similarity to the tumor than features extracted from distant ROIs.*Clinical Relevance/Application This study provides evidence in support of a breast cancer field effect that is identifiable through mammographic image analysis, which could improve risk assessment and guide screening.

RESULTS

KS test results indicated that 90.5% of feature distributions across all ROI regions achieved statistical equivalence. Distance between the tumor cluster geometric mean and the near, distant, and contralateral ROI cluster geometric means was 0.165, 0.219, and 0.197, respectively, with the tumor cluster showing more overlap with features from the near ROI region.

CLINICAL RELEVANCE/APPLICATION

This study provides evidence in support of a breast cancer field effect that is identifiable through mammographic image analysis, which could improve risk assessment and guide screening.

BR03-B9   Barriers And Facilitators To Implementation Of Breast Cancer Risk Assessment: The Healthcare Team Perspective

Participants
Lucy Spalluto, MD,MPH, Nashville, Tennessee (*Presenter*) Nothing to Disclose

PURPOSE

Breast cancer risk assessment (RA) tools can identify women at high risk for developing breast cancer. The American College of Radiology and American Society of Breast Surgeons recently issued recommendations for women to have breast cancer RA

performed no later than age 30. Yet, while breast cancer RA tools are widely available, they are not used routinely in standard clinical practice. This gap in evidence-based practice may lead to missed opportunities to identify women at high risk for breast cancer. The objective of our study is to assess healthcare professionals' perceived barriers and facilitators to the utilization of breast cancer risk assessment tools through stakeholder interviews.*Methods and Materials We performed a cross-sectional observational study of telephone interviews with healthcare team members with a role in breast cancer screening. We recruited from three organizations: 1) state breast and cervical screening program 2) federally qualified health center, and 3) safety net hospital. A research team member conducted recorded interviews that followed a semi-structured guide developed using the Consolidated Framework for Implementation Research (CFIR). An initial emergent hierarchical coding system was developed using the interview guide and a preliminary review of the transcripts. Reliability was established by three coders independently coding four transcripts. Coding was then compared and discrepancies resolved. Coders divided and independently coded the remaining quotes. The codebook evolved as new themes arose in subsequent transcripts. Analysis consisted of interpreting the coded quotations and identifying higher order themes.*Results Of 73 participants invited, 27 agreed to participate. Of those, 24 completed an interview. We identified several emerging themes. Perceived patient barriers: cost, insurance coverage, distrust, lack of interest/motivation. Clinic workflow barriers: shortage of staff, language barriers, staff buy-in, documentation. Barriers to follow-up: cost, transportation, finding high-quality care. Facilitators to increase utilization of RA: independent and workshop learning, team meetings, leadership buy-in, coordination of guidelines.*Conclusions We identified several emerging themes regarding barriers to and facilitators of implementation of breast cancer RA. Barriers include perceived patient barriers, clinic workflow and follow-up challenges. Facilitators include improved learning, leadership buy-in, and coordination of guidelines.*Clinical Relevance/Application Our results will inform a larger scale intervention study to develop implementation strategies to increase uptake of breast cancer risk assessment.

RESULTS

Of 73 participants invited, 27 agreed to participate. Of those, 24 completed an interview. We identified several emerging themes. Perceived patient barriers: cost, insurance coverage, distrust, lack of interest/motivation. Clinic workflow barriers: shortage of staff, language barriers, staff buy-in, documentation. Barriers to follow-up: cost, transportation, finding high-quality care. Facilitators to increase utilization of RA: independent and workshop learning, team meetings, leadership buy-in, coordination of guidelines.

CLINICAL RELEVANCE/APPLICATION

Our results will inform a larger scale intervention study to develop implementation strategies to increase uptake of breast cancer risk assessment.

IR03-C1 First-in-human Evaluation Of An AR Platform With Real-time Projection And Wireless Sharing Of Live Images During Ultrasound-guided Procedures

Participants
Gaurav Gadodia, MD, Cleveland, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

Current ultrasound (US) guided procedures utilize monitors fixed to machines or projected locally to screens usually within the procedure room. The purpose of this study is to describe the first-in-human clinical evaluation of an augmented reality (AR) platform that allows for customizable real-time holographic projection, sharing, and annotation of live-streaming images during US-guided procedures.*Methods and Materials A team at our institution developed an AR platform using the Microsoft Hololens (Washington, USA) head-mounted display (HMD) that can capture live images from an US machine and project them as holograms on a heads-up display on the HMD. The heads-up display can be moved anywhere in space by gestures made by the primary operator. Platform functionality also incorporates real-time sharing of the holograms projected on the heads-up display, including the live US images, to other devices via wireless transmission, with the ability for two-way communication. The first case of an IRB-approved study evaluating the utility of this platform in US-guided procedures has been completed so far, with the platform being used in a case of US-guided central venous access.*Results In this first use to date evaluating this platform, the moveable and scalable holographic heads-up display allowed the operator to position the US-images to a location in space per their preference. Furthermore, the image sharing and active communication features were used successfully, with a second operator able to watch the procedure from a first-person perspective of the on-site operator in real time from another location on their mobile device, and discuss the case directly with the primary operator during needle placement.*Conclusions First-in-human testing of this US-based AR HMD platform demonstrated the ability for improved ergonomic positioning of the live US images as compared to the traditional fixed monitor, which may allow for improved hand-eye coordination during needle placement. Additionally, successful use of the image sharing and communication functions exhibits the potential for remote collaboration. Further clinical investigation of this platform for use in US-guided procedures is ongoing.*Clinical Relevance/Application The improved ergonomics and potential resulting improved hand-eye coordination afforded by this AR HMD platform can improve success of needle placement and, thus, patient outcomes. Moreover, the remote collaboration functionality has implications for telehealth and procedural training.

RESULTS

In this first use to date evaluating this platform, the moveable and scalable holographic heads-up display allowed the operator to position the US-images to a location in space per their preference. Furthermore, the image sharing and active communication features were used successfully, with a second operator able to watch the procedure from a first-person perspective of the on-site operator in real time from another location on their mobile device, and discuss the case directly with the primary operator during needle placement.

CLINICAL RELEVANCE/APPLICATION

The improved ergonomics and potential resulting improved hand-eye coordination afforded by this AR HMD platform can improve success of needle placement and, thus, patient outcomes. Moreover, the remote collaboration functionality has implications for telehealth and procedural training.

IR03-C2 Initial Experience Using A Novel Computed Tomography System With Fully Integrated 3D Laser Guidance System For CT Based Interventions

Participants
Roy Marcus, MD, Meggen, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

The spectrum and precision of CT interventions highly benefit from dedicated either integrated or secondary add-on navigations systems. Integrated laser navigation systems are limited by providing a laser beam perpendicular to the x-ray beam (in plane) within the CT gantry while secondary nonintegrated systems require cumbersome calibration and image registration tasks. Here, we report our initial experience with a novel CT system enhanced with a fully integrated realtime 3D laser guidance system that allows needle guidance outside the CT gantry and needle track planning in double-oblique orientations (through plane). *Methods and Materials Various CT interventions of total 20 patients (tumor biopsy 17, abscess drainage 3) were performed on a novel 128 row MDCT scanner system with fully integrated 3D laser guidance navigation system. A total of 4 laser modules integrated into the front-face of the CT gantry allow the projection of two laser planes with a corresponding intersection line providing the needle path for the preplanned intervention. The laser 3D guidance is projected on the patient in a parking position outside the CT gantry. CT interventions were analyzed for ease of use, reliability, through plane intervention capability and compared to standard in gantry CT fluoroscopy procedures.*Results All 20 interventions were successfully performed using the novel 3D integrated Laser guidance system. The cutaneous puncture site was determined in all patients in park position outside the gantry using the guidance system. In all patients the needle advancement along the provided path was achieved up to half of the final distance by using the 3D system uniquely and was followed by a position control scan using a standard CT fluoroscopic mode in gantry approach. The

number of CT fluoroscopic views was reduced by approximately half the amount compared to standard guidance systems. The 3D planning tool made it possible to perform CT interventions off the normal in plane orientation, which would otherwise not have been possible using standard in gantry navigation systems.*Conclusions The use of a novel CT system with fully integrated 3D laser guidance system allows structured and dedicated pre-interventional planning, enhances safety during intervention with a fixed, laser guided puncture path and provides a comfortable and safe procedure outside of the gantry with the ultimate potential to reduce radiation dose due to lesser use of fluoroscopy views. Difficult CT interventions, requiring a double-oblique off plane needle path orientation, became possible using this 3D laser guidance system.*Clinical Relevance/Application 3D laser guidance system allows a safe and comfortable CT intervention with potential dose saving

RESULTS

All 20 interventions were successfully performed using the novel 3D integrated Laser guidance system. The cutaneous puncture site was determined in all patients in park position outside the gantry using the guidance system. In all patients the needle advancement along the provided path was achieved up to half of the final distance by using the 3D system uniquely and was followed by a position control scan using a standard CT fluoroscopic mode in gantry approach. The number of CT fluoroscopic views was reduced by approximately half the amount compared to standard guidance systems. The 3D planning tool made it possible to perform CT interventions off the normal in plane orientation, which would otherwise not have been possible using standard in gantry navigation systems.

CLINICAL RELEVANCE/APPLICATION

3D laser guidance system allows a safe and comfortable CT intervention with potential dose saving

IR03-C3   Non-anatomical Resections Vs. Image-guided Ablations In Multimodal Treatment Of Colorectal Cancer Liver Metastases: An Intraindividual Comparison

Participants
Lea Hitpass, MD, Aachen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To compare the results of local ablation and non-anatomical resection in patients who underwent both treatments as part of multimodal therapy of colorectal cancer liver metastases (CRCLM).*Methods and Materials All patients who underwent both image-guided ablation and non-anatomical parenchymal sparing resection of CRCLM in curative intent between January 2010 and December 2020 were included in this retrospective study. Only first treatments of each lesion were included, regardless of modality, and each lesion only received one kind of treatment. Both intraoperative US-guided and percutaneous CT-guided ablations were included. The incidence and time to local recurrence of the treated lesions within each treatment modality group were compared using the chi-square test and Kaplan-Meier analysis, respectively.*Results A total of 41 patients (27 male, 14 female) undergoing 110 non-anatomical resections and 66 ablations (mean 2.7 and 1.6 per patient, respectively) were analysed. Of the latter, 23/66 were radiofrequency ablations (RFA) and 43/66 microwave ablations (MWA). There were no statistically significant differences in recurrence rates between resections and ablations (n = 19, 17% vs. n = 8, 12%, p = 0.359) or between ablation types (RFA n = 2, 8,7% vs. MWA n = 6, 14%, p = 0.533). Moreover, there was no difference in time to local recurrence within 12 months (median 11.1 vs 11.0 months, p = 0.803) or 3 years (median 30.5 months vs 30.0 months, p = 0.921). Median follow-up was 20.5 month (range: 1-114 month).*Conclusions There is no significant difference in recurrence rates or time to local recurrence when non-anatomical parenchyma-sparing resections and local ablations of colorectal cancer liver metastases are compared in the same patients.*Clinical Relevance/Application An intraindividual comparison of non-anatomical resection and ablation demonstrates equivalent outcomes where recurrence rates and time to local recurrence are concerned. Therefore, choice of modality should be based on tumor localization and accessibility, as well as patient physical condition.

RESULTS

A total of 41 patients (27 male, 14 female) undergoing 110 non-anatomical resections and 66 ablations (mean 2.7 and 1.6 per patient, respectively) were analysed. Of the latter, 23/66 were radiofrequency ablations (RFA) and 43/66 microwave ablations (MWA). There were no statistically significant differences in recurrence rates between resections and ablations (n = 19, 17% vs. n = 8, 12%, p = 0.359) or between ablation types (RFA n = 2, 8,7% vs. MWA n = 6, 14%, p = 0.533). Moreover, there was no difference in time to local recurrence within 12 months (median 11.1 vs 11.0 months, p = 0.803) or 3 years (median 30.5 months vs 30.0 months, p = 0.921). Median follow-up was 20.5 month (range: 1-114 month).

CLINICAL RELEVANCE/APPLICATION

An intraindividual comparison of non-anatomical resection and ablation demonstrates equivalent outcomes where recurrence rates and time to local recurrence are concerned. Therefore, choice of modality should be based on tumor localization and accessibility, as well as patient physical condition.

IR03-C4   Magnetic Resonance Guided Focused Ultrasound Surgery For The Treatment Of Oligometastatic Prostate Cancer Bone Metastasis. Can Sound Waves Downstage Cancer Spread?

Participants
Alessandro De Maio, Rome, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To assess the ability of Magnetic Resonance guided Focused Ultrasound Surgery (MRgFUS) to target bone metastasis and so downstage patients affected by oligometastatic prostate cancer using a single treatment session.*Methods and Materials Eligibility criteria included the presence of bone metastasis accessible to MRgFUS (InSightec, Israel) for a safe procedure in locations accepted by international consensus. Baseline measurable patients' characteristics included dynamic contrast enhanced MRI study (Gd-BOPTA, Bracco; GE 750 3T magnet) with semiquantitative perfusion analysis, PSA levels (ng/ml) and choline PET Standardized Uptake Value (SUV). Such variables of interest were obtained at treatment time, 3 months, 12 months and 24 months follow-up, then analysed via paired samples t-test.*Results A total of 18 patients fulfilled the inclusion criteria for this study and safely underwent MRgFUS procedure for metastatic bone ablation. Lesions were located in the pelvis (n=11), scapula (n=3) and long bones (n=4). At baseline DCE perfusion imaging, all targeted metastases showed evidence of highly vascular characteristics. A mean perfusion reduction of 88% from baseline was found at 3 months follow-up (CI: 100-50; p<0.001), then stable at subsequent follow-up scans. Similarly, PSA levels decreased from a mean baseline of 19 (ng/ml) to mean values of 7.1 (p<0.001 for comparison), 2.9 and 2.1, respectively at 3, 12 and 24 moths follow-up. SUV showed a comparable trend of reduction from a baseline mean of 8.9 to subsequent follow-up mean values equal to 3.0 (p<0.001 for comparison), 2.3 and 1.7. No treatment-

related adverse events were reported during the study.*Conclusions MRgFUS is a non-invasive procedure that can obtain nearly complete bone metastasis ablation in patients affected by oligometastatic prostate cancer. The technique features a radiation-free approach that can significantly reduce the risk of toxic effects in oncological patients, not only for palliative purposes, but possibly ablative too. Larger-sample studies are needed in order to advance this possibility into practice.*Clinical Relevance/Application The presented study on feasibility of MRgFUS, targeting bone metastasis, for the purpose of downstaging in patients affected by oligometastatic prostate cancer shows promising initial results of such an application.

RESULTS

A total of 18 patients fulfilled the inclusion criteria for this study and safely underwent MRgFUS procedure for metastatic bone ablation. Lesions were located in the pelvis (n=11), scapula (n=3) and long bones (n=4). At baseline DCE perfusion imaging, all targeted metastases showed evidence of highly vascular characteristics. A mean perfusion reduction of 88% from baseline was found at 3 months follow-up (CI: 100-50; $p<0.001$), then stable at subsequent follow-up scans. Similarly, PSA levels decreased from a mean baseline of 19 (ng/ml) to mean values of 7.1 ($p<0.001$ for comparison), 2.9 and 2.1, respectively at 3, 12 and 24 moths follow-up. SUV showed a comparable trend of reduction from a baseline mean of 8.9 to subsequent follow-up mean values equal to 3.0 ($p<0.001$ for comparison), 2.3 and 1.7. No treatment-related adverse events were reported during the study.

CLINICAL RELEVANCE/APPLICATION

The presented study on feasibility of MRgFUS, targeting bone metastasis, for the purpose of downstaging in patients affected by oligometastatic prostate cancer shows promising initial results of such an application.

NMMI02-B2 Detection Of Additional Primary Neoplasms On 18F-FACBC PET/CT In Patients With Primary Prostate Cancer

Participants
Ashwin Parihar, MBBS, MD, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the detection rate of incidental second primary neoplasms in patients with prostate cancer on 18F-FACBC PET/CT.*Methods and Materials Imaging reports and patient demographic data were retrospectively reviewed from 663 clinical 18F-FACBC (FACBC) PET/CT studies, performed in 601 patients for the assessment of their prostate cancer from August 2016 to April 2021. SUVmax values of the suspected second neoplasms were determined. The results of FACBC PET/CT were correlated with clinical and radiological studies to determine the nature of the suspected second neoplasms.*Results 55 patients (9.1%) had findings suspicious for a second neoplasm. 39/55 had a known second malignancy diagnosis prior to the PET/CT. An incidental second primary neoplasm was first suspected on FACBC PET/CT in 16/601 patients (2.7%). 3/16 patients had PET/CT suggestive of a benign meningioma that was corroborated on magnetic resonance imaging (MRI). Of the remaining 13 patients, 11 had a tissue diagnosis confirming a malignancy. Second malignancies included renal cell carcinoma (RCC; 5/11; 45.5%), urothelial carcinoma (n=2), multiple myeloma, chondrosarcoma, cutaneous squamous cell carcinoma, squamous cell carcinoma of the esophagus and lung (n=1, each; except for esophageal and lung carcinoma being diagnosed in a single patient). Among histopathologic confirmed malignancies, clear-cell RCC had the lowest uptake (SUVmax 3.4), and cutaneous squamous cell carcinoma had the highest uptake (SUVmax 13.6). Of the two patients with no histopathologic confirmation, one had ultrasound and MRI findings corroborating the diagnosis of RCC. The other patient had a solitary lung nodule suspicious for primary lung carcinoma and elected to undergo observation.*Conclusions Incidental findings consistent with a second primary neoplasm are not infrequently seen on FACBC PET/CT for prostate cancer (9.1%). Of the incidentally detected primary cancers, RCC was the most common (45.5%). These findings indicate the need for a careful analysis of FACBC PET/CT images, and confirm the broad tumor imaging capabilities of FACBC. *Clinical Relevance/Application 18F-FACBC is a synthetic amino-acid analog and is not tumor-specific. This review of 663 FACBC PET/CT studies in 601 patients, which to our knowledge is the largest of its kind, has shown that some malignancies such as clear-cell RCC, can be identified on a routine PET/CT and need special attention to prompt further investigations. Additionally, abnormal areas of focal tracer avidity that are not typical of spread of prostate cancer need evaluation for a second neoplasm. In our series, incidental thyroid cancers were not a frequent finding, which differs from previously reported observations with 18F-FDG PET/CT.

RESULTS

55 patients (9.1%) had findings suspicious for a second neoplasm. 39/55 had a known second malignancy diagnosis prior to the PET/CT. An incidental second primary neoplasm was first suspected on FACBC PET/CT in 16/601 patients (2.7%). 3/16 patients had PET/CT suggestive of a benign meningioma that was corroborated on magnetic resonance imaging (MRI). Of the remaining 13 patients, 11 had a tissue diagnosis confirming a malignancy. Second malignancies included renal cell carcinoma (RCC; 5/11; 45.5%), urothelial carcinoma (n=2), multiple myeloma, chondrosarcoma, cutaneous squamous cell carcinoma, squamous cell carcinoma of the esophagus and lung (n=1, each; except for esophageal and lung carcinoma being diagnosed in a single patient). Among histopathologic confirmed malignancies, clear-cell RCC had the lowest uptake (SUVmax 3.4), and cutaneous squamous cell carcinoma had the highest uptake (SUVmax 13.6). Of the two patients with no histopathologic confirmation, one had ultrasound and MRI findings corroborating the diagnosis of RCC. The other patient had a solitary lung nodule suspicious for primary lung carcinoma and elected to undergo observation.

CLINICAL RELEVANCE/APPLICATION

18F-FACBC is a synthetic amino-acid analog and is not tumor-specific. This review of 663 FACBC PET/CT studies in 601 patients, which to our knowledge is the largest of its kind, has shown that some malignancies such as clear-cell RCC, can be identified on a routine PET/CT and need special attention to prompt further investigations. Additionally, abnormal areas of focal tracer avidity that are not typical of spread of prostate cancer need evaluation for a second neoplasm. In our series, incidental thyroid cancers were not a frequent finding, which differs from previously reported observations with 18F-FDG PET/CT.

NMMI02-B4 Intravenous Short-acting Insulin Therapy Impact On The 18F-FDG PET-CT Biodistribution On Incidentally Detected Hyperglycemic Patents

Participants
Aurora Mercado Sanchez, MD, Monterrey, Mexico (*Presenter*) Nothing to Disclose

PURPOSE

18F-FDG is the most used radiotracer in PET/CT, however, different situations may alter its biodistribution, hyperglycemia being one of the most frequent and with a great impact on its diagnostic accuracy; international guidelines have proposed different patient preparation protocols; with some controversy on the use of hypoglycemic agents on high FBG levels. The aim of this study is to evaluate the use of IV short-acting insulin through a safe and effective protocol to obtain acceptable image quality, without significant alteration of FDG biodistribution and the need to reschedule patients with hyperglycemia >190 mg/dl prior to the

administration of the radiotracer.*Methods and Materials A retrospective, cross-sectional, analytical study, was developed with 50 patients divided into two groups. Group I: with FBG>190 mg/dl and Group II: with FBG <180 mg/dl. Group I, received 25 IU IV short-acting insulin infusion until an FBG of <160 mg/dl was obtained, post insulin after 30 minutes radiotracer injection was given and PET/CT scan was obtained 60 min post radiotracer injection. A qualitative analysis of radiotracer was performed using a biodistribution score and a semi-quantitative analysis with the measurement of the standardized uptake value (SUV) on brain, myocardium, liver, and gluteal muscle.*Results Group I, showed a significant decrease in FBG levels (273.80 ± 48.59 to 135.30 ± 23.90mg/dL) and acceptable image quality, also when comparing to Group II, no significant difference on myocardium/liver SUVmean (2.86+1.45/2.28+0.63) respectively, was found. Diabetes was a significant factor for a non-acceptable biodistribution with p value <0.05. No patient had any complications.*Conclusions This protocol on hyperglycemic patients was safe and effective. Liver uptake, a standard measurement for many disorders, had no significant uptake alteration, being useful for accurate diagnosis. Group I showed acceptable biodistribution on 50%, nevertheless, 100% of the patients within revealed hypermetabolic tumor activity, without the need to reschedule.*Clinical Relevance/Application Short-acting insulin on hyperglycemic patients at hospitals with adequate infrastructure may be safe and effective and would reduce costs related to rescheduling and the delay in patient's diagnosis.

RESULTS

Group I, showed a significant decrease in FBG levels (273.80 ± 48.59 to 135.30 ± 23.90mg/dL) and acceptable image quality, also when comparing to Group II, no significant difference on myocardium/liver SUVmean (2.86+1.45/2.28+0.63) respectively, was found. Diabetes was a significant factor for a non-acceptable biodistribution with p value <0.05. No patient had any complications.

CLINICAL RELEVANCE/APPLICATION

Short-acting insulin on hyperglycemic patients at hospitals with adequate infrastructure may be safe and effective and would reduce costs related to rescheduling and the delay in patient's diagnosis.

HN01-A3   **Imaging Assessment Of Head And Neck Paragangliomas With Emphasis On Detection Of Gene Mutation, Posttreatment Changes, And Differentiation From Other Tumors**

Participants
Yoshiaki Ota, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is 1. To review genetics and tumorigenesis of hereditary head and neck paragangliomas2. To predict succinate dehydrogenase (SDH) mutations using diffusion-weighted images, MR spectroscopy, and T2 texture analysis3. To demonstrate post-radiation therapy changes and differentiation from other tumors using DCE-MRI

TABLE OF CONTENTS/OUTLINE

1. Genetics and tumorigenesis- Succinate dehydrogenase mutations: SDHA, SDHB, SDHC, SDHD, and SDHAF2 - Pathophysiology of tumorigenesis associated with loss of SDH 2. Prediction of SDH mutation status - MR spectroscopy- Diffusion-weighted images- T2 texture analysis 3. Assessment of post-radiation therapy changes and differentiation from other tumors using DCE-MRI- Conventional MRI- DCE-MRI

PD03-A2   **Risk Of Hypersensitivity Reactions To Iopromide In Children And Elderly: An Analysis Of 132,850 Patients From Four Observational Studies And Pharmacovigilance Covering 287 Million Administrations**

Participants
Jan Endrikat, Berlin, Germany (*Presenter*) Researcher, Bayer AG

PURPOSE

To analyze the risk of hypersensitivity reactions (HSRs) to iopromide in children and elderly patients in comparison to adults.*Methods and Materials Four observational studies were pooled and analyzed (Analysis I). In addition, spontaneous reports from 1985 to 2020 from the global pharmacovigilance database (GPV) were evaluated (Analysis II). All patients received iopromide for angiographic procedures or contrast enhanced computed tomography in various indications. Analysis I. An observational nested case-control analysis, including a multivariable logistic regression model, based on an integrated pooled database was performed. Cases were defined as patients with a typical and unequivocal HSR, controls were patients without any recorded reaction. Analysis II: All spontaneous reports on HSRs after iopromide administration recorded in the GPV database were descriptively analyzed. Exposure estimates were derived from sales data and data from market research. The primary target variable was the risk of HSR to iopromide in children (<18 years) and elderly patients (=65 years) compared to adults (=18 to <65 years).*Results Analysis I A total of 132,850 patients were included: 2978 children, 43,209 elderly and 86,663 adults. HSRs were significantly less frequent in children (0.47%) and elderly (0.38%) compared to adults (0.74%). The adjusted odds ratio (vs. adults) for children was 0.58 ([95% CI: 0.34 - 0.98], p<0.043) and 0.51 ([95% CI: 0.43 - 0.61] for elderly p<0.001), indicating a lower risk for both sub-populations as compared to adults. Analysis II: Of the overall >287 million iopromide administrations 5.87, 114.18 and 167.97 million administrations were applied to children, elderly and adults, respectively. The reporting rate for HSRs in children (0.0114%) and elderly (0.0071%) was significantly lower as compared to adults (0.0143%) (p<0.0001).*Conclusions HSRs to iopromide were significantly less frequent in children and elderly compared to adults. This could be related to the less active immune system in these age groups.*Clinical Relevance/Application HSRs are less frequent in the clinically important age groups of children and elderly.

RESULTS

Analysis I A total of 132,850 patients were included: 2978 children, 43,209 elderly and 86,663 adults. HSRs were significantly less frequent in children (0.47%) and elderly (0.38%) compared to adults (0.74%). The adjusted odds ratio (vs. adults) for children was 0.58 ([95% CI: 0.34 - 0.98], p<0.043) and 0.51 ([95% CI: 0.43 - 0.61] for elderly p<0.001), indicating a lower risk for both sub-populations as compared to adults. Analysis II: Of the overall >287 million iopromide administrations 5.87, 114.18 and 167.97 million administrations were applied to children, elderly and adults, respectively. The reporting rate for HSRs in children (0.0114%) and elderly (0.0071%) was significantly lower as compared to adults (0.0143%) (p<0.0001).

CLINICAL RELEVANCE/APPLICATION

HSRs are less frequent in the clinically important age groups of children and elderly.

VA05-A1   **Comparison Of 2D And 3D Quiescent Interval Slice-selective Non-contrast MR Angiography In Patients With Peripheral Artery Disease**

Participants
Akos Varga-Szemes, MD, PhD, Charleston, South Carolina (*Presenter*) Research Grant, Siemens AGResearch Consultant, Elucid Bioimaging IncResearch Consultant, Bayer AG

PURPOSE

To evaluate the potential clinical benefit of the superior spatial resolution of 3D prototype thin-slab stack-of-stars (tsSOS) quiescent interval slice-selective (QISS) MRA over standard 2D-QISS MRA for the detection peripheral artery disease (PAD), using computed tomography angiography (CTA) as reference.*Methods and Materials Twenty-three patients (70±8 years, 18 men) with PAD who had previously undergone run-off CTA were prospectively enrolled. Patients underwent non-contrast MRA using 2D-QISS and tsSOS-QISS at 1.5T. Eighteen arterial segments were evaluated for subjective and objective image quality (normalized signal-to-noise, nSNR), vessel sharpness, and area under the curve (AUC) for >50% stenosis detection.*Results Overall subjective image quality ratings for the entire run-off were not different between tsSOS-QISS and 2D-QISS (3 [3; 4] vs 4 [3; 4], respectively; P=0.813). Sharpness of primary branch vessels demonstrated improved image quality using tsSOS-QISS compared with 2D-QISS (4 [3; 4] vs 3 [2; 3], P=0.008). Objective image quality measures were not different between 2D-QISS and tsSOS-QISS (nSNR 5.0±1.9 vs 4.2±1.8; P=0.132). AUCs for significant stenosis detection by tsSOS-QISS and 2D-QISS were 0.877 and 0.856, respectively (P=0.336).*Conclusions The prototype 3D tsSOS-QISS technique provides similar accuracy in patients with PAD to a standard commercially available 2D-QISS technique, indicating that the use of relatively thick slices does not limit the diagnostic performance of 2D-QISS. However, subjective image quality for branch vessel depiction is improved using the 3D approach.*Clinical Relevance/Application The 3D tsSOS-QISS approach obviates the need for breath-holding in the abdomen and upper pelvis and improves image quality for branch vessel depiction, therefore may supplement standard QISS if visualization of small caliber arteries is needed.

RESULTS

Overall subjective image quality ratings for the entire run-off were not different between tsSOS-QISS and 2D-QISS (3 [3; 4] vs 4 [3; 4], respectively; P=0.813). Sharpness of primary branch vessels demonstrated improved image quality using tsSOS-QISS compared with 2D-QISS (4 [3; 4] vs 3 [2; 3], P=0.008). Objective image quality measures were not different between 2D-QISS and tsSOS-QISS (nSNR 5.0±1.9 vs 4.2±1.8; P=0.132). AUCs for significant stenosis detection by tsSOS-QISS and 2D-QISS were 0.877 and 0.856, respectively (P=0.336).

CLINICAL RELEVANCE/APPLICATION

The 3D tsSOS-QISS approach obviates the need for breath-holding in the abdomen and upper pelvis and improves image quality for branch vessel depiction, therefore may supplement standard QISS if visualization of small caliber arteries is needed.

CA04-B1   Diagnostic Value Of Dual-energy Cardiac CTA In Left Atrial Appendage Thrombus

Participants
Feifei Zhang, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To exploring the diagnosis value of dual-energy cardiac computed tomography angiography (CTA) in detecting left atrial appendage thrombus.*Methods and Materials 180 Patients with atrial fibrillation who underwent cardiac CTA protocol (dual-energy scan for arterial phase and conventional scan for delay phase) were retrospectively enrolled in our study. The diagnosis results based on the delay phase images served as the reference standard for left atrial appendage thrombus. Quantitative dual-energy parameters, including virtual non-contrast(VNC) CT value, the added contrast CT value(?CT value), iodine concentration(IC), normalized iodine concentration (NIC) and energy spectrum curve slope (Slope) were measured for the left atrial appendage regions. The between group differences were compared by independent t-test or Wilcoxon rank sum test regarding to the normality test. The diagnosis performance of the dual-energy parameters was assessed using receiver operating characteristic curve(ROC) analysis and area under curve(AUC).*Results A total of 52 patients (25 M/22 F;mean age 62.25 ± 9.65 years) with left atrial appendage thrombus (n=10) and circulatory stasis (n=42) were finally included. The?CT values, IC, NIC and Slope were demonstrated significantly difference between left atrial appendage thrombus and circulatory stasis group (?CT values:12.64 vs 62.94HU; IC:0.12 vs 2.47; NIC:0.00 vs 19.87; Slope: -0.20 vs -5.29; p<0.05, respectively). ROC analysis revealed Slope was the most predictive parameter with area under curve equal to 0.974.In addition,the radiation dose (mSV) in the duel-energy CTA was 2.48±0.38mSV.*Conclusions Dual-energy CTA scanning shows great diagnosis value in detecting left atrial appendage thrombus with lower radiation dose.*Clinical Relevance/Application Arterial phase duel-energy CTA is recommended to replace conventional two-phase acquisition to detecting left atrial appendage thrombus and obtaining clear anatomical structure in patients with atrial fibrillation.

RESULTS

A total of 52 patients (25 M/22 F;mean age 62.25 ± 9.65 years) with left atrial appendage thrombus (n=10) and circulatory stasis (n=42) were finally included. The?CT values, IC, NIC and Slope were demonstrated significantly difference between left atrial appendage thrombus and circulatory stasis group (?CT values:12.64 vs 62.94HU; IC:0.12 vs 2.47; NIC:0.00 vs 19.87; Slope: -0.20 vs -5.29; p<0.05, respectively). ROC analysis revealed Slope was the most predictive parameter with area under curve equal to 0.974.In addition,the radiation dose (mSV) in the duel-energy CTA was 2.48±0.38mSV.

CLINICAL RELEVANCE/APPLICATION

Arterial phase duel-energy CTA is recommended to replace conventional two-phase acquisition to detecting left atrial appendage thrombus and obtaining clear anatomical structure in patients with atrial fibrillation.

BR05-B1   Cardio Mammographic Serendipity Correlation Of Breast Vascular Calcification With Intima Media Thickness Surrogate Marker Of Cardiac Health

Participants
Sanjivanee Ingole, MBBS,MD, Amravati, India (*Presenter*) Nothing to Disclose

PURPOSE

To establish correlation of breast vascular calcification (BAC) with carotid intima media thickness(C-IMT) by comparing them with those without breast arterial calcifications, thus defining the status of cardiac health.*Methods and Materials Present study is hospital based prospective study. The sample size consisted of 272 women, all of whom underwent Mammogram. Relevant clinical history including diabetes mellitus, hypertension, heart disease & menopausal history was noted.The study group was divided into two groups of 136 subjects each depending on the presence of BAC. Group 1: Case group- BAC present. Group 2: Control group- BAC absent. All patients underwent ultrasound evaluation 8-13 MHz probe for C-IMT in bilateral common carotid arteries 1 cm proximal to the carotid bulb. The C-IMT in group 1 and group 2 were compared with vascular calcification seen on mammography.*Results The study included patients with age between 40-80 years. The mean age in case group was 56.89 ± 6.99 years and that in control group was 49.19 ± 7.59 years. Mean C-IMT in case group was 0.86 ± 0.14 mm and in control group was 0.63 ± 0.14 mm. Independent t test and Pearson correlation coefficient were performed. The study showed significant correlation of presence of BAC and increased C-IMT(p value = 0.009). Independent correlation of BAC was seen with diabetes, hypertension, heart disease (p value= 0.005) and with menopause (p value=0.00).*Conclusions ACR recommends screening mammograms for all women above 40 years of age for carcinoma screening. BAC is an incidental finding on a fair number of mammograms. C-IMT is a practical surrogate marker of coronary artery disease and in turn cardiovascular mortality and morbidity. C-IMT measurement is thus a predictor of future cardiovascuar morbidity and mortality. In this study we conclude that the presence of BAC shows statistically significant correlation increased C-IMT. In addition to this BAC also shows correlation with age, menopausal status & co-morbidities.*Clinical Relevance/Application Breast arterial calcification can give a clue toward cardiovascular health of the patient, guiding us towards further management thus reducing future cardiac morbidity and mortality

RESULTS

The study included patients with age between 40-80 years. The mean age in case group was 56.89 ± 6.99 years and that in control group was 49.19 ± 7.59 years. Mean C-IMT in case group was 0.86 ± 0.14 mm and in control group was 0.63 ± 0.14 mm. Independent t test and Pearson correlation coefficient were performed. The study showed significant correlation of presence of BAC and increased C-IMT(p value = 0.009). Independent correlation of BAC was seen with diabetes, hypertension, heart disease (p value= 0.005) and with menopause (p value=0.00).

CLINICAL RELEVANCE/APPLICATION

Breast arterial calcification can give a clue toward cardiovascular health of the patient, guiding us towards further management thus reducing future cardiac morbidity and mortality

BR05-B4   Using The Kaiser Score As A Clinical Decision Rule For Breast Lesion Classification: Do We Need Computer-assisted Curve Type Analysis?

Participants
Nina Poetsch, MD, Wien, Austria (*Presenter*) Nothing to Disclose

PURPOSE

The Kaiser score (KS) is a clinical decision rule to distinguish benign from malignant enhancing lesions in breast MRI. Enhancement curve type is the second most important criterion within the KS and can be assessed both visually and by using computer-assisted automated methods.*Methods and Materials For this IRB-approved retrospective cross-sectional study, we analyzed consecutive patients who underwent breast MRI for a BI-RADS 0, 4 or 5 rating in conventional imaging. Imaging was performed in prone position using a 1.5T scanner with a dedicated multichannel coil; the protocol included axial T2w and dynamic contrast enhanced sequences. The curve type was defined according to BI-RADS as Persistent, Plateau or Wash-out. Curve types were analyzed visually and with a pixel-wise computed parametric map (the latter using a relative initial enhancement threshold of 30%). The KS, a clinical decision rule was applied by rating five criteria (enhancement curve type, internal enhancement, margin features circumscribed vs. irregular, presence of spiculations and edema) resulting in assignment categories from 1 (= lowest risk of breast cancer) to 11 (= highest risk of breast cancer). Differences in curve type rating as well as final KS rating were compared using the AUC of the ROC curve. Inter-reader agreement was calculated with the Cohen's kappa statistics in a subset of 51 cases.*Results A total of 146 lesions (96 benign, 50 malignant) including mass (n=101 and 8 mass with associated non-mass) as well as non-mass lesions (n=37) were analyzed. Performance in distinguishing benign from malignant lesions using the KS did not differ significantly between visual analysis and parametric map (p=0.907; AUC visual 0.841 vs. AUC map 0.839). Using a KS >4 as a cut-off, we found a sensitivity of 92% and 94% at a specificity of 59% and 55% for visual analysis and parametric map respectively. Inter-reader agreement was moderate for both visual analysis (0.483) and parametric maps (0.428).*Conclusions Visual curve type analysis is as accurate as automatic curve type analysis using parametric maps.*Clinical Relevance/Application These results confirm the

robustness of the Kaiser score as its performance is not influenced by the way the enhancement curve type is assessed.

RESULTS

A total of 146 lesions (96 benign, 50 malignant) including mass (n=101 and 8 mass with associated non-mass) as well as non-mass lesions (n=37) were analyzed. Performance in distinguishing benign from malignant lesions using the KS did not differ significantly between visual analysis and parametric map (p=0.907; AUC visual 0.841 vs. AUC map 0.839). Using a KS >4 as a cut-off, we found a sensitivity of 92% and 94% at a specificity of 59% and 55% for visual analysis and parametric map respectively. Inter-reader agreement was moderate for both visual analysis (0.483) and parametric maps (0.428).

CLINICAL RELEVANCE/APPLICATION

These results confirm the robustness of the Kaiser score as its performance is not influenced by the way the enhancement curve type is assessed.

BR05-B6   Impact Of Race, Ethnicity, And Insurance Status On Breast Cancer Mortality At A Safety Net Academic Medical Center

Participants
Alexander Boyko, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Social determinants of health are factors impacting patient access to healthcare and affect disease outcomes. With decreased access, preventative interventions, such as routine screening mammography, are often underutilized, which may lead to increased mortality. We undertook this study to investigate whether race, ethnicity, and insurance status impact breast cancer mortality.*Methods and Materials This retrospective study was IRB-approved and HIPAA compliant. A review of the breast cancer registry at Boston Medical Center identified women diagnosed with breast cancer from 2008-2014. Data regarding the patient's demographics, insurance status, AJCC staging, and vital status was collected. Multivariate logistic regression modeling was used to assess mortality, and adjusted odds ratio (aOR) with 95% confidence interval (CI) were computed.*Results Of 1,155 patients who met the study criteria, 1,084 (93.9%) had complete information on all variables. The median age was 59 years (range 20-96). Distribution of race was as follows: White (n=477; 44.0%), Black (n=445, 41.1%) Asian (n=42, 3.9%) and Other (n=120, 11.1%). 909 (83.9%) patients identified as non-Hispanics. Distribution of insurance was as follows: Medicaid (n=370; 34.1%), Medicare (n=318, 29.3%), Private insurance (n=251, 23.2%), unspecified (n=62, 5.7%) and uninsured (n=83, 7.7%). Early and advanced-stage disease were present in 86% (n=932), and 14% (n=152), respectively. In multivariate analysis, no significant difference in mortality were noted by race (p=0.409) and ethnicity (p=0.398). Increasing age (aOR=1.03, 95% CI=1.01-1.05, p=0.0003) and advanced stage disease (aOR=8.24, 95% CI=5.47-12.41, p<0.0001) were associated with increased risk of death. Compared to privately insured patients, patients on Medicare had worse survival (aOR=1.77, 95% CI=1.02-3.08, p=0.041) but no difference was noted for patients on Medicaid (p=0.793), unspecified insurance (p=0.425) and uninsured (p=0.066).*Conclusions Race and ethnicity were not associated with survival in this study. Increasing age and patients with Medicare insurance reported worse survival after accounting for patient and clinical factors. Future analysis will explore these factors' impact on access to and compliance with screening mammography.*Clinical Relevance/Application Identifying factors that impact breast cancer mortality will help direct interventions to improve overall disease outcomes.

RESULTS

Of 1,155 patients who met the study criteria, 1,084 (93.9%) had complete information on all variables. The median age was 59 years (range 20-96). Distribution of race was as follows: White (n=477; 44.0%), Black (n=445, 41.1%) Asian (n=42, 3.9%) and Other (n=120, 11.1%). 909 (83.9%) patients identified as non-Hispanics. Distribution of insurance was as follows: Medicaid (n=370; 34.1%), Medicare (n=318, 29.3%), Private insurance (n=251, 23.2%), unspecified (n=62, 5.7%) and uninsured (n=83, 7.7%). Early and advanced-stage disease were present in 86% (n=932), and 14% (n=152), respectively. In multivariate analysis, no significant difference in mortality were noted by race (p=0.409) and ethnicity (p=0.398). Increasing age (aOR=1.03, 95% CI=1.01-1.05, p=0.0003) and advanced stage disease (aOR=8.24, 95% CI=5.47-12.41, p<0.0001) were associated with increased risk of death. Compared to privately insured patients, patients on Medicare had worse survival (aOR=1.77, 95% CI=1.02-3.08, p=0.041) but no difference was noted for patients on Medicaid (p=0.793), unspecified insurance (p=0.425) and uninsured (p=0.066).

CLINICAL RELEVANCE/APPLICATION

Identifying factors that impact breast cancer mortality will help direct interventions to improve overall disease outcomes.

BR05-B7   Features Of COVID-19 Vaccination Induced Axillary Lymphadenopathy And Subsequent Outcomes In Women Presenting For Breast Imaging

Participants
Aishwarya Gulati, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

To assess features and outcomes of COVID-19 vaccination induced axillary lymphadenopathy (LAD) in women presenting for breast imaging.*Methods and Materials Rolling retrospective study of women with recent COVID-19 vaccine administration who presented for either screening or diagnostic mammogram or axillary ultrasound (US) between January-April 2021. All included patients had axillary LAD, underwent axillary ultrasound, and had at least one vaccine dose prior to imaging. Patients with breast cancer history or findings in the breast were not excluded. Those with systemic disease known to cause LAD were excluded. Patient characteristics, US features of LAD, and management of these patients were reviewed.*Results 30 women met inclusion criteria with an average age of 51.4 ± 13 years. 19 cases of LAD were incidentally identified on screening mammography and recalled for further evaluation; 11 cases presented for diagnostic imaging of which 72% were for axillary symptoms. The diagnostic US was a mean of 19 ± 14 days after the most recent vaccination dose. In all cases LAD was seen only ipsilateral to the side of vaccine administration and in the majority of cases (70%, 21/30) multiple enlarged nodes were seen. Mean dimensions of the largest node in each patient were 20 x 13 mm (± 6. 5 x 5.6 mm). Average cortical thickness of enlarged nodes was 4.7 ± 1.6 mm. Asymmetric cortical thickening was the most commonly seen feature (70%, 21/30) followed by partial loss of fatty hilum (23%, 7/30). 4 cases demonstrated non-hilar blood flow. Two of these patients had ipsilateral breast findings, one of which was benign and one malignant, the nodes were benign in both cases. At the time of conclusion, 66% (20/30) patients were assigned continued follow-up (BIRADs 3).*Conclusions LAD due to COVID-19 vaccination retains characteristics of benign reactive nodes such as increased cortical thickness, multiplicity, and is predominantly without non-hilar blood flow or change in shape. Reporting patterns suggest radiologists are more comfortable assigning BIRADs 3 than BIRADs 2 for this finding. Continued follow-up imaging is awaited to

better understand natural progression and timeline for resolution of LAD.*Clinical Relevance/Application This study allows better understanding of imaging features of COVID-19 vaccine induced axillary LAD, its natural history, and management patterns, both for patients with a history of breast malignancy and without.

RESULTS

30 women met inclusion criteria with an average age of 51.4 ± 13 years. 19 cases of LAD were incidentally identified on screening mammography and recalled for further evaluation; 11 cases presented for diagnostic imaging of which 72% were for axillary symptoms. The diagnostic US was a mean of 19 ± 14 days after the most recent vaccination dose. In all cases LAD was seen only ipsilateral to the side of vaccine administration and in the majority of cases (70%, 21/30) multiple enlarged nodes were seen. Mean dimensions of the largest node in each patient were 20 x 13 mm (± 6. 5 x 5.6 mm). Average cortical thickness of enlarged nodes was 4.7 ± 1.6 mm. Asymmetric cortical thickening was the most commonly seen feature (70%, 21/30) followed by partial loss of fatty hilum (23%, 7/30). 4 cases demonstrated non-hilar blood flow. Two of these patients had ipsilateral breast findings, one of which was benign and one malignant, the nodes were benign in both cases. At the time of conclusion, 66% (20/30) patients were assigned continued follow-up (BIRADs 3).

CLINICAL RELEVANCE/APPLICATION

This study allows better understanding of imaging features of COVID-19 vaccine induced axillary LAD, its natural history, and management patterns, both for patients with a history of breast malignancy and without.

BR05-B8   Subclinical Unilateral Axillary Lymphadenopathy After COVID-19 Vaccination

Participants
Sean Raj, MD, Dallas, Texas (*Presenter*) Nothing to Disclose

PURPOSE

This retrospective study aims to evaluate prevalence of unilateral axillary lymphadenopathy (LAD) on screening mammogram in women who have received either the first or second dose of the Pfizer-BioNTech or Moderna COVID-19 vaccines compared to women who have not. Unilateral axillary LAD can be concerning for underlying malignancy, warranting diagnostic workup and associated cost. Other vaccines such as the influenza vaccine can cause reactive lymphadenopathy and has been observed that the highly immunogenic mRNA COVID-19 vaccines cause reactive and often subclinical lymphadenopathy.*Methods and Materials In this IRB-approved study from 12/14/20 to 4/14/21, 1027 patients presented for screening mammography to our breast imaging centers across North Texas and met inclusion criteria, encompassing the date the first COVID-19 vaccine was administered and the four months following. All women who received a screening mammogram were included in the study. Vaccination status was considered if received within the 4 weeks preceding mammography. History of baseline LAD or prior cancer diagnosis were excluded. All BIRADS 0 exams for patients with any additional findings in the breast were excluded. Prior imaging results were cross-referenced to evaluate for new LAD.*Results 43 women were recalled for unilateral LAD (4.2%). 34 women (3.3%) received a COVID-19 vaccination on the ipsilateral side as the LAD (Pfizer n=19, 44.2%; Moderna n=15, 34.9%). Vaccinated women represented 79% of patients recalled for unilateral LAD. Incidence of unilateral axillary LAD was significantly higher (p-value<0.01) in those who received a COVID-19 vaccination in the 4 weeks preceding screening mammogram. The Pfizer-BioNTech vaccine produced a more robust lymphatic response compared to the Moderna vaccine, trending towards significance.*Conclusions Women who have received COVID-19 vaccines may benefit from scheduling their screening mammogram before they get vaccinated or consider delaying screening mammography to avoid a potentially extensive, financially costly, and emotionally taxing false positive work-up.*Clinical Relevance/Application Unilateral axillary LAD on screening mammography can be concerning for breast cancer and warrants diagnostic evaluation and possible biopsy. However, unilateral axillary LAD can be a normal sign of an immune response in the setting of vaccination, such as the COVID-19 vaccines. Women who received COVID-19 vaccination have presented with unilateral axillary LAD, either palpable or incidental on mammography, after vaccination. Updating screening recommendations to suggest patients schedule their mammograms either before vaccination or several weeks after vaccination can help avoid both of these issues.

RESULTS

43 women were recalled for unilateral LAD (4.2%). 34 women (3.3%) received a COVID-19 vaccination on the ipsilateral side as the LAD (Pfizer n=19, 44.2%; Moderna n=15, 34.9%). Vaccinated women represented 79% of patients recalled for unilateral LAD. Incidence of unilateral axillary LAD was significantly higher (p-value<0.01) in those who received a COVID-19 vaccination in the 4 weeks preceding screening mammogram. The Pfizer-BioNTech vaccine produced a more robust lymphatic response compared to the Moderna vaccine, trending towards significance.

CLINICAL RELEVANCE/APPLICATION

Unilateral axillary LAD on screening mammography can be concerning for breast cancer and warrants diagnostic evaluation and possible biopsy. However, unilateral axillary LAD can be a normal sign of an immune response in the setting of vaccination, such as the COVID-19 vaccines. Women who received COVID-19 vaccination have presented with unilateral axillary LAD, either palpable or incidental on mammography, after vaccination. Updating screening recommendations to suggest patients schedule their mammograms either before vaccination or several weeks after vaccination can help avoid both of these issues.

CH02-A1   Cochrane 'Living' Systematic Review On Diagnostic Accuracy Of Chest Imaging For COVID-19: Version 4

Participants
Sanam Ebrahimzadeh, Ottawa, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

This fourth version of an ongoing Cochrane 'living' systematic review aims to evaluate the diagnostic accuracy of chest imaging (computed tomography (CT), X-ray and ultrasound) in individuals with suspected COVID-19.*Methods and Materials The Bern COVID-19 Living Database, Cochrane COVID-19 Register, and CDC Library were searched through 17/02/2021. Cross-sectional diagnostic accuracy studies involving participants of all ages with suspected COVID-19 were included. Screening, data extraction, and risk of bias assessments using the QUADAS-2 tool were completed independently, in duplicate. Pooled accuracy estimates and 95% confidence intervals (CI) were determined using a bivariate random effects model. Modalities were compared using meta-regression.*Results Ninety-nine studies (38604 participants, 19905 (52%) cases) were included; 91 studies evaluated one imaging modality each, and eight studies evaluated two modalities each. All studies used reverse transcriptase polymerase chain reaction (RT-PCR) as the reference standard. Risk of bias concerning: participant selection was high in 12 and unclear in 43 studies; reference standard was high in 27 and unclear in 36 studies; index test was high in 8 and unclear in 36 studies; and flow and timing was high in 10 and unclear in 43 studies. Chest CT (73 studies, 28937 participants) had pooled: sensitivity of 86.9% (95%CI 83.7-89.4) and specificity of 79.3% (74.3-83.5). Chest X-ray (18 studies, 9065 participants) had pooled: sensitivity of 74.4% (65.7-81.4) and specificity of 72.6% (61.8-81.3). Ultrasound (16 studies, 2259 participants) had pooled: sensitivity of 82.8% (73.8-89.1) and specificity of 29.3% (17.3-45.1). Chest CT had a higher sensitivity than chest X-ray (p<0.001); ultrasound had similar sensitivities compared to chest CT and X-ray (p>0.05). Chest CT and chest X-ray had higher specificities than ultrasound (p<0.001 for both); chest CT and X-ray had similar specificities (p>0.05).*Conclusions Chest CT is sensitive and moderately specific for diagnosing individuals with suspected COVID-19. Chest X-ray is moderately sensitive and moderately specific. Ultrasound is moderately sensitive, but not specific. However, the high or unclear risk of bias of included studies limits confidence in these findings. Compared to the findings of our previous reviews, specificity of chest CT has notably increased since the initial review version, and specificity of ultrasound has decreased since version three. Sensitivities of all modalities and specificity of chest X-ray have remained similar across all versions.*Clinical Relevance/Application Chest CT may be useful for ruling out COVID-19 in suspected individuals, but not for distinguishing COVID-19 from other respiratory illnesses.

RESULTS

Ninety-nine studies (38604 participants, 19905 (52%) cases) were included; 91 studies evaluated one imaging modality each, and eight studies evaluated two modalities each. All studies used reverse transcriptase polymerase chain reaction (RT-PCR) as the reference standard. Risk of bias concerning: participant selection was high in 12 and unclear in 43 studies; reference standard was high in 27 and unclear in 36 studies; index test was high in 8 and unclear in 36 studies; and flow and timing was high in 10 and unclear in 43 studies. Chest CT (73 studies, 28937 participants) had pooled: sensitivity of 86.9% (95%CI 83.7-89.4) and specificity of 79.3% (74.3-83.5). Chest X-ray (18 studies, 9065 participants) had pooled: sensitivity of 74.4% (65.7-81.4) and specificity of 72.6% (61.8-81.3). Ultrasound (16 studies, 2259 participants) had pooled: sensitivity of 82.8% (73.8-89.1) and specificity of 29.3% (17.3-45.1). Chest CT had a higher sensitivity than chest X-ray (p<0.001); ultrasound had similar sensitivities compared to chest CT and X-ray (p>0.05). Chest CT and chest X-ray had higher specificities than ultrasound (p<0.001 for both); chest CT and X-ray had similar specificities (p>0.05).

CLINICAL RELEVANCE/APPLICATION

Chest CT may be useful for ruling out COVID-19 in suspected individuals, but not for distinguishing COVID-19 from other respiratory illnesses.

CH02-A3   The Comparative Spectrum Of Chest CT Manifestations In COVID-19 Associated Acute Pneumonia Patients With And Without Cards (COVID-19 Associated Acute Respiratory Distress Syndrome); Mortality Influencing Factors.

Participants
Arturs Shilovs, MD, Riga, Latvia (*Presenter*) Nothing to Disclose

PURPOSE

Today, more than a billion of COVID-19 pneumonia patients worldwide are at potential risk of developing CARDS, which brings major challenges for healthcare systems and patients survival. Verification of prognostic CARDS factors, including radiology, are essential. We present our data and comparative analysis of early chest CT acute pneumonia signs in association with main clinical factors in COVID-19 patients with and without CARDS.*Methods and Materials Acute patients with confirmed SARS-CoV 2 infection upon hospitalization treated in a university hospital were enrolled in retrospective analysis study. Patients gender, age, comorbidities, general complains, clinical severity, chest CT findings and hospital outcomes were assessed. Severe illness patients were grouped according presence or absence of CARDS. Mild illness patients were excluded. Chest CT was assessed using originally created

protocol with detailed evaluation of typical radiological COVID-19 signs. Descriptive and analytical statistics was performed using SPSS software, significance was considered with p<0.05.*Results Study group comprised 245 patients with median age 67.0 [Confidence interval: 64.0 - 68.0]. 33% had no comorbidities. Overall hospital death outcome was in 26.9%; in CARDS group 75.0%. Upon hospitalization only dyspnea showed significant correlation with CARDS (p=0.01). CARDS progressed more frequently in patients with early chest CT showing consolidations, mediastinal lymphadenopathy and lung damage volume over 25% (p=0.001, p<0.001, p<0.001, respectively). There was no correlation between lung damage volume and comorbidities (p>0.05). However, diabetes and coronary artery disease had significant association with patients developing CARDS (p<0.001, p=0.01, respectively).*Conclusions Lung damage volume, mediastinal lymphadenopathy, and consolidations on CT are independent factors associated with CARDS. Patients with comorbidities and higher lung damage volume showed higher frequency of developing CARDS, which corresponds to higher mortality in this group of patients.*Clinical Relevance/Application Study shows importance of early detailed chest CT symptoms assessment in acute severe COVID-19 pneumonia patients. Definite radiological signs can be a prognostic factor of intra-hospital risk for developing CARDS and higher mortality risk.

RESULTS

Study group comprised 245 patients with median age 67.0 [Confidence interval: 64.0 - 68.0]. 33% had no comorbidities. Overall hospital death outcome was in 26.9%; in CARDS group 75.0%. Upon hospitalization only dyspnea showed significant correlation with CARDS (p=0.01). CARDS progressed more frequently in patients with early chest CT showing consolidations, mediastinal lymphadenopathy and lung damage volume over 25% (p=0.001, p<0.001, p<0.001, respectively). There was no correlation between lung damage volume and comorbidities (p>0.05). However, diabetes and coronary artery disease had significant association with patients developing CARDS (p<0.001, p=0.01, respectively).

CLINICAL RELEVANCE/APPLICATION

Study shows importance of early detailed chest CT symptoms assessment in acute severe COVID-19 pneumonia patients. Definite radiological signs can be a prognostic factor of intra-hospital risk for developing CARDS and higher mortality risk.

CH02-A4 Does Imaging Pattern Differ Between COVID19 Infection Due To Initial Sars-cov-2 Virus And Variant Of Concern 202012/1 Known As The Uk Variant?

Participants
Olivier Lucidarme, MD, Paris, France (*Presenter*) Speaker, Bracco Group;Speaker, F. Hoffmann-La Roche Ltd;Expert Witness, Bayer AG

PURPOSE

A variant of concern (VOC-202012/1 known as the UK variant) of SARS-COV-2 virus was identified in early October 2020 and rapidly replaced the Wuhan strains. The authors reported in early 2021 that infections with this new variant were associated with a significantly increased risk of death. The patterns of Covid19-induced pulmonary CT were described during 2020 prior to the emergence of this variant and the objective of this study was to investigate whether pulmonary involvement is different with this new variant.*Methods and Materials This retrospective study was approved by our institutional review board. Between December 22, 2020, and March 19, 2021, a senior chest radiologist reviewed chest CT scans of 242 patients with RT-PCR positive for SARS-COV-2. She was unaware of the results of the genotyping variant identification performed for each patient or the quantification of virus copies. She used a standardized reading grid that included the indication and timing of CT and the CT patterns classically reported in the literature. Comparison between the groups of patients infected with Wuhan strain and VOC 202012/1 and correlations with the virus copy number were performed.*Results 118 patients (mean age 66 years, men 57%) were infected with Wuhan strain (group 1), 124 (mean age 65 years, men 52%) with VOC 202012/1 (group 2). Bilateral and multifocal ground-glass opacities (GGO) were observed in 92% and 91% of patients in groups 1 and 2 respectively (NS). Consolidations were found in 69% (group 1) and in 72% (group 2)(NS), Crazy paving was present in 70% (group 1) and 78% (group 2)(NS). A pulmonary embolism was found in 9% in group 1 and in 4% in group 2 (NS). The topography of the lesion was also similar, essentially peripheral for both groups. The extension of the disease did not vary significantly between both groups and was not correlated with the viral load (virus copy number).*Conclusions The CT signature of the Wuhan and UK variants did not differ.*Clinical Relevance/Application The UK variant of SARS-COV2 induces macroscopically the same lesions on chest CT as the original Wuhan virus. Chest CT cannot be used to distinguish between these two viruses.

RESULTS

118 patients (mean age 66 years, men 57%) were infected with Wuhan strain (group 1), 124 (mean age 65 years, men 52%) with VOC 202012/1 (group 2). Bilateral and multifocal ground-glass opacities (GGO) were observed in 92% and 91% of patients in groups 1 and 2 respectively (NS). Consolidations were found in 69%(group 1) and in 72% (group 2)(NS), Crazy paving was present in 70% (group 1) and 78% (group 2)(NS). A pulmonary embolism was found in 9% in group 1 and in 4% in group 2 (NS). The topography of the lesion was also similar, essentially peripheral for both groups. The extension of the disease did not vary significantly between both groups and was not correlated with the viral load (virus copy number).

CLINICAL RELEVANCE/APPLICATION

The UK variant of SARS-COV2 induces macroscopically the same lesions on chest CT as the original Wuhan virus. Chest CT cannot be used to distinguish between these two viruses.

CH02-A7 Diffuse Alveolar Hemorrhage: A Practical Approach For The General Radiologist

Participants
Julia Asmar, MD, Kansas City, Missouri (*Presenter*) Nothing to Disclose

TEACHING POINTS

Discuss etiology, histopathology and clinical presentation of diffuse alveolar hemorrhage (DAH)

TABLE OF CONTENTS/OUTLINE

Alveolar hemorrhage is defined pulmonary alveolar blood and often manifests with hemoptysis, but up to 30% of patients have nonspecific symptoms. Most exhibit diffuse alveolar hemorrhage (DAH), based on extent of involvement, but focal hemorrhage also occurs. Idiopathic pulmonary hemorrhage/hemosiderosis (IPH) is a distinct entity, but other conditions associated with DAH must be excluded including autoimmunity (capillaritis), bland hemorrhage (e.g. edema, anticoagulation). DAH often presents a diagnostic challenge for radiologists, particularly in the absence of hemoptysis or when associated conditions are not known or considered.We

present a practical strategy for the imaging assessment of DAH optimized for the general radiologist that relies on careful analysis of clinical history and laboratory findings. Specific clinical scenarios include:1. Anti-glomerular basement membrane disease (Goodpasture syndrome), granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MCP) cause DAH and renal failure; GPA and MCP are often associated with neuropathy.2. DAH may affect young women with systemic lupus erythematosus, but is rarely the initial manifestation.3. Antiphospholipid syndrome may produce various vascular manifestations including DAH.4. Drug toxicity may manifest with DAH.5. Pulmonary fibrosis is a known complication of recurrent DAH, particularly IPH.

SDP-MS-1   Hyperpolarized 13C-pyruvate MR Imaging In Rodent Model Of Ventricular Fibrillation Cardiac Arrest: A Feasibility Study

Participants
Ilwoo Park, PhD, Gwangju, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To explore the feasibility of hyperpolarized (HP) 13C MRI in assessing metabolic changes in brain within 1 hour of return of spontaneous circulation (ROSC) in the rodent model of ventricular fibrillation-induced cardiac arrest (VFCA).*Methods and Materials 9-week-old 8 male rats, including 5 cardiac arrest (CA) and 3 sham controls, were included. Under isoflurane anesthesia, oral intubation and mechanical ventilation were performed. VFCA was induced by trans-esophageal electrical stimulation. After 7min of untreated VFCA, resuscitation was started with manual chest compressions (250/min). At 2 minutes of CPR, defibrillation attempts repeated every 2min. Epinephrine (20ug/kg) and bicarbonate (1mEq/kg) were given iv 30s prior to the start of CPR. Epinephrine alone at 10ug/kg was administered 90s after the start of CPR and repeated every 2min during CPR. Upon achieving spontaneous circulation that defined mean arterial pressure above 50mmHg for 5min and after 20 minutes stabilizing period, animals were transferred to scanner for MR exam. MR data were obtained within 1 hour of return of ROSC using a 3T scanner with a multi-nuclear capability. Slice-localized (25mm) 13C MRS data were acquired from brain with injection of 3mL, 100 mM 13C1-pyruvate solution, which had been polarized using DNP polarizer. At 72 hours post-CA, the brains of rats were harvested for pathology.*Results Fig1 shows representative 13C dynamic spectra. CA models had significantly higher Lactate/Pyruvate than sham control (Fig2), indicating a cellular metabolic change occurring in the brain of CA animals at early ROSC. Pathological analysis revealed marked differences between the brains of CA and sham animals. In contrast to sham, a large amount of neuronal damage and reactive astrocytes appeared in region CA1 of CA model.*Conclusions We demonstrated that HP 13C MRI can identify the metabolic changes within 1 hour of return of ROSC in rodent model of VFCA.*Clinical Relevance/Application This novel technique may provide a unique and noninvasive imaging biomarker for identifying the sign of neurologic abnormality, which is a fundamental base of post-CA care for further supportive interventions.

RESULTS

Fig1 shows representative 13C dynamic spectra. CA models had significantly higher Lactate/Pyruvate than sham control (Fig2), indicating a cellular metabolic change occurring in the brain of CA animals at early ROSC. Pathological analysis revealed marked differences between the brains of CA and sham animals. In contrast to sham, a large amount of neuronal damage and reactive astrocytes appeared in region CA1 of CA model.

CLINICAL RELEVANCE/APPLICATION

This novel technique may provide a unique and noninvasive imaging biomarker for identifying the sign of neurologic abnormality, which is a fundamental base of post-CA care for further supportive interventions.

SDP-MS-2   Worklist Reprioritization Using Artifical Intelligence Improves Turnaround Times Of Chest CT Examinations Positive For Acute Pulmonary Embolism

Participants
Brendan Harrison, MD, Burlington, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the effect of an AI algorithm for the detection of pulmonary embolism on study turnaround time.*Methods and Materials A total of 4,069 CT chest with contrast scans performed at a tertiary care medical center between October 2019 and February 2020 were retrospectively identified (ED - 1470, Inpatient - 667, Outpatient - 1932). During this time period, 2,742 scans were analyzed by a commercially available artificial intelligence (AI) algorithm utilized for the detection of PE (CT pulmonary angiograms) and incidental PE (on contrast enhanced CT of the chest not performed to evaluate for PE). Positive cases were flagged by the algorithm and brought to the top of the radiology worklist. The remaining 1,327 scans, were read according to their priority, with no AI prioritization. All 4,069 cases reports were classified as positive or negative for pulmonary embolism using Natural Language Processing (NLP) on the radiology report to establish ground truth. The radiology turnaround time (RTAT) between positive and negative cases was compared for the cases that had AI result, and cases that didn't, and stratified by patient class. RTAT was defined as the time difference between scan completion and report completion time (when the report enters preliminary or final status, whichever comes earlier). An RTAT threshold was set for each patient class to exclude extreme outliers : ED - 160 minutes, IP - 300 minutes, OP - 500 minutes.*Results The average TAT of positive pulmonary embolism (by NLP) cases that were analyzed by AI was 34.2 minutes, while the average TAT of negative pulmonary embolism cases was 68.25 minutes. The difference between positive and negative cases of pulmonary embolism was 34.05 minutes (CI: 21.3275 to 46.7725 P < 0.01). The average TAT of positive pulmonary embolism (by NLP) cases that were NOT analyzed by AI was 58.80 minutes while the average TAT of negative incidental pulmonary embolism cases was 51.18 minutes. The difference between positive and negative cases of incidental pulmonary embolism was +7.62 minutes.*Conclusions Using an AI algorithm that prioritizes cases with a positive pulmonary embolism, positive cases of pulmonary embolism, including incidentally detected pulmonary embolism have a substantially shorter

turnaround time when compared to negative cases.*Clinical Relevance/Application Through the implementation of commercially available AI software which accurately and quickly identifies cases of pulmonary embolism for worklist prioritization, radiology practices can improve their turnaround time of positive cases, allowing for expedited therapeutic intervention.

RESULTS

The average TAT of positive pulmonary embolism (by NLP) cases that were analyzed by AI was 34.2 minutes, while the average TAT of negative pulmonary embolism cases was 68.25 minutes. The difference between positive and negative cases of pulmonary embolism was 34.05 minutes (CI: 21.3275 to 46.7725 P < 0.01). The average TAT of positive pulmonary embolism (by NLP) cases that were NOT analyzed by AI was 58.80 minutes while the average TAT of negative incidental pulmonary embolism cases was 51.18 minutes. The difference between positive and negative cases of incidental pulmonary embolism was +7.62 minutes.

CLINICAL RELEVANCE/APPLICATION

Through the implementation of commercially available AI software which accurately and quickly identifies cases of pulmonary embolism for worklist prioritization, radiology practices can improve their turnaround time of positive cases, allowing for expedited therapeutic intervention.

SDP-MS-3   Dynamic Nuclear Polarization MRI For Detecting The Reactive Oxygen Species Using Spin-trapping Agent

Participants
Shinichi Shoda, RT,PhD, Gifu City, Japan (*Presenter*) Nothing to Disclose

PURPOSE

With the aim of developing a technique for visualizing the Reactive Oxygen Species (ROS) caused by inflammation and radiation, we attempted to visualize hydroxyl radicals (•OH) production using Dynamic Nuclear Polarization-MRI (DNP-MRI). In addition, we investigated the imaging of the effect of thiol compounds on •OH production as an antioxidant by DNP-MRI.*Methods and Materials We used a low magnetic field DNP-MRI system (Keller) using electron spin resonance as hyperpolarized MRI. The Fenton reaction was used in the phantom tubes to generate hydroxyl radicals. A spin trap agent, 5,5-dimethyl-1-pyrroline N-oxide (DMPO), was used to detect •OH, and DMPO-OH was detected as its spin adduct. First, the generation of hydroxyl radicals was confirmed by detecting DMPO-OH using an X-band EPR. In DNP-MRI, phantom imaging by DNP-MRI was performed while changing the EPR irradiation frequency from 460 to 483 MHz at intervals of 0.5 MHz or 1 MHz in order to determine the optimum EPR excitation irradiation frequency. Subsequently, a thiol compound was added to the phantom as a radical scavenger, and an antioxidant for •OH production was evaluated by EPR. After that, the OH scavenging effect was imaged by DNP-MRI using the determined optimum EPR irradiation frequency.*Results •OH produced by the Fenton reaction was reacted with DMPO, and four peaks (ratio 1: 2: 2: 1) were detected in the EPR spectrum, confirming that DMPO-OH was generated. Imaged by DNP-MRI at various EPR frequencies to obtain the DNP effect, the maximum enhancement of DMPO-OH was observed at 474.5 MHz. The augmentation factor (DNP on / DNP off) was 3.07 at 474.5MHz. Furthermore, it was shown that the use of DMSO, which inhibits OH production, suppresses the DNP enhancement of DMPO-OH. We then selected multiple thiol compounds and realized that the radical scavenging effects of multiple DNP-MRI samples could be visualized simultaneously.*Conclusions We succeeded in visualizing hydroxyl radicals using DNP-MRI and DMPO, and showed that the effect of scavenging hydroxyl radicals can be evaluated.*Clinical Relevance/Application Visualization of •OH may help in the early diagnosis of reactive oxygen species-related inflammations and diseases. In KORTUC, which is attracting attention as a new radiation sensitization treatment, radiation therapy is performed after injecting a drug containing H2O2 into tumor tissue. It is considered that •OH imaging can be used to obtain information on radical localization in the treatment area. It is expected to expand to new seranostics by enhancing the radiotherapy effect and at the same time visualizing the therapeutic area.

RESULTS

•OH produced by the Fenton reaction was reacted with DMPO, and four peaks (ratio 1: 2: 2: 1) were detected in the EPR spectrum, confirming that DMPO-OH was generated. Imaged by DNP-MRI at various EPR frequencies to obtain the DNP effect, the maximum enhancement of DMPO-OH was observed at 474.5 MHz. The augmentation factor (DNP on / DNP off) was 3.07 at 474.5MHz. Furthermore, it was shown that the use of DMSO, which inhibits OH production, suppresses the DNP enhancement of DMPO-OH. We then selected multiple thiol compounds and realized that the radical scavenging effects of multiple DNP-MRI samples could be visualized simultaneously.

CLINICAL RELEVANCE/APPLICATION

Visualization of •OH may help in the early diagnosis of reactive oxygen species-related inflammations and diseases. In KORTUC, which is attracting attention as a new radiation sensitization treatment, radiation therapy is performed after injecting a drug containing H2O2 into tumor tissue. It is considered that •OH imaging can be used to obtain information on radical localization in the treatment area. It is expected to expand to new seranostics by enhancing the radiotherapy effect and at the same time visualizing the therapeutic area.

SDP-MS-4   Employing A Natural Language Processing (NLP) Model To Predict And Compare Case Acuity Based On Radiological Reports In A 5-Hospital Academic Health System

Participants
Sina Mazaheri, MD, Atlanta, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

There has been limited research on acuity specifically pertaining to radiologic image findings, or report acuity. Report acuity can be leveraged as a triage process for patients within their care pathway. The purpose of this study was to develop a tool to assess report acuity and compare acuity across 5 hospitals within our Academic Health System (AHS).*Methods and Materials Hospital records were used to collect descriptive characteristics. The radiology reports of emergency room patients in 2019 were extracted and annotated by 5 radiology residents under faculty supervision using an annotation key developed by ACR's Actionable Reporting Work Group. A Transformer-based NLP called Bidirectional Encoder Representations from Transformers (BERT) was employed to analyze the multi-modal radiology reports and classify them into Non-Acute, Acute and Critical categories. Report acuity was calculated as the fraction of Acute and Critical cases.*Results Hospital 1 is a Safety Net Hospital (SNH) and a comprehensive stroke and Level 1 trauma center. Hospitals 1, 2 and 3 are the major teaching hospitals. Hospitals 4 and 5 are community-based. Hospital 1 had a higher volume of emergency department imaging than the remaining hospitals combined (166,789 vs. 159,767). Hospital 1 had significantly higher acute and critical imaging findings (28.9% vs. 15.2-15.6%, p < 0.001). The BERT NLP model

achieved 93% precision, 95% recall and 0.94 f1-score for identifying acute cases, and 82% precision and recall with a 0.82 f1-score for critical cases. The algorithm achieved high performance for non-acute cases (98 precision, 96% recall and 0.97 f1-score). The overall NLP accuracy was 95%.*Conclusions The BERT NLP model achieved a high performance in predicting acuity of multi-modal emergency imaging studies, demonstrating a higher level of acuity in Hospital 1 compared to other hospitals in our AHS. This type of information provided by similar NLP models may be beneficial in tasks such as patient triage, resource allocation, and staffing.*Clinical Relevance/Application Understanding report acuity can aid in beneficial tasks such as patient triage, resource allocation, and staffing models across busy health systems.

RESULTS

Hospital 1 is a Safety Net Hospital (SNH) and a comprehensive stroke and Level 1 trauma center. Hospitals 1, 2 and 3 are the major teaching hospitals. Hospitals 4 and 5 are community-based. Hospital 1 had a higher volume of emergency department imaging than the remaining hospitals combined (166,789 vs. 159,767). Hospital 1 had significantly higher acute and critical imaging findings (28.9% vs. 15.2-15.6%, p < 0.001). The BERT NLP model achieved 93% precision, 95% recall and 0.94 f1-score for identifying acute cases, and 82% precision and recall with a 0.82 f1-score for critical cases. The algorithm achieved high performance for non-acute cases (98 precision, 96% recall and 0.97 f1-score). The overall NLP accuracy was 95%.

CLINICAL RELEVANCE/APPLICATION

Understanding report acuity can aid in beneficial tasks such as patient triage, resource allocation, and staffing models across busy health systems.

SDP-MS-5 **High-Resolution MRI With Extended Delayed Imaging For Identification Of Peritoneal Disease**

Participants
Milica Medved, PhD, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

We introduce a novel, high-resolution (HR) MRI protocol with extended delayed imaging for improved detection of malignant peritoneal mesothelioma (MPM). We examine MPM signal enhancement patterns to identify optimal post-contrast imaging delay time.*Methods and Materials 14 patients with MPM scheduled for laparoscopy/laparotomy received MRI scans on a 3T Philips Ingenia dStream scanner. The MRI protocol included pre-contrast axial 2D T2w and coronal 2D T2w, pre-contrast free breathing axial T2w with fat saturation, and pre-and post-contrast (10 min delay) axial 3D T1w sequences at spatial resolutions of 1.2-1.7 mm in-plane. The novel sequences included a pre-contrast free breathing HR coronal 2D T2w sequence at 0.8 mm spatial resolution and pre-and post-contrast 3-breatholds HR coronal 3D T1w mDixon sequences at 1.2 mm spatial resolution, centered on the liver dome and acquired with an approximately 7, 13, 16, and 20 min delay after injection of a double dose of gadoterate meglumine. MPM lesions were identified with reference to laparoscopy. Lesion signal was measured on the HR coronal 3D T1w images, normalized to fat at each post-contrast timepoint, and modeled as a linear function of time. We explored the correlation of slope (Sl) of the normalized signal change with time with lesion shape (mass vs linear) on a per-lesion basis. Average Sl was correlated with histologic grade, pathology score, presence of heart disease, prior chemotherapy status, and age on a per-patient basis. Multiple regression analysis was used to construct an improved predictor of Sl.*Results Average Sl was 0.009 ± 0.067 1/min (range -0.04 - 0.20 1/min). Statistically significant correlation (r = -0.56) of Sl with pathology score was observed, with higher scores predicting a washout pattern (Sl < 0). Presence of heart disease correlated with an uptake pattern (Sl > 0). A composite classifier including pathology score and presence of heart disease achieved a correlation coefficient of r = 0.65.*Conclusions A moderately delayed (7-12 min) T1w sequence may be more sensitive to high-grade MPM in patients without heart disease, while a longer delay (15+ min) may be more sensitive in patients with low-grade MPM and heart disease.*Clinical Relevance/Application A 10 min post-contrast high resolution T1w MRI is appropriate for high grade peritoneal disease. A longer delay may show higher sensitivity in low grade disease or patients with heart disease.

RESULTS

Average Sl was 0.009 ± 0.067 1/min (range -0.04 - 0.20 1/min). Statistically significant correlation (r = -0.56) of Sl with pathology score was observed, with higher scores predicting a washout pattern (Sl < 0). Presence of heart disease correlated with an uptake pattern (Sl > 0). A composite classifier including pathology score and presence of heart disease achieved a correlation coefficient of r = 0.65.

CLINICAL RELEVANCE/APPLICATION

A 10 min post-contrast high resolution T1w MRI is appropriate for high grade peritoneal disease. A longer delay may show higher sensitivity in low grade disease or patients with heart disease.

HN03-C1 **Dual-energy Parathyroid CT: Optimizing Differentiation Of Parathyroid Lesions From Thyroid Using Noncontrast Virtual Monoenergetic Images**

Participants
Paul Latterman, MD, Winston Salem, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

Noncontrast dual-energy CT (DECT) 40 keV virtual monoenergetic images (VMI) reportedly facilitate discrimination of parathyroid lesions from thyroid gland by disproportionately increasing thyroid attenuation and the associated thyroid:parathyroid contrast-to-noise ratio (CNR) compared to standard (70 keV VMI) noncontrast DECT images.We hypothesize additional CNR gains at keVs intermediate between 40 and 70 keV VMI resulting by balancing the disproportionate increase in thyroid iodine attenuation at lower keV against the cost of increased noise. Our purpose is to test this hypothesis through quantitative image assessment.*Methods and Materials This single institution, retrospective study included patients undergoing parathyroid DECT prior to parathyroidectomy for primary hyperparathyroidism. Patients were excluded for prior thyroidectomy or if the largest pathologically-proven parathyroid lesion measured less than 1 cm.Regions of interest (ROIs) were placed within the thyroid, the largest proven parathyroid lesion, and subcutaneous neck fat by a radiology resident on noncontrast 40, 45, 50, 55, 60, 65, and 70 keV VMI. Mean and SD HU attenuation were recorded.Thyroid:parathyroid CNR was calculated using: (ROIthy - ROIpar)/SD, where ROIthy = mean thyroid HU, ROIpar = mean parathyroid lesion HU, and SD = SD of mean subcutaneous fat HU.*Results The final cohort included 24 patients (10 male, 14 female, median age 64 years).Median thyroid:parathyroid CNR for the overall cohort was greatest (4.95) at 45 keV and least at 70 keV (4.46; p=0.007, Wilcoxon signed rank test).Among individuals, thyroid:parathyroid CNR was greatest at a keV intermediate between 40 and 70 keV in 17 (71%) patients, greatest at 40 keV in 7 (29%) patients, and greatest at 70 keV in 0 patients.Among the 17 for whom CNR was greatest at an intermediate keV, CNR was maximum at 65 keV for 10, 60 keV for 1, 55 keV for 4, 50 keV for 1, and 45 keV for 1.Overall cohort median CNR at 40 keV (4.83) was not significantly different from 45 keV (4.95, p=0.48, Wilcoxon signed rank test), 50 keV (4.82, p=0.30), 55 keV (4.93, p=0.35), 60 keV (4.83, p=0.77), or 65 keV (4.79, p=0.62).*Conclusions Although noncontrast parathyroid DECT VMI spanning 45 keV to 65 keV enable small increases in thyroid:parathyroid CNR for most patients compared to CNR at 40 keV, these increases are not statistically significant, and there is no single optimal keV that maximizes CNR in all patients.*Clinical Relevance/Application No optimal intermediate VMI keV was identified for discriminating parathyroid lesions from thyroid gland on the noncontrast phase of parathyroid DECT. As such, we will continue our baseline practice of reconstructing and reviewing both 40 keV and 70 keV noncontrast VMI in all patients.

RESULTS

The final cohort included 24 patients (10 male, 14 female, median age 64 years).Median thyroid:parathyroid CNR for the overall cohort was greatest (4.95) at 45 keV and least at 70 keV (4.46; p=0.007, Wilcoxon signed rank test).Among individuals, thyroid:parathyroid CNR was greatest at a keV intermediate between 40 and 70 keV in 17 (71%) patients, greatest at 40 keV in 7 (29%) patients, and greatest at 70 keV in 0 patients.Among the 17 for whom CNR was maximum at 65 keV for 10, 60 keV for 1, 55 keV for 4, 50 keV for 1, and 45 keV for 1.Overall cohort median CNR at 40 keV (4.83) was not significantly different from 45 keV (4.95, p=0.48, Wilcoxon signed rank test), 50 keV (4.82, p=0.30), 55 keV (4.93, p=0.35), 60 keV (4.83, p=0.77), or 65 keV (4.79, p=0.62).

CLINICAL RELEVANCE/APPLICATION

No optimal intermediate VMI keV was identified for discriminating parathyroid lesions from thyroid gland on the noncontrast phase of parathyroid DECT. As such, we will continue our baseline practice of reconstructing and reviewing both 40 keV and 70 keV noncontrast VMI in all patients.

RI03-C1 **Chiari II And Percutaneous Fetoscopic Spina Bifida Repair: Frequency Of Imaging Findings In Fetal MRI.**

Participants
Mariana Rodrigues, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

Chiari II malformation has a relatively high prevalence with possible prenatal correction, which provides better motor outcomes and reduces the need for ventricular shunt. Our aim was to describe Chiari II malformation imaging findings, their associations, and review pre and post fetoscopic repair features in fetal MRI.*Methods and Materials Our database of fetal MRI was fully reviewed from 2006 to 2020 in our institution. Inclusion criteria encompassed fetuses with diagnosis of Chiari II malformation and complete central nervous system characterization, submitted to exams in 1.5 MRI equipment. We have listed the imaging findings and investigated their associations. We have reviewed cases according to ventricular dilation degree, third ventricle diameter, measure of tonsillar herniation, grading of cerebellar ectopia and subarachnoid space (SAS), categorized myelomeningocele sac (flaccid versus tense) and sagittal superior sinus (SSS) diameter.*Results Among 129 fetal mri exams, 49 were diagnosed with Chiari II malformations, which represented 38 different pregnant patients, including 11 exams performed post fetoscopy surgery.Enlarged SAS in fetuses without surgery were more common in tense sacs, 11/16 of cases, and no case of sulcal effacement among tense sacs were observed. On the other hand, flaccid sacs were associated with partial SAS effacement 16/20, or total extra-axial cerebrospinal fluid effacement 4/20 cases (P< 0.05). The SSS diameter was thinner in tense sacs fetuses compared to flaccid / poorly defined sacs and post surgery measures, a medium size of 3.19, 3.31 and 3.56 respectively (boxplot chart). The regression of the tonsillar herniation was observed in all cases (11/11) that underwent percutaneous fetoscopic spina bifida repair, and enlargement of ventricles after surgery was present in 11/11 of cases.*Conclusions Besides fundamental features of Chiari II malformation, our study provides data supporting percutaneous fetoscopic spina bifida repair for meningomyelocele repair, direct association of the tension of sacs with enlargement of SAS and conversely proportion tendency of sagittal sinus diameter and the tension of myelomeningocele sacs.*Clinical Relevance/Application A well described report containing complete information helps on central nervous system assessment and supports the decision on whether or not to operate in utero. A comparison of pre and post percutaneous fetoscopic spina bifida repair is also essential to the improvement of surgery technique.

RESULTS

Among 129 fetal mri exams, 49 were diagnosed with Chiari II malformations, which represented 38 different pregnant patients, including 11 exams performed post fetoscopy surgery.Enlarged SAS in fetuses without surgery were more common in tense sacs, 11/16 of cases, and no case of sulcal effacement among tense sacs were observed. On the other hand, flaccid sacs were associated with partial SAS effacement 16/20, or total extra-axial cerebrospinal fluid effacement 4/20 cases (P< 0.05). The SSS diameter was thinner in tense sacs fetuses compared to flaccid / poorly defined sacs and post surgery measures, a medium size of 3.19, 3.31 and 3.56 respectively (boxplot chart). The regression of the tonsillar herniation was observed in all cases (11/11) that underwent percutaneous fetoscopic spina bifida repair, and enlargement of ventricles after surgery was present in 11/11 of cases.

CLINICAL RELEVANCE/APPLICATION

A well described report containing complete information helps on central nervous system assessment and supports the decision on whether or not to operate in utero. A comparison of pre and post percutaneous fetoscopic spina bifida repair is also essential to the improvement of surgery technique.

NMMI04-D1 DIFFERENTIATION OF RENAL ONCOCYTOMA FROM RENAL CELL CARCINOMA BY MEANS OF 99MTC-SESTAMIBI SPECT/CT

Participants
Antonios Tzortzakakis, Stockholm, Sweden (*Presenter*) Nothing to Disclose

PURPOSE

An increasing body of literature indicates the beneficial role of 99mTc-Sestamibi SPECT/CT in the non-invasive differentiation of renal oncocytoma (RO) from renal cell carcinoma (RCC). We present a comprehensive approach of 99mTc-Sestamibi SPECT/CT examination following the implementation of quantitative tools in addition to visual assessment. An additional aim is to explain the differences in 99mTc-Sestamibi uptake among the different RCC subgroups on histometabolomic grounds.*Methods and Materials 57 radiologically detected kidney tumours from 52 patients were examined. Each participant underwent a 99mTc-Sestamibi SPECT/CT examination before nephrectomy or percutaneous kidney biopsy. Kidney tumours with increased 99mTc-Sestamibi uptake were classified as positive. In contrast, those with equal or decreased 99mTc-Sestamibi compared to the ipsilateral non-tumoral kidney parenchyma were classified as negative. Following the visual assessment, quantitative SUVmean and SUVmax measurements performed in the examined kidney tumour and the non-tumoral kidney parenchyma that correlated with the histopathological results. Additional immunohistochemical investigation, in situ metabolomics profile characterisation and correlation of mitochondrial content with 99mTc-Sestamibi SPECT/CT data, were performed.*Results Visual assessment of 99mTc-Sestamibi SPECT/CT resulted in a sensitivity of 82% whereas, the quantitative assessment showed a sensitivity of 64% regarding the preoperative characterisation of RO. 99mTc-Sestamibi SPECT/CT identifies a larger Sestamibi-positive tumour group containing RO, hybrid oncocytic chromophobe tumour (HOCT) and the majority of chromophobe RCC (chRCC). A discriminatory metabolomic signature was identified for Sestamibi positive Birt-Hogg-Dubè-associated HOCT vs other renal oncocytic tumours. Metabolomic differences were found between Sestamibi positive and negative chRCCs.*Conclusions Sestamibi positive kidney tumours on SPECT/CT are possibly of benign nature. Quantitative assessment with SUV SPECT measurements did not improve the diagnostic performance of 99mTc-Sestamibi SPECT/CT.*Clinical Relevance/Application Sestamibi negative kidney tumours should be considered for surgery due to their possibly malignant nature. On the other hand, Sestamibi positive kidney tumours could be suited for biopsy and/or follow up according to surveillance protocols.

RESULTS

Visual assessment of 99mTc-Sestamibi SPECT/CT resulted in a sensitivity of 82% whereas, the quantitative assessment showed a sensitivity of 64% regarding the preoperative characterisation of RO. 99mTc-Sestamibi SPECT/CT identifies a larger Sestamibi-positive tumour group containing RO, hybrid oncocytic chromophobe tumour (HOCT) and the majority of chromophobe RCC (chRCC). A discriminatory metabolomic signature was identified for Sestamibi positive Birt-Hogg-Dubè-associated HOCT vs other renal oncocytic tumours. Metabolomic differences were found between Sestamibi positive and negative chRCCs.

CLINICAL RELEVANCE/APPLICATION

Sestamibi negative kidney tumours should be considered for surgery due to their possibly malignant nature. On the other hand, Sestamibi positive kidney tumours could be suited for biopsy and/or follow up according to surveillance protocols.

NMMI04-D2 A Role Of 18F-FDG-PET/CT In The Detection Of The Cause Of Fever In Post-COVID-19 Syndrome

Participants
Jiri Ferda, MD, PhD, Pilsen, Czech Republic (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the relationship between the 18F-FDG-PET/CT findings and the detection of the febrile state in postCovid-19 patients*Methods and Materials During the secondary and tertiary pandemic wave of the infections by new coronavirus SARS-CoV2, there were performed 43 examinations of the patients (19 female, males, 24 males, mean age 59,6). All patients suffered from the recurrent febrile state of uncertain origin occuring more than 14 days after they underwent COVID-19, and remained unclear after clinical, laboratory or conventional imaging. PET/CT including intravenous application of the iodinated contrast material (80 ml, 370 mg I/ml, and with the application of 2.5 MBq/kg of 18F-fluorodeoxyglucose. Data acquisition started after 60 min after the radiopharmaceutical aplication.*Results The following findings were seen to be related with the febrile state: 14 cases of persistent inflammatory, FDG avid changes in lung parenchyma, 11 cases of colitis (in 7 of them followed confirmation of Clostridium difficile), 6 cases of the FDG avid multiple lymph nodes in mediastinum or in retroperitoneum, 3 cases of detected lung tumors, 3 cases of vasculitis with the FDG accumulation within the arterial wall, and no relevant finding in 6 cases thus the cause of fever remained undetected.*Conclusions Even the most frequent finding in febrile post-COVID-19 syndrome is teh presence of the metabolical active lung involvement, the important group of the patients are those who suffering from the colitis. The Clostridium difficile is relatively frequently found, probable as a consequence to the excessive use of wide-spectral antibiotics during severe state of COVID-19 pneumonia.*Clinical Relevance/Application PET/CT with the application of 18-fluorodeoxyglucose aids in the detection of the complications after COVID-19 in patients suffering from febrile state, the results may to trigger relevant therapy.

RESULTS

The following findings were seen to be related with the febrile state: 14 cases of persistent inflammatory, FDG avid changes in lung parenchyma, 11 cases of colitis (in 7 of them followed confirmation of Clostridium difficile), 6 cases of the FDG avid multiple lymph nodes in mediastinum or in retroperitoneum, 3 cases of detected lung tumors, 3 cases of vasculitis with the FDG accumulation within the arterial wall, and no relevant finding in 6 cases thus the cause of fever remained undetected.

CLINICAL RELEVANCE/APPLICATION

PET/CT with the application of 18-fluorodeoxyglucose aids in the detection of the complications after COVID-19 in patients suffering from febrile state, the results may to trigger relevant therapy.

NMMI04-D3 Normal Tissue Uptake Of 18F-fluorestradiol In Whole Body PET/CT Imaging To Develop Guidelines For Quantitative Analysis.

Participants
Mark Muzi, MS,PhD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

18F-fluoroestradiol (FES), a commercially available PET-tracer, enables in-vivo visualization of estrogen receptor status in breast cancer patients. For quantitative analysis, adequate knowledge of normal tissue uptake and distribution are indispensable for clinical assessment of breast cancer patients. This study aimed to quantitatively examine normal tissue FES uptake of in the most prevalent metastatic sites of breast cancer assessing the range of uptake to develop guidelines for clinical assessment of FES imaging of metastatic disease.*Methods and Materials Sixty-five FES PET/CT whole-body scans from 32 breast cancer patients were retrospectively evaluated. Volumes-of-interests were placed in normal sites from brain, lung, breast, liver, uterus and bone (thoracic, lumbar, ilium). Analysis used mean, max, and peak standardized uptake value (SUVmean, SUVmax, and SUVpeak). Additional normalization for lean-body mass was also applied. Qualitatively, anomalous uptake patterns were documented for potential pitfalls in clinical interpretation of FES uptake, particularly in the gastrointestinal (G.I.) tract.*Results SUVmax uptake in normal brain, lung, breast, and bone regions were not statistically different between each other (Figure 1). A table of normal FES uptake values, ranges and 95% CI are presented for clinical reference. FES uptake above normal limits (mean+95% CI) for these regions (SUVmax>1.5) would be considered elevated uptake for potential tumor delineation. Elevated uptake in liver was expected due to hepatic metabolism of FES, and in the uterus, an estrogen receptor rich organ. Anomalous uptake patterns were observed in the venous line leading to the heart and in the G.I. tract.*Conclusions An empirical threshold of FES SUVmax>1.5 has been used clinically for the assessment of tumor metastases. Statistical evaluation of normal tissue FES uptake confirms this level. Potential pitfalls were documented to prevent clinical misinterpretation, like G.I. tract uptake, intense liver metabolism of FES and in the venous injection line. In response monitoring trials using FES PET imaging, normal tissue uptake will lay the groundwork for clinical interpretation of metastatic disease.*Clinical Relevance/Application Normal tissue FES uptake provides a threshold SUVmax that can be used in combination with other clinical information for the determination of metastatic disease sites in breast cancer patients.

RESULTS

SUVmax uptake in normal brain, lung, breast, and bone regions were not statistically different between each other (Figure 1). A table of normal FES uptake values, ranges and 95% CI are presented for clinical reference. FES uptake above normal limits (mean+95% CI) for these regions (SUVmax>1.5) would be considered elevated uptake for potential tumor delineation. Elevated uptake in liver was expected due to hepatic metabolism of FES, and in the uterus, an estrogen receptor rich organ. Anomalous uptake patterns were observed in the venous line leading to the heart and in the G.I. tract.

CLINICAL RELEVANCE/APPLICATION

Normal tissue FES uptake provides a threshold SUVmax that can be used in combination with other clinical information for the determination of metastatic disease sites in breast cancer patients.

NMMI04-D4 The Value Of PSMA-targeted 18F-DCFPyL PET-CT Scan In The Management Of Patients With Prostate Cancer, A Prospective Study

Participants
Soheil Kooraki, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

PURPOSE

A second generation prostate-specific membrane antigen (PSMA)-targeted tracer, 18F-DCFPyL has been promising for detection of intraprostatic and extraprostatic lesions in patients with biochemical recurrence (BCR) of treated prostate cancer (PCa). This study aimed to investigate the efficacy and clinical impact of 18F-DCFPyL PET/CT scan in various clinical status of PCa.*Methods and Materials This IRB-approved, HIPAA-compliant, open label, single-center, prospective clinical trial has been conducted since April 2020 in patients with histologically proven PCa. The preliminary study cohort included 63 men (mean age 72 years, ranged 57-92) divided into three subcohorts based on the indication of the study: initial staging (N=12), restaging in patients under active surveillance (N=34), and restaging in BCR of treated PCa (N=14). All patients underwent PET/CT approximately one hour after injection of 9 ± 1 mCi 18F-DCFPyL. The pre- and post- PET/CT questionnaires were completed by the referring physician within two weeks before and four weeks after reviewing the results of the 18F-DCFPyL PET/CT study, respectively.*Results 18F-DCFPyL PET/CT scan upgraded the initially presumed PCa stage in 35.9% (23/64) of the study cohort. The clinical surveys showed that by using 18F-DCFPyL PET/CT, additional diagnostic images or invasive procedures were precluded in 38.1% (24/63) of patients. In the other hand, 18F-DCFPyL PET/CT results prompted performing prostate, lymph node or bone biopsy in 14.3% (9/63) of the study cohort. Overall, 18F-DCFPyL PET/CT altered the clinical management in 47.6% (30/63) of the study cohort. In the subcohorts of PCa-BCR, PCa-initial staging and PCa-restaging, the management plan were altered in 71.4% (10/14), 41.7% (5/12) and 44.1% (15/34) of individuals, respectively.*Conclusions 18F-DCFPyL PET/CT scan resulted in altering the clinical management in 47.6% of the patients with PCa. Acquiring 18F-DCFPyL PET/CT scan was of particular benefit in individuals with BCR of treated PCa.*Clinical Relevance/Application The preliminary results show that 18F-DCFPyL PET/CT scan can act as an important diagnostic tool for localization of intraprostatic and extraprostatic lesions in patients with initially diagnosed PCa, those under active surveillance or in patients with BCR of treated PCa.

RESULTS

18F-DCFPyL PET/CT scan upgraded the initially presumed PCa stage in 35.9% (23/64) of the study cohort. The clinical surveys showed that by using 18F-DCFPyL PET/CT, additional diagnostic images or invasive procedures were precluded in 38.1% (24/63) of

patients. In the other hand, 18F-DCFPyL PET/CT results prompted performing prostate, lymph node or bone biopsy in 14.3% (9/63) of the study cohort. Overall, 18F-DCFPyL altered the clinical management in 47.6% (30/63) of the study cohort. In the subcohorts of PCa-BCR, PCa-initial staging and PCa-restaging, the management plan were altered in 71.4% (10/14), 41.7% (5/12) and 44.1% (15/34) of individuals, respectively.

CLINICAL RELEVANCE/APPLICATION

The preliminary results show that 18F-DCFPyL PET/CT scan can act as an important diagnostic tool for localization of intraprostatic and extraprostatic lesions in patients with initially diagnosed PCa, those under active surveillance or in patients with BCR of treated PCa.

SDP-GU-1   Comprehensive Application Of PI-RADS V2.1 And Deep Learning-based Prostate AI In The Diagnosis Of CSPCa

Participants
Wei Xie, MMed, Kunming, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the efficacy of PI-RADS V2.1, prostate AI and their integration model in the diagnosis of clinically significant prostate cancer(CSPCa), and to explore the comprehensive application of these methods.*Methods and Materials Cases with suspected PCa for qualitative diagnosis were screened from the mpMRI follow-up database of our hospital from February 2015 to December 2017. All enrolled cases underwent 3.0T prostate mpMRI: T2WI (three directions), DWI (0/1000/1400 s/mm2), and DCE (temporal resolution=15s). PCa prediction were performed by learning-based prostate AI, and the highest predicted value lesions were recorded directly in patients as the original AI prediction. Significant false-positive predictors were removed (extraprostatic detection, hemorrhage, abscess, etc.) as revised AI prediction. Another experienced radiologist performed retrospective PI-RADS V2.1 scoring without knowing the pathological and clinical information. Then the PI-RADS V2.1 + AI score was obtained by the radiologist referring to the revised prediction results of prostate AI. The results of biopsy and surgical pathology and Gleason score were taken as the gold standard (the Gleason score =3 + 4 or =T3 was CSPCa). ROC curve was used to compare the diagnostic efficacy of original AI prediction, revised AI prediction, PI-RADS V2.1 score and PI-RADS V2.1 + AI score in the diagnosis of CSPCa by SPSS 23.0.*Results A total of 398 patients were enrolled in this study. There were 112 cases of CSPCa and 286 of Non-CSPCa(CISPCa and Non-PCa). The cut-off value was defined as =4 according to the Youden index. The AUC, sensitivity, specificity, PPV, NPV, and accuracy of original AI prediction/ revised AI prediction/ PI-RADS V2.1 score/ PI-RADS + AI score were 0.749/0.777/0.843/0.871, 91.1%/91.1%/92.0%/93.8%, 58.7%/64.3%/76.6%/80.4%, 46.4%/50%/60.6%/65.2%, 94.4%/94.9%/96.1%/97.1%, 67.8%/71.9%/80.9%/84.2%. PI-RADS V2.1 + AI score was superior to the other three, and the improvement of PI-RADS V2.1 score compared to PI-RADS V2.1 was not statistically significant (P > 0.05) , but was significantly higher than that of original AI prediction and revised AI prediction (P = 0.000) .*Conclusions Prostate AI has high diagnostic sensitivity, but it is not specific enough. Moreover, there are a few false positive results in the original prediction. The combination of the revised prediction with the PI-RADS V2.1 score could further improve the diagnostic efficacy for CSPCa.*Clinical Relevance/Application There is deficiency to apply the prediction result of prostate AI directly to clinic. Based on the PI-RADS V2.1, the prediction result of prostate AI is used to adjust the score, it is helpful to further improve the diagnosis of CSPCa.

RESULTS

A total of 398 patients were enrolled in this study. There were 112 cases of CSPCa and 286 of Non-CSPCa(CISPCa and Non-PCa). The cut-off value was defined as =4 according to the Youden index. The AUC, sensitivity, specificity, PPV, NPV, and accuracy of original AI prediction/ revised AI prediction/ PI-RADS V2.1 score/ PI-RADS + AI score were 0.749/0.777/0.843/0.871, 91.1%/91.1%/92.0%/93.8%, 58.7%/64.3%/76.6%/80.4%, 46.4%/50%/60.6%/65.2%, 94.4%/94.9%/96.1%/97.1%, 67.8%/71.9%/80.9%/84.2%. PI-RADS V2.1 + AI score was superior to the other three, and the improvement of PI-RADS V2.1 score compared to PI-RADS V2.1 was not statistically significant (P > 0.05) , but was significantly higher than that of original AI prediction and revised AI prediction (P = 0.000) .

CLINICAL RELEVANCE/APPLICATION

There is deficiency to apply the prediction result of prostate AI directly to clinic. Based on the PI-RADS V2.1, the prediction result of prostate AI is used to adjust the score, it is helpful to further improve the diagnosis of CSPCa.

SDP-GU-10   Clear Cell Renal Cell Carcinoma: Value Of Dynamic Enhanced CT Combined With Different Levels Of Volume Of Interest Delineation Uncertainties In Machine Learning-based Fuhrman Nuclear Grade Prediction

Participants
Ruili Wei, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the predictive value of different machine learning models for the discrimination of low and high nuclear grade clear cell renal cell carcinoma (ccRCC) by using dynamic contrast enhanced CT when introducing with various levels of volume of interest (VOI) delineation uncertainties.*Methods and Materials This study retrospectively collected 177 patients with pathologically proven ccRCC, including 124 low-grade (grade 1 or 2) and 53 high-grade (grade 3 or 4) ccRCC. VOI was obtained for each tumor by manual segmentation, followed by introducing different levels of uncertainties on VOIs delineations as follows: (i) contour-focused VOI, (ii) erosive by 2 mm or 4 mm (VOI_e2 or VOI_e4) and (iii) dilated with perirenal fat (Fat_d2, Fat_d4, Fat_d6) or peritumoral renal parenchyma (Margin_d2, Margin_d4, Margin_d6) by 2 mm or 4 mm or 6 mm. Radiomics features were extracted from four-phase CT images [unenhanced phase (UP), corticomedullary phase (CMP), nephrographic phase (NP) and excretory phase (EP)], including 14 shape features, 18 first-order features and 75 texture features. 15 concatenations of the four-phasic features (UP, CMP, NP, EP, UP+CMP, UP+NP, UP+EP, CMP+NP, CMP+EP, NP+EP, UP+CMP+NP, UP+CMP+EP, UP+NP+EP, CMP+NP+EP, UP+CMP+NP+EP) were fed

into 176 classification models (built with 8 classifiers and 22 feature selection methods), the classification performances of the 2640 resultant discriminative models were compared, the best graphic processing and superior CT phase were elected, and the top-ranked features were analyzed.*Results CT Image features extracted from UP demonstrated outstanding performances over features from other three phases, followed by EP. Shape features showed superior discriminate capabilities over others. The model composed of "Random Forest" and "CIFE" yielded satisfactory performance of AUC of 0.87 with radiomics features extracted from UP and EP based on VOI. VOI, VOI_e2, Fat_d2, Margin_d2 achieved similar performance.*Conclusions Features extracted from UP+EP images (especially shape features) are more effective than other single/combined phase(s) in differentiating low and high nuclear grade ccRCC. Furthermore, compared with original VOI, there is no apparent performance differences on nuclear grading capability by introducing different delineation uncertainties on the VOIs.*Clinical Relevance/Application Segmentation is one of the most critical and challenging procedures of radiomics studies. Identifying the appropriate VOI could provide a reference for further radiomics investigations with manual or automated segmentation.

RESULTS

CT Image features extracted from UP demonstrated outstanding performances over features from other three phases, followed by EP. Shape features showed superior discriminate capabilities over others. The model composed of "Random Forest" and "CIFE" yielded satisfactory performance of AUC of 0.87 with radiomics features extracted from UP and EP based on VOI. VOI, VOI_e2, Fat_d2, Margin_d2 achieved similar performance.

CLINICAL RELEVANCE/APPLICATION

Segmentation is one of the most critical and challenging procedures of radiomics studies. Identifying the appropriate VOI could provide a reference for further radiomics investigations with manual or automated segmentation.

SDP-GU-11   Noninvasive Assessment Of Chronic Kidney Disease In Children With Blood Oxygenation Level-dependent MRI And Intravoxel Incoherent Motion Diffusion-weighted Imaging

Participants
Ping Liang, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the diagnostic performance of blood oxygenation level-dependent MRI (BOLD-MRI) and intravoxel incoherent motion diffusion-weighted imaging (IVIM-DWI) for evaluating renal function in children with chronic kidney disease (CKD).*Methods and Materials Fifty-one children with CKD stage 1-3, 12 children with CKD stage 4-5, and 11 healthy volunteers underwent a renal MRI including conventional coronal T2-weighted (T2WI), axial T1-weighted (T1WI), T2-weighted (T2WI) and BOLD, DWI sequences. We measured T2*, ADC, Dt, Dp, and fp values of the renal cortex and medulla on BOLD and DWI images. We applied appropriate statistical methods to compare the differences of MRI-derived parameters between the three groups, and calculated the correlation coefficient between MRI-derived parameters and clinical data. Receiver operating characteristic (ROC) analysis was used to evaluate the diagnostic performance of MRI-derived parameters.*Results Cortex T2*, ADC, Dt, fp and medulla T2*, ADC, Dt showed significant differences between the three groups. Cortex Dp and medulla Dp, fp showed no significant differences between the three groups. The values of cortex T2*, ADC, Dt, DP, fp and medulla T2*, ADC, Dt, Dp, fp were in the order of CKD stage 4-5 < CKD stage 1-3 < healthy volunteers. Cortex and medulla T2*, ADC, Dt were all significantly correlated with eGFR, serum creatinine, cystatin C. In addition, cortex T2* and eGFR showed the highest correlation coefficient (r = 0.824, P < 0.001). Cortex Dt and medulla T2* were optimal parameters for differentiating healthy volunteers and CKD stage 1-3 or CKD stage 1-3 and CKD stage 4-5, respectively.*Conclusions BOLD and IVIM-DWI might be feasible for noninvasive evaluation of renal function in children with CKD.*Clinical Relevance/Application Multiparametric MRI including BOLD MRI and IVIM-MRI, especially T2* relaxation time, ADC and Dt values, might be feasible for noninvasive evaluation of renal function in children with CKD.

RESULTS

Cortex T2*, ADC, Dt, fp and medulla T2*, ADC, Dt showed significant differences between the three groups. Cortex Dp and medulla Dp, fp showed no significant differences between the three groups. The values of cortex T2*, ADC, Dt, DP, fp and medulla T2*, ADC, Dt, Dp, fp were in the order of CKD stage 4-5 < CKD stage 1-3 < healthy volunteers. Cortex and medulla T2*, ADC, Dt were all significantly correlated with eGFR, serum creatinine, cystatin C. In addition, cortex T2* and eGFR showed the highest correlation coefficient (r = 0.824, P < 0.001). Cortex Dt and medulla T2* were optimal parameters for differentiating healthy volunteers and CKD stage 1-3 or CKD stage 1-3 and CKD stage 4-5, respectively.

CLINICAL RELEVANCE/APPLICATION

Multiparametric MRI including BOLD MRI and IVIM-MRI, especially T2* relaxation time, ADC and Dt values, might be feasible for noninvasive evaluation of renal function in children with CKD.

SDP-GU-12   Vascular, Extracellular, And Restricted Diffusion For Cytometry In Tumors MRI For The Detection And Assessment Of Clinically Significant Prostate Cancer

Participants
Xiangyu Wang, Shenzhen, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic efficiency of parameters derived from the Vascular, Extracellular, and Restricted Diffusion for Cytometry in Tumors (VERDICT) model in discriminating clinically significant PCa from insignificant PCa.*Methods and Materials After multiparametric and VERDICT acquisition in our institution, MRI/US fusion-guided targeted biopsy of index lesions and 12-core routine systematic biopsies were then performed. Data from 40 PCa foci, 28 stromal BPH foci and 31 nonstromal BPH foci of 56 participants were analyzed. The VERDICT parameters included fEES (extracellular extravascular space fraction), fIC (intracellular volume fraction) and fVASC (vascular fraction). Dunn's Kruskal-Wallis multiple comparison test, Mann-Whitney test, Delong test, logistic regression and receiver operating characteristic (ROC) analyses were performed.*Results The fIC, fEES and fVASC parameters were significantly different between the PCa group and nonstromal BPH group and between the clinically significant and insignificant PCa groups (all P <0.001) but not significantly different between the PCa and stromal BPH groups. Compared with the ADC value, the VERDICT parameters showed higher diagnostic efficiency in differentiating clinically significant and insignificant PCa, but there was no significant difference (adjusted P > 0.05). However, the AUC of the fIC+fEES+fVASC parameter was significantly higher than that of ADC (adjusted P <0.001).*Conclusions Both VERDICT parameters and ADC can be used as quantitative parameters in the differentiation between benign and cancer regions. In addition, the VERDICT parameters can improve the diagnostic performance in discriminating clinically significant PCa from insignificant PCa compared with the ADC value.*Clinical

Relevance/Application a) The VERDICT model provides useful microstructural parameter assessments,including cellular, vascular, extravascular, and extracellular volume assessments.b) fIC, fEES and fVASC were significantly different between PCa group and non-stromalBPH group, between clinically significant and insignificant PCa group.c) Compared to ADC value, The VERDICT parameters provide better diagnosticperformance of clinically insignificant PCa which can potentially reduceunnecessary treatment.d) The combination of VERDICT parameters showed the best diagnostic efficiency in detection and assessment of clinically significant PCa.

RESULTS

The fIC, fEES and fVASC parameters were significantly different between the PCa group and nonstromal BPH group and between the clinically significant and insignificant PCa groups (all P <0.001) but not significantly different between the PCa and stromal BPH groups. Compared with the ADC value, the VERDICT parameters showed higher diagnostic efficiency in differentiating clinically significant and insignificant PCa, but there was no significant difference (adjusted P > 0.05). However, the AUC of the fIC+fEES+fVASC parameter was significantly higher than that of ADC (adjusted P <0.001).

CLINICAL RELEVANCE/APPLICATION

a) The VERDICT model provides useful microstructural parameter assessments,including cellular, vascular, extravascular, and extracellular volume assessments.b) fIC, fEES and fVASC were significantly different between PCa group and non-stromalBPH group, between clinically significant and insignificant PCa group.c) Compared to ADC value, The VERDICT parameters provide better diagnosticperformance of clinically insignificant PCa which can potentially reduceunnecessary treatment.d) The combination of VERDICT parameters showed the best diagnostic efficiency in detection and assessment of clinically significant PCa.

SDP-GU-13 Comparison Of Biparametric And Multiparametric MRI For Prostate Cancer Of Peripheral Zone Detection With Pi-rads Version 2.1

Participants
Jiahui Zhang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the diagnostic performance for detecting Prostate Cancer (PCa) and clinically significant Prostate Cancer (csPCa) in peripheral zone of biparametric MRI (bpMRI) and multiparametric MRI (mpMRI) using the Prostate Imaging and Reporting Data System version 2.1 (PI-RADS v2.1).*Methods and Materials Clinical and MRI datas of 334 prostate patients admitted to our hospital from January 2015 to September 2018 were retrospectively collected. BpMRI without Dynamic contrast enhanced (DCE) sequence and mpMRI with DCE were independently scored by two radiologists. All patients were scored using a double-blind method using the PI-RADS v2.1. Using PI-RADS=4 as the positive threshold and pathology of biopsy or prostatectomy as the gold standard, the diagnostic efficacy of bpMRI and mpMRI in PCa and csPCa of peripheral zone were compared. Statistical analysis was performed using the kappa statistic and McNemar and Delong tests.*Results A total of 307 prostate patients were included in the study, including 142 non-PCa patients and 165 PCa patients, 130 of which were csPCa. The AUCs of PCa diagnosed by mpMRI and bpMRI were 0.717 and 0.733, respectively, and the difference was not statistically significant (P=0.317). The sensitivity, specificity and accuracy of mpMRI in PCa diagnosis were 89.1%, 54.2% and 73.0%, respectively. The sensitivity, specificity and accuracy of bpMRI in PCa diagnosis were 81.8%, 64.8% and 73.9%, respectively. The AUCs of csPCa diagnosed by mpMRI and bpMRI were 0.594 and 0.602, respectively, and the difference was not statistically significant (P=0.756). The sensitivity, specificity and accuracy of mpMRI in csPCa diagnosis were 93.1%, 25.7% and 78.8%, respectively. The sensitivity, specificity and accuracy of bpMRI in csPCa diagnosis were 86.2%, 34.3% and 75.2%, respectively. The sensitivity of mpMRI in the diagnosis of PCa and csPCa was higher than that of bpMRI, but the specificity of mpMRI was lower than that of bpMRI (All P < 0.001).When PI-RADS was 3 and 4 scores, the detection rates of PCa and csPCa in peripheral zone were different between mpMRI and bpMRI, but the differences were not statistically significant (All P > 0.05).*Conclusions For detecting PCa and csPCa using PI-RADS v2.1, the diagnostic performance of bpMRI was comparable with those of mpMRI. Moreover, bpMRI has higher diagnostic specificity and can avoid unnecessary biopsy.*Clinical Relevance/Application BpMRI of PI-RADS v2.1 can be used to detect Prostate Cancer of peripheral zone.

RESULTS

A total of 307 prostate patients were included in the study, including 142 non-PCa patients and 165 PCa patients, 130 of which were csPCa. The AUCs of PCa diagnosed by mpMRI and bpMRI were 0.717 and 0.733, respectively, and the difference was not statistically significant (P=0.317). The sensitivity, specificity and accuracy of mpMRI in PCa diagnosis were 89.1%, 54.2% and 73.0%, respectively. The sensitivity, specificity and accuracy of bpMRI in PCa diagnosis were 81.8%, 64.8% and 73.9%, respectively. The AUCs of csPCa diagnosed by mpMRI and bpMRI were 0.594 and 0.602, respectively, and the difference was not statistically significant (P=0.756). The sensitivity, specificity and accuracy of mpMRI in csPCa diagnosis were 93.1%, 25.7% and 78.8%, respectively. The sensitivity, specificity and accuracy of bpMRI in csPCa diagnosis were 86.2%, 34.3% and 75.2%, respectively. The sensitivity of mpMRI in the diagnosis of PCa and csPCa was higher than that of bpMRI, but the specificity of mpMRI was lower than that of bpMRI (All P < 0.001).When PI-RADS was 3 and 4 scores, the detection rates of PCa and csPCa in peripheral zone were different between mpMRI and bpMRI, but the differences were not statistically significant (All P > 0.05).

CLINICAL RELEVANCE/APPLICATION

BpMRI of PI-RADS v2.1 can be used to detect Prostate Cancer of peripheral zone.

SDP-GU-14 Diagnostic Accuracy And Inter-reader Reliability Of Ultrasound O-RADS Risk Stratification Amongst Less Experienced Readers In A North American Institution With And Without Pre-test Training

Participants
Prayash Katlariwala, BSC, Edmonton, Alberta (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic accuracy and inter-reader reliability of ultrasound O-RADS risk stratification amongst less experienced readers in a North American institution without and with pre-test training.*Methods and Materials A single center retrospective cohort study evaluating 50 adult female-sex pelvic ultrasounds with ovarian lesions of varying O-RADS classifications was performed. Reference standard O-RADS scores were established through consensus of three fellowship-trained body imaging radiologists. Three PGY-4 residents were independently evaluated for diagnostic accuracy and inter-reader reliability without and with pre-test O-RADS training performed 6 weeks apart. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), area and under the curve (AUC) were used to measure accuracy. Fleiss kappa and weighted quadratic (pairwise)

kappa values were used to measure inter-reader reliability. Statistical significance was p < 0.05.*Results Mean patient age was 40 ± 16 years with a range of lesion sizes from 1.2 cm to 22.5 cm. Readers demonstrated excellent specificities (85-100% pre-training and 91-100% post-training) and NPVs (89-100% pre-training and 91-100% post-training) across the O-RADS categories. Sensitivities were variable, particularly for higher O-RADS categories (55-100% pre-training and 64-100% post-training). Considering O-RADS 4 and O-RADS 5 lesions as malignant,pre-training and post-training AUC values were 0.87-0.95 and 0.94-098, respectively (P < 0.001). Fleiss kappa inter-reader reliability was 'good' for pre-training and post-training assessment (k= 0.76 and 0.77, respectively). Pairwise inter-reader reliability was 'very good' for pre-training and post-training assessment (k= 0.77-0.87 and 0.85-0.89, respectively).*Conclusions Excellent specificities and AUC values with very good pairwise inter-reader reliability can be achieved by less experienced readers in North America. Less experienced readers may be subject to misclassification of potentially malignant lesions, and specific training around typical ultrasound dermoid features and smooth versus irregular inner wall/septation morphology may help improve sensitivity.*Clinical Relevance/Application Less experienced readers in North America can successfully adopt and integrate the O-RADS risk classification with good outcomes with or without training. Specific training on dermoid features and inner wall morphology may help improve performance.

RESULTS

Mean patient age was 40 ± 16 years with a range of lesion sizes from 1.2 cm to 22.5 cm. Readers demonstrated excellent specificities (85-100% pre-training and 91-100% post-training) and NPVs (89-100% pre-training and 91-100% post-training) across the O-RADS categories. Sensitivities were variable, particularly for higher O-RADS categories (55-100% pre-training and 64-100% post-training). Considering O-RADS 4 and O-RADS 5 lesions as malignant,pre-training and post-training AUC values were 0.87-0.95 and 0.94-098, respectively (P < 0.001). Fleiss kappa inter-reader reliability was 'good' for pre-training and post-training assessment (k= 0.76 and 0.77, respectively). Pairwise inter-reader reliability was 'very good' for pre-training and post-training assessment (k= 0.77-0.87 and 0.85-0.89, respectively).

CLINICAL RELEVANCE/APPLICATION

Less experienced readers in North America can successfully adopt and integrate the O-RADS risk classification with good outcomes with or without training. Specific training on dermoid features and inner wall morphology may help improve performance.

SDP-GU-15 Application Of Deep Learning-based Reconstruction Of Ultra-low Dose Abdominal CT In The Diagnosis Of Renal Calculi

Participants
Xiaoxiao Zhang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the image quality, diagnostic ability and radiation dose of abdominal ultra-low dose CT deep learning-based reconstruction (DLR) algorithm in the diagnosis of renal calculi.*Methods and Materials From November 2020 to December 2020, 60 patients with suspected renal calculi were prospectively scanned with low-dose and ultra-low-dose CT. Low-dose CT images were reconstructed with hybrid iterative reconstruction((adaptive iterative dose reduction [AIDR] 3D,LD-AIDR 3D) and ultra-low dose CT images were reconstruction with AIDR 3D (UD-AIDR 3D) and deep learning-based reconstruction (UD-DLR).A radiologist recorded the number of renal calculi and the diameter of the largest stones in these three groups of images, evaluated the number of lesions in abdominal organs and the diameter of maximum lesions, measured the CT value and noise of abdominal tissues and organs, and calculated the contrast noise ratio (CNR) and signal-to-noise ratio (SNR). The image quality of the three groups of images was evaluated, and the radiation doses of low dose and ultra-low dose scanning were compared.*Results A total of 130 kidney stones were detected in LD-AIDR 3D images (76 in left kidney and 54 in right kidney). Taking LD-AIDR 3D as the standard, the detection rates of stones in UD-AIDR 3D and UD-DLR images were 96.2% and 98.5% and the ratio was 100% for stones larger than 3mm. There was no statistical difference in the diameter of the largest stone among the three groups(P>0.05). Except for 3 cases of hepatic cysts smaller than 5mm, the lesions detected by LD-AIDR 3D images could be observed in UD-DLR images. There was no significant difference in image noise between LD-AIDR 3D and UD-DLR (7.97±1.25HU vs. 7.58±1.67HU) (P>0.05), both of them were significantly lower than UD-AIDR 3D image noise (12.14±2.13HU) (P<0.05).There was no significant difference in CT value and CNR of liver, spleen, kidney and aorta between LD-AIDR 3D image and UD-DLR image(P>0.05), which was higher than that of UD-AIDR 3D images(P<0.05), SNR of each organ and tissue of UD-DLR images was higher than that of LD-AIDR 3D and UD-AIDR 3D, and the subjective image quality of LD-AIDR 3D was similar to that of UD-DLR images, which was better than that of UD-AIDR 3D images. The mean effective radiation dose of low dose scan and ultra-low dose scan was2.75±0.50mSv,0.64±0.17mSv. The radiation dose of ultra-low dose scanning is about 77% lower than that of low dose scanning.*Conclusions Abdominal ultra-low dose CT scan combined with DLR reconstruction can greatly reduce the radiation dose while maintaining the image quality, and can be used in the clinical diagnosis of renal calculi.*Clinical Relevance/Application The study could promote the clinical application of ultra-low dose CT scan for renal calculi.

RESULTS

A total of 130 kidney stones were detected in LD-AIDR 3D images (76 in left kidney and 54 in right kidney). Taking LD-AIDR 3D as the standard, the detection rates of stones in UD-AIDR 3D and UD-DLR images were 96.2% and 98.5% and the ratio was 100% for stones larger than 3mm. There was no statistical difference in the diameter of the largest stone among the three groups(P>0.05). Except for 3 cases of hepatic cysts smaller than 5mm, the lesions detected by LD-AIDR 3D images could be observed in UD-DLR images. There was no significant difference in image noise between LD-AIDR 3D and UD-DLR (7.97±1.25HU vs. 7.58±1.67HU) (P>0.05), both of them were significantly lower than UD-AIDR 3D image noise (12.14±2.13HU) (P<0.05).There was no significant difference in CT value and CNR of liver, spleen, kidney and aorta between LD-AIDR 3D image and UD-DLR image(P>0.05), which was higher than that of UD-AIDR 3D images(P<0.05), SNR of each organ and tissue of UD-DLR images was higher than that of LD-AIDR 3D and UD-AIDR 3D, and the subjective image quality of LD-AIDR 3D was similar to that of UD-DLR images, which was better than that of UD-AIDR 3D images. The mean effective radiation dose of low dose scan and ultra-low dose scan was2.75±0.50mSv,0.64±0.17mSv. The radiation dose of ultra-low dose scanning is about 77% lower than that of low dose scanning.

CLINICAL RELEVANCE/APPLICATION

The study could promote the clinical application of ultra-low dose CT scan for renal calculi.

SDP-GU-4 A Novel Radiogenomics Biomarkerbased On Hypoxic-genesubset : Accurate Survival And Prognostic Prediction Of Renal Clear Cell Carcinoma

Participants

Jiahao Gao, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To construct a novel radiogenomics biomarker based on hypoxic-gene subset for the accurate prognostic prediction of renal clear cell carcinoma.*Methods and Materials Firstly, we screened for the desired hypoxic-gene sbuset by performing KEEG analysis in the TCGA database. And by univariate and multivariate cox regression to discover survival-related hypoxia genes, a genomics signature was constructed in the TCGA-KIRC database. Immediately afterwards, we successfully built a hypoxia-gene related radiogenomics biomarker (prediction of hypoxia-genes signature by contrast-enhanced CT radiomics) in the TCIA database by extracting features in venous phase of contrast-enhanced CT images, selecting features using the mRMR and LASSO algorithm, and building logistic regression models. Finally, we validated the prognostic ability of the new prognostic biomarker for patients with renal clear cell carcinoma in an independent validation cohort at Huashan Hospital, Shanghai, China.*Results The hypoxia-gene related genomics signature consisting of five genes, IFT57, PABPN1, RNF10, RNF19B and UBE2T, was shown to be significantly associated with the survival status for patients with renal clear cell carcinoma in the TCGA-KIRC database (by grouping of signature: low or high risk). In the TCIA database, we constructed a radiogenomics biomarker consisting of 13 radiomics features that were good predictors of hypoxia-gene signature expression levels (low or high risk) in patients at each institution, acquring AUC values of 0.91 and 0.91 in the training and validation group, respectively. In the independent validation cohort at Huashan Hospital, our radiogenomics biomarker was significantly associated with prognostic survival of patients with renal clear cell carcinoma (p=0.0018).*Conclusions The novel prognostic radiogenomics biomarker we built achieved good survival prediction results in both the cohort of TCIA/TCGA database and the independent validation cohort in Huashan hospital for patients with renal clear cell carcinoma, and may assist in clinical preferential treatment decisions and promote the process of precision theranostics in the future.*Clinical Relevance/Application This radiogenomics bimarker is expected to serve as a potential clinical non-invasive prognostic marker for renal clear cell carcinoma and to facilitate the process of individualized and accurate diagnosis and treatment of renal clear cell carcinoma.

RESULTS

The hypoxia-gene related genomics signature consisting of five genes, IFT57, PABPN1, RNF10, RNF19B and UBE2T, was shown to be significantly associated with the survival status for patients with renal clear cell carcinoma in the TCGA-KIRC database (by grouping of signature: low or high risk). In the TCIA database, we constructed a radiogenomics biomarker consisting of 13 radiomics features that were good predictors of hypoxia-gene signature expression levels (low or high risk) in patients at each institution, acquring AUC values of 0.91 and 0.91 in the training and validation group, respectively. In the independent validation cohort at Huashan Hospital, our radiogenomics biomarker was significantly associated with prognostic survival of patients with renal clear cell carcinoma (p=0.0018).

CLINICAL RELEVANCE/APPLICATION

This radiogenomics bimarker is expected to serve as a potential clinical non-invasive prognostic marker for renal clear cell carcinoma and to facilitate the process of individualized and accurate diagnosis and treatment of renal clear cell carcinoma.

SDP-GU-5   **Impact Of Deep Learning Reconstruction Combined With Sharpening Filter On High-resolution Single-shot Fast Spin Echo T2-weighted MRI Of The Uterus.**

Participants
Takahiro Tsuboyama, MD, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the effect of deep learning reconstruction (DL) and post-processing sharpening filter on the image quality of high-resolution single-shot fast spin echo (SSFSE) T2-weighted MRI of the uterus.*Methods and Materials Thirty patients with uterine diseases underwent pelvic MRI. Parasagittal T2-weighted imaging at 4-mm thickness was obtained with periodically rotated overlapping parallel lines with enhanced reconstruction (PROPELLER) and SSFSE. In-plane resolution was 0.75×0.75 and 0.8×0.8 mm, and the mean scan time was 204 and 22 sec in PROPELLER and SSFSE, respectively. Three types of SSFSE images were generated by the following techniques: conventional reconstruction (SSFSE-C), deep learning reconstruction (SSFSE-DL), and DL with post-processing sharpening filter (SSFSE-DLF). PROPELLER and the three types of SSFSE imaging were quantitatively and qualitatively assessed by one and two radiologists, respectively, and compared using repeated measures of ANOVA or Friedman's test.*Results In the quantitative comparisons, SSFSE-C had significantly the lowest signal-to-noise ratio (SNR) (P < .01). SSFSE-DL provided significantly the highest SNR (P < .01) but the lowest contrast between junctional zone and the myometrium (P < .01). SSFSE-DLF showed the same SNR and contrast between junctional zone and the myometrium with PROPELLER. There was not significant difference in contrast between malignant tumors and piriformis muscle among the 4 types of imaging. In Qualitative assessment, 3 types of SSFSE were significantly superior to PROPELLER in motion artifacts (P < .01). SSFSE-C and SSFSE-DL showed significantly lower sharpness but SSFSE-DLF provided significantly higher sharpness than PROPELLER (P < .01). Furthermore, conspicuity of the uterine architecture and lesions were significantly the highest on SSFSE-DLF (P < .01). SSFSE-DLF exhibited overall image quality significantly higher than SSFSE-C and SSFSE-DL, and comparable to PROPELLER (P < .01).*Conclusions The combination of deep learning reconstruction and post-processing sharpening filter extremely increases the image quality of high-resolution SSFSE of the uterus to the same level of PROPELLER.*Clinical Relevance/Application High-resolution SSFSE with DL and post-processing sharpening filter yields high image quality in a short acquisition time and can be a powerful back-up sequence or even have a potential to replace the conventional FSE imaging.

RESULTS

In the quantitative comparisons, SSFSE-C had significantly the lowest signal-to-noise ratio (SNR) (P < .01). SSFSE-DL provided significantly the highest SNR (P < .01) but the lowest contrast between junctional zone and the myometrium (P < .01). SSFSE-DLF showed the same SNR and contrast between junctional zone and the myometrium with PROPELLER. There was not significant difference in contrast between malignant tumors and piriformis muscle among the 4 types of imaging. In Qualitative assessment, 3 types of SSFSE were significantly superior to PROPELLER in motion artifacts (P < .01). SSFSE-C and SSFSE-DL showed significantly lower sharpness but SSFSE-DLF provided significantly higher sharpness than PROPELLER (P < .01). Furthermore, conspicuity of the uterine architecture and lesions were significantly the highest on SSFSE-DLF (P < .01). SSFSE-DLF exhibited overall image quality significantly higher than SSFSE-C and SSFSE-DL, and comparable to PROPELLER (P < .01).

CLINICAL RELEVANCE/APPLICATION

High-resolution SSFSE with DL and post-processing sharpening filter yields high image quality in a short acquisition time and can be a powerful back-up sequence or even have a potential to replace the conventional FSE imaging.

SDP-GU-6   Association Of US/MRI Misregistration And False Negative Fusion Biopsy Of PI-RADS 4 And 5 Lesions On MRI

Participants
Miyad Movassaghi, MD,MSc, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

To investigate whether misregistration between US and MRI during fusion biopsy, caused by discrepant prostate segmentation, and other patient or imaging-based factors are associated with a false negative (FN) fusion biopsy of PI-RADS 4/5.*Methods and Materials 530 consecutive patients with 685 PI-RADS 4 or 5 lesions on MRIs performed 11/2015-12/2020 and subsequent US/MRI fusion biopsy were retrospectively collected. Biopsied lesions were separated into true positive (TP), false positive (FP) and false negative (FN) using a combination of systematic and fusion biopsy and grade group 2 or higher as the reference standard. FP cases were excluded. FN fusion biopsy was defined as negative targeted fusion cores with adjacent positive systematic cores. The impact of patient and imaging specific factors including PSA, use of an enema prep before MRI, lesion size, prostate volume, absolute and percent difference in segmented prostate volume between US and MRI during the fusion process, and urologist performing the biopsy, on the probability of a FN fusion biopsy were tested using logistic regression.*Results 361 lesions in 290 patients (median age 69 years, IQR 63-75, median PSA 6.5 ng/ml, IQR 4.7-9.3), including 67 (19%) FN and 294 TP (81%) were included. There was a significant inverse association between lesion size and probability of FN (odds ratio (OR): 0.90, 95%CI: 0.85-0.95, p-value: <0.0001). Similarly, PSA level was inversely associated with FN, (OR: 0.86, 95%CI: 0.77-0.93, p-value: 0.0003). However, the probability of a FN fusion biopsy was not associated with use of an enema prep before MRI, size of prostate gland, discrepancy between US and MRI segmented prostate volume or the operator (p-value>0.05).*Conclusions Lower PSA values and smaller PI-RADS 4/5 lesions are associated with FN fusion biopsy. Discrepant US and MRI prostate segmentation volumes derived as part of fusion biopsy were not associated with a FN biopsy.*Clinical Relevance/Application Discrepant US and MRI segmentation volumes during the fusion biopsy process may not contribute significantly to missed MRI lesions during biopsy.

RESULTS

361 lesions in 290 patients (median age 69 years, IQR 63-75, median PSA 6.5 ng/ml, IQR 4.7-9.3), including 67 (19%) FN and 294 TP (81%) were included. There was a significant inverse association between lesion size and probability of FN (odds ratio (OR): 0.90, 95%CI: 0.85-0.95, p-value: <0.0001). Similarly, PSA level was inversely associated with FN, (OR: 0.86, 95%CI: 0.77-0.93, p-value: 0.0003). However, the probability of a FN fusion biopsy was not associated with use of an enema prep before MRI, size of prostate gland, discrepancy between US and MRI segmented prostate volume or the operator (p-value>0.05).

CLINICAL RELEVANCE/APPLICATION

Discrepant US and MRI segmentation volumes during the fusion biopsy process may not contribute significantly to missed MRI lesions during biopsy.

SDP-GU-7   Inter-observer Reliability Of Mr Angiography For Preoperative Assessment Of Potential Renal Donors

Participants
Ali Elmokadem, MD,PhD, Mansoura, Egypt (*Presenter*) Nothing to Disclose

PURPOSE

To assess the inter-observer reliability of non-enhanced MR angiography as a non-invasive method for evaluating the anatomical findings of potential living kidney donors.*Methods and MaterialsAll potential donors were referred from specialized kidney transplantation unit and underwent non contrast MR angiography of the renal arteries on a 1.5-T closed MRI unit using a respiratory-triggered magnetization prepared three-dimensional balanced steady-state free precession (b-SSFP) with inversion recovery pulses and fat saturation (Inhance 3D Inflow IR; GE health care). Two experienced radiologists evaluated non-contrast MRA images. Observers were asked to evaluate both renal arteries anatomy and their branching pattern, presence of accessory or aberrant renal arteries, and identify any anatomical variant. Lin's correlation test was performed to test MRA readings by each of the two observers against CTA findings which considered as the gold standard for assessment of renal arteries. Additionally, observers were asked to assess the image quality based on sharpness, presence of artifacts, and diagnostic acceptability.*ResultsThis study included 60 potential kidney donors (43 males & 17 females) with mean age ± SD of 31.3 ± 5.6 years. Excellent to very good inter-observer agreement was found between both observers in the assessment of renal arteries by non-enhanced MRA. There was perfect concordance between MRA and CTA findings in detecting early arterial division, caliber, and length of left extra-parenchymal segmental branches. Moderate concordance was found in the assessment of the supplied segments of extra-parenchymal segmental renal arterial branches. There was substantial concordance between both MRA observers' findings in the remaining variables of the study. There was excellent agreement between both observers in the assessment of image quality parameters.*ConclusionsNon-contrast enhanced MR angiography for the renal arteries is an effective alternative for CTA without the risks of radiation or contrast media.*Clinical Relevance/Application MR angiography for the renal donors without contrast administration can have an impact on donor selection, operative planning, and minimizing post-operative complication.

RESULTS

This study included 60 potential kidney donors (43 males & 17 females) with mean age ± SD of 31.3 ± 5.6 years. Excellent to very good inter-observer agreement was found between both observers in the assessment of renal arteries by non-enhanced MRA. There was perfect concordance between MRA and CTA findings in detecting early arterial division, caliber, and length of left extra-parenchymal segmental branches. Moderate concordance was found in the assessment of the supplied segments of extra-parenchymal segmental renal arterial branches. There was substantial concordance between both MRA observers' findings in the remaining variables of the study. There was excellent agreement between both observers in the assessment of image quality parameters.

CLINICAL RELEVANCE/APPLICATION

MR angiography for the renal donors without contrast administration can have an impact on donor selection, operative planning, and minimizing post-operative complication.

Compressed Sensing And Deep Learning Reconstruction On Women's Pelvic MRI At 1.5 T MR System: Utility For Improving Image Quality And Examination Time As Compared With Parallel Imaging

Participants
Takahiro Ueda, Toyoake, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To determine the utility of compressed sensing (CS) and deep learning reconstruction (DLR) for improving image quality and examination time on women's pelvic MRI at 1.5 T system as compared with parallel imaging (PI).*Methods and Materials 52 consecutive female patients with various pelvic diseases underwent T1WI and T2WI by CS and PI. Then, each CS data was reconstructed with and without DLR, and examination times of CS and PI were recorded in all patients. For quantitative assessment, SNR of muscle and CNR between fat tissue and iliac muscle on T1WI, and endometrium and myometrium on T2WI were determined by ROI measurement. For qualitative assessment, two board certified radiologists assessed overall image quality and diagnostic confidence level by 5-point scales, and each final score was determined as consensus of two readers. To compare the capability for examination time reduction, mean examination times of both sequences were compared among all data sets by Tukey's HSD test. To determine quantitative image quality improvement on each CS data by DLR, SNRs and CNRs were compared among all methods by Tukey's HSD test. On qualitative image quality evaluations, inter-observer agreement on each data set was assessed by ? statistics followed by ?2 test. Finally, both indexes on T1WI and T2WI were compared among all methods by Wilcoxon signed-rank test.*Results Mean examination times of T1WI and T2WI obtained by CS and reconstructed with and without DLR were significantly shorter than that of PI (T1WI: $p<0.001$; T2WI, $p<0.001$). On T1WI and T2WI, SNR and CNR of CS with DLR were significantly higher than those of CS without DLR and PI ($p<0.05$). Inter-observer agreements were determined as 'substantial' or 'almost perfect' ($0.71<?<0.99$, $p<0.0001$). On T1WI and T2WI, overall image quality of CS with DLR was significantly higher than that of PI and CS without DLR ($p<0.001$). Diagnostic confidence level of T2WI by CS with DLR was significantly higher than that by PI and CS without DLR ($p<0.05$).*Conclusions CS with DLR is considered as useful for image quality improvement with reducing examination time on women's pelvic MRI at 1.5 T system, when compared with PI.*Clinical Relevance/Application CS with DLR is considered as useful for image quality improvement with reducing examination time on women's pelvic MRI at 1.5 T system as compared with PI.

RESULTS

Mean examination times of T1WI and T2WI obtained by CS and reconstructed with and without DLR were significantly shorter than that of PI (T1WI: $p<0.001$; T2WI, $p<0.001$). On T1WI and T2WI, SNR and CNR of CS with DLR were significantly higher than those of CS without DLR and PI ($p<0.05$). Inter-observer agreements were determined as 'substantial' or 'almost perfect' ($0.71<?<0.99$, $p<0.0001$). On T1WI and T2WI, overall image quality of CS with DLR was significantly higher than that of PI and CS without DLR ($p<0.001$). Diagnostic confidence level of T2WI by CS with DLR was significantly higher than that by PI and CS without DLR ($p<0.05$).

CLINICAL RELEVANCE/APPLICATION

CS with DLR is considered as useful for image quality improvement with reducing examination time on women's pelvic MRI at 1.5 T system as compared with PI.

Deep Learning With Bayesian Inference For Prostate Cancer Diagnosis Across Longitudinal Biparametric MRI

Participants
Anindo Saha, MSc, Nijmegen, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

Despite increasing use of active surveillance via biparametric MR imaging (bpMRI) for prostate cancer (PCa) management, there is a lack of research in medical image computing that utilize longitudinal studies to assist present-day diagnosis. Our goal is to investigate the efficacy of a deep learning-based PCa detection model, that integrates past bpMRI exams and population-level anatomical priors via Bayesian inference.*Methods and Materials This retrospective study included 250 consecutive biopsy-naïve men (median age: 64 yrs; IQR: 60-69) with elevated levels of PSA (median level: 8 ng/mL; IQR: 5-11), who underwent at least two consecutive MRI exams between 2016-2018 (N=500). Intra-patient bpMRI scans were rigidly registered, paired with expert voxel-level annotations of PI-RADS 2-5 lesions and subsequently used to train a deep learning model to predict and localize all PI-RADS findings. Radiologists utilize prior studies to inform present-day diagnosis. Similarly, for each patient case, computer-aided diagnosis for the follow-up bpMRI exam was derived via Bayesian modelling; probabilistically integrating past exams and a population prior for spatial PCa prevalence and zonal anatomy. Diagnostic performance was evaluated by the ability to accurately discriminate patients with benign prostatic tissue (n=10) or PI-RADS = 3 lesions (n=159), from those carrying PI-RADS = 4 lesions (n=81), over 5-fold cross-validation. Normalized Wilcoxon Mann-Whitney U statistic was used to derive AUROC and confidence intervals were computed over 5000 replications of bootstrapping.*Results Computer-aided diagnosis of follow-up studies without priori, yielded an AUROC of 0.77 (95% CI: 0.71, 0.83), F0.5 score of 0.51 (95% CI: 0.42, 0.61), positive predictive value (PPV) of 0.51 (95% CI: 0.40, 0.60) and negative predictive value (NPV) of 0.78 (95% CI: 0.71, 0.83). Computer-aided diagnosis of follow-up studies with the inclusion of priori via Bayesian inference yielded an AUROC of 0.80 (95% CI: 0.76, 0.84), F0.5 score of 0.58 (95% CI: 0.48, 0.68), PPV of 0.60 (95% CI: 0.48, 0.72) and NPV of 0.78 (95% CI: 0.72, 0.85). In comparison to stand-alone diagnosis, factoring in prior studies resulted in a 41.4% reduction of AUROC standard deviation across each fold.*Conclusions Incorporating past studies and clinical priors via Bayesian inference can improve diagnostic certainty and robustness of deep learning in follow-up patient exams.*Clinical Relevance/Application Prostate cancer is one of the most prevalent cancers in men worldwide. In the absence of experienced radiologists, its morphological heterogeneity can lead to low inter-reader agreement. Automated, reliable detection algorithms can improve diagnostic accuracy with consistent quantitative analysis.

RESULTS

Computer-aided diagnosis of follow-up studies without priori, yielded an AUROC of 0.77 (95% CI: 0.71, 0.83), F0.5 score of 0.51 (95% CI: 0.42, 0.61), positive predictive value (PPV) of 0.51 (95% CI: 0.40, 0.60) and negative predictive value (NPV) of 0.78 (95% CI: 0.71, 0.83). Computer-aided diagnosis of follow-up studies with the inclusion of priori via Bayesian inference yielded an AUROC of 0.80 (95% CI: 0.76, 0.84), F0.5 score of 0.58 (95% CI: 0.48, 0.68), PPV of 0.60 (95% CI: 0.48, 0.72) and NPV of 0.78 (95% CI: 0.72, 0.85). In comparison to stand-alone diagnosis, factoring in prior studies resulted in a 41.4% reduction of AUROC standard deviation across each fold.

CLINICAL RELEVANCE/APPLICATION

Prostate cancer is one of the most prevalent cancers in men worldwide. In the absence of experienced radiologists, its morphological heterogeneity can lead to low inter-reader agreement. Automated, reliable detection algorithms can improve diagnostic accuracy with consistent quantitative analysis.

CA03-D2 **T1 And T2 Map-based MRI Radiomics Analysis Improves The Diagnostic Accuracy Of Chronic Myocardial Inflammation Detection In Heart Failure With Reduced Ejection Fraction Patients**

Participants
Tilman Emrich, MD, Charleston, South Carolina (*Presenter*) Speaker, Siemens AG;Travel support, Siemens AG

PURPOSE

The purpose of this study was to evaluate the diagnostic accuracy of myocardial T1 and T2 mapping based radiomics analysis for the detection of chronic myocardial inflammation against endomyocardial biopsy-(EMB) as reference in patients with Heart Failure with reduced Ejection Fraction (HFrEF).*Methods and Materials The study population consisted of 58 retrospectively identified HFrEF patients who had previously undergone EMB and myocardial T1 and T2 mapping MRI at 3T. EMB served as the reference standard for the presence of myocardial inflammation. Radiomics analysis on T1 and T2 maps was performed using Slicer (Version-Nr 4.10.2 r28257). Out of 779 features identified, features with the highest accuracy were selected by recursive feature elimination, and a classification model was created using a linear support vector machine with 10-fold cross validation. The model-based analysis was subsequently compared to conventional T1 and T2 relaxation times in regard to diagnostic accuracy.*Results Out of the 58 patients with HFrEF, 32 patients (55.2%) had chronic myocardial inflammation detected by EMB. Left ventricular EF in the EMB+ and EMB- groups was 31±12% and 31±13%, respectively (p=0.97). The average T1 and T2 values between EMB+ and EMB- patients were not statistically different (T1: 1289 ± 76 and 1299 ± 63 ms, respectively, p=0.76; T2: 40.0 ± 6.4 ms and 40.1 ± 3.5 ms, respectively, p=0.49), resulting in poor diagnostic power (T1: AUC 0.6 Sensitivity 56% Specificity 69%; T2: AUC 0.53, Sensitivity 94%, Specificity 15%). The T2 map-based radiomics analysis model significantly improved diagnostic accuracy for the discrimination of EMB+ and EMB- HFrEF patients (AUC: 0.87, Sensitivity 78%, Specificity 99%) and outperformed the T1 map-based radiomics analysis model (AUC: 0.83, Sensitivity 68%, Specificity 99%) .*Conclusions Adding radiomics analysis of T1 and T2 maps to conventional T1 and T2 map assessment improves diagnostic accuracy of the detection of chronic myocardial inflammation in HFrEF patients.*Clinical Relevance/Application Non-invasive detection of chronic myocardial inflammation by radiomics analysis may reduce the need for invasive procedures and serve as a marker for treatment monitoring under immunosuppression.

RESULTS

Out of the 58 patients with HFrEF, 32 patients (55.2%) had chronic myocardial inflammation detected by EMB. Left ventricular EF in the EMB+ and EMB- groups was 31±12% and 31±13%, respectively (p=0.97). The average T1 and T2 values between EMB+ and EMB- patients were not statistically different (T1: 1289 ± 76 and 1299 ± 63 ms, respectively, p=0.76; T2: 40.0 ± 6.4 ms and 40.1 ± 3.5 ms, respectively, p=0.49), resulting in poor diagnostic power (T1: AUC 0.6 Sensitivity 56% Specificity 69%; T2: AUC 0.53, Sensitivity 94%, Specificity 15%). The T2 map-based radiomics analysis model significantly improved diagnostic accuracy for the discrimination of EMB+ and EMB- HFrEF patients (AUC: 0.87, Sensitivity 78%, Specificity 99%) and outperformed the T1 map-based radiomics analysis model (AUC: 0.83, Sensitivity 68%, Specificity 99%) .

CLINICAL RELEVANCE/APPLICATION

Non-invasive detection of chronic myocardial inflammation by radiomics analysis may reduce the need for invasive procedures and serve as a marker for treatment monitoring under immunosuppression.

MS04-B1   **"Making The Unknown Known": Choosing The Appropriate Radiological Investigation In Cancer Of Unknown Primary.**

Participants
Alice Spencer, MBBS, London, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

True cancer of unknown primary (CUP) are metastatic malignancies with positive histological diagnoses, but no identifiable primary tumour site. CUP diagnoses account for up 3-5% of malignant epithelial diagnoses, but accounts for the third to fourth highest cause of cancer-related deaths worldwide. A unique radiological challenge, patients who come through a CUP pathway have had varying imaging at diagnosis. Our single centre analysis over 5 years considers which imaging modality adds the most value to establishing a primary site.*Methods and Materials Data for 5 years (2016-2021) of multidisciplinary team (MDT) meetings for Cancer of Unknown Primary were obtained for our institution, a tertiary cancer centre providing for a population of 1.5 million. These patients were analysed to define a cohort of 72 "true" CUP patients, whose primary malignancy site was not established after initial investigations. From this we analysed investigations in the 3 months surrounding their discussion in MDT meetings to establish which investigation of CT, nuclear medicine, and MRI added the most value.*Results 58 patients received a CT scan of chest, abdomen and pelvis as a first imaging modality (as recommended by the NICE and suggested by NIH) around the time of MDT. Of these patients, a later PET scan added diagnostic value in 10 patients (17.2%). MRI imaging as a secondary modality confirmed sites of disease in 2 patients. A nuclear medicine bone scan, when performed before PET-CT, added value in 0 patients.*Conclusions Our data suggests that MRI adds little diagnostic value in imaging patients with cancer of unknown primary. As PET-CT becomes more widely accessible, it is a recommendable first modality of good diagnostic value. For those patients who had CT imaging first, PET adds value. A bone scan was performed in a small proportion of patients, and added no value.*Clinical Relevance/Application Cancer of unknown primary (CUP) patients have no identifiable primary tumor site. Choosing the correct imaging will help improve use of resources and reduce patient radiation doses.

RESULTS

58 patients received a CT scan of chest, abdomen and pelvis as a first imaging modality (as recommended by the NICE and suggested by NIH) around the time of MDT. Of these patients, a later PET scan added diagnostic value in 10 patients (17.2%). MRI imaging as a secondary modality confirmed sites of disease in 2 patients. A nuclear medicine bone scan, when performed before PET-CT, added value in 0 patients.

CLINICAL RELEVANCE/APPLICATION

Cancer of unknown primary (CUP) patients have no identifiable primary tumor site. Choosing the correct imaging will help improve use of resources and reduce patient radiation doses.

GI02-A10   **High Visceral Fat Area Is Associated With Posttransplant Early Allograft Dysfunction In Liver Transplantation Recipients: A Propensity Score Analysis**

Participants
Guanjie Yuan, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to evaluate the association between adipose tissue distribution and the occurrence of early allograft dysfunction (EAD) in liver transplantation recipients.*Methods and Materials A total of 175 patients who received liver transplantation (LT) from January 2015 to September 2020 were enrolled in this retrospective study. The areas of abdominal adipose tissue and skeletal muscle of all patients were measured based on the preoperative CT images. The appropriate statistical methods including the propensity score-matched (PSM) analysis were performed to identify the association between adipose tissue distribution and the occurrence of EAD.*Results Of 175 liver transplantation recipients, 55 patients (31.4%, 55/175) finally developed EAD. The multivariate logistic analysis revealed that preoperative serum albumin (OR: 0.34, 95% CI: 0.17 to 0.70, p=0.004), platelet-lymphocyte ratio (OR: 2.35, 95% CI: 1.16 to 4.79, p=0.018), and visceral fat area (OR: 3.17, 95% CI: 1.56 to 6.44, p=0.001) were independent risk factors of the occurrence of EAD. After PSM analysis, visceral fat area was still significantly associated with EAD (OR: 3.95, 95% CI: 1.65-9.46, p=0.002). The visceral fat area demonstrated good prediction of EAD according to the receiver operating characteristic (ROC) curves. The area under ROC curves were 0.67 (95% CI: 0.58-0.76) and 0.71(95% CI: 0.60-0.81) before and after PSM analysis, respectively. The ability of visceral fat area to predict long-term prognosis including one-year graft failure and overall survival(OS) was also studied. No significant difference was identified in one-year graft failure (hazard ratio 2.11, p=0.22), and conversely result was identified in OS (hazard ratio 4.10, p=0.01).But the multivariate Cox regression analysis showed that the value of visceral fat area in predicting OS was limited (hazard ratio 3.48, p=0.19). *Conclusions High visceral fat area was an independent risk factor for the occurrence of EAD, and it might also have certain clinical value for predicting the long-term prognosis of patients undergoing LT.*Clinical Relevance/Application The results of this study suggest that clinicians should take timely steps to lose weight (especially the steps to reduce waistlines) in recipients with high visceral fat area before liver transplantation to improve short - and long-term outcomes.

RESULTS

Of 175 liver transplantation recipients, 55 patients (31.4%, 55/175) finally developed EAD. The multivariate logistic analysis revealed that preoperative serum albumin (OR: 0.34, 95% CI: 0.17 to 0.70, p=0.004), platelet-lymphocyte ratio (OR: 2.35, 95% CI: 1.16 to 4.79, p=0.018), and visceral fat area (OR: 3.17, 95% CI: 1.56 to 6.44, p=0.001) were independent risk factors of the occurrence of EAD. After PSM analysis, visceral fat area was still significantly associated with EAD (OR: 3.95, 95% CI: 1.65-9.46, p=0.002). The visceral fat area demonstrated good prediction of EAD according to the receiver operating characteristic (ROC) curves. The area under ROC curves were 0.67 (95% CI: 0.58-0.76) and 0.71(95% CI: 0.60-0.81) before and after PSM analysis, respectively. The ability of visceral fat area to predict long-term prognosis including one-year graft failure and overall survival(OS) was also studied. No significant difference was identified in one-year graft failure (hazard ratio 2.11, p=0.22), and conversely result was identified in OS (hazard ratio 4.10, p=0.01).But the multivariate Cox regression analysis showed that the value of visceral fat area in predicting OS was limited (hazard ratio 3.48, p=0.19).

CLINICAL RELEVANCE/APPLICATION

The results of this study suggest that clinicians should take timely steps to lose weight (especially the steps to reduce waistlines) in recipients with high visceral fat area before liver transplantation to improve short - and long-term outcomes.

GI02-A12   **Fontan-associated Liver Disease (FALD) In Adult Patients: What Radiologists Need To Know**

Participants
Yasaman Moazeni, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

TEACHING POINTS

1. Fontan-Associated Liver Disease (FALD) and other late post-Fontan complications in adult patients are more commonly encountered in daily practice as an increasing number of these patients survive into adulthood. 2. FALD encompasses a spectrum of diffuse and focal liver pathologies with overlapping imaging findings. Advanced fibrosis and hepatocellular carcinoma (HCC) are the direst complications in this spectrum. Accurate non-invasive diagnosis of these conditions can be challenging.

TABLE OF CONTENTS/OUTLINE

Introduction • Indications and surgical aspects of Fontan procedure • Effects of Fontan procedure on the hemodynamics of liver perfusion FALD: Pathophysiology and imaging manifestations • Diffuse Diseases: Fibrosis, Sinusoidal Dilatation • Focal Diseases: Regenerative Hyperplasia, FNH-like Lesions, HCC Pitfalls and Challenges in Imaging-based Diagnosis of FALDs • Low specificity of conventional morphological criteria and elastography for detection of advanced fibrosis, given the presence of congestive hepatopathy. • Low specificity of OPTN and ACR LIRADS criteria for detection of HCC Future Directions • MR-Elastography as a

marker of Fontan pressure • Novel quantitative techniques Volumetric analysis

GI02-A13   MR Imaging Of Perianal Fistulas

Awards
Cum Laude

Participants
David Ballard, MD, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is to:1. Illustrate normal perianal anatomy on MR, provide a search pattern and discuss patterns of perianal fistulas2. Discuss perianal fistulas in Crohn disease and the role of MR in monitoring response to therapy3. Provide a case-based review of the appearance of common and complex fistula patterns with a focus on using different MR sequences to the radiologist's advantage

TABLE OF CONTENTS/OUTLINE

1. Anatomy: Internal and external sphincters, anorectal junction, surrounding soft tissue structures and their appearance on MR2. MR techniquei. Building blocks of perianal MR protocolii. Axial and coronal imaging planes relative to the anal canaliii. Role of different sequences with illustrative examplesiv. Practical pairing a perianal MR protocol with MR enterography3. MR implications for patient managementi. ACR Appropriateness Criteria on Anorectal Disease4. Patterns of perianal fistulasi. Parks and St. James classification systemsii. Inter-, trans-, supra- and extra-sphincteric perianal fistulasiii. Complex perianal fistulasiv. Abscess formation and locationv. Scarring and closure/improvement of fistula tracts5. Perianal fistula in Crohn diseasei. Prevalence and treatment optionsii. MR imaging as a response to medical therapyiii. MR scoring systemsA. Van Assche index (VAI) and modified VAIB. MAGNIFI-CD6. Pitfalls and special considerationsi. Identifying setons on MRii. Suboptimal imaging planesiii. Cancer formation in chronic fistula tractsiv. 3D printed models in treatment planning

GI02-A6   Application Of Intravoxel Incoherent Motion In Preoperative Evaluation Of The Lymphovascular Invasion Of Esophageal Squamous Cell Carcinoma

Participants
Tao Song, MMed, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the value of intravoxel incoherent motion(IVIM) in preoperative evaluating and predicting lymphovascular invasion (LVI) in esophageal squamous cell carcinoma (ESCC).*Methods and Materials Sixty-three patients who planned to undergo resection of esophageal cancer from April 2016 to April 2019 were prospectively collected. All patients underwent IVIM sequence and routine MR examination before operation. The apparent diffusion coefficient (ADC), true diffusion coefficient (D), pseudodiffusion coefficient (D*) and pseudodiffusion fraction (f) were measured. The differences of parameter values between ESCC with and without LVI were analyzed using Student's t test and Wilcoxon rank sum tests. Receiver operating characteristic (ROC) curves were performed to compare the diagnosis performance for identifying LVI.*Results 63 patients were divided into LVI group (30 cases) and no LVI group (33 cases). The difference of ADC, D and f values between two groups showed statistically significant (all P<0.001). The D* values showed no statistically significant differences between ESCC with and without LVI (P>0.05). The ROC analyses demonstrated that the areas under the curve (AUC) of ADC, D and f values in predicting LVI of ESCC were 0.787, 0.822 and 0.853, respectively. D combined with f had highest AUC (0.917) in predicting the LVI of ESCC, sensitivity and specificity were 93.3% and 75.8%.*Conclusions IVIM can provide effective functional information to preoperative evaluate and predict the LVI of ESCC. The combined application of D and f values could provide the highest accuracy in predicting ESCC with and without LVI.*Clinical Relevance/Application IVIM could be used as an effective functional imaging modality for preoperative evaluation and prediction of the LVI of ESCC.

RESULTS

63 patients were divided into LVI group (30 cases) and no LVI group (33 cases). The difference of ADC, D and f values between two groups showed statistically significant (all P<0.001). The D* values showed no statistically significant differences between ESCC with and without LVI (P>0.05). The ROC analyses demonstrated that the areas under the curve (AUC) of ADC, D and f values in predicting LVI of ESCC were 0.787, 0.822 and 0.853, respectively. D combined with f had highest AUC (0.917) in predicting the LVI of ESCC, sensitivity and specificity were 93.3% and 75.8%.

CLINICAL RELEVANCE/APPLICATION

IVIM could be used as an effective functional imaging modality for preoperative evaluation and prediction of the LVI of ESCC.

GI02-A8   Machine-learning Models Based On Magnetic Resonance Enterography (MRE) Improves The Assessment Of Mucosal Healing In Pediatric Crohn's Disease (CD)

Participants
Itai Guez, Karmiel, Israel (*Presenter*) Nothing to Disclose

PURPOSE

Mucosal healing (MH) is considered a major Crohn's Disease (CD) treatment goal. Simple Endoscopic Score of Crohn's Disease (SES-CD) assessed by ileocolonoscopy is a standard quantitative score for assessing MH. While the majority of patients have terminal ileum (TI) involvement, intubation failure is common. Our aim is to assess the added value of machine-learning (ML) models in imputing TI SES-CD from MRE data.*Methods and Materials This is a substudy of the ImageKids study in which 240 pediatric patients with CD (22 centers, age 14.2 ± 2.5 years) underwent a baseline ileocolonoscopy scored by SES-CD, followed by an MRE examination within 14 days. We used a non-linear ML random-forest (RF) model and a multiple linear regression model (LR) with two sets (in total 4 models) of biomarkers as input: Magnetic Resonance Index of Activity (MaRIA) biomarkers (wall thickness, ulcers, edema, relative contrast enhancement (RCE)) and the Pediatric Inflammatory Crohn's MRE Index (PICMI) biomarkers (wall thickness, diffusion weighted imaging, ulcers, edema, comb sign). We used stratified 2-fold validation, repeated 50 times, in order to train each algorithm version with a random set of patients used for derivation and validation. We assessed the added-value of ML models in imputing SES-CD values by comparing RF-MaRIA vs. LR-MaRIA, and for RF-PICMI vs. LR-PICMI. We determined which set of biomarkers (PICMI vs. MaRIA) provides more accurate predictions. The mean squared error (MSE) from the reference SES-CD was

used as accuracy measure . Statistical analysis was performed with the Wilcoxon non-parametric test on the validation cohort MSE.*Results The overall ileal intubation failure rate was 17%. A subsample of 107 patients had all relevant TI items scored by central radiologists and reference SES-CD. RF-based models significantly reduced MSE over MLR-based models for both the PICMI biomarkers (RF-PICMI 11.74 [10.46,12.54] vs. LR-PICMI 12.49 [11.64,13.79], p-value<1e-5) and the MaRIA biomarkers (RF-MaRIA 12.07 [11.05,13.23] LR-MaRIA 13.56 [12.54,14.57], p-value<1e-5) PICMI-based models had lower MSE compared to MaRIA-based models (LR-PICMI vs LR-MaRIA p-value<1e-5, RF-PICMI vs RF-MARIA p- value<1e-5).*Conclusions ML non-linear models are more accurate than linear regression models in predicting TI SES-CD when using the same MRE-based biomarkers. PICMI-based models are more accurate than MaRIA-based models in predicting TI SES-CD using same data from Imagekids.*Clinical Relevance/Application Ileal intubation failure during ileocolonoscopy occurs in 20% to 25% of pediatric CD patients, challenging the role of endoscopic assessment as the gold standard for clinical trials. Therefore, accurate SES-CD imputation by an imaging modality is necessary.

RESULTS

The overall ileal intubation failure rate was 17%. A subsample of 107 patients had all relevant TI items scored by central radiologists and reference SES-CD. RF-based models significantly reduced MSE over MLR-based models for both the PICMI biomarkers (RF-PICMI 11.74 [10.46,12.54] vs. LR-PICMI 12.49 [11.64,13.79], p-value<1e-5) and the MaRIA biomarkers (RF-MaRIA 12.07 [11.05,13.23] LR-MaRIA 13.56 [12.54,14.57], p-value<1e-5) PICMI-based models had lower MSE compared to MaRIA-based models (LR-PICMI vs LR-MaRIA p-value<1e-5, RF-PICMI vs RF-MARIA p- value<1e-5).

CLINICAL RELEVANCE/APPLICATION

Ileal intubation failure during ileocolonoscopy occurs in 20% to 25% of pediatric CD patients, challenging the role of endoscopic assessment as the gold standard for clinical trials. Therefore, accurate SES-CD imputation by an imaging modality is necessary.

GI02-A9   Natural History Of LIRADS 2 And 3 Observations: A Retrospective Cross Sectional Study.

Participants
Damithri Ranathunga, MD,FRCPC, Ottawa, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

LR-2 category includes probably benign observations and LR-3 category includes observations with intermediate probability of malignancy. Percentages of hepatocellular carcinoma (HCC) are 16% for LR-2 and 37% for LR3. However, these estimates are not considered to be accurate, primarily due to selection and confirmation bias. The purpose of this retrospective cross-sectional study was to determine the natural history of LR-2 and LR-3 observations.*Methods and Materials IRB-approved search of the institutional database was performed to select a consecutive sample of 100 patients meeting the following inclusion criteria: patients meeting LIRADS v2018 criteria for high risk of HCC with untreated LR-2 or 3 observations on CT or MRI; at least 12 months follow-up with CT or MRI; minimum technical parameters recommended by LIRADS v2018. Exclusion criteria: patients with known non-HCC malignancy with active disease within 5 years; minimally invasive local therapies and non-localized therapies prior to the index test or between the index and follow-up study.Four radiologists independently verified the LIRADS categories of index and follow-up observations (50 patients each) as per LI-RADS v2018 criteria with discrepancies resolved by consensus discussion with a third reviewer.*Results Ninety-eight patients with: 50 LR-2 and 189 LR-3 index observations (11 on CT, 228 on MR) were included. Two (4%, 95% CI: 0.484 - 14.4) LR-2 and 4 (2.12%,95% CI: 0.58-5.4) LR-3 observations progressed to LR-5 and none (0%, 95% CI: 0 - 7.38) of the LR-2 and 8 (4.23%, 95% CI: 1.83-8.36) LR-3 observations progressed to LR-4 on follow-up with no statistically significant difference. Eleven (22%, 95% CI: 11.0-39.4) LR-2 and 106 (56.1%, 95% CI: 45.9-67.8) LR-3 observations regressed to a lower LIRADS category on follow-up. The remaining observations stayed in the same category on follow-up.*Conclusions Observations categorized as LR-2 or LR-3 in high-risk patients have a lower likelihood of progressing to LR-4 or LR-5 categories than estimated in recent systematic reviews. This confirm the hypothesis that prior work is prone to selection and confirmation bias.*Clinical Relevance/Application This study suggests that LIRADS v2018 follow-up recommendations for LR-2 and LR-3 observations are reasonable, given the lower percentage of LR-2 and LR-3 observations that progressed to LR-4 and LR-5 than previously identified.

RESULTS

Ninety-eight patients with: 50 LR-2 and 189 LR-3 index observations (11 on CT, 228 on MR) were included. Two (4%, 95% CI: 0.484 - 14.4) LR-2 and 4 (2.12%,95% CI: 0.58-5.4) LR-3 observations progressed to LR-5 and none (0%, 95% CI: 0 - 7.38) of the LR-2 and 8 (4.23%, 95% CI: 1.83-8.36) LR-3 observations progressed to LR-4 on follow-up with no statistically significant difference. Eleven (22%, 95% CI: 11.0-39.4) LR-2 and 106 (56.1%, 95% CI: 45.9-67.8) LR-3 observations regressed to a lower LIRADS category on follow-up. The remaining observations stayed in the same category on follow-up.

CLINICAL RELEVANCE/APPLICATION

This study suggests that LIRADS v2018 follow-up recommendations for LR-2 and LR-3 observations are reasonable, given the lower percentage of LR-2 and LR-3 observations that progressed to LR-4 and LR-5 than previously identified.

IR04-D1   **Long-term Survival And Local Recurrence With A Minimum Of 5 Years Of Follow Up After Thermal Ablation For Renal Cell Carcinoma**

Participants
Wenhui Zhou, MD, PhD, Menlo Park, California (*Presenter*) Nothing to Disclose

PURPOSE

To assess the long-term oncological outcomes of image-guided percutaneous thermal ablation for cT1N0M0 renal cell carcinoma (RCC).*Methods and Materials This retrospective study includes 152 consecutive patients (M: F = 99:53, mean age = 72 yrs) who had a minimum imaging follow-up time of 5 years after computed tomography-guided thermal ablation. Assessment of the rates of complications, residual disease and local recurrence was performed. Local recurrence-free, metastatic-free and overall survival rates were calculated using the Kaplan-Meier method.*Results 158 biopsy-proven T1 RCC measuring 0.4 to 6.1 cm (mean = 2.8 cm) were successfully treated without major complications. During the median follow-up time of 7.4 yrs, (SD = 1.7 yrs), residual disease was observed in 10/158 (6%) of cases, all of which were successfully re-treated with thermal ablation. Local recurrence occurred in 14/158 (9%) of cases. At the 10-year follow-up, the calculated RCC-specific survival rate was 94% (95% CI: 87%-98%), local recurrence free survival was 84% (95% CI: 82%-95%), and metastatic free survival was 90% (95% CI: 80%-93%).*Conclusions Over a minimum follow-up period of at least 5 years, thermal ablation achieved durable tumor control, low rate of local recurrence and favorable survival outcomes, thereby representing a reliable treatment strategy for cT1 RCC.*Clinical Relevance/Application Thermal ablation offers an effective and durable non-surgical treatment for patients with T1 renal cell carcinoma. Future studies are needed to determine the optimal imaging interval to monitor for disease recurrence.

RESULTS

158 biopsy-proven T1 RCC measuring 0.4 to 6.1 cm (mean = 2.8 cm) were successfully treated without major complications. During the median follow-up time of 7.4 yrs, (SD = 1.7 yrs), residual disease was observed in 10/158 (6%) of cases, all of which were successfully re-treated with thermal ablation. Local recurrence occurred in 14/158 (9%) of cases. At the 10-year follow-up, the calculated RCC-specific survival rate was 94% (95% CI: 87%-98%), local recurrence free survival was 84% (95% CI: 82%-95%), and metastatic free survival was 90% (95% CI: 80%-93%).

CLINICAL RELEVANCE/APPLICATION

Thermal ablation offers an effective and durable non-surgical treatment for patients with T1 renal cell carcinoma. Future studies are needed to determine the optimal imaging interval to monitor for disease recurrence.

IR04-D3   **Liver Abscess Formation After Drug Eluting Chemoembolization (dtace) In Patients With Metastatic Hepatic Tumors: A Single Center Retrospective Study Of 137 Cases**

Participants
Xiangwen Xia, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

Liver abscess formation is a severe complication after intraarterial chemoembolization in patients with hepatic tumors; however, the incidence rate and risk factors of liver abscess formation after drug-eluting bead chemoembolization (DEB-TACE) in patients with metastatic hepatic tumors are far less investigated.*Methods and Materials In this study, we retrospectively analyzed the clinical data of 137 patients with metastatic hepatic tumors who received DEB-TACE in our institute from June 2015 to September 2020. Patients were evaluated for the presence or absence of liver abscess occurring at least 1 month after DEB-TACE procedure. Univariable and multivariable analyses were used to investigate risk factors of liver abscess formation.*Results The incidence of liver abscess formation after DEB-TACE procedure was 8.76% per patient and 5.53% per procedure. Univariable and multivariable analyses showed that grade 2 embolization and systemic chemotherapy within 3 months before DEB-TACE procedure were independent risk factors.*Conclusions The incidence rate of liver abscess formation after DEB-TACE procedure in patients with metastatic hepatic tumors appears to be higher than those with primary hepatic tumors reported in literatures. Grade 2 embolization and systemic chemotherapy within 3 months before procedure were independent risk factors.*Clinical Relevance/Application These findings indicate that interventional radiologists should be more cautious when designing DEB-TACE strategies in patients with metastatic hepatic tumors who have these risk factors.

RESULTS

The incidence of liver abscess formation after DEB-TACE procedure was 8.76% per patient and 5.53% per procedure. Univariable and multivariable analyses showed that grade 2 embolization and systemic chemotherapy within 3 months before DEB-TACE procedure were independent risk factors.

CLINICAL RELEVANCE/APPLICATION

These findings indicate that interventional radiologists should be more cautious when designing DEB-TACE strategies in patients

with metastatic hepatic tumors who have these risk factors.

CH05-B2   **Deep Screening: A Deep Learning Based Screening Model To Predict Pulmonary Function Through Chest CT**

Participants
Hyunjung Park, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To propose a screening model with deep learning to predict pulmonary function through chest CT presenting anatomical lung and chest organs among health check-up examinees.*Methods and Materials 16164 participants who undertook low dose CT (LDCT) images and pulmonary function test (PFT) on the same day as health check-up in XXX from 2014-2018, their CT images and PFT data were collected. Dataset was split into two groups, internal (N = 13444) and external datasets (N=2720) based on the year of the first visit: date of first visits in 2014-2017 as internal data set and in 2018 as external data set. The internal set again was split randomly into 3 groups of training, tuning, validation sets. CT images, which originally have 2.51 ± 0.09 mm slice thickness and $0.69 \pm. 0.05$ mm pixel spacing, were resampled into 2.5mm isotropic voxel. Each volume was cropped or padded to make 180 * 140 * 178 sizes. A GoogLeNet based I3D (inflated-3D) network was trained to predict PFT parameters such as forced expiratory volume in one second (FEV1) and forced vital capacity (FVC) with LDCT scans in a regression manner, using mean squared error as loss function. Performance was evaluated by the coefficient of determination(R^2) of a regression model, root mean squared error (RMSE), and mean absolute error (MAE). Bland-Altman plots were also used to evaluate the agreement and characteristics of difference between actual and predicted PFT values.*Results For predicting FVC, R2, MAE, RMSE were 0.8602, and 0.2458, 0.3159, respectively and for FEV1, R2, MAE, and RMSE were 0.7972, 0.2367, and 0.3025, respectively in the external validation data set. In the same validation, limit of agreements of Bland-Altman plot for both sexes were -0.57 and 0.66(bias=0.05); -0.61 and 0.69 in male, and -0.48 and 0.59 in female for FVC prediction. For FEV1 prediction, -0.57 and 0.61 for both sexes; -0.62 and 0.66 in male, -0.48 and 0.52 in female. Grad-CAM from each of the models for predicting FVC and FEV1 shows more attention on the right lung but spotted slightly different sites based on different PFT parameters.*Conclusions Bland-Altman plot showed that the predicted values converge to the mean value of the target label. The PFT values could be predicted with relatively nice performances with this deep learning model on volumetric chest CT, which could be used as a screening tool for classifying patients with low pulmonary function.*Clinical Relevance/Application Estimating high-risk factors of respiratory diseases on CT images with this model may be useful to screen patients in early stage of respiratory diseases.

RESULTS

For predicting FVC, R2, MAE, RMSE were 0.8602, and 0.2458, 0.3159, respectively and for FEV1, R2, MAE, and RMSE were 0.7972, 0.2367, and 0.3025, respectively in the external validation data set. In the same validation, limit of agreements of Bland-Altman plot for both sexes were -0.57 and 0.66(bias=0.05); -0.61 and 0.69 in male, and -0.48 and 0.59 in female for FVC prediction. For FEV1 prediction, -0.57 and 0.61 for both sexes; -0.62 and 0.66 in male, -0.48 and 0.52 in female. Grad-CAM from each of the models for predicting FVC and FEV1 shows more attention on the right lung but spotted slightly different sites based on different PFT parameters.

CLINICAL RELEVANCE/APPLICATION

Estimating high-risk factors of respiratory diseases on CT images with this model may be useful to screen patients in early stage of respiratory diseases.

MK05-B2 **A New Photon Counting Detector CT For Assessment Of Osseointegration In Joint Replacement Implants. A Case Report Of Two Acetabular Cup Revisions**

Participants
Anders Persson, MD, PhD, Linkoping, Sweden (*Presenter*) Nothing to Disclose

PURPOSE

To assess superiority of a new photon counting detector CT to detect osseointegration through increased spatial resolution in comparison with a standard CT.*Methods and Materials We used two acetabular implants retrieved during revision surgery. Patient 1 had a primary uncemented cup revised due to prosthetic joint infection. Patient 2 had his cemented primary cup revised due to extensive osteolysis. Both cups showed areas with osseointegration during extraction and on visual inspection. We used a photon-counting detector CT (PCD-CT; SOMATOM Count Plus; Siemens Healthineers, Forchheim, Germany) and an energy integrating detector CT (EID-CT; SOMATOM Force; Siemens Healthineers, Forchheim, Germany) to assess osseointegration radiographically. Osseointegration was defined as trabeculae attached to the implant or cement surface and was assessed with an inner ear high resolution protocol. The PCD-CT was operated at 140 kVp, 179 mAs, slice thickness 0.2 mm (0.1 mm increment), Kernel Br89u, 1024 matrix. The EID-CT was operated at Sn150 kV, 112 mAs, 0.4/0.1 mm, kernel U77 with ADMIRE strength 3. A visual comparison between the images was done.*Results The PCD-CT allowed visualization of the implant-bone interface with higher resolution. In specific, particular trabeculae could be visualized more clearly.*Conclusions With the higher resolution in the PCD-CT the interface between bone and implant could be evaluated more properly. Further investigations to assess implant loosening pre-operatively are warranted.*Clinical Relevance/Application The increased spatial resolution of the PCD-CT system might help in the assessment of implant osseointegration and thereby aid in the decision making for or against revision surgery.

RESULTS

The PCD-CT allowed visualization of the implant-bone interface with higher resolution. In specific, particular trabeculae could be visualized more clearly.

CLINICAL RELEVANCE/APPLICATION

The increased spatial resolution of the PCD-CT system might help in the assessment of implant osseointegration and thereby aid in the decision making for or against revision surgery.

MS02-A1   Ordering Characteristics Associated With Positive Head CT In The Emergency Department Setting

Participants
Debayan Bhaumik, MD, Denver, Colorado (*Presenter*) Nothing to Disclose

PURPOSE

Determine patient and ordering factors which correlate with positive head CT findings.*Methods and Materials Retrospective analysis was conducted within a single institution for all patients who underwent a single non-contrast Head CT exam between January 2010 and January 2017. Each exam's impression was assessed and deemed to be positive if it contained acute findings which would alter medical management or demonstrated interval worsening of prior findings. Indications for each exam as well patient demographics and time and date of the study were also recorded. After exclusion of cases with missing data, 6,904 exams met inclusion criteria. Patient and ordering characteristics were analyzed via multivariate logistic regression to identify significant associations with odds of a positive CT scan.*Results Patient age significantly correlated to CT positivity, increasing on a yearly basis (p < 0.001). Study indications of "trauma" and "vertigo/dizziness" were associated with an odds ratio less than 1 (p <0.001 and p < 0.05 respectively). Study indications of "malignancy" and any "focal neurologic complaint" had odds ratios greater than 1 (p < 0.001 and p < 0.01 respectively). Other indications including "altered mental status", "headache", "seizure", "nausea", "syncope/arrest", and "vascular concerns/complaints" had no significant correlation with positivity. The three most common order indications were trauma, altered mental status, and headache. Studies ordered during the day (7am - 7pm) had a significantly higher rate of positivity (p < 0.05) compared with studies ordered during the evening (7 pm - 7 am).*Conclusions Noncontrast head CTs ordered in the emergency department for the indications of trauma and vertigo/dizziness had lower odds of positivity, suggesting head CT may be overutilized in these settings. Older patients and patients with a history/concern for malignancy or focal neurologic deficits had a higher odds of a positive CT scan, suggesting that the clinical threshold to image such patients should be low. Studies ordered at night had lower odds of positivity, suggesting comparative over ordering during these hours.*Clinical Relevance/Application This work suggests there are certain clinical scenarios in which noncontrast head CT exams are being over-utilized. Ordering clinicians must be made aware of these trends in order to reduce costs and yield higher value care. In addition, when radiologists see higher risk indications and increasing patient age in the order requisition, they should consider triaging those exams ahead of other lower acuity studies and evaluate those exams rigorously for positive findings.

RESULTS

Patient age significantly correlated to CT positivity, increasing on a yearly basis (p < 0.001). Study indications of "trauma" and "vertigo/dizziness" were associated with an odds ratio less than 1 (p <0.001 and p < 0.05 respectively). Study indications of "malignancy" and any "focal neurologic complaint" had odds ratios greater than 1 (p < 0.001 and p < 0.01 respectively). Other indications including "altered mental status", "headache", "seizure", "nausea", "syncope/arrest", and "vascular concerns/complaints" had no significant correlation with positivity. The three most common order indications were trauma, altered mental status, and headache. Studies ordered during the day (7am - 7pm) had a significantly higher rate of positivity (p < 0.05) compared with studies ordered during the evening (7 pm - 7 am).

CLINICAL RELEVANCE/APPLICATION

This work suggests there are certain clinical scenarios in which noncontrast head CT exams are being over-utilized. Ordering clinicians must be made aware of these trends in order to reduce costs and yield higher value care. In addition, when radiologists see higher risk indications and increasing patient age in the order requisition, they should consider triaging those exams ahead of other lower acuity studies and evaluate those exams rigorously for positive findings.

MS02-A2   AI-CADt Algorithm For Pulmonary Embolism (PE) Detection In Single- And Dual-energy CT Pulmonary Angiography: Performance Based On PE Location

Participants
Fatemeh Homayounieh, MD, Bethesda, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

To assess performance of AI-based triaging computer-aided detection algorithm (CADt, Aidoc) for detecting PE on single- (SECTPA) and dual (DECTPA)-energy CT pulmonary angiography and with variations in PE distribution.*Methods and Materials Our IRB-approved, HIPAA-compliant study included 356 patients who underwent CT (GE 750HD, Siemens Force/Flash) with SECTPA (n =112 patients; mean age 61±16 years; M:F 57:55) or DECTPA (n = 244 patients; 63±17 years; M:F 113:131) protocols for assessing PE. Data (previously unseen by the CADt) were enriched to include PE at different locations with matched controls. Subjects with suboptimal contrast enhancement or motion artifacts were excluded. Two radiologists independently evaluated each CTPA for presence and location (main, lobar, segmental and subsegmental) of PE to establish the ground truth. Separately, PE-CADt algorithm processed all CTPA exams after automatically selecting the image series. For each PE-positive CTPA exam, the algorithm produced a key image where the highest confidence PE finding was annotated. We estimated sensitivity, specificity, accuracy and area under the curve (AUC) with receiver operating characteristics along with 95% confidence interval.*Results Per the ground truth, 138 CTPA were positive for PE and 218 were PE negative. Overall, CADt was successful in ruling in or ruling out PE regardless

of scanners, scanning techniques and PE distribution (sensitivity 97%, specificity 89%, accuracy 92%, AUC 0.93, 95% CI 0.90-0.96). CADt had 100% sensitivity for detecting all 68 central PE up to lobar level and 93% sensitivity for 59 segmental PE. There was no significant difference in CADt accuracy in detecting PE on SECTPA (based on CT vendor 88-96%) and DECTPA (92-97%) (p>0.5). Most missed PEs were segmental and on CTPA with artifacts and/or suboptimal contrast-enhancement.*Conclusions The assessed CADt algorithm for PE retains high sensitivity, specificity and accuracy regardless of variations in acquisition technique (SECTPA vs DECTPA) and PE distribution (central vs peripheral down to subsegmental level).*Clinical Relevance/Application PE triaged algorithm based on machine learning can be applied with confidence regardless of scanners, scanning techniques and distribution of PE.

RESULTS

Per the ground truth, 138 CTPA were positive for PE and 218 were PE negative. Overall, CADt was successful in ruling in or ruling out PE regardless of scanners, scanning techniques and PE distribution (sensitivity 97%, specificity 89%, accuracy 92%, AUC 0.93, 95% CI 0.90-0.96). CADt had 100% sensitivity for detecting all 68 central PE up to lobar level and 93% sensitivity for 59 segmental PE. There was no significant difference in CADt accuracy in detecting PE on SECTPA (based on CT vendor 88-96%) and DECTPA (92-97%) (p>0.5). Most missed PEs were segmental and on CTPA with artifacts and/or suboptimal contrast-enhancement.

CLINICAL RELEVANCE/APPLICATION

PE triaged algorithm based on machine learning can be applied with confidence regardless of scanners, scanning techniques and distribution of PE.

MS02-A3   Infection Induced Tumors And Tumor-like Conditions Of The Abdomen And Pelvis: Multimodality Imaging Findings With Pathologic Correlation

Participants
Moataz Ahmed Sayed Mohammed Soliman, BMBCh, CHICAGO, Illinois (*Presenter*) Nothing to Disclose

TEACHING POINTS

- Different infectious causes that are can be associated with certain malignant conditions - Multimodality imaging findings of these tumors and tumor mimics with pathology correlation - Relevant differential considerations and management options - Potential pitfalls in imaging diagnosis

TABLE OF CONTENTS/OUTLINE

Introduction Mechanism of infection induced DNA mutation (oncogenic mutations) - Oncogenic effect - Chronic inflammation - Immune system suppression Infection induced tumors - Viral causes: EBV (Lymphoma, lymphoproliferative disease of transplant patients) HBV, HCV (Hepatocellular carcinoma) HPV 16, 18 (Anal, cervical, vaginal, vulval, and penile cancers)HTLV-1 (Lymphocytic leukemia and non-Hodgkin lymphoma) HIV:Kaposi sarcoma (HHV-8)Multicentric Castleman disease (HHV-8) - Bacterial causes: H. pylori infection (MALTOMA) - Parasitic causes - Opisthorchis viverrini and Clonorchis sinensis - Schistosomiasis (squamous cell carcinoma of the urinary bladder) - Tumor like conditions: - Infectious mononucleosis (IMN) - Adenovirus hepatic mass lesion (Inflammatory pseudotumor of the liver) - Liver abscess - TB Granuloma, abscess, milliary TB - Cholangitis - Chagas disease - Xanthogranulomatous inflammation - Disseminated fungal infection - Actinomycosis - Fitz-Hugh-Curtis syndrome Multimodality imaging findings of these pathologic entities and relevant differential considerations Potential pitfalls in imaging diagnosis Impact of imaging findings on management approach

MK02-A1   Feasibility Study On Quantitative Assessment Osteoporosis By Virtual Noncontrast Scan Of Dual Energy Ct

Participants
Xin Wang, Heifei, China (*Presenter*) Nothing to Disclose

PURPOSE

Taking the bone mineral density (BMD) measured by QCT as the gold standard, explore the feasibility of virtual non-contrast scan(VNC) of dual -energy CT(DECT) to quantitatively evaluate bone mineral density(BMD) and the degree of osteoporosis without a phantom.*Methods and Materials A retrospective collection of 100 patients who underwent abdominal true non-contrast scan(TNC) and spectrum mode three-phase enhanced scan were randomly divided into test group and validation group with 50 cases each.To measure the BMD of L1 vertebral body by QCT Pro software. In the test group, the difference between the CT values of the L1 vertebral body in the TNC and the VNC was compared, the correlation between the vertebral body CT value of VNC and the BMD was determined, and the regression equation for predicting BMD was established. The validation group was used to evaluate the accuracy of the equation in diagnosing osteoporosis.*Results The CT value of the L1 vertebral body of the VNC is lower than that of TNC (CTTNC=133.57±48.42, CTVNC=71.24±26.38, P<0.001); after subtracting the TNC, the total radiation dose of the image is reduced by 21.94%; The multiple linear regression model of CT value of VNC to predict vertebral body BMD is: BMD=102.375+1.349×CT value-0.321×age-0.433×height (R2=0.979); The cut-off value of VNC vertebral body CT value quantitatively diagnoses osteoporosis and osteopenia are 64.5 HU and 54.3 HU, respectively.*Conclusions Without the body phantom, the CT attenuation of the lumbar spine vertebral body on VNC of DECT predict bone mineral density reliably, and can be used as a useful supplement to quantitative CT to evaluate bone mineral density.*Clinical Relevance/Application For patients undergoing DECT abdominal enhancement examinations in hospitals, in the absence of QCT phantoms, DECT virtual non-contrast scan can not only provide diagnostic information of abdominal diseases, but also provide bone health information such as bone mineral density without a Phantoms.And accurately diagnose osteoprosis and osteopenia are beneficial supplements to QCT and have certain clinical application value.

RESULTS

The CT value of the L1 vertebral body of the VNC is lower than that of TNC (CTTNC=133.57±48.42, CTVNC=71.24±26.38, P<0.001); after subtracting the TNC, the total radiation dose of the image is reduced by 21.94%; The multiple linear regression model of CT value of VNC to predict vertebral body BMD is: BMD=102.375+1.349×CT value-0.321×age-0.433×height (R2=0.979); The cut-off value of VNC vertebral body CT value quantitatively diagnoses osteoporosis and osteopenia are 64.5 HU and 54.3 HU, respectively.

CLINICAL RELEVANCE/APPLICATION

For patients undergoing DECT abdominal enhancement examinations in hospitals, in the absence of QCT phantoms, DECT virtual non-contrast scan can not only provide diagnostic information of abdominal diseases, but also provide bone health information such as bone mineral density without a Phantoms.And accurately diagnose osteoprosis and osteopenia are beneficial supplements to QCT and have certain clinical application value.

NPM01-A1   **7-Tesla MRI Does Not Cause Increased Mercury Release From Dental Fillings**

Participants
Brian Burkett, MD, MPH, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

In recent years, 7-Tesla MRI has become an FDA-approved technology used in clinical practice. Elevated mercury (Hg) excretion from dental fillings following 7T MRI has been previously reported (Yilmaz, Radiology 288.3, 2018). Further investigation of the potential safety concern of toxic Hg release during 7T MRI is warranted. Additionally, Hg concentrations following 3T MRI of dental amalgam have not been investigated, which may impact a much larger number of patients. The purpose of this study is to further investigate the potential of Hg release from amalgam during 7T MRI, with technical improvements over previous research, as well as to evaluate Hg release during 3T MRI.*Methods and Materials Extracted human teeth with drilled caries were filled by a dentist using standard amalgam capsules containing 438 mg Hg. After 9-days storage in normal saline, 80 restored teeth were placed in 15 mL of artificial saliva solution for the following conditions: unscanned controls (n=20), MRI at 1.5T (n=20), 3.0T (n=20), and 7.0T (n=20). After 24-hours, Hg concentration was analyzed with inductively coupled plasma mass spectroscopy. Teeth were next tested under varied 9-day storage conditions in addition to the previous teeth using normal saline storage, including a dry sealed box (n=20) and immersion in artificial saliva (n=20) to ensure saline storage did not artificially decrease the Hg concentration. All teeth were transferred to new artificial saliva for scanning and/or Hg testing.*Results No significant difference in Hg concentration was observed between unscanned teeth and MRI at 1.5T, 3T, 7T (F=2.42, p=0.072), using one-way ANOVA with Holm post hoc test. Mean Hg concentrations were 13.72 ug/L for unscanned controls, 10.88 ug/L at 1.5T, 12.65 ug/L at 3T, and 8.88 ug/L at 7T. For teeth stored in artificial saliva or in a dry box, no significant difference in Hg concentration was observed with 7T MRI exposure (F=2.28, p=0.14) or by storage solution (F=1.55, p=0.22). With dry box storage, mean Hg concentrations were 12.49 ug/L after 7T MRI and 3.77 ug/L for unscanned controls. In artificial saliva storage, mean Hg concentrations were 4.72 ug/L after 7T MRI and 2.65 ug/L in controls.*Conclusions Hg release was not significantly increased after exposure to MRI at 1.5T, 3T, or 7T field strength. No significant increase in Hg concentration was associated with 7T MRI in any storage condition tested. The Hg concentration observed after 7T in various storage conditions, ranging from 4.72 to 12.49 ug/L, was markedly lower (between 53.9 and 142.6-fold) than previously reported (673 ug/L).*Clinical Relevance/Application Mercury excretion from dental fillings is not increased after exposure to 3T or 7T MRI. Dental amalgam should not create a barrier to obtaining clinical MRI examinations.

RESULTS

No significant difference in Hg concentration was observed between unscanned teeth and MRI at 1.5T, 3T, 7T (F=2.42, p=0.072), using one-way ANOVA with Holm post hoc test. Mean Hg concentrations were 13.72 ug/L for unscanned controls, 10.88 ug/L at 1.5T, 12.65 ug/L at 3T, and 8.88 ug/L at 7T. For teeth stored in artificial saliva or in a dry box, no significant difference in Hg concentration was observed with 7T MRI exposure (F=2.28, p=0.14) or by storage solution (F=1.55, p=0.22). With dry box storage, mean Hg concentrations were 12.49 ug/L after 7T MRI and 3.77 ug/L for unscanned controls. In artificial saliva storage, mean Hg concentrations were 4.72 ug/L after 7T MRI and 2.65 ug/L in controls.

CLINICAL RELEVANCE/APPLICATION

Mercury excretion from dental fillings is not increased after exposure to 3T or 7T MRI. Dental amalgam should not create a barrier to obtaining clinical MRI examinations.

NPM01-A2   **Faculty Development Effects Of A "resident Managed Peer-mentoring Program": Laddered Mentoring In Research Engages Academic Community From Students To Professors.**

Participants
Dhairya Lakhani, MD, Morgantown, West Virginia (*Presenter*) Nothing to Disclose

PURPOSE

Using a resident managed peer mentoring program that has increased resident participation in research, we reviewed the extent of change in faculty research productivity by academic rank in the two years before and the two years after implementing the intervention. Intervention consisted of identifying and extending to a resident interested in research and leadership substantial supervised autonomy to champion research and engage medical students and other residents in research projects. Briefly, novice researchers were given tasks and instruction for completing the tasks and in overall methods for bringing a research project to publication.*Methods and Materials This was an observational study designed to assess the faculty by rank outcomes of "Resident Managed Peer Mentoring Program". The program was implemented in November 2019. Primary outcomes were defined as peer-reviewed PubMed indexed publications and secondary outcomes were defined as number of abstracts and radiology physicians who published. The attendings where then classified based on their ranking for comparative analysis.*Results We report increased number of peer-reviewed PMID publications, reported by both residents and faculty members, following implementation of this program (50%, in year 1; 91.3% in year 2, as compared to pre-intervention years). Similar trends were obtained for number of abstracts presented, and number of physicians who authored PMID publications as compared to pre-intervention years. Faculty increases in participation and publications were more marked in the assistant professor and full professor ranks, and notably less in

the Associate Professor rank.*Conclusions The "Resident managed peer-mentoring program" was productive and engaging for students, residents, and for faculty physicians (particularly full professor and assistant professor ranks) in our training program. This intervention may help foster stronger departmental research culture.*Clinical Relevance/Application The "Resident managed peer-mentoring program" proved a successful method for residents, students, and faculty members. Its application may foster stronger departmental research culture in training programs.

RESULTS

We report increased number of peer-reviewed PMID publications, reported by both residents and faculty members, following implementation of this program (50%, in year 1; 91.3% in year 2, as compared to pre-intervention years). Similar trends were obtained for number of abstracts presented, and number of physicians who authored PMID publications as compared to pre-intervention years. Faculty increases in participation and publications were more marked in the assistant professor and full professor ranks, and notably less in the Associate Professor rank.

CLINICAL RELEVANCE/APPLICATION

The "Resident managed peer-mentoring program" proved a successful method for residents, students, and faculty members. Its application may foster stronger departmental research culture in training programs.

NPM01-A4   Embracing Diversity In Radiology: Understanding Cultural Competence And Cultural Humility

Participants
Shama Jaswal, MBBS, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

TEACHING POINTS

After reviewing this exhibit, the viewer will: 1) Understand the difference between cultural competence and cultural humility 2) Identify the importance of cultural competence and humility in radiology 3) Identify strategies for fostering cultural competence and practicing cultural humility.

TABLE OF CONTENTS/OUTLINE

1. Definitions: a. Culture: A body of knowledge, beliefs, and behaviors that are specific to ethnic, racial, religious, geographic, and social groups. b. Cultural Competence: The understanding, appreciation, and respect of different cultures; a process that requires ongoing training for providing quality care to diverse patients. c. Cultural Humility: A lifelong, learning-oriented process of self-exploration and assessment to address diverse cultures and recognition of power dynamics. 2. Key challenges faced within radiology in delivering care to diverse patient populations a. Power imbalance b. Stigmatizing patients c. Implicit and explicit biases 3. Role of cultural competence and humility in radiology a. Cultural competence improves the effectiveness of interactions with others; cultural humility enhances provider's capability to deliver patient-centered and culturally appropriate care while addressing systemic biases 4. Practical strategies for fostering cultural competence and practicing cultural humility a. Cultural competence and humility training tools b. Ongoing self-awareness and learning c. Partner with patients and communities: seek to understand cultural realities of diverse patients

GU04-A2   Prostate Biopsy In The Era Of MRI-targeting: Do All Men Require Additional Systematic Biopsy?

Participants
Dominik Deniffel, MD, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The combination of MRI-targeted (TB) and systematic biopsy (SB) results in higher clinically significant prostate cancer (csPCa)-detection rates and is, therefore, routinely performed in many institutions. We aimed to identify patient groups which may forego concurrent SB in favor of MRI-TB alone to reduce the risk associated with additional biopsy cores.*Methods and Materials Retrospective study in 742 patients who underwent multiparametric MRI and combined biopsy (CB). Primary outcome was an upgrade to csPCa, defined as grade group (GG) =2 or =3, on CB versus MRI-TB alone. Logistic regression was used to estimate the association of variables (PI-RADS score, lesion size, location, number of lesions, number of targeted cores, Software-based versus cognitive Fusion, PSA density, prostate volume, history of previous biopsy, age) with outcomes. The clinical utility of biopsy optimization strategies was assessed by decision curve analysis. Among men who underwent radical prostatectomy (RP) within 1 year, upgrading of GG versus biopsy was recorded.*Results Compared to MRI-TB alone, CB resulted in the detection of additional GG =2 cancers in 6% (47/742) and GG =3 in 3% (21/742) of men. Adjusted odds ratios for upgrade to GG =2 were 0.31 (95% CI, 0.09- 0.91; p=0.033) and 0.34 (95% CI, 0.12-0.81; p=0.013) for PI-RADS 5 versus PI-RADS 3 and PI-RADS 4, respectively, 0.42 (95% CI, 0.20-0.82; p=0.01) for history of previous negative biopsy and 1.67 (95% CI, 1.11-2.52; p=0.013) for age (per 10-year increase). Decision curve analysis identified the omission of additional SB in all men with PI-RADS 5 and those with PI-RADS 5 aged <66 years as most clinically useful strategies, resulting in 27% (199/742) and 10% (77/742) fewer SB, whilst missing upgrades to GG =2/GG =3 in 3%/4% and 1%/3% of avoided SB, respectively. In 123 men undergoing RP, using CB versus MRI-TB alone resulted in fewer GG-upgrades on RP: -10% (12/123) for the entire cohort, -5% (2/42) for men with PI-RADS 5, -9% (7/74) for PI-RADS 4, -6% (2/35) for men with a history of previous negative biopsy, and -10% (8/82) for previous positive biopsy.*Conclusions Not all men benefit equally from the combination of SB and MRI-TB. The yield of additional csPCas on CB versus MRI-TB alone was lower in men with PI-RADS 5, previous negative biopsy and younger age, supporting the omission of additional SB in these patient groups.*Clinical Relevance/Application PI-RADS scores, biopsy history and age may help select men who can forego systematic biopsy in favor of MRI-targeted biopsy alone, thus minimizing the risks of excess biopsies.

RESULTS

Compared to MRI-TB alone, CB resulted in the detection of additional GG =2 cancers in 6% (47/742) and GG =3 in 3% (21/742) of men. Adjusted odds ratios for upgrade to GG =2 were 0.31 (95% CI, 0.09- 0.91; p=0.033) and 0.34 (95% CI, 0.12-0.81; p=0.013) for PI-RADS 5 versus PI-RADS 3 and PI-RADS 4, respectively, 0.42 (95% CI, 0.20-0.82; p=0.01) for history of previous negative biopsy and 1.67 (95% CI, 1.11-2.52; p=0.013) for age (per 10-year increase). Decision curve analysis identified the omission of additional SB in all men with PI-RADS 5 and those with PI-RADS 5 aged <66 years as most clinically useful strategies, resulting in 27% (199/742) and 10% (77/742) fewer SB, whilst missing upgrades to GG =2/GG =3 in 3%/4% and 1%/3% of avoided SB, respectively. In 123 men undergoing RP, using CB versus MRI-TB alone resulted in fewer GG-upgrades on RP: -10% (12/123) for the entire cohort, -5% (2/42) for men with PI-RADS 5, -9% (7/74) for PI-RADS 4, -6% (2/35) for men with a history of previous negative biopsy, and -10% (8/82) for previous positive biopsy.

CLINICAL RELEVANCE/APPLICATION

PI-RADS scores, biopsy history and age may help select men who can forego systematic biopsy in favor of MRI-targeted biopsy alone, thus minimizing the risks of excess biopsies.

NR03-A1   Curriculum Learning With Deep Learning For Predicting Stroke Onset Within 4.5 Hours Using DWI-FLAIR Mismatch

Participants
Yujin Nam, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop curriculum learning based classifier using diffusion weighted imaging - fluid attenuated inversion recovery (DWI-FLAIR) mismatch to predict stroke onset time within 4.5 hours.*Methods and Materials A total of 355 stroke patients with DWI and FLAIR at Asan Medical Center who had clear stroke onset time were enrolled. The stroke onset time before or after 4.5 hours of each patient was classified. The input image is a combination of apparent diffusion coefficient (ADC), FLAIR, and b1000 axial slices. Since infarct region is an important factor in determining stroke onset time, only slices with an infarct area = 1 cm² or = 0.25 cm² were used as input images. Based on size selection, these images were divided into training (n=178, slices=808), tuning (n=19, slices=145), and validation sets (n=42, slice=228) and based on area, into training (n=238, slices=1231), tuning (n=60, slices=242), and validation (n=56, slices=333). The curriculum learning, in which fine-tuning a model was performed on the entire axial images after initial training a model with infarct-specified patch images, was performed. We compared the performances of the curriculum learning and the baseline models that was trained directly using entire images. The ResNet50 + CBAM networks were used as a backbone network and the area under curve (AUC), accuracy, specificity and sensitivity were evaluated.*Results In case of infarct area = 1 cm², and the largest infarct slice evaluation per patient sensitivity, specificity, accuracy, and AUC of our method were 0.84, 0.88, 0.85, and 0.95. In case of infarct area = 1 cm² or 0.25 cm², AUC of our method were 0.95 and 0.89, respectively, whereas AUC of the baseline is 0.83 and 0.78, respectively. In evaluation of the largest infarct slice, all ROCs of curriculum models show significantly better than those of the baseline models. (p < 0.05)*Conclusions Our curriculum learning based model with deep learning shows better and more robust performance for predicting stroke onset time based on 4.5 hours, which could be helpful in the actual clinical setting.*Clinical Relevance/Application Our model could be helpful in predicting the onset time of onset unclear stroke patient to perform thrombolysis in the actual clinical setting.

RESULTS

In case of infarct area = 1 cm², and the largest infarct slice evaluation per patient sensitivity, specificity, accuracy, and AUC of our method were 0.84, 0.88, 0.85, and 0.95. In case of infarct area = 1 cm² or 0.25 cm², AUC of our method were 0.95 and 0.89, respectively, whereas AUC of the baseline is 0.83 and 0.78, respectively. In evaluation of the largest infarct slice, all ROCs of curriculum models show significantly better than those of the baseline models. (p < 0.05)

CLINICAL RELEVANCE/APPLICATION

Our model could be helpful in predicting the onset time of onset unclear stroke patient to perform thrombolysis in the actual clinical setting.

NR03-A11   CNS HIV Infection: From Pathophysiology To Management With Emphasis On Advanced Neuroimaging

Awards
Certificate of Merit

Participants
Yoshiaki Ota, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

TEACHING POINTS

The purpose of this exhibit is:1. To review the pathophysiology of CNS HIV infection and consequent brain injury 2. To demonstrate neuroimaging of CNS HIV infection, opportunistic infections, and malignancies3. To review treatment and treatment-related complications

TABLE OF CONTENTS/OUTLINE

1. Pathophysiology of CNS HIV infection- Neuronal damage- Neuroinflammation/demyelination- Breakdown of blood-brain barrier/vasculopathy/vasculitis2. Neuroimaging of HIV infection - Conventional CT, MRI: evaluation and characterization for brain lesions, gross brain structures, and brain atrophy- DWI: evaluation for cytotoxic/vasogenic edema and cellularity- PET-CT: evaluation for metabolic disturbances- Diffusion tensor image: neuroinflammation, microstructure assessment- DSC-MRI: blood-brain permeability- MRS: neuroinflammation3. Neuroimaging and pitfalls of CNS HIV infection, opportunistic infections and malignancies, and treatment-related complications- CNS HIV infection: brain atrophy, encephalopathy, vasculopathy- Opportunistic infections: progressive multifocal leukoencephalopathy, toxoplasmosis, Cryptococcus meningitis, CMV, VZV- Malignancy: primary central nervous system lymphoma (PCNSL) - Treatment-related complications: CD8 encephalitis, Immune reconstitution inflammatory syndrome (IRIS)

NR03-A4   Forecasting Demand For Image-guided Endovascular Thrombectomy In The United States

Participants
Cathy Yu, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

PURPOSE

Endovascular thrombectomy (EVT) has become life-saving for patients experiencing stroke due to large vessel occlusion. However, it is only available at specialized centers which are not uniformly distributed throughout the United States. The purpose of this study is to forecast how population and demographic changes will affect EVT accessibility at the national level in the future.*Methods and Materials Population data from 2009-2019 was obtained from the United States Census Bureau's American Community Survey 5-Year Estimates. Stroke incidence data from 2009-2017 was obtained from the Center for Disease Control based on stroke hospitalization rate. Linearized trends in total population, patient demographics, and stroke incidence were used to forecast future stroke events through 2024 in each census tract. EVT centers were identified from national and state organizations that certify stroke centers. Driving times between census tracts and their nearest EVT centers were calculated using real-world road networks. All analyses were done at the census tract level for census tracts within the contiguous United States.*Results In total, 371 EVT centers and 71,986 census tracts were included, encompassing a population of 322,521,2553 in 2019. In 2019, Americans lived a median of 26.4 minutes (IQR: 14.8, 54.9) from an EVT center; 55.0% lived within a 30-minute drive and 77.7% within a 60-minute drive. By 2024, Americans are forecast to live a median of 26.2 minutes (IQR: 14.9, 54.0) from an EVT center, a 1% decrease in time; 55.3% lived within a 30-minute drive and 78.2% within a 60-minute drive. Among stroke patients, the median time to an EVT center was 30.2 minutes (16.2, 61.7) in 2019; 49.7% were within a 30-minute drive and 74.2% were within a 60-minute drive. By 2024, likely stroke patients are forecast to live a median 30.7 minutes (16.2, 64.7) from an EVT center, a 2% increase; 49.3% will live within a 30-minute drive and 72.9% within a 60-minute drive.*Conclusions Population and stroke incidence changes between 2019 and 2024 are forecast to result in a 2% increase in median travel time to an EVT center. Future planning for stroke systems of care must anticipate these changes in order to preserve access to EVT.*Clinical Relevance/Application A comprehensive understanding of both current and future demand for thrombectomy access is necessary not only for clinical decision-making regarding treatment modality, but also hospital and resource planning to improve treatment availability.

RESULTS

In total, 371 EVT centers and 71,986 census tracts were included, encompassing a population of 322,521,2553 in 2019. In 2019, Americans lived a median of 26.4 minutes (IQR: 14.8, 54.9) from an EVT center; 55.0% lived within a 30-minute drive and 77.7% within a 60-minute drive. By 2024, Americans are forecast to live a median of 26.2 minutes (IQR: 14.9, 54.0) from an EVT center, a 1% decrease in time; 55.3% lived within a 30-minute drive and 78.2% within a 60-minute drive. Among stroke patients, the median time to an EVT center was 30.2 minutes (16.2, 61.7) in 2019; 49.7% were within a 30-minute drive and 74.2% were within a 60-minute drive. By 2024, likely stroke patients are forecast to live a median 30.7 minutes (16.2, 64.7) from an EVT center, a 2% increase; 49.3% will live within a 30-minute drive and 72.9% within a 60-minute drive.

CLINICAL RELEVANCE/APPLICATION

A comprehensive understanding of both current and future demand for thrombectomy access is necessary not only for clinical decision-making regarding treatment modality, but also hospital and resource planning to improve treatment availability.

NR03-A5   Early Intervention With Multiple CT-guided Pudendal Nerve Blocks Offers Hope For Controlling Pudendal Neuralgia

Participants
Dennis Phan, Rochester, New York (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed toevaluate the benefit of multiple regularly spaced computed tomography (CT) guided nerve blocks (>3) with a combination of anesthetics and steroids for the treatment of pudendal neuralgia. The accuracy of localization of the pudendal nerve during blockade, demographics, and social factors were analyzed to determine their influence on CT-guided pudendal nerve blocks.*Methods and Materials 217 patients diagnosed with pudendal neuralgia per the NANTES criteria underwent CT-guided pudendal nerve block and were assessed for outcome and response rate. The patients' demographics, inciting events, initial pain criteria, treatment data, and follow-up data were collected. Non-responders to treatment were compared to responders using unpaired t-test for continuous variables, Fisher's exact test for binary variables and chi squared test for categorical variables. Univariate logistic regression was used to examine prediction of response to the nerve block. A p value <0.05 was indicative of a significant difference.*Results The most common chief complaint was pain during sitting or squatting and most common areas of pain involved the vulva, labia, perineum, and vagina (44.2%). Treatment response rates increased with the number of blocks with a maximum response rate of 92.2% after the 4th dose. Responders underwent more nerve blocks in the first year when compared to treatment non-responders (3.1±1.5 vs. 2.6±1.6, p=0.026). 29.4% of treatment non-responders were on disability compared to 9.7% of responders (p=0.043). History of preadolescent sexual abuse was present in 41.7% of non-responders versus 15.7% in responders (p=0.046) and was a significant predictor of response to treatment (odds ratio = 0.27, p=0.04).*Conclusions CT guided pudendal nerve block improves pain in patients meeting NANTES criteria. A significant predictor of response included the number of blocks administered within the first year. Other predictors included history of preadolescent sexual abuse and being on disability at the time of treatment.*Clinical Relevance/Application Approaches to managing pudendal neuralgia are varied with mixed outcomes. Improving and standardizing treatment necessitates further investigation of current practices.

RESULTS

The most common chief complaint was pain during sitting or squatting and most common areas of pain involved the vulva, labia, perineum, and vagina (44.2%). Treatment response rates increased with the number of blocks with a maximum response rate of 92.2% after the 4th dose. Responders underwent more nerve blocks in the first year when compared to treatment non-responders (3.1±1.5 vs. 2.6±1.6, p=0.026). 29.4% of treatment non-responders were on disability compared to 9.7% of responders (p=0.043). History of preadolescent sexual abuse was present in 41.7% of non-responders versus 15.7% in responders (p=0.046) and was a significant predictor of response to treatment (odds ratio = 0.27, p=0.04).

CLINICAL RELEVANCE/APPLICATION

Approaches to managing pudendal neuralgia are varied with mixed outcomes. Improving and standardizing treatment necessitates further investigation of current practices.

NR03-A6   Inaccuracies Of AI-based Intracranial Hemorrhage Detection On CTs

Participants
Muhannad Seyam, MD, Basel, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To classify inaccurately flagged findings (false positives) of a deep learning algorithm for detecting intracranial hemorrhage on CT.*Methods and Materials We classified false-positive findings of a deep learning algorithm for detecting intracranial hemorrhage on emergent cranial NCCTs obtained at our university hospital between November 2019 and October 2020. The radiology report, generated by at least two radiologists (at least one board-certified neuroradiologist), served as the ground-truth for our analysis. As per the report, indeterminate reasons for incorrectly flagged findings were reviewed by two radiologists for classification or remained indeterminate if the review was inconclusive. The deep learning algorithm evaluated emergent cranial CTs prospectively and prompted a window alert with the critical findings if applicable.*Results The study included 3215 emergent cranial CT examinations, of which 5.3% (169/3215) were classified as false-positive findings per radiology report. The majority comprised of post-operative and post-ischemic defects (24.9%, 42/169), followed by other artifacts (20.1%, 34/169), tumors (14.8%, 25/169), calcifications (9.5%, 16/169), and fluids (edema, hygroma, seroma, irrigation, subdural and subcutaneous fluid) (6.5%, 11/169). Other findings included arteriovenous malformations, arteriovenous fistulas, cavernomas, contrast agent, cerebral venous thrombosis, cysts, hyperdense vessels, a hyperdense media sign, or remained indeterminate (2.4%, 4/169). Notably, six previously unreported but flagged intracranial hemorrhages (3.6%) were detected in this review and consisted of two intracerebral hemorrhages, three subdural hematomas, and one intraventricular hemorrhage.*Conclusions Relatively common secondary findings may compromise the accuracy of AI-based tools for detecting intracranial hemorrhage on CT.*Clinical Relevance/Application Awareness of various false-positive imaging findings may assist in optimizing future deep learning algorithms.

RESULTS

The study included 3215 emergent cranial CT examinations, of which 5.3% (169/3215) were classified as false-positive findings per radiology report. The majority comprised of post-operative and post-ischemic defects (24.9%, 42/169), followed by other artifacts (20.1%, 34/169), tumors (14.8%, 25/169), calcifications (9.5%, 16/169), and fluids (edema, hygroma, seroma, irrigation, subdural and subcutaneous fluid) (6.5%, 11/169). Other findings included arteriovenous malformations, arteriovenous fistulas, cavernomas, contrast agent, cerebral venous thrombosis, cysts, hyperdense vessels, a hyperdense media sign, or remained indeterminate (2.4%, 4/169). Notably, six previously unreported but flagged intracranial hemorrhages (3.6%) were detected in this review and consisted of two intracerebral hemorrhages, three subdural hematomas, and one intraventricular hemorrhage.

CLINICAL RELEVANCE/APPLICATION

Awareness of various false-positive imaging findings may assist in optimizing future deep learning algorithms.

NR03-A7   Anatomical Variants Of The Circle Of Willis Do Not Determine Cerebral Collateral Circulation In Ischemic Stroke Due To M1 Occlusion

Participants
Karolina Brzegowy, Krakow, Poland (*Presenter*) Nothing to Disclose

PURPOSE

In acute ischemic stroke, tissue fate and treatment results are dependent on collateral circulation. The purpose of this study was to determine whether variations in the anatomy of the Circle of Willis (CoW) affect collateral blood flow in acute M1 occlusion.*Methods and Materials We performed a retrospective assessment of radiological examinations of patients with stroke due to middle cerebral artery M1 segment occlusion. All patients underwent mechanical thrombectomy from January 2015 until March 2021. The anatomy of the CoW was assessed on initial CT-angiography and DSA. Cranial collateral vasculature status and cortical vein opacification score (COVES) were graded on CTA. Non-contrast CT scans and ASPECTS scores (using RAPID software) were used to determine the ischemic area.*Results A total of 100 patients were included in the analysis (58 females and 42 males, mean age: 71.6 +/- 13.9). Patients with fully continuous CoW had worse COVES scores than those with CoW incomplete at both anterior and posterior portion (89% vs 68% with COVES 0-2, p=0.179). No statistically significant results were found when comparing the enhancement of collaterals between these two groups (p=0.390). The COVES scores were similar for patients with complete and incomplete anterior portions of CoW (77% vs 80% with COVES 0-2, p=0.812). Patients with incomplete posterior portions of CoW had lower COVES scores than those with complete (80% vs 67% with COVES 0-2, p=0.206). No statistically significant differences were discovered when comparing different types of posterior communicating artery (adult, transitional and fetal). Analysis of ischemic areas determined as ASPECTS scores pre- and post-thrombectomy yielded no significant differences between any of the groups.*Conclusions Although certain variants of the CoW have been reported to increase the risk of ischemic stroke, our results show that the anatomy of CoW has no large effect on collateral blood flow during acute M1 occlusion. Pial arterioles may play a more important role in determining cerebral collateral circulation than anatomical variants of major cerebral arteries.*Clinical Relevance/Application Detailed knowledge about factors that influence collateral blood flow is crucial as may aid in identification of patients prone to worse outcomes of ischemic stroke. Anatomical variants of CoW do not play a major role in formation of cerebral collaterals.

RESULTS

A total of 100 patients were included in the analysis (58 females and 42 males, mean age: 71.6 +/- 13.9). Patients with fully continuous CoW had worse COVES scores than those with CoW incomplete at both anterior and posterior portion (89% vs 68% with COVES 0-2, p=0.179). No statistically significant results were found when comparing the enhancement of collaterals between these two groups (p=0.390). The COVES scores were similar for patients with complete and incomplete anterior portions of CoW (77% vs 80% with COVES 0-2, p=0.812). Patients with incomplete posterior portions of CoW had lower COVES scores than those with complete (80% vs 67% with COVES 0-2, p=0.206). No statistically significant differences were discovered when comparing different types of posterior communicating artery (adult, transitional and fetal). Analysis of ischemic areas determined as ASPECTS scores pre- and post-thrombectomy yielded no significant differences between any of the groups.

CLINICAL RELEVANCE/APPLICATION

Detailed knowledge about factors that influence collateral blood flow is crucial as may aid in identification of patients prone to worse outcomes of ischemic stroke. Anatomical variants of CoW do not play a major role in formation of cerebral collaterals.

NR03-A8   Effect Of Quantitative Collateral-core Ratio On Predicting Functional Independence In Patients With Acute Ischemic Stroke

Participants

Jinhao Lyu, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

The study was to test the hypothesis that a collateral perfusion - core ratio as measured by quantitative arterial spin labeling (ASL) and diffusion-weighted imaging (DWI) is predictable for clinical outcome in acute ischemic large vessel occlusive stroke.*Methods and Materials A prospective, observational cohort study was conducted at 12 academic hospital-based centers in China. Participants with acute ischemic stroke caused by anterior circulation large vessel occlusion underwent two post-labeling delays (PLD, 1.5s, and 2.5s) ASL and DWI. Quantitative collateral - core ratio was calculated by (volume of collateral perfusion / volume of DWI hyperintensity). The volume of collateral perfusion was obtained by volumetric measurement of residual signal on 2 PLD cerebral blood flow subtraction map by in-house software. 90 day modified Rankin Scale (mRS) was followed and recorded. Enrollment took place from January 1, 2019. Data was central reviewed and analyzed.*Results 149 patients remained eligible after exclusion in the study. There were 84 patients with mRS = 2 (favorable outcome) and 65 patients with mRS > 2 (unfavorable outcome). The optimal collateral-core ratio for predictive for 90 day mRS >2 was 0.7. 57 (38.2%) patients were classified as low collateral-core ratio (<0.7) and 92 (61.8%) patients were high collateral-core ratio (=0.7). Figure 1 shows scatter plots for all enrolled patients according to infarct core volume and collateral-core ratio stratified by clinical outcome. The NIHSS, infarct core volume, was significantly higher in patients with unfavorable outcome than those with favorable outcome, whereas collateral perfusion volume showed no significantly different. Collateral-core ratio were significantly lower in patients with unfavorable outcome. After adjusted for baseline characteristics, risk factors, treatment, lesion location, infarct core volume, and collateral perfusion volume, NIHSS (OR 1.1996, 95%CI 1.0842 - 1.3272) and collateral-core ratio (OR 0.7563, 95%CI 0.5779 to 0.9897) were independently significantly associated with unfavorable outcome. Predictive models showed significant improvement after recruiting collateral-core ratio in the model than NIHSS alone (Figure 2).*Conclusions Collateral - core ratio determined using 2 PLD ASL is robustly associated with clinical outcome in patients with acute ischemic anterior circulation large vessel occlusive stroke.*Clinical Relevance/Application We introduce collateral - core ratio, a novel imaging marker determined using arterial spin labeling perfusion, to evaluate the interaction effect of collateral circulation and volume of infarct core on clinical outcome in patients with acute ischemic anterior circulation large vessel occlusive stroke.

RESULTS

149 patients remained eligible after exclusion in the study. There were 84 patients with mRS = 2 (favorable outcome) and 65 patients with mRS > 2 (unfavorable outcome). The optimal collateral-core ratio for predictive for 90 day mRS >2 was 0.7. 57 (38.2%) patients were classified as low collateral-core ratio (<0.7) and 92 (61.8%) patients were high collateral-core ratio (=0.7). Figure 1 shows scatter plots for all enrolled patients according to infarct core volume and collateral-core ratio stratified by clinical outcome. The NIHSS, infarct core volume, was significantly higher in patients with unfavorable outcome than those with favorable outcome, whereas collateral perfusion volume showed no significantly different. Collateral-core ratio were significantly lower in patients with unfavorable outcome. After adjusted for baseline characteristics, risk factors, treatment, lesion location, infarct core volume, and collateral perfusion volume, NIHSS (OR 1.1996, 95%CI 1.0842 - 1.3272) and collateral-core ratio (OR 0.7563, 95%CI 0.5779 to 0.9897) were independently significantly associated with unfavorable outcome. Predictive models showed significant improvement after recruiting collateral-core ratio in the model than NIHSS alone (Figure 2).

CLINICAL RELEVANCE/APPLICATION

We introduce collateral - core ratio, a novel imaging marker determined using arterial spin labeling perfusion, to evaluate the interaction effect of collateral circulation and volume of infarct core on clinical outcome in patients with acute ischemic anterior circulation large vessel occlusive stroke.

NR03-A9   Comparative Costs Of Direct To Angiography Suite Vs. Standard-Of-Care CT Pathway For Stroke Patients With Suspected Large Vessel Occlusion Using Time-driven Activity-based Costing

Participants

Kinpritma Sangha, PhD,MPH, Malvern, Pennsylvania (*Presenter*) Employee, Siemens AG

PURPOSE

Direct to angiography (DTA) is a new care pathway for treatment of patients with stroke due to large vessel occlusion. While DTA pathway has the potential to lower time to treatment and improve clinical outcomes for acute ischemic stroke (AIS), the costs of implementing a DTA care pathway have not been studied. The purpose of this study is to measure and compare the relative cost differences between the DTA and standard-of-care CT suite pathways based on four treatment scenarios using IV-tPA and EVT.*Methods and Materials We apply the Time Driven Activity Based Costing (TDABC) model to assess the costs of both DTA and standard-of-care CT pathways from the healthcare institution perspective. Four scenarios were considered based on patient eligibility for treatment with IV-tPA and EVT: a) IV-tPA+ EVT, b) IV-tPA+ no EVT, c) No IV-tPA+ EVT, d) No IV-tPA+ no EVT. We utilize process mapping to outline all activities, materials, and equipment for each step needed to perform in each pathway for AIS patients with suspected large vessel occlusion. TDABC uses time equations to estimate the time spent on each activity within a pathway and the associated costs. The outcomes measured in this study include total costs and cost per patient for both pathways.*Results Total costs to manage an acute ischemic stroke patient with LVO using the DTA and the CT suite pathway were: IV-tPA+EVT= $26,004.65 and $26,077.80, IV-tPA but no EVT= $8,694.52 and $8,649.43, no IV-tPA+EVT= $17,595.03 and $17,668.18, no IV-tPA and no EVT= $284.90 and $228.79 per patient. Material costs (IV-tPA and EVT), with a total amount of $24,656.45, were the highest cost driver in both pathways, comprising nearly 95% of the total costs in the IV-tPA+EVT group. However, in the no IV-tPA+no EVT group with no treatment, personnel costs become the highest cost driver, comprising 92% and 91% of the total costs in the DTA and CT pathways.*Conclusions While the DTA approach will incur similar per-patient costs to the CT pathway, the costs vary based on treatment. Costs of IV-tPA and EVT are the highest cost drivers in both pathways, while, in the absence of any treatment, personnel costs become the highest cost driver. Figure 1: DTA and standard-of-care CT costs class="MsoNormal">*Clinical Relevance/Application Implementation of DTA pathway can allow for lower time to treatment and improve clinical outcomes for Acute ischemic stroke patients with suspected LVO at similar costs as the standard-of-care CT pathway.

RESULTS

Total costs to manage an acute ischemic stroke patient with LVO using the DTA and the CT suite pathway were: IV-tPA+EVT= $26,004.65 and $26,077.80, IV-tPA but no EVT= $8,694.52 and $8,649.43, no IV-tPA+EVT= $17,595.03 and $17,668.18, no IV-tPA and no EVT= $284.90 and $228.79 per patient. Material costs (IV-tPA and EVT), with a total amount of $24,656.45, were the highest cost driver in both pathways, comprising nearly 95% of the total costs in the IV-tPA+EVT group. However, in the no IV-tPA+no EVT group with no treatment, personnel costs become the highest cost driver, comprising 92% and 91% of the total costs

in the DTA and CT pathways.

CLINICAL RELEVANCE/APPLICATION

Implementation of DTA pathway can allow for lower time to treatment and improve clinical outcomes for Acute ischemic stroke patients with suspected LVO at similar costs as the standard-of-care CT pathway.

BR01-A10   Comparison Of Hyperplasic Axillary Lymph Nodes Reaction After COVID-19 M-RNA Vaccine Between Different Age Groups.

Participants
Alba Cristina Igual Rouilleault, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To study axillary lymph node response to the COVID-19 mRNA vaccination between young and middle-aged patients.*Methods and Materials Ninety-one volunteer employees from our center were prospectively ruled-out between February to April 2021. The study was conducted with the approval of our IRB and all participants provided written consent to participate. Patients recruited were Pfizer-BioNTech COVID-19 vaccine recipients and each one underwent a total of three axillary ultrasound (US) evaluations of the ipsilateral vaccinated arm. The first axillar US exam was obtained within the week before vaccine administration (basal control), the second one the week after the first dose (control 1) and the last one, the week after the second dose (control 2). Findings recorded in our study included: the total number of visible nodes, the maximum measurements of the long-axis size and cortical thickness (mm), Bedi's classification (grade 1 to 6) and color Doppler evaluation (grade 0 to 3, being 0 no color signal and 3 high intense color signal). Patients were classified in two age groups using 45 years of age as a cut-off. Data collected were compared between both groups in the follow-up evaluations using unpaired-sample Student's t-test for quantitative continuous variables and Mann-Whitney U test for ordinal variables.*Results The mean age of patients included was 44 y/o with 43 patients younger than 45 y/o and 48 older than 45 y/o. In basal US examination, a higher cortical thickness (mean 1.8 vs 1.4 mm; p=0.037), a higher grade of Bedi's classification (90.6% vs 77.1% of grade 2; p=0.024) and a greater grade of color Doppler (60% of grade 1 vs 56% of grade 0; p=0.009) were identified in younger group vs middle-age group. In control 1 and 2, statistically significant differences were also found comparing these three parameters between younger and middle-age patients. However, total visible nodes and maximum long-axis measurement didn't' show statistically significant differences between both age groups in any of the three US examinations.*Conclusions Comparative analyses between younger and middle-age patients showed more cortical thickness, Bedi's grade and Doppler scale in the first group among the three US examinations. *Clinical Relevance/Application Hyperplasic axillary lymphadenopathy can be consider a normal response to COVID-19 vaccine, showing higher morphological changes in younger patients.

RESULTS

The mean age of patients included was 44 y/o with 43 patients younger than 45 y/o and 48 older than 45 y/o. In basal US examination, a higher cortical thickness (mean 1.8 vs 1.4 mm; p=0.037), a higher grade of Bedi's classification (90.6% vs 77.1% of grade 2; p=0.024) and a greater grade of color Doppler (60% of grade 1 vs 56% of grade 0; p=0.009) were identified in younger group vs middle-age group. In control 1 and 2, statistically significant differences were also found comparing these three parameters between younger and middle-age patients. However, total visible nodes and maximum long-axis measurement didn't' show statistically significant differences between both age groups in any of the three US examinations.

CLINICAL RELEVANCE/APPLICATION

Hyperplasic axillary lymphadenopathy can be consider a normal response to COVID-19 vaccine, showing higher morphological changes in younger patients.

BR01-A2   Synthetic Post-contrast Breast MRI For Imaging Malignant Lesions Using Deep Learning

Participants
Maggie Chung, MD, San Francisco, California (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the feasibility of simulating post-contrast T1 breast MR images from pre-contrast MR images using a 3D fully convolutional neural network and to evaluate its diagnostic quality through a multi-reader study.*Methods and Materials A 3D fully convolutional deep neural network based on the U-net architecture was used to generate synthetic post-contrast T1 breast MRs (syMR) from 5 pre-contrast series: T1 with and without fat saturation (FS), T2 FS, DWI, and ADC. The dataset consisted of 101 breast MRs performed from 1/2015-1/2019 in women with newly diagnosed invasive breast cancer. The first post-contrast phase of the conventional dynamic contrast-enhanced T1 MR (cMR) was used as the ground-truth. Independent training and testing sets were used with training/test ratio of 85/15. Ten cMRs from the test set demonstrating a measurable index malignancy were included in the reader study. cMRs with only non-mass enhancement without detectable enhancing mass were excluded. The 10 pairs of cMR and syMR were randomized between two sessions separated by a 2-week washout period. Three blinded breast radiologists independently assessed whether each case looked like a cMR, image quality (5-point Likert-type scale), presence of tumor enhancement, and maximum index mass measurement. Quality scores of "excellent," "good," and "acceptable" were considered acceptable for diagnostic use. Paired t-test assessed difference in the mean tumor size between cMR and syMR. Wilcoxon signed-rank test evaluated difference in image quality scores.*Results All syMRs were assessed by the three readers as having the appearance of a cMR and demonstrating tumor enhancement. Mean tumor sizes for cMR and syMR were 23mm (range 12-39mm) and 22mm (range 12-41 mm), respectively; mean difference was 1.0 mm (95% CI -0.9, 3.0)(p=0.3). Image quality of the

MR was statistically lower for syMR compared to cMR (p<0.0001). The majority of cMRs (53%) were assessed as "excellent", while most syMRs (77%) were assessed as "good" or "acceptable." Of the 10 syMRIs, the majority were considered acceptable for diagnostic use by each of the three readers (10/10, 9/10, and 7/10, respectively).*Conclusions This pilot feasibility study demonstrates that syMR generated using a 3D deep fully convolutional neural network has the appearance of cMR with comparable tumor enhancement and similar lesion size. Image quality of syMR was slightly less than cMR, but the majority were of acceptable diagnostic quality.*Clinical Relevance/Application Simulated post-contrast breast MR is a promising deep learning technique that has the potential to extend the benefits and accessibility of contrast-enhanced breast MR to patients while reducing the necessity of gadolinium contrast administration.

RESULTS

All syMRs were assessed by the three readers as having the appearance of a cMR and demonstrating tumor enhancement. Mean tumor sizes for cMR and syMR were 23mm (range 12-39mm) and 22mm (range 12-41 mm), respectively; mean difference was 1.0 mm (95% CI -0.9, 3.0)(p=0.3). Image quality of the MR was statistically lower for syMR compared to cMR (p<0.0001). The majority of cMRs (53%) were assessed as "excellent", while most syMRs (77%) were assessed as "good" or "acceptable." Of the 10 syMRIs, the majority were considered acceptable for diagnostic use by each of the three readers (10/10, 9/10, and 7/10, respectively).

CLINICAL RELEVANCE/APPLICATION

Simulated post-contrast breast MR is a promising deep learning technique that has the potential to extend the benefits and accessibility of contrast-enhanced breast MR to patients while reducing the necessity of gadolinium contrast administration.

BR01-A4   Consistent Breast Density Calculation In Screening Breast MRI

Participants
Riccardo Samperna, MSc, Nijmegen, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

Personalized breast cancer screening allows for more accurate and cost-effective women care. Breast density is a well-known risk factor for future development of breast cancer and may be used to stratify women to alternative screening modalities (e.g. breast MRI). Automatic breast density calculation in breast MRI is thus required to be able to re-adjust screening recommendations and provide further screening personalization. It is essential that measured density in MRI is consistent over time, in order to only change the screening advice in women who have a significant decrease in density.*Methods and Materials 197 patients with a total of 611 studies (on average 3 per patient, with an average time-interval of 1 year between scans) were selected from the breast screening MRI database available at our institution based on the availability of two or more studies with T1 weighted Dixon acquisitions (in phase, opposed phase and reconstructed water and fat images). Breast volume was automatically calculated by using a deep-learning based segmentation solution. Fibroglandular tissue volume was calculated via subtraction of T1 fat-suppressed images and T1 water-suppressed images following Otsu thresholding. Density classes were defined using the thresholds applied by Volpara Density Grade (VDG) and {non-dense, dense} categorization based on calculated volumetric breast density. Per-patient consistency of density over sequential studies was evaluated.*Results The distribution over the density classes at baseline was a = 24%, b = 23%, c = 28%, d =25%. VDG classes had an average of 76.8% consistency between follow-up studies. In non-consistent classes: 16.4% of studies changed to a lower class and 6.8% of studies changed to a higher class. The categorization {non-dense, dense} showed 91.5% consistency between follow-up studies. In non-consistent categories: 6.3% of studies changed from dense to non-dense and 2.2% changed from non-dense to dense.*Conclusions The automatic VDG class assignment and the {non-dense, dense} categorization of intra-patient breast screening MRI proved to be highly consistent over two or multiple studies. Non-consistent results are at expected levels, due to the known decrease of breast density in ageing women and changes in body composition.*Clinical Relevance/Application Reliable automatic breast density calculation over time for MRI eliminates interobserver human variability and may be used to provide patients with a personalized screening advice.

RESULTS

The distribution over the density classes at baseline was a = 24%, b = 23%, c = 28%, d =25%. VDG classes had an average of 76.8% consistency between follow-up studies. In non-consistent classes: 16.4% of studies changed to a lower class and 6.8% of studies changed to a higher class. The categorization {non-dense, dense} showed 91.5% consistency between follow-up studies. In non-consistent categories: 6.3% of studies changed from dense to non-dense and 2.2% changed from non-dense to dense.

CLINICAL RELEVANCE/APPLICATION

Reliable automatic breast density calculation over time for MRI eliminates interobserver human variability and may be used to provide patients with a personalized screening advice.

BR01-A5   Outcomes Of Benign Concordant Mri-guided Breast Biopsy And Follow-up Recommendations

Participants
Lonie Salkowski, MD,PhD, Madison, Wisconsin (*Presenter*) Nothing to Disclose

PURPOSE

MRI-guided vacuum assisted breast biopsies (MR VABB) are increasingly used for histologic diagnosis of suspicious lesions on screening/diagnostic MRI. Currently there are no standard guidelines for imaging follow-up after a benign concordant biopsy. The purpose of this study was to determine imaging follow-up recommendations and outcomes of benign, concordant MR VABB.*Methods and Materials An IRB approved, HIPAA compliant retrospective review was performed of 9-gauge MR VABB with clip placement, performed at a single academic institution from 2013 through 2019, with prospective radiology-pathology concordance assessment. We collected lesion/clip location, histology, radiology-pathology concordance, and timing of follow-up MRI recommendations. Follow-up intervals after MR VABB were defined as 6 months (5-9 months), 12 month (=9-15 months) and long-term (>15 months). The cancer detection rates (CDR) were compared with a two-tailed Fischer exact test.*Results Of 444 MR VABB, 258 were benign and concordant with 46 lost to follow-up. Of the remaining 212 biopsies (193 patients), 145 biopsies satisfied our inclusion criteria based on the timing of the first follow-up breast MRI. 100 biopsies had MRI follow-up at 6-months, 23 at 12-months, and 22 long term. The CDR were 2% (2/100), 0% (0/23), and 0% (0/22) (P=1), respectively. At 6-months, 2 cases were recommended for biopsy and 3 assessed for short interval follow-up (BI-RADS 3). The cancers were Stage 0 (DCIS) and Stage IA (invasive ductal carcinoma). The overall false-negative rate of the benign concordant MR VABB was 1.38% (2/145). A 6-month follow-up breast MRI was recommended for 90% (190/212) of the benign concordant MR VABB; however, only 50.5% (96/190) obtained MRI follow-up at 6 months.*Conclusions Follow-up breast MRI should be performed after benign concordant MR VABB given the 1.38% overall false negative rate. However, the timing of the first follow-up (6 versus 12 months) may not be clinically

significant as the two cancers detected at 6-month MRI follow-up were small size and lymph node negative. Although the majority of benign concordant MR VABB were recommended for a 6-month follow-up breast MRI, only half were performed at that interval.*Clinical Relevance/Application Given the relatively low CDR (2%) and favorable pathologic features of the cancers detected at 6-month follow-up MRI, it may be clinically acceptable to perform the initial follow-up MRI at 12 months.

RESULTS

Of 444 MR VABB, 258 were benign and concordant with 46 lost to follow-up. Of the remaining 212 biopsies (193 patients), 145 biopsies satisfied our inclusion criteria based on the timing of the first follow-up breast MRI. 100 biopsies had MRI follow-up at 6-months, 23 at 12-months, and 22 long term. The CDR were 2% (2/100), 0% (0/23), and 0% (0/22) (P=1), respectively. At 6-months, 2 cases were recommended for biopsy and 3 assessed for short interval follow-up (BI-RADS 3). The cancers were Stage 0 (DCIS) and Stage IA (invasive ductal carcinoma). The overall false-negative rate of the benign concordant MR VABB was 1.38% (2/145). A 6-month follow-up breast MRI was recommended for 90% (190/212) of the benign concordant MR VABB; however, only 50.5% (96/190) obtained MRI follow-up at 6 months.

CLINICAL RELEVANCE/APPLICATION

Given the relatively low CDR (2%) and favorable pathologic features of the cancers detected at 6-month follow-up MRI, it may be clinically acceptable to perform the initial follow-up MRI at 12 months.

BR01-A7   Breast US/MRI Fusion Technology Helps Reduce The Need For MRI Guided Biopsies

Participants
Adrian K. Lim, MD, FRCR, London, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

Breast US/MRI fusion has been challenging particularly requiring a supine MRI sequence, not possible on all scanners. Advancing fusion technology on a new system has significantly improved image synchronization working with any MRI scan and patient position. The feasibility of this scanner in characterizing incidental MRI detected breast lesions was assessed.*Methods and Materials Patients requiring a second look breast US following an incidentally MRI detected lesion were recruited prospectively. All MRI studies were performed in the prone position using a 3T Verio scanner (Siemens) and the US/MRI fusion was performed with an Aplio i800 scanner (Canon). All US/MRI fusion studies were performed by A.L. who initially undertook a baseline US survey and documented if the lesion could be confidently identified. Subsequently, the US was then fused with MRI sequences depicting the hypervascular lesion and again noted if a lesion was present. US guided biopsies were then undertaken as per routine clinical protocol. Where there was no defined lesion, the operator biopsied the area corresponding to that seen on the MRI study as indicated by the fusion system. The results were correlated with histology.*Results 30 patients have been recruited to date. All patients had a known newly diagnosed breast cancer requiring a second look ultrasound following an incidental MRI detected lesion. These were performed within 1 week. 11 lesions could be detected with US alone. In 17 cases, US/MRI fusion was needed to identify the lesion/area; 14 of which were biopsied influencing clinical management; the 3 lesions not biopsied were normal lymph nodes. In 2 cases, the lesion could not be seen with US or fusion and thus had MRI guided biopsies. These results were statistically significant (Fisher's exact test: p<0.001). The US/fusion system obviated the need for MRI guided biopsy in a significant number of cases. The US/MRI fusion was quick and easy to use with improved image registration when there was another identifiable lesion (e.g., a cyst), in addition to the nipple to provide accurate synchronization. The system allows fusion with up to three sequences at once and a color coded option to help denote the lesion of interest.*Conclusions Breast US/MRI Fusion significantly improves localization of incidentally detected MRI lesions which are occult on an initial US survey alone, thus reducing the need for MRI guided biopsies.*Clinical Relevance/Application The US/MRI fusion technology will reduce the need for MRI guided biopsies and improve patients experience and save costs.

RESULTS

30 patients have been recruited to date. All patients had a known newly diagnosed breast cancer requiring a second look ultrasound following an incidental MRI detected lesion. These were performed within 1 week. 11 lesions could be detected with US alone. In 17 cases, US/MRI fusion was needed to identify the lesion/area; 14 of which were biopsied influencing clinical management; the 3 lesions not biopsied were normal lymph nodes. In 2 cases, the lesion could not be seen with US or fusion and thus had MRI guided biopsies. These results were statistically significant (Fisher's exact test: p<0.001). The US/fusion system obviated the need for MRI guided biopsy in a significant number of cases. The US/MRI fusion was quick and easy to use with improved image registration when there was another identifiable lesion (e.g., a cyst), in addition to the nipple to provide accurate synchronization. The system allows fusion with up to three sequences at once and a color coded option to help denote the lesion of interest.

CLINICAL RELEVANCE/APPLICATION

The US/MRI fusion technology will reduce the need for MRI guided biopsies and improve patients experience and save costs.

BR01-A9   A Comprehensive AI Platform To Identify Women At Risk Of Interval Breast Cancer After Negative Mammography Screening - Enabling Supplemental MRI

Participants
Fredrik Strand, MD,PhD, Stockholm, Sweden (*Presenter*) Speaker, Lunit Inc

PURPOSE

Studies using extremely high mammographic density to select women for supplemental MRI have shown a dramatic reduction in interval cancer rates. In our retrospective study, we examine the ability of an AI platform to identify women at risk of interval cancer.*Methods and Materials A comprehensive platform was designed based on combining the scores from three AI networks trained for different purposes: masking assessment, risk prediction and cancer detection. The networks were a mix of in-house and commercial (Lunit Inc., South Korea). For comparison, quantitative mammographic percent density was calculated by validated software. Performance was evaluated in a held-back test set of negative mammograms from a previously published case-control dataset in population-based screening. All mammography equipment were from the same vendor (Hologic Inc., USA).*Results Within 23 months of a normal screening, 2023 women remained healthy and 113 women were diagnosed with interval breast cancer. After oversampling healthy observations to attain a population-level 0.2% interval cancer rate, the following number of interval cancers were observed when selecting the top 8% scores: 15 (13%) for mammographic density, 36 (32%) for AI, 34 (30%) for AI without masking assessment, 31 (27%) for AI without risk prediction, and 32 (28%) for AI without cancer detection. Selection by mammographic density had to be expanded to the top 25% scores to achieve inclusion of 36 interval cancers.*Conclusions Nearly

one in three interval cancers were included by the top 8% of AI score. Removing any of the three AI networks from the comprehensive model reduced this number. For mammographic density, 25% of women had to be included to obtain the same number of interval cancers.*Clinical Relevance/Application Using a combination of AI networks to triage women after negative screening holds promise to markedly increase the number of interval cancers preempted by a realistic proportion of supplemental MRI. We have recently implemented a similar approach in a randomized controlled trial of screening MRI at our institution.

RESULTS

Within 23 months of a normal screening, 2023 women remained healthy and 113 women were diagnosed with interval breast cancer. After oversampling healthy observations to attain a population-level 0.2% interval cancer rate, the following number of interval cancers were observed when selecting the top 8% scores: 15 (13%) for mammographic density, 36 (32%) for AI, 34 (30%) for AI without masking assessment, 31 (27%) for AI without risk prediction, and 32 (28%) for AI without cancer detection. Selection by mammographic density had to be expanded to the top 25% scores to achieve inclusion of 36 interval cancers.

CLINICAL RELEVANCE/APPLICATION

Using a combination of AI networks to triage women after negative screening holds promise to markedly increase the number of interval cancers preempted by a realistic proportion of supplemental MRI. We have recently implemented a similar approach in a randomized controlled trial of screening MRI at our institution.

SDP-PD-1 **Neurovascular Coupling Alteration Of The Cingulate Cortex In Children With Idiopathic Generalized Epilepsy**

Participants
Jie Hu, Zunyi, China (*Presenter*) Nothing to Disclose

PURPOSE

Idiopathic generalized epilepsy (IGE) is associated with increased risk of cognitive impairment, for which altered neuronal activity and cerebral vascular hemodynamics are important etiologies. However, their coupling alterations and its effects on cognitive in IGE remain unknown. Thus, the aim of this study is to investigate neurovascular coupling alterations and its potential contribution to cognitive function in IGE by using functional connectivity strength (FCS) and cerebral blood flow (CBF).*Methods and Materials A total of 25 children with IGE and 26 sex- and age-matched healthy controls (Table 1) were included in this study. All subjects exhibited normal radiologic presentations in routine neuroimaging examination and underwent resting-state functional MRI (rs-fMRI) and arterial spin labeling imaging (ASL). FCS and CBF were calculated from rs-fMRI and ASL, respectively. The CBF/FCS ratio (the amount of blood supply per unit of connectivity strength), CBF and FCS of each voxel were compared between the 2 groups. Multiple comparisons were corrected using a voxel-wise Gaussian random field method (voxel P < 0.005, cluster P < 0.05, two tailed). The mean CBF/FCS ratio, CBF and FCS of each cluster with significant group differences was extracted and was correlated with clinical variables in IGE group by using partial correlation analysis (age, sex and education as covariates). Multiple comparisons were corrected using the Bonferroni method (P < 0.05/4 = 0.0125).*Results Compared with healthy controls, IGE patients showed increased CBF/FCS ratio in the left median cingulate gyrus (Table 2, Figure 1A), decreased FCS in the left putamen (Table 3, Figure 1B). IGE patients also showed increased CBF in the right superior parietal gyrus, middle occipital gyrus and decreased CBF in the left postcentral gyrus (Table 4, Figure 1C). In IGE group, the increased CBF/FCS ratio was negatively correlated with full-scale intelligence quotient (FIQ) and verbal intelligence quotient (VIQ) of Wechsler Intelligence Scale in the left median cingulate gyrus (r=-5.39, P=0.010; r=-5.55, P=0.007; Bonferroni corrected) (Figure 2). FIQ was also negatively correlated with CBF in the left postcentral gyrus, and positively correlated with FCS in the left putamen in IGE patients (r=-0.424, P=0.049; r=0.424, P=0.049; uncorrected) (Table 5).*Conclusions The results suggest that children with IGE show abnormal neurovascular coupling in the left median cingulate cortex, which is associated cognitive impairments.*Clinical Relevance/Application The results may contribute to the monitoring of IGE progression and provide insight into the pathophysiology of the cognitive impairment in these children.

RESULTS

Compared with healthy controls, IGE patients showed increased CBF/FCS ratio in the left median cingulate gyrus (Table 2, Figure 1A), decreased FCS in the left putamen (Table 3, Figure 1B). IGE patients also showed increased CBF in the right superior parietal gyrus, middle occipital gyrus and decreased CBF in the left postcentral gyrus (Table 4, Figure 1C). In IGE group, the increased CBF/FCS ratio was negatively correlated with full-scale intelligence quotient (FIQ) and verbal intelligence quotient (VIQ) of Wechsler Intelligence Scale in the left median cingulate gyrus (r=-5.39, P=0.010; r=-5.55, P=0.007; Bonferroni corrected) (Figure 2). FIQ was also negatively correlated with CBF in the left postcentral gyrus, and positively correlated with FCS in the left putamen in IGE patients (r=-0.424, P=0.049; r=0.424, P=0.049; uncorrected) (Table 5).

CLINICAL RELEVANCE/APPLICATION

The results may contribute to the monitoring of IGE progression and provide insight into the pathophysiology of the cognitive impairment in these children.

SDP-PD-10 **Application Of 70kvp In Abdominal CT Angiography To Reduce Both Radiation And Contrast Dosage And Improve Patient Comfort For Children**

Participants
Jianying Li, Beijing, China (*Presenter*) Employee, General Electric Company

PURPOSE

To evaluate the application of 70kVp in pediatric abdominal CT angiography (CTA) to reduce radiation and contrast dose and improve patient comfort.*Methods and Materials Forty-six children needing abdominal CTA were enrolled in the study group using low-dose scanning protocol with 70kVp and 0.7-1.1ml/kg contrast dose, and reconstructed with 50%ASIR-V. They were compared with another 46 children (control group) with matching body weight who underwent conventional CT scans with 100kVp, 1.2-1.8ml/kg contrast dose and reconstructed using 50%ASIR. The image quality of large vessels was evaluated using a 5-point scale, and the number of superior mesenteric artery branches identifiable by a computer-aided detection (CAD) system was recorded. The CT value and standard deviation of descending aorta (Ao) was measured, and signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) calculated. Radiation dose, contrast dose and the maximum injection pressure were compared between the two groups.*Results The score for displaying large vessels using 70kVp images was 3.91±0.28, and up to 3 superior mesenteric artery branches could be identified, all of which met the diagnostic requirements. The CT value of Ao was 390.87±86.79HU in the study group, higher than the 343.93±49.94HU in the control group, while there was no difference in SNR and CNR between the two groups. The radiation dose, contrast dose and injection pressure of the study group was 1.23±0.39mGy, 12.67±7.27ml and

43.83±17.16psi, respectively, significantly lower than the 1.95±0.37mGy, 22.67±7.39ml, and 77.59±19.68psi of the control group.*Conclusions 70kVp scanning meets the diagnostic requirements in pediatric abdominal CTA while providing significant radiation dose, contrast dose and injection pressure reduction.*Clinical Relevance/Application 70kVp scanning could reduce the requirement for radiation dose, contrast medium dose, and improve patient comfort for children.

RESULTS

The score for displaying large vessels using 70kVp images was 3.91±0.28, and up to 3 superior mesenteric artery branches could be identified, all of which met the diagnostic requirements. The CT value of Ao was 390.87±86.79HU in the study group, higher than the 343.93±49.94HU in the control group, while there was no difference in SNR and CNR between the two groups. The radiation dose, contrast dose and injection pressure of the study group was 1.23±0.39mGy, 12.67±7.27ml and 43.83±17.16psi, respectively, significantly lower than the 1.95±0.37mGy, 22.67±7.39ml, and 77.59±19.68psi of the control group.

CLINICAL RELEVANCE/APPLICATION

70kVp scanning could reduce the requirement for radiation dose, contrast medium dose, and improve patient comfort for children.

SDP-PD-11 Feasibility Of Performing Chest CT In Children With An X-ray Film Dosage (0.04msv) By Using A Deep Learning Image Reconstruction (dlir)

Participants
Jianying Li, Beijing, China (*Presenter*) Employee, General Electric Company

PURPOSE

To assess feasibility of performing chest CT in children with radiation dose level of x-ray films by using a Deep Learning Image Reconstruction (DLIR) algorithm.*Methods and Materials 26 children (age range 3-12y, average 7.3±3.0 years) underwent ultra-low-dose plain chest CT in a follow-up scan with 80kV (for 3-6 years) or 100kV (for 7-12 years), 10mA, 0.5s rotation time. Images were reconstructed with 50% and 100% Adaptive Statistical Iterative Reconstruction-V (ASIR-V) with standard kernel and DLIR with low (DL-L), medium (DL-M) and high (DL-H) settings at slice thickness of 5mm. Two radiologists in consensus evaluated images for lung opacity, lung markings, large airways, small airways and mediastinum on a 5-point scale (5, excellent, 4, good, 3, measurable and acceptable, 2, detectable and 1, not acceptable), and recorded abnormal CT findings. Image noise of left ventricle (LV), muscle, and lung were measured for objective image quality and statistically compared between the 5 reconstruction groups and calculated the number of lesion (consolidation, air bronchogram sign). Finally, radiation dose was recorded based on the report of ICRP103.*Results The average CTDIvol and effective dose was 0.07±0.03mGy and 0.04±0.01mSv, respectively. The image noise (in HU) of LV was 21.1±2.0 with 50%ASIR-V, 12.9±1.8 with 100%ASIR-V, 28.2±5.0 with DL-L, 23.4±4.8 with DL-M and 18.5±4.7 with DL-H images. The image quality scores for lung opacity and large airways were all higher than 3 points with DL-H being the highest at 3.6±0.4 and 4.7±0.3, respectively. However, only DL-H provided acceptable image quality for small airways with score of 3.2±0.3, and none of the images at such low dose level had acceptable image quality for mediastinum. 33 consolidations and occupations were identified on all image groups, but DL-M and DL-H images detected more small airway lesions than ASIR-V images (5 lesions on DL-M and DL-H vs. 4 on 50%ASIR-V and 2 on 100%ASIR-V).*Conclusions It is feasible to provide acceptable CT images using a DL-H algorithm for evaluating lungs for children at dose level similar to X-ray films.*Clinical Relevance/Application Ultra-low-dose chest CT has radiation dose level of plan X-Ray films, and together with DLIR may provide clinically relevant details.

RESULTS

The average CTDIvol and effective dose was 0.07±0.03mGy and 0.04±0.01mSv, respectively. The image noise (in HU) of LV was 21.1±2.0 with 50%ASIR-V, 12.9±1.8 with 100%ASIR-V, 28.2±5.0 with DL-L, 23.4±4.8 with DL-M and 18.5±4.7 with DL-H images. The image quality scores for lung opacity and large airways were all higher than 3 points with DL-H being the highest at 3.6±0.4 and 4.7±0.3, respectively. However, only DL-H provided acceptable image quality for small airways with score of 3.2±0.3, and none of the images at such low dose level had acceptable image quality for mediastinum. 33 consolidations and occupations were identified on all image groups, but DL-M and DL-H images detected more small airway lesions than ASIR-V images (5 lesions on DL-M and DL-H vs. 4 on 50%ASIR-V and 2 on 100%ASIR-V).

CLINICAL RELEVANCE/APPLICATION

Ultra-low-dose chest CT has radiation dose level of plan X-Ray films, and together with DLIR may provide clinically relevant details.

SDP-PD-12 Gadopiclenol Pharmacokinetics, Safety And Efficacy In Pediatric Patients Aged 2 To 17 Years

Participants
Silvia Tsvetkova, Plovdiv, Bulgaria (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the pharmacokinetic (PK) profile, safety and efficacy of gadopiclenol, a new high-relaxivity gadolinium-based contrast agent, in children aged 2 to17 years.*Methods and Materials Children scheduled to undergo contrast-enhanced MRI of the Central Nervous System (CNS cohort) or other organs (Body cohort) were included into 3 age groups (12-17, 7-11 and 2-6 years). Gadopiclenol was administered at the dose of 0.05 mmol/kg. A sparse sampling approach was applied, four blood samples per child were collected (up to 8h post-injection). Population PK modeling was used for the analysis, including the CNS cohort and adult subjects from a previous study. Adverse events (AEs) were recorded, and efficacy was assessed for all children.*Results Eighty children were included (male: 51.3%): 60 in the CNS cohort and 20 in the Body cohort. The two-compartment model with linear elimination from the central compartment developed in adults was also suitable for children. PK parameters were very similar between adults and children. Terminal half-life was 1.82 h for adults and 1.77 to 1.29 h for age classes 12-17 to 2-6 years. Median clearance ranged from 0.08 L/h/kg in adults and 12-17 years to 0.12 L/h/kg in 2-6 years. Median central and peripheral volume of distribution were 0.11-0.12 L/kg and 0.06 L/kg, respectively, for both adults and children. Simulations of plasma concentrations showed minor differences and median area under the curve was 590 mg.h/L for adults and 403 to 582 mg.h/L for children. Two patients (2.5%) experienced AEs considered related to gadopiclenol (none serious): a mild QT interval prolongation and a moderate maculopapular rash. As for diagnostic efficacy in this population, there was no difference among the pediatric age groups.*Conclusions Gadopiclenol PK in children aged 2 to17 years seems similar to that observed in adults. Gadopiclenol had a good safety profile in these patients and positive efficacy results were obtained.*Clinical Relevance/Application There is no indication for dose adaptation based on age, and comparable plasma gadopiclenol concentrations are predicted to be achieved with body weight-based dosing in children aged 2 to17 years.

RESULTS

Eighty children were included (male: 51.3%): 60 in the CNS cohort and 20 in the Body cohort. The two-compartment model with linear elimination from the central compartment developed in adults was also suitable for children. PK parameters were very similar between adults and children. Terminal half-life was 1.82 h for adults and 1.77 to 1.29 h for age classes 12-17 to 2-6 years. Median clearance ranged from 0.08 L/h/kg in adults and 12-17 years to 0.12 L/h/kg in 2-6 years. Median central and peripheral volume of distribution were 0.11-0.12 L/kg and 0.06 L/kg, respectively, for both adults and children. Simulations of plasma concentrations showed minor differences and median area under the curve was 590 mg.h/L for adults and 403 to 582 mg.h/L for children. Two patients (2.5%) experienced AEs considered related to gadopiclenol (none serious): a mild QT interval prolongation and a moderate maculopapular rash. As for diagnostic efficacy in this population, there was no difference among the pediatric age groups.

CLINICAL RELEVANCE/APPLICATION

There is no indication for dose adaptation based on age, and comparable plasma gadopiclenol concentrations are predicted to be achieved with body weight-based dosing in children aged 2 to17 years.

SDP-PD-13 An Audit Of The Yield Of MRI In Adolescent Idiopathic Scoliosis

Participants
Ann Foran, MBBCh, Dublin, Ireland (*Presenter*) Nothing to Disclose

PURPOSE

Adolescent Idiopathic Scoliosis (AIS) is the most common type of scoliosis, with a prevalence of 1-5.4%. Currently, there are no established guidelines for the use of MRI in AIS. Some literature proposes that all children with AIS should have MRI with a yield of significant findings up to 15%, others recommend MRI for specific indications only such as an atypical curve or those with clinical neurological findings on examination. This study assessed the indications for MRI in our institution and the yield of the MRI with the view of comparing with the generally accepted indications to develop a protocol.*Methods and Materials This is a retrospective review of patients undergoing an initial MRI for AIS over a 4 year period to assess the yield of performing MRI. Patients aged 12-16, referred through the National Scoliosis referral pathway to our service were included. We also identified clinical findings or risk factors that may be associated with a positive finding and categorized patients by the King-Moe and the Lenke Classifications.*Results 158 patients were identified, 128 were female with a median age of 14. 43% was referred for adolescent idiopathic scoliosis, not otherwise specified. Overall 11% had MRI findings. Only 4% had findings which could potentially change management, all of whom were referred for specific indications that are considered generally acceptable.*Conclusions The yield of MRI for adolescent idiopathic scoliosis was low, prioritisation for MRI should be given to patients who have generally acceptable indications such as neurological findings, atypical or severe curve and pain.*Clinical Relevance/Application From the findings of this audit we plan on developing a protocol for doing MRI Spine on patients with presumed AIS, to ensure patient selection is appropriate as well as guiding prioritisation of these scans.

RESULTS

158 patients were identified, 128 were female with a median age of 14. 43% was referred for adolescent idiopathic scoliosis, not otherwise specified. Overall 11% had MRI findings. Only 4% had findings which could potentially change management, all of whom were referred for specific indications that are considered generally acceptable.

CLINICAL RELEVANCE/APPLICATION

From the findings of this audit we plan on developing a protocol for doing MRI Spine on patients with presumed AIS, to ensure patient selection is appropriate as well as guiding prioritisation of these scans.

SDP-PD-14 Intravoxel Incoherent Motion MRI In Pediatric Patients With Synovitis Of The Knee Joint: A Prospective Pilot Study

Participants
Britta Huch, MD, Ulm, Germany (*Presenter*) Nothing to Disclose

PURPOSE

We investigated diagnostic accuracy of diffusion-weighted (DWI) MRI with intravoxel incoherent motion (IVIM) imaging compared to contrast-enhanced MRI for detecting synovitis of the knee joint in a pediatric population. Further we compared quantitative measures of synovial diffusion and perfusion to a group of healthy volunteers.*Methods and Materials In this prospective study, 8 pediatric patients (6 girls, median age 13 years) with known or suspected synovitis underwent pre- and post-contrast 3.0 T MRI of the knee and additional DWI sequences between October 2016 and July 2019. For comparison we enrolled 5 healthy young adults (2 women, median age 27 years) with contrast-free MRI of both knees. Post-contrast T1w images and DWI images at b = 1000s/mm2 with apparent diffusion coefficient (ADC) maps of patients were separately rated by two independent and blinded readers with different levels of experience for the presence or absence and degree of synovitis along with the level of confidence. We measured signal intensity on DWI of synovium, joint effusion and muscle with regions of interests and calculated the IVIM-parameters tissue diffusion coefficient (D) and perfusion fraction (f) for patients and volunteers.*Results All patients showed at least some synovial contrast enhancement, 8 (80%) children were diagnosed with synovitis on ce-T1w, the diagnostic standard. Ratings by the 1st and 2nd reader on ce-T1w and DWI showed full agreement (kappa=1) in diagnosing synovitis and substantial agreement (k=0.655) for the degree of synovial enhancement. Interobserver agreement on DWI showed fair agreement (k=0.220) between both readers. Diagnostic confidence was lower on DWI. Mean D- and f-values of muscle was comparable between patients and volunteers. Effusion mean D was higher, mean f was lower, synovial mean D was lower, mean f higher in patients than in volunteers (all p<0.05).*Conclusions Diffusion-weighted MRI with IVIM imaging remains a promising, though reader-dependent alternative to intravenous contrast-enhanced imaging in pediatric patients to reliably diagnose, or rule out, synovitis of the knee joint. We detected significantly restricted synovial diffusion and increased synovial perfusion in patients compared to healthy volunteers.*Clinical Relevance/Application Diagnosing synovial inflammation by administration of gadolinium-based contrast agents is limited by invasiveness and possible side effects, especially in children and adolescents.

RESULTS

All patients showed at least some synovial contrast enhancement, 8 (80%) children were diagnosed with synovitis on ce-T1w, the diagnostic standard. Ratings by the 1st and 2nd reader on ce-T1w and DWI showed full agreement (kappa=1) in diagnosing synovitis and substantial agreement (k=0.655) for the degree of synovial enhancement. Interobserver agreement on DWI showed fair agreement (k=0.220) between both readers. Diagnostic confidence was lower on DWI. Mean D- and f-values of muscle was comparable between patients and volunteers. Effusion mean D was higher, mean f was lower, synovial mean D was lower, mean f

higher in patients than in volunteers (all p<0.05).

CLINICAL RELEVANCE/APPLICATION

Diagnosing synovial inflammation by administration of gadolinium-based contrast agents is limited by invasiveness and possible side effects, especially in children and adolescents.

SDP-PD-2   Can We Use Adult-Oriented Artificial Intelligence-based Lesion Detection Software On Pediatric Chest Radiographs?

Participants
Hyun-joo Shin, MD, Gyeonggi-do, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate whether artificial intelligence (AI)-based lesion detection software developed and approved for adults' chest radiographs could be used for pediatric chest radiographs.*Methods and Materials Pediatric patients who underwent chest radiographs in March 2021 were included in this retrospective study. Radiographs on lateral, decubitus views or infantogram were excluded for the analysis. AI-based lesion detection software on chest radiographs were applied and presence of nodule, consolidation, fibrosis, atelectasis, cardiomegaly, mediastinal widening, pleural effusion, pneumothorax, and pneumoperitoneum were analyzed. The results were presented with region-of-interest and its abnormality scores. A board-certified pediatric radiologist evaluated the presence of lesions in each chest radiograph. Considering the result by radiologist as a standard reference, diagnostic performance of the software was assessed.*Results Among total 777 chest radiographs, 691 radiographs had analyzed results using the software. Among them, 142 radiographs had positive result by software and 95 radiographs had positive result by radiologist. The sensitivity, specificity, positive predictive value (PPV), negative predictive values (NPV), and accuracy of the software were 82%, 88.55%, 51.4%, 97.1%, and 87.7%, respectively. When we exclude cardiomegaly and mediastinal widening results, the specificity, PPV and accuracy were significantly increased (94.7%, 69.5%, and 92.8%, respectively, all p<0.001), while sensitivity and NPV showed no statistical significant differences (80.2%, 96.9%, p>0.15).*Conclusions AI-based lesion detection software developed with adult chest radiographs could be used on pediatric chest radiographs with high accuracy. The specificity, PPV, and accuracy were improved when excluding mediastinal widening and cardiomegaly results on pediatric chest radiographs.*Clinical Relevance/Application Artificial intelligence (AI)-based lesion detection software was developed and approved for adults' chest radiographs for commercial use. However, there is no study assessed diagnostic performance of this software on pediatric population. This study evaluated accuracy of the software on pediatric chest radiographs and according to the specific lung lesions.

RESULTS

Among total 777 chest radiographs, 691 radiographs had analyzed results using the software. Among them, 142 radiographs had positive result by software and 95 radiographs had positive result by radiologist. The sensitivity, specificity, positive predictive value (PPV), negative predictive values (NPV), and accuracy of the software were 82%, 88.55%, 51.4%, 97.1%, and 87.7%, respectively. When we exclude cardiomegaly and mediastinal widening results, the specificity, PPV and accuracy were significantly increased (94.7%, 69.5%, and 92.8%, respectively, all p<0.001), while sensitivity and NPV showed no statistical significant differences (80.2%, 96.9%, p>0.15).

CLINICAL RELEVANCE/APPLICATION

Artificial intelligence (AI)-based lesion detection software was developed and approved for adults' chest radiographs for commercial use. However, there is no study assessed diagnostic performance of this software on pediatric population. This study evaluated accuracy of the software on pediatric chest radiographs and according to the specific lung lesions.

SDP-PD-3   Motor Function Is Associated With Structural Alterations Of Gray Matter In Children With Spastic Cerebral Palsy

Participants
Jie Hu, Zunyi, China (*Presenter*) Nothing to Disclose

PURPOSE

Periventricular leukomalacia (PVL) has been investigated as the major neuropathological substrate of the motor deficits of spastic cerebral palsy (SCP), but the relationship between gray matter changes and motor function in these children has been unknown. The aim of this study was to characterize the relationship between the structural alterations of gray matter and motor function in children with PVL and SCP.*Methods and Materials A total of 30 children with PVL and SCP, and 24 age-sex-paired health controls (HCs) were included in this study (Table1). 3D-MPRAGE T1WIs were performed in a 3T scanner (GE, Signa HDxt) with 8-channel head coil. All SCP children accepted Gross Motor Function Classification System (GMFCS) and Manual Ability Classification System (MACS) assessment. Voxel-based morphometry (VBM) was used to quantify differences in gray matter volume between SCP children and the control group using SPM12 (Statistical Parametric Mapping) and CAT12 (Computational Anatomy Toolbox). Significance threshold was set at P < 0.05, false discovery rate (FDR) corrected for multiple comparisons. The regions showing significant differences were defined as regions of interest (ROIs). We extracted the mean gray matter volume in each ROI and used partial correlation analysis (controlling for age) to examine the correlation between gray matter volume and motor function (GMFCS, MACS) in SCP group.*Results The gray matter volume of the bilateral Parietal lobe, Thalamus, Cerebellum, and right Frontal lobe, Putamen was significantly higher in the HC group as compared to the SCP group (Table 2 and Figure 1). Negative correlations were found between the gray matter volume of bilateral Thalamus, right Cerebelum_6, left Median cingulate, paracingulate gyri and GMFCS level in SCP group (r were -0.668, -0.397, -0.414, and P were <0.001, 0.033, 0.025, respectively). Similarly, there were also negative correlations between the gray matter volume of bilateral Thalamus, right Putamen and MACS level in the SCP group (r were -0.557, -0.630,and P were 0.002, <0.001, respectively) (Figure 2).*Conclusions Gray matter changes are observed and several of these changes are associated with motor impairment in children with PVL and SCP.*Clinical Relevance/Application Understanding of structure-function relationships will be helpful in the clinical context and also as a basis for investigation of causal pathways in motor impairment of these children.

RESULTS

The gray matter volume of the bilateral Parietal lobe, Thalamus, Cerebellum, and right Frontal lobe, Putamen was significantly higher in the HC group as compared to the SCP group (Table 2 and Figure 1). Negative correlations were found between the gray matter volume of bilateral Thalamus, right Cerebelum_6, left Median cingulate, paracingulate gyri and GMFCS level in SCP group (r were -0.668, -0.397, -0.414, and P were <0.001, 0.033, 0.025, respectively). Similarly, there were also negative correlations between the

gray matter volume of bilateral Thalamus, right Putamen and MACS level in the SCP group (r were -0.557, -0.630,and P were 0.002, <0.001, respectively) (Figure 2).

CLINICAL RELEVANCE/APPLICATION

Understanding of structure-function relationships will be helpful in the clinical context and also as a basis for investigation of causal pathways in motor impairment of these children.

SDP-PD-4   To Evaluate The Diagnostic Role Of 18 F FDG PET-CT In Children With Fever Of Unknown Origin Or Unexplained Signs Of Inflammation

Participants
Sikandar Shaikh, DMRD, Hyderabad, India (*Presenter*) Nothing to Disclose

PURPOSE

As we all know that Fever of unknown origin (FUO) and various unexplained signs of inflammation are challenging medical problems especially in children and most of them are predominantly caused by infections, malignancies or non infectious inflammatory diseases. The basic aim of this study was to assess the diagnostic value of (18)F-FDG PET and PET/CT in the diagnostic work-up in paediatric patients of the above mentioned conditions.*Methods and Materials This was the retrospective study, comprising of the 96 FDG PET and 60 PET/CT scans from 138 children (median age 8.1 years, range 0.2-18.1 years, 36 male, 33 female) were analysed. The whole body study was done from the vertex of skull to the feet in most of the pediatric patients after injecting the FDG contrast.The diagnostic efficacy of PET in evaluation of the paediatric patients presenting with Fever of unknown origin (88 whole body scans) or unexplained various signs of inflammation without fever (66 scans) were analysed*Results Based on the SUV max values of various lesions in various parts of the body the diagnosis in paediatric patients with FUO or unexplained signs of inflammation could be established in 64 patients (54%). Of all scans, 126 (82%) were abnormal, and of the total number of 144 PET and PET/CT scans 70 (45%) were clinically helpful. In patients with a final diagnosis, after the PET-CT scans were found to have contributed to the diagnosis in 73%. Laboratory, demographic or clinical parameters of the children did not predict the usefulness of FDG PET scans*Conclusions Thus FDG PET and PET/CT are valuable tools for the evaluation of children with FUO and unexplained signs of inflammation. By evaluation of the above mentioned criterias it is of more useful at a times . Thus the combination of PET with CT is significantly superior and can evaluate site of inflammation more accurately.*Clinical Relevance/Application Thus FDG PET-CT is the important imaging modality for the evaluation of the FUO and inflammations

RESULTS

Based on the SUV max values of various lesions in various parts of the body the diagnosis in paediatric patients with FUO or unexplained signs of inflammation could be established in 64 patients (54%). Of all scans, 126 (82%) were abnormal, and of the total number of 144 PET and PET/CT scans 70 (45%) were clinically helpful. In patients with a final diagnosis, after the PET-CT scans were found to have contributed to the diagnosis in 73%. Laboratory, demographic or clinical parameters of the children did not predict the usefulness of FDG PET scans

CLINICAL RELEVANCE/APPLICATION

Thus FDG PET-CT is the important imaging modality for the evaluation of the FUO and inflammations

SDP-PD-5   Post-lymphangiographic CT (plct) In Protein-losing Enteropathy (PLE): A Retrospective Study

Participants
Xingpeng Li, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the imaging features and clinical value of post lymphangiographic CT (PLCT) in diagnosis and differential diagnosis in protein-losing enteropathy (PLE).*Methods and Materials Forty-two patients diagnosed as PLE were recruited in this retrospective study from Jan of 2011 to June of 2017, including 42 primary intestinal lymphangiectasia (PIL), and 15 other kinds of PLE. All patients underwent PLCT, endoscopy and pathological examinations. All the imaging data were blinded reviewed by two radiologists respectively, with the imaging features of intestinal wall thickening, dilation of intestinal lumen, edematous lesions, abnormal distribution of contrast agents, reflux, lymph nodes and fistula. Statistical analyses were performed with P < 0.05.*Results Compared with other kinds of PLE, patients with PIL demonstrated lower onset age (14.7 ± 10.6 Vs. 38.8 ± 10.7,P<0.01). For imaging features, the proportion of abnormal distribution of contrast media in intestinal wall and mesentery and lymph reflux are higher in PIL than other PLE. While no statistical difference was found in intestinal wall dilatation, edematous lesions, abnormal distribution of contrast media in other abdominal cavity, fistula and lymph node (all P>0.05).*Conclusions PLCT demonstrates capability in detection of location, distribution and range of abnormal lymphatics, which is useful for differential diagnosis and therapeutic adoptions for PLE.*Clinical Relevance/Application It is necessary to evaluate the systematic lymphatic circulation abnormality for with PLCT in patients with PLE, which is very important for therapeutic options

RESULTS

Compared with other kinds of PLE, patients with PIL demonstrated lower onset age (14.7 ± 10.6 Vs. 38.8 ± 10.7,P<0.01). For imaging features, the proportion of abnormal distribution of contrast media in intestinal wall and mesentery and lymph reflux are higher in PIL than other PLE. While no statistical difference was found in intestinal wall dilatation, edematous lesions, abnormal distribution of contrast media in other abdominal cavity, fistula and lymph node (all P>0.05).

CLINICAL RELEVANCE/APPLICATION

It is necessary to evaluate the systematic lymphatic circulation abnormality for with PLCT in patients with PLE, which is very important for therapeutic options

SDP-PD-6   Pleuroparenchymal Fibroelastosis-like Lesions After Hematopoietic Cell Transplantation In Children: A Propensity Score-matched Analysis

Participants
Tae Yeon Jeon, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the incidence of, risk factors for, and clinical outcomes of PPFE-like lesions in pediatric HCT recipients.*Methods and Materials In this single-center, retrospective, case-control study, 738 consecutive patients who underwent chest CT 3 months after HCT between January 2000 and June 2018 were reviewed. We identified patients who fulfilled radiologic criteria of PPFE-like lesions and assessed clinical characteristics and radiologic findings of PPFE-like lesions in these patients. Propensity score matching was performed using 4 covariates (age, sex, HCT type, and primary disease). The risk factors and clinical outcomes of PPFE-like lesions were analyzed using Fine and Gray regression model and stratified log rank test in the matched groups.*Results PPFE-like lesions were identified in 4% (31/738) pediatric HCT recipients with a median time of 3 years after HCT, and it occurred following allogeneic (5%, 15/317), autologous (4%, 15/379), or both (2%, 1/42). Matching yielded 30 cases in the PPFE group and 130 in control. The late-onset noninfectious pulmonary complications (LONIPCs) and respiratory infection 3 months after HCT were more frequent in the PPFE group (P<0.05). Multivariable analysis showed a significantly higher risk of PPFE-like lesions in HCT recipients who had respiratory infection 3 months after HCT (hazard ratio=10.8, P<0.001). PPFE group showed poorer overall survival with 73% of mortality rate and 6.8 years of median survival time than that of the control group (P<0.001).*Conclusions PPFE-like lesions can represent LONIPCs after HCT with high mortality. HCT recipients who had respiratory infection after HCT may have an increased risk of PPFE-like lesions.*Clinical Relevance/Application Early recognition of the clinical and radiologic characteristic of PPFE-like lesions in HCT recipients is pivotal in establishing a presumptive diagnosis and referral for lung transplantation.

RESULTS

PPFE-like lesions were identified in 4% (31/738) pediatric HCT recipients with a median time of 3 years after HCT, and it occurred following allogeneic (5%, 15/317), autologous (4%, 15/379), or both (2%, 1/42). Matching yielded 30 cases in the PPFE group and 130 in control. The late-onset noninfectious pulmonary complications (LONIPCs) and respiratory infection 3 months after HCT were more frequent in the PPFE group (P<0.05). Multivariable analysis showed a significantly higher risk of PPFE-like lesions in HCT recipients who had respiratory infection 3 months after HCT (hazard ratio=10.8, P<0.001). PPFE group showed poorer overall survival with 73% of mortality rate and 6.8 years of median survival time than that of the control group (P<0.001).

CLINICAL RELEVANCE/APPLICATION

Early recognition of the clinical and radiologic characteristic of PPFE-like lesions in HCT recipients is pivotal in establishing a presumptive diagnosis and referral for lung transplantation.

SDP-PD-7   Could We Better Detect Pars Interarticularis Defects In Teens Before Completion?

Participants
Riti Kanesa-Thasan, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

To identify predictive factors of osseous stress response in the lumbar pars interarticularis in pediatric patients with low back pain.*Methods and Materials A PACS database was retrospectively searched for noncontrast lumbar spine MRIs from performed between 2006-2021 on patients 10 to 18 years old. Patients with evidence of unrelated trauma including vertebral body fractures were excluded. MRIs were reviewed to identify subjects with bone marrow edema at the pars interarticularis or pedicle, with or without incomplete fracture. Pediatric patients undergoing noncontrast lumbar spine for low back pain without pars osseous stress response were randomly selected as controls. Demographics, transitional lumbosacral anatomy, scoliosis, and disc pathology at MRI were recorded. BMI and sports participation was recorded for those with available electronic medical records. Radiology report addendums and follow up imaging findings were noted. Mann-Whiney U, Chi-square, and Fisher's exact tests were used for comparisons.*Results Mean subject group age 15.3±1.6 years without significant difference compared to controls (p=.858). Subjects had significantly lower incidence of disc bulges and scoliosis compared to controls (39% vs 60%, p=.002; and 6.4% vs 16%, p=.026), with similar incidence of transitional lumbosacral anatomy (12% vs 9%, p=0.533). Subjects were more likely than controls to be male (68% vs 40%, p=001), play sports (71% vs 41%, p=0.001), and have a lower BMI (21.7 vs 23.9, p=0.021). 71% (68/96) of athletes were involved in contact sports. 90% (35/39) of female subjects participated in sports, and 23% (8/35) of female athletes were gymnasts. In 5.6% (7/126) of subjects, pars edema/stress response was not mentioned in the original radiology report, which was later addended. On follow up imaging for 14 patients (1-92 months apart, average 20 months), 29% resolved, 50% improved, 14% were stable, and 7% completed pars fracture. New areas of osseous stress were noted on follow up in 21% (3/14).*Conclusions Osseous stress response at the pars interarticularis can be a source of pain leading to lumbar spine MRI in young patients, and should be reported. Patients with osseous stress response in the lumbar pars interarticularis are more likely to be athletes, particularly in contact sports and in gymnasts, and have a lower BMI. 5% of pars stress lesions were missed on initial imaging review.*Clinical Relevance/Application Osseous stress response at the pars interarticularis should be included in the search pattern for young, athletic patients undergoing MRI of the lumbar spine for back pain, given the opportunity for patients to heal from these lesions when detected.

RESULTS

Mean subject group age 15.3±1.6 years without significant difference compared to controls (p=.858). Subjects had significantly lower incidence of disc bulges and scoliosis compared to controls (39% vs 60%, p=.002; and 6.4% vs 16%, p=.026), with similar incidence of transitional lumbosacral anatomy (12% vs 9%, p=0.533). Subjects were more likely than controls to be male (68% vs 40%, p=001), play sports (71% vs 41%, p=0.001), and have a lower BMI (21.7 vs 23.9, p=0.021). 71% (68/96) of athletes were involved in contact sports. 90% (35/39) of female subjects participated in sports, and 23% (8/35) of female athletes were gymnasts. In 5.6% (7/126) of subjects, pars edema/stress response was not mentioned in the original radiology report, which was later addended. On follow up imaging for 14 patients (1-92 months apart, average 20 months), 29% resolved, 50% improved, 14% were stable, and 7% completed pars fracture. New areas of osseous stress were noted on follow up in 21% (3/14).

CLINICAL RELEVANCE/APPLICATION

Osseous stress response at the pars interarticularis should be included in the search pattern for young, athletic patients undergoing MRI of the lumbar spine for back pain, given the opportunity for patients to heal from these lesions when detected.

SDP-PD-8   Comparison Of CTA Image Quality Between Adaptive Statistical Repeated Reconstruction-V (ASIR-V) And Deep Learning Reconstruction "TrueFidelity" (TF) In Children With Congenital Heart Disease (CHD)

Participants
Kun Hee Kim, MD, Yangsan, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To determine the best CT angiography image set among "Adapted Statistical Repeated Reconstruction-V" (ASIR-V) and Deep Learning Reconstruction "TrueFidelity" (TF) in children with congenital heart disease (CHD)*Methods and Materials Fifty children (3.1±3.11 months; 28 men) with CHD who underwent CTA were enrolled between June and September 2020. Images were reconstructed by two ASIR-V (blending factor of 80% (AV-80) and 100% (AV-100)) and three TF (low-, medium-, and high-strength-level (TF-L-M-H) settings). For quantitative analyses, three objective image qualities (attenuation, noise, signal to noise ratio (SNR)) were measured in the great vessels and heart chambers. The contrast to noise ratio (CNR) was also evaluated between left ventricle and the myocardial wall. For qualitative analyses, the degree of quantum mottle and blurring at the upper level to the first branch of the main pulmonary artery were assessed by independent two radiologists.*Results When the level or strength of the ASIR-V blending factor and TF is higher, the noise is lower and the SNR is higher. The image noise and SNR of TF-H was significantly lower and higher than that of AV-100 except right atrium (p<0.01). For CNR comparison between AV 100 and TF-H, TF-H was significantly better than AV 100 (p<0.01). In addition, when subjectively assessing the degree of quantum mottle and blurring, TF-H scored the highest among all the image sets examined. (p<0.01).*Conclusions TF-H is superior to AV-100 when comparing objective and subjective image quality. Consequently, TF-H was the best image set for CTA in children with CHD.*Clinical Relevance/Application Because CT angiography was performed using a very low tube voltage of 70kVP for pediatric patients under 1 year of age, increase in noise is inevitably expected. So our aim is to determine which reconstruction method will maintain image attenuation or image texture while reducing noise.

RESULTS

When the level or strength of the ASIR-V blending factor and TF is higher, the noise is lower and the SNR is higher. The image noise and SNR of TF-H was significantly lower and higher than that of AV-100 except right atrium (p<0.01). For CNR comparison between AV 100 and TF-H, TF-H was significantly better than AV 100 (p<0.01). In addition, when subjectively assessing the degree of quantum mottle and blurring, TF-H scored the highest among all the image sets examined. (p<0.01).

CLINICAL RELEVANCE/APPLICATION

Because CT angiography was performed using a very low tube voltage of 70kVP for pediatric patients under 1 year of age, increase in noise is inevitably expected. So our aim is to determine which reconstruction method will maintain image attenuation or image texture while reducing noise.

SDP-PD-9   Assessment Of Mediastinal Shift Angle In Congenital Pulmonary Airway Malformation; A New Fetal MRI Indicator Of Congenital Lung Disease

Participants
Jun Tsukamoto, Kitakyushu, Japan (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this research was to establish the normal range of the mediastinal shift angle (MSA) on fetal MRI in a control group, to evaluate the MSA of fetuses with congenital pulmonary airway malformation (CPAM), to compare the MSA with an established index, and to assess how MR image characteristics and the MSA vary.*Methods and Materials To establish normal range, measurement of bilateral MSA was obtained in 125 fetuses without any lung abnormality (control group). Subsequently, measurement of the MSA was carried out in 32 fetuses who had a pathological diagnosis of CPAM. We compared MSA between CPAM and control group for both hemithoraces with statistical analysis. Also, comparison between MSA and the CPAM volume ratio (CVR) as an established index was carried out. The relationship between MSA and image characteristics whether typically cystic or atypically solid was evaluated. A receiver-operating characteristics (ROC) curve was constructed to assess the predictive value of MSA on the time to surgery.*Results In the right hemithorax, the mean value for a normal MSA was 19.1° (range 10.9-34.5°) and was 26.2° (13.4-38.4°) in the left hemithorax. The MSA of left side CPAM (mean 38.7°, range 17.4-61.4°) was larger than right side CPAM (mean 35.9°, range 25.2-51°). Using the Student t-test, statistical analysis revealed a significant difference of MSA between CPAM and control group in both hemithoraces(P value <.0001). There was a positive statistical correlation between the MSA and the CVR determined by ultrasound (right: r = 0.76, left: r = 0.61) and MRI (right: r = 0.81, left: r = 0.61). The MSA of patients with atypical solid type CPAM (n=4) were larger than in other patients. Based on the point estimate of ROC-Area Under the Curve (AUC), MSA showed higher discriminatory ability. in terms of whether the time of surgery was within 24 hours or 1 month after birth compared with CVR of MRI .*Conclusions The MSA might be a new, easy and useful tool for evaluating the severity of CPAM during the fetal period. It correlates well with the CVR and may predict urgent surgical treatment.*Clinical Relevance/Application Mediastinal shift angle (MSA) is a new and simple indicator for CPAM patients, it may replace CPAM volume ratio (CVR) to predict time to surgery.

RESULTS

In the right hemithorax, the mean value for a normal MSA was 19.1° (range 10.9-34.5°) and was 26.2° (13.4-38.4°) in the left hemithorax. The MSA of left side CPAM (mean 38.7°, range 17.4-61.4°) was larger than right side CPAM (mean 35.9°, range 25.2-51°). Using the Student t-test, statistical analysis revealed a significant difference of MSA between CPAM and control group in both hemithoraces(P value <.0001). There was a positive statistical correlation between the MSA and the CVR determined by ultrasound (right: r = 0.76, left: r = 0.61) and MRI (right: r = 0.81, left: r = 0.61). The MSA of patients with atypical solid type CPAM (n=4) were larger than in other patients. Based on the point estimate of ROC-Area Under the Curve (AUC), MSA showed higher discriminatory ability. in terms of whether the time of surgery was within 24 hours or 1 month after birth compared with CVR of MRI .

CLINICAL RELEVANCE/APPLICATION

Mediastinal shift angle (MSA) is a new and simple indicator for CPAM patients, it may replace CPAM volume ratio (CVR) to predict time to surgery.

IN03-C2   **Tracking Results And Utilization Of Artificial Intelligence (tru-AI) In Radiology: Early-stage COVID-19 Pandemic Observations On Intracranial Hemorrhage**

Participants
Axel Wismueller, MD,PhD, Pittsford, New York (*Presenter*) Research Grant, Aidoc Medical Ltd;Advisory Board Member, Aidoc Medical Ltd

PURPOSE

To introduce a method for tracking results and utilization of Artificial Intelligence (tru-AI) in radiology. By tracking both large-scale utilization and AI results data, the tru-AI approach aims at calculating surrogates for important disease-related observational quantities over time, such as the prevalence of intracranial hemorrhage during the early COVID-19 pandemic outbreak.*Methods and Materials To quantitatively investigate the clinical applicability of the tru-AI approach, we tracked service requests and AI-based image analysis results for automatically identifying intracranial hemorrhage (ICH) on non-contrast head CT using a commercial AI solution (Aidoc, Tel Aviv, Israel). This software is typically used for AI-based prioritization of radiologists' reading lists for reducing turnaround times in patients with emergent clinical findings, such as ICH. We analyzed data of N=9,421 emergency-setting non-contrast head CT studies at a major US healthcare system acquired from November 1, 2019 through June 2, 2020, and compared two observation periods, namely (i) a pre-pandemic epoch from November 1, 2019 through February 29, 2020, and (ii) a period during the early COVID-19 pandemic outbreak, April 1-30, 2020. A chi-square test of independence was performed to examine the relation between AI-based ICH detection and observation during one of the two tracking periods defined above, namely prior to and after the COVID-19 pandemic outbreak.*Results Although daily CT scan counts were significantly lower during (40.1±7.9) than before (44.4±7.6) the early phase of the COVID-19 outbreak, we found that ICH was more likely to be observed by AI during than before the COVID-19 outbreak (p<0.05), with approximately one daily ICH+ case more than statistically expected.*Conclusions Our results suggest an increased prevalence of ICH on head CT studies in the scanned patient population during the pandemic outbreak. We conclude that by tracking both large-scale utilization and AI image analysis results data, the tru-AI approach can help identify temporal changes in observed disease prevalence under unusual conditions, such as for ICH during the early phase of the COVID-19 outbreak.*Clinical Relevance/Application Automated tracking of both AI image analysis and service utilization data can provide useful contributions to monitoring the prevalence of clinically relevant disease entities, such as intracranial hemorrhage observed during the early COVID-19 pandemic outbreak.

RESULTS

Although daily CT scan counts were significantly lower during (40.1±7.9) than before (44.4±7.6) the early phase of the COVID-19 outbreak, we found that ICH was more likely to be observed by AI during than before the COVID-19 outbreak (p<0.05), with approximately one daily ICH+ case more than statistically expected.

CLINICAL RELEVANCE/APPLICATION

Automated tracking of both AI image analysis and service utilization data can provide useful contributions to monitoring the prevalence of clinically relevant disease entities, such as intracranial hemorrhage observed during the early COVID-19 pandemic outbreak.

PH03-D10   Deep Learning-based Effective Atomic Number Conversion From Single Energy Computed Tomography

Participants
Jimin Lee, Ulsan, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate a Deep Learning-based effective atomic number conversion technique from single energy computed tomography (CT) for accurate dose calculation in radiation therapy*Methods and Materials The whole dataset consisted of 120 kVp CT images and effective atomic number (Zeff) maps of 66 patients acquired by dual-layer dual energy CT scanner (IQon Spectral CT, Philips, Best, The Netherlands) from 2019 to 2020. Among the patients, 19 patients underwent chest examinations, 23 patients underwent abdomen-pelvic examinations, and 24 patients underwent head and brain CT. The dataset was randomly divided into 56 patients' data for training stage and the other 10 patients' data for test stage.To develop a Deep Learning-based Zeff conversion technique, a convolutional neural network (CNN) with encoder-decoder structure was implemented. In the training stage, the CNN model was trained to translate the 120 kVp CT images (input) to Zeff maps (target). The model was trained with the summation of mean squared error and structural similarity losses for parameter updating. In the test stage, to evaluate the conversion performance of the trained CNN, pearson correlation coefficient (PCC), structural similarity (SSIM), and peak signal-to-noise ratio (PSNR) between the outputs from the model and the targets were calculated.*Results The trained CNN model showed superior Zeff conversion performance for the test dataset. Average PCC, SSIM, and PSNR scores from the test data were 0.959, 0.926, and 28.638, respectively. Referring to the difference maps between the targets and outputs in the figure, discrepancy occurred in some areas outside the body. However, it doesn't matter since only the area inside the body is used for radiation therapy planning. These results can assist to differentiate benign and malignant lesions and improve the diagnostic performance. Furthermore, the results can be used for further accurate dose calculation in radiation therapy.*Conclusions The Deep Learning-based Zeff conversion technique from single energy CT has been successfully developed and shown superior conversion performance.*Clinical Relevance/Application The proposed Zeff conversion technique from single energy CT can be used for further accurate dose calculation in radiation therapy planning.

RESULTS

The trained CNN model showed superior Zeff conversion performance for the test dataset. Average PCC, SSIM, and PSNR scores from the test data were 0.959, 0.926, and 28.638, respectively. Referring to the difference maps between the targets and outputs in the figure, discrepancy occurred in some areas outside the body. However, it doesn't matter since only the area inside the body is used for radiation therapy planning. These results can assist to differentiate benign and malignant lesions and improve the diagnostic performance. Furthermore, the results can be used for further accurate dose calculation in radiation therapy.

CLINICAL RELEVANCE/APPLICATION

The proposed Zeff conversion technique from single energy CT can be used for further accurate dose calculation in radiation therapy planning.

PH03-D3   MRI For Evaluating Renal Metabolism In A Rat Model Of Hypertension

Participants
El-Sayed Ibrahim, PhD, Milwaukee, Wisconsin (*Presenter*) Nothing to Disclose

PURPOSE

Enhanced sensitivity of blood pressure to salt diet in animal models is associated with abnormal mitochondrial function and substrate utilization in the kidney. In this study, we used blood oxygenation level dependent (BOLD) MRI to investigate renal metabolism in a rat model of salt-sensitive hypertension.*Methods and Materials Nine rats were imaged on a 9.4T small-animal Bruker scanner using T2*-based BOLD MRI. Three normal Sprague Dawley (SD) rats were fed a normal 1% NaCl diet and compared to three 12-weeks old Dahl salt-sensitive (SS) rats and three salt-resistant SS.BN13 consomic rats of the same age (SS rats with chromosome 13 inherited from Brown Norway rats) maintained on a 0.4% NaCl diet since weaning. The effects of a high salt diet (4% NaCl) on tissue oxygenation was studied by sequentially determining changes in response to switching to the high salt at days 7 and 21 post initiation of the high-salt diet.*Results The BOLD images showed gradual decreases in the oxygenation level between the cortex and outer medulla in the SD rats when fed the high salt diet. The SS rats exhibited heterogenous regions of poorly oxygenation of the kidney (deoxygenated hemoglobin). The results showed that the kidney of the SS rats became increasingly deoxygenated as seen by increasing heterogeneity in the BOLD maps, first with greater regions of decreased T2* at day 7 leading to even greater heterogeneity by day 21 in both the renal cortex and medulla, indicating a chronically hypoxic kidney. In contrast, the average T2* values in the kidney of the SD and SS.BN13 rats were significantly higher compared to SS rats and maintained relatively unchanged at the different imaging timepoints in response to the high salt diet.*Conclusions MRI BOLD imaging provides a method to non-invasively and sequentially determine the progressive effects of a high salt diet on tissue oxygenation in rats with a strong potential for making similar determinations in hypertensive human subjects before and following antihypertensive therapy.*Clinical Relevance/Application The proposed approaches provide opportunities to gain greater understanding of metabolic

stress and oxygenation of salt-sensitive and salt-resistant hypertensive human subjects pre and post therapy.

RESULTS

The BOLD images showed gradual decreases in the oxygenation level between the cortex and outer medulla in the SD rats when fed the high salt diet. The SS rats exhibited heterogenous regions of poorly oxygenation of the kidney (deoxygenated hemoglobin). The results showed that the kidney of the SS rats became increasingly deoxygenated as seen by increasing heterogeneity in the BOLD maps, first with greater regions of decreased T2* at day 7 leading to even greater heterogeneity by day 21 in both the renal cortex and medulla, indicating a chronically hypoxic kidney. In contrast, the average T2* values in the kidney of the SD and SS.BN13 rats were significantly higher compared to SS rats and maintained relatively unchanged at the different imaging timepoints in response to the high salt diet.

CLINICAL RELEVANCE/APPLICATION

The proposed approaches provide opportunities to gain greater understanding of metabolic stress and oxygenation of salt-sensitive and salt-resistant hypertensive human subjects pre and post therapy.

PH03-D6 Proposed Approach For Assessing The Performance Of Ultrasound Imaging Systems: Statistics-based Analyses Of Simulated Random Spherical Void Phantoms

Participants
Mark Holland, PHD, Indianapolis, Indiana (*Presenter*) Nothing to Disclose

PURPOSE

To explore the potential of using statistics-based, quantitative measurements of images obtained from random spherical void (RSV) phantoms as an approach for assessing the performance of ultrasound imaging systems.*Methods and Materials Ten computer-simulated RSV phantoms with a RSV volume fraction of 0.15 were generated. Simulated ultrasound images were produced and degradation of imaging system performance was modeled by averaging 1 to 9 neighboring planes to represent increasing elevation plane thicknesses. Quantification of the performance of the imaging system was determined by measuring the: 1) mean number of observed circle cross sections per frame; 2) mean fractional area of circle cross-sections per frame; and 3) agreement of observed circle cross section radii histograms with the theoretical distribution (Chi-square statistic).*Results For 150 image plane analyses, the degraded RSV phantom images show decreasing: mean number of circle cross sections detected per frame (31.5±0.3, 28.4±0.3, 28.2±0.3, 26.3±0.3 and 25.3±0.3); mean fractional area of circle cross-section per frame (0.157±0.002, 0.133±0.001, 0.133±0.001, 0.111±0.001 and 0.108±0.001); and agreement with theoretical radii histogram distribution (chi-square: 0.070±0.004, 0.140±0.005, 0.149±0.007, 0.379±0.011 and 0.518±0.010) for 1, 3, 5, 7 and 9 neighboring plane averages, respectively.*Conclusions This simulation study suggests that statistics-based analyses of images from RSV phantoms may represent an approach for providing quantitative assessment of ultrasound system performance in a quantitative, reproducible fashion.*Clinical Relevance/Application Quantitative, statistics-based analyses of images from random spherical void phantoms may provide a useful approach for assessing and predicting the clinical performance of ultrasound imaging systems.

RESULTS

For 150 image plane analyses, the degraded RSV phantom images show decreasing: mean number of circle cross sections detected per frame (31.5±0.3, 28.4±0.3, 28.2±0.3, 26.3±0.3 and 25.3±0.3); mean fractional area of circle cross-section per frame (0.157±0.002, 0.133±0.001, 0.133±0.001, 0.111±0.001 and 0.108±0.001); and agreement with theoretical radii histogram distribution (chi-square: 0.070±0.004, 0.140±0.005, 0.149±0.007, 0.379±0.011 and 0.518±0.010) for 1, 3, 5, 7 and 9 neighboring plane averages, respectively.

CLINICAL RELEVANCE/APPLICATION

Quantitative, statistics-based analyses of images from random spherical void phantoms may provide a useful approach for assessing and predicting the clinical performance of ultrasound imaging systems.

PH03-D7 Study On Hepatic Alveolar Echinococcosis In Mice Based On 7T Small Animal MRI

Participants
Hai Hua Bao, Xining, China (*Presenter*) Nothing to Disclose

PURPOSE

Hepatic alveolar echinococcosis(HAE) slowly infiltrates and grows outwards by means of exophytic spores. The growth characteristics are complex and diverse. In the study, 7T small animal MR was used to analyze and study the MRI characteristics of secondary mouse hepatic alveolar echinococcus animal models.*Methods and Materials The secondary mouse HAE animal model was prepared by intraperitoneal injection of HAE tissue suspension, and 10 mice that had been successfully inoculated with HAE were selected through ultrasound screening. the mice were examined by 7T small animal MR at 15 weeks after inoculation, and the performance of the mouse HAE lesions on T1WI, T2WI, and DWI was analyzed.*Results (1) 10 mice were inoculated with the suspension of HAE tissue for 15 weeks. 10 mice were successfully inoculated with HAE tissue suspension by ultrasound screening, with a success rate of 100%.(2) There were a total of 63 lesions in the liver of 10 mouse HAE models, including 47.62% (30/63) lesions in the right lobe, 25.40% (16/63) lesions in the left lobe, 1.58% (1/63) lesions in the left and right lobe, and 25.40% (16/63) lesions in the hilar. No obvious portal vein invasion was observed in 84.13% (53/63) cases.Compression and narrowing of portal vein and its branches were observed in 15.87% (10/63) of the lesions. The main portal vein and left branch were invaded in 80.00% (8/10) of the lesions, and the main portal vein and right branch were invaded in 20.00% (2/10) of the lesions. In the liver, 76.20% (48/63) of the lesions were mainly cystic, 23.80% (15/63) of the lesions were mainly cystic. (3) HAE lesions showed low signal intensity on T1WI and varied in size. the lesion showed multilocular cystic hyperintensity On T2WI. On DWI , the lesion showed hyperintensity with perifocal low-signal shadow surrounding. Some lesions were complex in composition. Small vesicle structures of different sizes were observed with solid components. The solid components showed isosignal on T1WI , and isosignal or slightly lower on T2WI .On DWI , there were isosignal and low signal. (4) In the liver, the lesions were mainly distributed along the main portal vein and the left and right branches. Some lesions grew around the portal vein, showing thickening and compression of the main portal vein and branches. And some lesions were not clearly separated from the lesions.(5) In the abdominal cavity, the lesions were diffusely distributed with different sizes. The MR manifestations were similar to those of liver lesions.*Conclusions HAE lesions in mice showed characteristic manifestations on 7T small animal MR.*Clinical Relevance/Application The basic research based on the model of HAE in small animals under 7T MR can well transfer the current basic research results to clinical practice.

RESULTS

(1) 10 mice were inoculated with the suspension of HAE tissue for 15 weeks. 10 mice were successfully inoculated with HAE tissue suspension by ultrasound screening, with a success rate of 100%.(2) There were a total of 63 lesions in the liver of 10 mouse HAE models, including 47.62% (30/63) lesions in the right lobe, 25.40% (16/63) lesions in the left lobe, 1.58% (1/63) lesions in the left and right lobe, and 25.40% (16/63) lesions in the hilar. No obvious portal vein invasion was observed in 84.13% (53/63) cases.Compression and narrowing of portal vein and its branches were observed in 15.87% (10/63) of the lesions. The main portal vein and left branch were invaded in 80.00% (8/10) of the lesions, and the main portal vein and right branch were invaded in 20.00% (2/10) of the lesions. CLINICAL RELEVANCE/APPLICATION

The basic research based on the model of HAE in small animals under 7T MR can well transfer the current basic research results to clinical practice.

PH03-D8 **Performance Testing And Capability Of Carbon Nanotube Based X-ray Tubes**

Participants
Brian Gonzales, PhD, SeaTac, Washington (*Presenter*) Scientist, Micro-X Ltd

PURPOSE

Cold cathode electronically controlled x-ray tubes are emerging as a new and potentially disruptive x-ray technology that enables lighter and most cost-effective x-ray imaging along with new fixed gantry tomography imaging. Historically, this technology has been limited by low electron current and short lifetime performance that prevented the application of the technology into medical imaging. We have developed a unique approach to delivering a stable long-life high current carbon nanotube (CNT) based x-ray tube. In this presentation we present our unique approach along with test data demonstrating current and life performance of the CNT electron emitter.*Methods and Materials We will present an overview of the unique physics of our CNT x-ray tube, focused on our unique approach to creating a stable long life high current electron emitter. Our testing consisted of testing different sized CNT emitters, all created using the same method, to demonstrate size versus peak current; testing emitters under varying pulse lengths and currents to demonstrate are variety of electric field stress on the CNT; and accelerated life testing to show long term performance of CNT electron emitters. The tests CNT emitters were tested both individually in a vacuum chamber and integrated into an x-ray tube.*Results We have demonstrated a variety of large area CNT emitter sizes ranging from 1mm2 to 100mm2. We show that a peak stable current of the emitter is partially dependent on the size of the emitter, but even our very small emitters achieve at least 100mA of current. We show that the lifetime stability of our CNT emitter depends on the combination of the current and size of the emitter, the larger emitters deliver stable long-life up to at least 200mA. We demonstrate that when an emitter begins to degrade, due to high current over stressing, our emitter will recover and re-stabilize when current is lower.*Conclusions Our unique CNT emitter provides a stable long life electron source, providing up to 200mA of current that can be used for 5+ years in an x-ray tube. We show that our unique approach allows for an adaptable emitter design for a variety of applications.*Clinical Relevance/Application Our unique CNT x-ray tube and CNT electron emitter are already deployed in two FDA certified medical devices, the Carestream DRX Revolution Nano and the Micro-X Rover. Additionally, the flexibility, reliability, and performance demonstrated in this data provides the bases for future x-ray tube designs that could increase the application of the technology to lightweight deployable fixed gantry tomosynthesis and CT applications, bringing three-dimensional imaging to patients bedside and outside the hospital.

RESULTS

We have demonstrated a variety of large area CNT emitter sizes ranging from 1mm2 to 100mm2. We show that a peak stable current of the emitter is partially dependent on the size of the emitter, but even our very small emitters achieve at least 100mA of current. We show that the lifetime stability of our CNT emitter depends on the combination of the current and size of the emitter, the larger emitters deliver stable long-life up to at least 200mA. We demonstrate that when an emitter begins to degrade, due to high current over stressing, our emitter will recover and re-stabilize when current is lower.

CLINICAL RELEVANCE/APPLICATION

Our unique CNT x-ray tube and CNT electron emitter are already deployed in two FDA certified medical devices, the Carestream DRX Revolution Nano and the Micro-X Rover. Additionally, the flexibility, reliability, and performance demonstrated in this data provides the bases for future x-ray tube designs that could increase the application of the technology to lightweight deployable fixed gantry tomosynthesis and CT applications, bringing three-dimensional imaging to patients bedside and outside the hospital.

PH03-D9 **Comparison Of Digital Variance Angiography And Digital Subtraction Angiography In Selective Lower Limb Interventions**

Participants
Istvan Gog, Budapest, Hungary (*Presenter*) Researcher, Kinepict Health Ltd

PURPOSE

The evaluation of potential benefits of Digital Variance Angiography (DVA) in selective lower limb angiography and to compare the performance of the conventional DVA1 versus the recently developed DVA2 algorithm.*Methods and Materials 112 iodine contrast media (ICM) angiograms from 15 peripheral artery disease (PAD) patients and 42 CO2 angiograms from 13 PAD patients were collected from November 2019 to May 2020. DVA files were retrospectively generated from the same source files as Digital Subtraction Angiography (DSA) images. The contrast-to-noise ratio (CNR) and image quality (IQ) of DSA, DVA1 and DVA2 images were compared. The visual evaluation was performed by 6 radiologists from two different institutions using a 5-grade Likert scale.*Results Irrespective of the contrast media (CM) used, a significant 2-fold increase in CNR values and significant higher IQ scores were generated by both DVA algorithms in comparison to DSA. Overall IQ scores for DSA, DVA1 and DVA2 using ICM were 3.61±0.05, 4.30±0.05 and 4.33±0.04. Using CO2, scores were 3.09±0.13, 3.61±0.13 and 3.34±0.13, respectively.*Conclusions Regardless of the CM used, a higher CNR and significant better IQ can be provided by DVA for selective lower limb interventions.

DVA1 is the first choice in the direct comparison of the DVA algorithms. It provides identical or better IQ than DVA2, whilst requiring shorter processing time (DVA1 1-2 sec, DVA2 up to 7 sec). A possible daily clinical implementation could be beneficial by assisting the intra-operative decision-making process.*Clinical Relevance/Application For selective lower limb angiography DVA can provide higher IQ and greater CNR compared to DSA, with either ICM or CO2 as contrast.

RESULTS

Irrespective of the contrast media (CM) used, a significant 2-fold increase in CNR values and significant higher IQ scores were generated by both DVA algorithms in comparison to DSA. Overall IQ scores for DSA, DVA1 and DVA2 using ICM were 3.61±0.05, 4.30±0.05 and 4.33±0.04. Using CO2, scores were 3.09±0.13, 3.61±0.13 and 3.34±0.13, respectively.

CLINICAL RELEVANCE/APPLICATION

For selective lower limb angiography DVA can provide higher IQ and greater CNR compared to DSA, with either ICM or CO2 as contrast.

CH04-C4   **Effect Of Beta-blocker Therapy On Aortic Hemodynamics In Patients With Bicuspid Aortic Valve**

Participants
Ashitha Pathrose, MBBS, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

Beta-blockers (BB) are hypothesized to delay ascending aortic (AAo) dilation in bicuspid aortic valve (BAV) patients by decreasing the rate of increase in central arterial pressure. This is thought to reduce forces of flowing blood on the aortic wall (wall shear stress, WSS) and aortic stiffness (measured as pulse wave velocity, PWV). This longitudinal study investigated changes in 4D flow-derived aortic hemodynamics in BAV patients before and after BB initiation.*Methods and Materials Our institutional database with ~2500 4D flow BL exams was queried for adult BAV patients with follow-up (FU) 4D flow MRI. After excluding patients with a history of dissections, genetic syndromes, or surgical interventions, n=25 patients who initiated BB between their BL and FU were identified (BBc: 48±12 years; 17 males). Age, sex-matched BAV control groups were also identified, including a group receiving BB at both BL and FU (BB+: n=25; 49±14 years; 16 males) and a BB naïve group (BB-: n=25; 46±15 years; 19 males). Velocity maximal intensity projections were used to measure the peak-systolic velocity (Vmax) at the AAo. 3D aortic peak-systolic WSS was calculated at the AAo. Aortic PWV was quantified using a cross-correlation approach.*Results There were no significant differences in AAo Vmax (2.26±0.85m/s vs. 2.30±0.94m/s, p=0.514), AAo WSS (1.99±0.69Pa vs. 2.00±0.65Pa, p=0.962), or aortic PWV (6.55±1.43m/s vs. 6.67±1.48m/s, p=0.636) in BBc patients before and after the onset of BB therapy. However, in BB+ and BB- groups, Vmax, WSS, and PWV were significantly higher at FU than at BL. Comparison of the longitudinal AAo Vmax, WSS, and PWV between the BBc, BB+, and BB- groups using mixed-model ANOVA showed no significant effect due to BB treatment (Vmax: F=0.132, p=0.876; WSS: F=0.464, p=0.630; PVW: F=0.387, p=0.680).*Conclusions In BAV patients, the initiation of BB therapy did not significantly change 4D flow-derived aortic hemodynamics. However, significant increase in AAo Vmax, WSS, and PWV on FU among matched BB+ patients may be due to a more severe disease requiring medical therapy. While in BB- patients this significant increase may indicate the natural progression of the disease.*Clinical Relevance/Application The benefits of BB treatment in BAV has not been proven in clinical trials. Our longitudinal study using 4D flow MRI-derived aortic hemodynamics in a cohort of BAV patients found no significant benefits. 4D flow MRI is a useful tool to investigate drugs that affect hemodynamics.

RESULTS

There were no significant differences in AAo Vmax (2.26±0.85m/s vs. 2.30±0.94m/s, p=0.514), AAo WSS (1.99±0.69Pa vs. 2.00±0.65Pa, p=0.962), or aortic PWV (6.55±1.43m/s vs. 6.67±1.48m/s, p=0.636) in BBc patients before and after the onset of BB therapy. However, in BB+ and BB- groups, Vmax, WSS, and PWV were significantly higher at FU than at BL. Comparison of the longitudinal AAo Vmax, WSS, and PWV between the BBc, BB+, and BB- groups using mixed-model ANOVA showed no significant effect due to BB treatment (Vmax: F=0.132, p=0.876; WSS: F=0.464, p=0.630; PVW: F=0.387, p=0.680).

CLINICAL RELEVANCE/APPLICATION

The benefits of BB treatment in BAV has not been proven in clinical trials. Our longitudinal study using 4D flow MRI-derived aortic hemodynamics in a cohort of BAV patients found no significant benefits. 4D flow MRI is a useful tool to investigate drugs that affect hemodynamics.

IR04-C3   Feasibility Of Velocity Quantification In A Stenotic Iliac Artery Phantom Model Using Quantitative DSA

Participants
Ece Meram, MD, Madison, Wisconsin (*Presenter*) Research Grant, Koninklijke Philips NV

PURPOSE

For patients with peripheral arterial disease, there is no direct objective and standardized intra-procedural method for determining a successful endovascular revascularization endpoint. Quantitative 2D digital subtraction angiography (qDSA) is a recently introduced postprocessing technique that leverages the inherent pulsatility in arterial blood to quantify blood velocity. qDSA has been correlated with intravascular Doppler and 4D Flow MRI, but not yet been evaluated in a stenosis model. This study aimed to assess the feasibility of using qDSA to quantify arterial velocity in a stenotic iliac artery phantom model.*Methods and Materials A silicon-based flexible iliac artery phantom was used with varying degrees of stenosis (based on luminal diameter reduction: no stenosis, mild, <50%; moderate, 50-70%; severe, >70%). A pulsatile pump was used to mimic physiologic arterial flow. DSAs (30 fps) were acquired by injecting 50% contrast at 2.5 mL/s injection rate for 8 seconds via a 5 Fr angled Glidecatheter positioned at the proximal left common iliac artery. 12-second 3D-DSAs were obtained for evaluation of vessel caliber. Downstream flow was measured in the iliac artery using an ultrasonic flow sensor. Velocities were calculated just distal to the stenosis and the results were evaluated with descriptive statistics. The change in flow was correlated with the change in velocities.*Results Average baseline arterial flow without a stenosis was 5.6 mL/s. Diameter reductions were 30% with mild, 60% with moderate and 85% with severe stenosis. The degree of stenosis corresponded to the following changes (i.e. decrease) in flow: 2% in mild (5.5 mL/s), 8% in moderate (5.2 mL/s) and 42% in severe (3.3 mL/s) stenosis. Average blood velocities were 12.2 ± 0.6 cm/s (no stenosis), 13.1 ± 0.6 cm/s (mild), 29.8 ± 1.1 cm/s (moderate), and 34.8 ± 4.6 cm/s (severe). These corresponded to 7% (mild), 145% (moderate) and 186% (severe) increases in local blood velocity. The change in blood velocity inversely correlated with the change in downstream flow with a Pearson r of -0.80 (p<0.001).*Conclusions qDSA was able to successfully characterize changes in blood velocity with varying degrees of stenosis despite turbulent flow conditions observed with moderate and severe stenoses. Further studies are indicated to investigate the accuracy of qDSA velocity quantification in stenotic iliac arteries in animal models and patients.*Clinical Relevance/Application After further validation, qDSA could be implemented into the clinical workflow to calculate arterial velocity changes during lower extremity revascularization, which in turn may help establish objective, reproducible quantitative endpoints to improve patient outcomes.

RESULTS

Average baseline arterial flow without a stenosis was 5.6 mL/s. Diameter reductions were 30% with mild, 60% with moderate and 85% with severe stenosis. The degree of stenosis corresponded to the following changes (i.e. decrease) in flow: 2% in mild (5.5 mL/s), 8% in moderate (5.2 mL/s) and 42% in severe (3.3 mL/s) stenosis. Average blood velocities were 12.2 ± 0.6 cm/s (no stenosis), 13.1 ± 0.6 cm/s (mild), 29.8 ± 1.1 cm/s (moderate), and 34.8 ± 4.6 cm/s (severe). These corresponded to 7% (mild), 145% (moderate) and 186% (severe) increases in local blood velocity. The change in blood velocity inversely correlated with the change in downstream flow with a Pearson r of -0.80 (p<0.001).

CLINICAL RELEVANCE/APPLICATION

After further validation, qDSA could be implemented into the clinical workflow to calculate arterial velocity changes during lower extremity revascularization, which in turn may help establish objective, reproducible quantitative endpoints to improve patient outcomes.

IR04-C4   Motion Correction In Digital Subtraction Angiography Using Generative Adversarial Networks: An Implementation And Evaluation Of The Gradient-Consistency Loss Function

Participants
Brendan Crabb, BS, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

PURPOSE

Digital subtraction angiography (DSA) is a commonly used method for the visualization of vasculature throughout the human body. However, artifacts due to patient motion limit the diagnostic utility of this technique. Generative adversarial networks (GAN) represent a viable solution to the significant problem of motion artifacts in DSA. In this study, we investigated the use of a gradient-consistency (GC) loss function to enhance the anatomical accuracy and diagnostic capabilities of this promising approach.*Methods and Materials An IRB approved dataset containing 29,656 cerebral DSA images with minimal artifacts due to patient motion was collected and split into training, validation, and testing datasets. Using these images as ground truth, the pix2pix GAN was trained to produce DSAs directly from the post-contrast fluoroscopic image, without the use of a pre-contrast mask. Training was performed with both an L1 + adversarial loss and an L1 + GC + adversarial loss. Progress was tracked using the L1 loss and a visual review of generated DSAs. Following training, the algorithm was evaluated on the testing dataset and generated DSAs were assessed for diagnostic quality with a quantitative structural similarity index (SSIM) metric and a visual review.*Results The pix2pix GAN trained with an L1 + GC + adversarial loss had a statistically significant improvement in SSIM on the testing dataset when compared to an L1 + adversarial loss alone (SSIM 0.837 (95% CI 0.835 to 0.839) vs. 0.833 (95% CI

0.831 to 0.835), p-value 0.004). Visual review of the images demonstrated notable instances where the addition of the GC loss improved the vessel demarcation and anatomical accuracy of the resultant DSA images.*Conclusions The inclusion of a GC loss during training improves the ability of the algorithm to accurately demarcate the vasculature of interest when performing motion correction in DSA with a GAN. This iterative improvement brings GANs one step closer to providing a reliable and diagnostic solution to the significant problem of motion artifacts in DSA.*Clinical Relevance/Application DSA is a commonly used technique for imaging vasculature that can be limited by artifacts due to patient motion. Elimination of motion artifacts in real time with a GAN that is enhanced by a GC loss function may improve the diagnostic utility of this approach.

RESULTS

The pix2pix GAN trained with an L1 + GC + adversarial loss had a statistically significant improvement in SSIM on the testing dataset when compared to an L1 + adversarial loss alone (SSIM 0.837 (95% CI 0.835 to 0.839) vs. 0.833 (95% CI 0.831 to 0.835), p-value 0.004). Visual review of the images demonstrated notable instances where the addition of the GC loss improved the vessel demarcation and anatomical accuracy of the resultant DSA images.

CLINICAL RELEVANCE/APPLICATION

DSA is a commonly used technique for imaging vasculature that can be limited by artifacts due to patient motion. Elimination of motion artifacts in real time with a GAN that is enhanced by a GC loss function may improve the diagnostic utility of this approach.

IR04-C5   Clinical Predictors Of Active Arterial Extravasation On CT Angiography (CTA) In Patients With Suspected GI Bleed: A Multi-hospital Retrospective Case-control Study With Risk Modeling

Participants
Brett Marinelli, MD,MS, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to identify clinical predictors of active arterial extravasation on CTA in patients with suspected GI bleeding.*Methods and Materials Review of CTA reports (4,342) across multiple hospitals from January 1, 2011 to July 30, 2019 yielded 1,763 studies performed for suspected GI bleeding. Curation of images by faculty revealed 231 studies with active arterial extravasation and accessible medical charts. 1:1 matching by age, gender, site, and time period was performed. Clinical variables extracted included patient characteristics (demographics, hospital, inpatients versus emergency department, shift and time period), history of recent bleeding events, past medical history, presenting symptoms, medications, vitals, and laboratory values. Univariate analysis was performed using Chi-square and t-tests for binary and continuous variables, respectively. Clinical variables significantly correlated (p<0.05) with extravasation on univariate analysis were entered into a multivariate logistic regression (MLR) risk model yielding adjusted odds-ratios (ORs) and area under the receiver operating curve (AUROC) statistics.*Results Univariate testing demonstrated significant unadjusted ORs (95%CI) of 3.6 (2.3-5.8) for bleeding event within the last 7 days, 1.9 (1.2-2.9) for diverticulosis, 2.8 (1.1-6.5) for diverticulitis, 2.1 (1.3-3.3) for varices/hemorrhoids, 2.0 (1.4-2.9) for hematochezia, 2.6 (1.4-5.0) for syncope, 1.6 (1.1-2.3) for NSAID use, 1.9 (1.3-2.8) for PPIs, 2.9 (1.7-4.8) for any anticoagulation, 3.8 (1.7-9.4) for coumadin, 2.2 (1.4-3.2) for recent transfusion in last 24 hours, 2.2 (2.2-4.0) for active pressors, and 1.5 (1.0-2.3) for hemoglobin less than 7.5 mg/dL. On MLR significant adjusted ORs were 3.4 (1.3-10.0) for diverticulitis, 2.3 (1.5-3.7) for hematochezia, 2.2 (1.1-4.7) for syncope, 2.2 (1.1-4.6) for any anticoagulation, 1.9 (1.2-3.1) for transfusion in last 24 hours and 2.1 (1.0-4.3) for active pressors. The AUROC for the MLR risk model was 0.74 (95%CI: 0.70-0.79).*Conclusions In patients with suspected GI bleeding several clinical variables predict extravasation on CTA. Risk models incorporating these clinical variables may guide mobilization of resources for emergent embolization by interventional radiology.*Clinical Relevance/Application GI bleeding is a life-threatening condition that can be emergently treated with transarterial embolization by interventional radiology. Successful embolization is more likely if extravasation is visualized on CTA prior to intervention. Recognizing clinical predictors of high (or low) likelihood of active arterial extravasation on CTA can guide mobilization of technical and staffing resources for emergent intervention.

RESULTS

Univariate testing demonstrated significant unadjusted ORs (95%CI) of 3.6 (2.3-5.8) for bleeding event within the last 7 days, 1.9 (1.2-2.9) for diverticulosis, 2.8 (1.1-6.5) for diverticulitis, 2.1 (1.3-3.3) for varices/hemorrhoids, 2.0 (1.4-2.9) for hematochezia, 2.6 (1.4-5.0) for syncope, 1.6 (1.1-2.3) for NSAID use, 1.9 (1.3-2.8) for PPIs, 2.9 (1.7-4.8) for any anticoagulation, 3.8 (1.7-9.4) for coumadin, 2.2 (1.4-3.2) for recent transfusion in last 24 hours, 2.2 (2.2-4.0) for active pressors, and 1.5 (1.0-2.3) for hemoglobin less than 7.5 mg/dL. On MLR significant adjusted ORs were 3.4 (1.3-10.0) for diverticulitis, 2.3 (1.5-3.7) for hematochezia, 2.2 (1.1-4.7) for syncope, 2.2 (1.1-4.6) for any anticoagulation, 1.9 (1.2-3.1) for transfusion in last 24 hours and 2.1 (1.0-4.3) for active pressors. The AUROC for the MLR risk model was 0.74 (95%CI: 0.70-0.79).

CLINICAL RELEVANCE/APPLICATION

GI bleeding is a life-threatening condition that can be emergently treated with transarterial embolization by interventional radiology. Successful embolization is more likely if extravasation is visualized on CTA prior to intervention. Recognizing clinical predictors of high (or low) likelihood of active arterial extravasation on CTA can guide mobilization of technical and staffing resources for emergent intervention.

IN01-A2   Racial Diversity In Deep Learning Chest X-ray Interpretation

Participants

Brandon Price, Tallahassee, Florida (*Presenter*) Nothing to Disclose

PURPOSE

A common misconception of deep learning systems is that due to their seemingly objective interpretation of data, they are incapable of bias. However, this has been demonstrated to be false in multiple studies. Often, bias is introduced into the training data unknowingly or a group is under sampled causing susceptible models to develop bias. As the rapid development of deep learning in medicine continues, there are concerns of potential bias when interpreting radiological images. In this study, we investigate how a model trained on a dataset without racial diversity could hinder detection of pathology in underrepresented minority patients.*Methods and Materials In this study, we used the MIMIC-CXR dataset with over 300,000 images. This dataset consists of 14 labeled findings. Lateral images were excluded and due to the low sample size of other races/ethnicities, only images of "Black" and "White" patients were included. One training dataset was composed entirely of "White" patients, while the other training dataset included both "Black" and "White" patients, creating a mixed dataset of 26% "Black" and 74% "White" patients. Datasets were filtered so an equal distribution of labeled findings was shared between them. A DenseNet model was trained on each dataset 25 times. The ROC-AUC and sensitivity, with a specificity threshold of 0.75, were compared for each of the 14 labeled findings with subsequent confidence intervals.*Results Models trained with a diverse training dataset had a significantly better ROC-AUC performance at identifying 6 of the 14 labeled findings in a test dataset of only black patients compared to a model trained on only white patients (p<0.05). In addition, the models trained with a diverse dataset found a significant increase in sensitivity performance for 6 of the 14 labeled findings on a test dataset of only black patients compared to the model trained with only white patients (p<0.05).*Conclusions As more AI systems are developed, it is imperative that they are fair and perform equally well with groups that have been historically underserved. This study demonstrates the importance of using diverse datasets while training models in order to ensure fair outcomes.*Clinical Relevance/Application As future medical AI systems are approved by regulators, it is crucial that model performance on different racial/ethnic groups is shared to ensure that safe and fair systems are being implemented.

RESULTS

Models trained with a diverse training dataset had a significantly better ROC-AUC performance at identifying 6 of the 14 labeled findings in a test dataset of only black patients compared to a model trained on only white patients (p<0.05). In addition, the models trained with a diverse dataset found a significant increase in sensitivity performance for 6 of the 14 labeled findings on a test dataset of only black patients compared to the model trained with only white patients (p<0.05).

CLINICAL RELEVANCE/APPLICATION

As future medical AI systems are approved by regulators, it is crucial that model performance on different racial/ethnic groups is shared to ensure that safe and fair systems are being implemented.

IN01-A3   Automated Kidney Segmentation In Magnetic Resonance Imaging In Patients With Autosomal-dominant Polycystic Kidney Disease: A Multicenter Study.

Participants

Piotr Woznicki, Warszawa, Poland (*Presenter*) Smart Reporting, working student

PURPOSE

Imaging-based total kidney volume (TKV) is a major prognostic factor in autosomal-dominant polycystic kidney disease (ADPKD). However, manual or semi-automated kidney segmentation is extremely time-consuming. Therefore, the purpose of this study was to develop a fully automated method for kidney segmentation in magnetic resonance imaging (MRI) in patients with ADPKD and to evaluate its purpose in a multimodal, multicentric setting.*Methods and Materials Deep convolutional neural network based on the U-Net architecture was trained on a dataset consisting of 406 abdominal MRI scans of 101 patients, including different MRI sequences (T2 TSE, T2 SPIR, T2 mapping). Manual segmentation of both kidneys delivered the ground-truth labels. The model's performance was evaluated on a test dataset of 25 patients, 17 of whom had longitudinal follow-up data, as well as an external dataset of 324 patients (485 MRI scans, acquired from multiple MRI scanners). Standard similarity metrics were calculated, including Dice score as well as correlation and agreement between TKV derived from automated segmentation and from manual segmentation and between TKV growth over time.*Results The segmentation model yielded excellent performance on the segmentation task, achieving a mean per-study Dice score of 0.93±0.04 on the test dataset. The automatically computed TKV was highly correlated with manually measured TKV (intraclass correlation coefficient: 0.996) with low bias and high precision (0.2±4.3%). For longitudinal analysis of TKV growth, bias and precision were -0.6±1.7% and there was no significant difference between automated and manual estimations. In the external dataset, the model achieved a mean bias and precision of -3.5±8.8%.*Conclusions Our deep learning model enabled accurate segmentation of the kidneys and objective assessment of TKV in patients with ADPKD. This approach could aid the clinicians in the precise and rapid assessment of disease progression.Importantly, this approach was shown to work in scans obtained using MRIs from 40 different MR scanners as well as longitudinal monitoring, making implementation in clinical routine care

possible.*Clinical Relevance/Application Our method is a robust tool for estimation of TKV and TKV growth over time. It was extensively validated in longitudinal as well as external datasets, which proves its applicability in the clinical setting.

RESULTS

The segmentation model yielded excellent performance on the segmentation task, achieving a mean per-study Dice score of 0.93±0.04 on the test dataset. The automatically computed TKV was highly correlated with manually measured TKV (intraclass correlation coefficient: 0.996) with low bias and high precision (0.2±4.3%). For longitudinal analysis of TKV growth, bias and precision were -0.6±1.7% and there was no significant difference between automated and manual estimations. In the external dataset, the model achieved a mean bias and precision of -3.5±8.8%.

CLINICAL RELEVANCE/APPLICATION

Our method is a robust tool for estimation of TKV and TKV growth over time. It was extensively validated in longitudinal as well as external datasets, which proves its applicability in the clinical setting.

GU05-A1   Neoadjuvant Chemotherapy In Ovarian Cancer: Response Assessment And Predictors Of Survival

Participants
Molly Roseland, MD, Northville, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

Neoadjuvant chemotherapy is often administered for advanced high grade serous ovarian carcinoma (HGSC) prior to definitive cytoreductive surgery, and accurate response assessment is necessary for guiding treatment and prognosis. Goal of study was to compare response evaluated by CT (simplified peritoneal carcinomatosis index; S-PCI), pathology (chemotherapy response score; CRS), laboratory markers (CA-125), and surgical outcomes, and to examine which factors were predictive of disease-free survival.*Methods and Materials For this retrospective, HIPAA-compliant, IRB-approved study, we identified 396 women with HGSC receiving neoadjuvant chemotherapy between 2010-2019. Patients were excluded if debulking surgery was not performed or if imaging and histologic specimens were unavailable for review, leaving 97 patients for analysis. Radiologists blinded to outcome rated pre- and post-treatment abdominopelvic CTs with S-PCI scores of 0-24 (higher score indicating more visible tumor). One pathologist assigned surgical specimens a CRS of 1-3 (ranging from minimal to complete treatment response). Clinical data were obtained via chart review. Univariate and multivariate analysis was performed using R 3.6.3 and survival analysis was performed using SAS 9.4.*Results Interreader agreement was good for CT readers' pre-treatment S-PCI scores (ICC 0.64) and excellent for post-treatment S-PCI scores (ICC 0.82). Although there was a significant decrease in S-PCI scores after treatment (single paired t-test, p<0.001), the mean percentage decrease in S-PCI did not differ significantly among the three CRS categories (one-way ANOVA test; p=0.51) or between patients who were optimally vs. suboptimally debulked (two sample t-test; p=0.29). In a survival analysis incorporating time to disease progression, log-rank test demonstrated lower CRS score to be a significant predictor of progression (p<0.001). Cox proportional-hazards models demonstrated that, while both CRS score (HR 4.3, p<0.0001) and change in CA-125 (HR 1.8; p=0.01) were significantly associated with progression, change in S-PCI score was not (HR 0.99, p=0.80).*Conclusions HGSC response to neoadjuvant therapy evaluated by CT S-PCI was not associated with pathologic CRS score, surgical success, or clinical progression, revealing discordance between imaging and pathologic, biochemical, and surgical assessments of disease response.*Clinical Relevance/Application The role of imaging in determining response and guiding management for HGSC remains uncertain. Further studies are needed to clarify if macroscopic disease truly does not predict microscopic findings, or if alternative methods to quantify burden of disease by CT would better correlate with clinical outcomes.

RESULTS

Interreader agreement was good for CT readers' pre-treatment S-PCI scores (ICC 0.64) and excellent for post-treatment S-PCI scores (ICC 0.82). Although there was a significant decrease in S-PCI scores after treatment (single paired t-test, p<0.001), the mean percentage decrease in S-PCI did not differ significantly among the three CRS categories (one-way ANOVA test; p=0.51) or between patients who were optimally vs. suboptimally debulked (two sample t-test; p=0.29). In a survival analysis incorporating time to disease progression, log-rank test demonstrated lower CRS score to be a significant predictor of progression (p<0.001). Cox proportional-hazards models demonstrated that, while both CRS score (HR 4.3, p<0.0001) and change in CA-125 (HR 1.8; p=0.01) were significantly associated with progression, change in S-PCI score was not (HR 0.99, p=0.80).

CLINICAL RELEVANCE/APPLICATION

The role of imaging in determining response and guiding management for HGSC remains uncertain. Further studies are needed to clarify if macroscopic disease truly does not predict microscopic findings, or if alternative methods to quantify burden of disease by CT would better correlate with clinical outcomes.

GU05-A2   Toward Reliable Predictors Of Stress Urinary Incontinence Surgery Success Based On Quantitative Dynamic And Static Pelvic MRI Parameters

Participants
Mohamed A. El-Ghar, MSc, MD, Mansoura, Egypt (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to analyze preoperative 3T quantitative static and dynamic pelvic MRI parameters in a trial to detect the parameters predicting the successful surgical correction of stress urinary incontinence.*Methods and Materials 42 female patients with stress urinary incontinence were recruited in our study, their age ranged from 35 to 65 years. 3T pelvic MRI examination was conducted at rest and during straining, preoperative and 6 months post-operative. Logistic regression of the MRI parameters was done to determine their ability to predict the success of the surgery. Also, ROC curve analysis was performed to detect the cut off value, sensitivity and specificity of the different MRI variables.*Results Logistic regression revealed that the pubovaginal space was the most significant parameter with p value (0.03) followed by H line during straining (p value=0.05). According to ROC curve, the cut off value of pubovaginal space was (2.65 cm) demonstrating sensitivity and specificity of (77.1%& 62.5%) respectively with AUC of (0.741) which represents the highest AUC value compared to other MRI parameters. The cut off value of H line during straining was (7.45 cm) demonstrating sensitivity and specificity of (74.3%& 62.5%) respectively with AUC of (0.720).*Conclusions The specific MRI parameters that predict the success of SUI surgery should be looked thoroughly preoperatively during pelvic floor

MRI evaluation.*Clinical Relevance/Application Preoperative pelvic floor MRI parameters that can predict the success of stress urinary incontinence surgery can help to avoid the unnecessary surgery

RESULTS

Logistic regression revealed that the pubovaginal space was the most significant parameter with p value (0.03) followed by H line during straining (p value=0.05). According to ROC curve, the cut off value of pubovaginal space was (2.65 cm) demonstrating sensitivity and specificity of (77.1%& 62.5%) respectively with AUC of (0.741) which represents the highest AUC value compared to other MRI parameters. The cut off value of H line during straining was (7.45 cm) demonstrating sensitivity and specificity of (74.3%& 62.5%) respectively with AUC of (0.720).

CLINICAL RELEVANCE/APPLICATION

Preoperative pelvic floor MRI parameters that can predict the success of stress urinary incontinence surgery can help to avoid the unnecessary surgery

SDP-GI-1   Esophageal Wall Thickness On CT Scans: Can It Predict The T Stage Of Primary Thoracic Esophageal Squamous Cell Carcinoma?

Participants
Yue Wang, Jinan, China (*Presenter*) Nothing to Disclose

PURPOSE

To determine and validate the optimal esophageal wall thickness (EWT) threshold on CT to distinguish lesions with different T stages in esophageal squamous cell carcinoma (ESCC) patients.*Methods and Materials 1102 consecutive patients with histopathologically verified ESCC between July 2014 and April 2020 were retrospectively reviewed. All patients underwent preoperative CT examination and surgical treatment.The maximal EWT of the lesions on CT was measured. Patients were divided into pT1, pT2, pT3 and pT4 subgroups according to pathologic stage. We employed the support vector machine, where linear kernels were leveraged to determine the optimal threshold to classify samples with different T stages. 90% of samples for each subgroup were selected randomly as the training set, while the remainder comprised the test set.*Results The mean EWTs of the pT1, pT2, pT3 and pT4 subgroups were 4.9±2.6mm, 8.1±2.3mm, 12.4±3.6mm, and 18.6±4.4mm, respectively. Differences in the EWT between four subgroups or between adjacent subgroups were significant (p=0.000), and esophageal wall became thicker with increasing pT. Multivariate logistic regression analysis indicated that the EWT was a predictor of pathologic T stage in ESCC (p=0.000). We utilized MATLAB 2020a to implement the SVM model and ran the code 10 times. The accuracy of the model was 60.29±2.33%. The thresholds between samples from pT1/pT2, pT2/pT3 and pT3/pT4 lesions were 5.5±0.3mm, 10.8±0.8mm and 15.9±0.5mm, respectively.*Conclusions EWT correlates closely with pathologic T stage and demonstrates acceptable accuracy for T-staging prediction of ESCC.*Clinical Relevance/Application This study can provide a reference for pre-treatment T-staging evaluation of esophageal cancer based on CT.

RESULTS

The mean EWTs of the pT1, pT2, pT3 and pT4 subgroups were 4.9±2.6mm, 8.1±2.3mm, 12.4±3.6mm, and 18.6±4.4mm, respectively. Differences in the EWT between four subgroups or between adjacent subgroups were significant (p=0.000), and esophageal wall became thicker with increasing pT. Multivariate logistic regression analysis indicated that the EWT was a predictor of pathologic T stage in ESCC (p=0.000). We utilized MATLAB 2020a to implement the SVM model and ran the code 10 times. The accuracy of the model was 60.29±2.33%. The thresholds between samples from pT1/pT2, pT2/pT3 and pT3/pT4 lesions were 5.5±0.3mm, 10.8±0.8mm and 15.9±0.5mm, respectively.

CLINICAL RELEVANCE/APPLICATION

This study can provide a reference for pre-treatment T-staging evaluation of esophageal cancer based on CT.

SDP-GI-10   Assessment Of Lymph Node Status And Tumor Response After Chemoradiation Therapy In Locally Advanced Rectal Cancer: Comparison Of Three Methods Of Region Of Interest For Intravoxel Incoherent Motion Parameters

Participants
Yi Yuan, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

To assess the diagnostic performance of region of interest (ROI) methods of intravoxel incoherent motion (IVIM) for determining lymph node metastases (LNM) and tumor response after chemoradiation therapy (CRT) in locally advanced rectal cancer and which risk factors related to early recurrence.*Methods and Materials 79 patients underwent preoperative IVIM and diffusion-weighted imaging before and after CRT. Slow diffusion coefficient (D), fast diffusion coefficient (D*), perfusion-related diffusion fraction (f), apparent diffusion coefficient (ADC) value and their percentage changes (?%) were obtained according to three ROI methods: whole-volume, single-slice and small samples. Risk factors were evaluated through multivariate logistic regression analyses. Areas under the receiver operating characteristic curves (AUCs) and prescision-recall curves were calculated to evaluate diagnostic performance. 2-year recurrence-free survival was estimated using Kaplan-Meier survival curves.*Results Interobserver agreement were good for pre- and post-CRT whole-volume ROI and single-slice ROI (intraclass correlation coefficient [ICC], 0.775-0.953), and moderate for small samples ROI (ICC, 0.581-0.905). At multivariate analysis, whole-volume ROI-derived ?%D values was an independent risk factor for discriminating LNM, non-pathological complete response (non-pCR) and poor response (odds ratio,0.947,0.952,0.805; p=0.001,<0.001,<0.001, respectively). AUC for whole-volume ROI-derived ?%D values showed the best AUC of 0.810, 0.851 and 0.903 for identifying LNM, non-pCR and poor response. After CRT, only patients with LNM showed earlier recurrence (hazard ratio, 3.253; 95% confidence interval, 1.229-8.608; p=0.018).*Conclusions Whole-volume ROI-derived ?%D values provided high diagnostic performance for evaluating LNM and tumor response. Furthermore, only patients with LNM after CRT was associated with early recurrence.*Clinical Relevance/Application Whole-volume ROI-derived ?%D values was an independent risk factor and provided higher diagnostic performance for determining LNM and tumor response, and those patients with LNM were associated with early recurrence.

RESULTS

Interobserver agreement were good for pre- and post-CRT whole-volume ROI and single-slice ROI (intraclass correlation coefficient [ICC], 0.775-0.953), and moderate for small samples ROI (ICC, 0.581-0.905). At multivariate analysis, whole-volume ROI-derived ? %D values was an independent risk factor for discriminating LNM, non-pathological complete response (non-pCR) and poor response (odds ratio,0.947,0.952,0.805; p=0.001,<0.001,<0.001, respectively). AUC for whole-volume ROI-derived ?%D values showed the best AUC of 0.810, 0.851 and 0.903 for identifying LNM, non-pCR and poor response. After CRT, only patients with LNM showed earlier recurrence (hazard ratio, 3.253; 95% confidence interval, 1.229-8.608; p=0.018).

CLINICAL RELEVANCE/APPLICATION

Whole-volume ROI-derived ?%D values was an independent risk factor and provided higher diagnostic performance for determining LNM and tumor response, and those patients with LNM were associated with early recurrence.

SDP-GI-100 Prediction Of High-risk Esophageal Varices With Liver Multifrequency MR Elastography In Cirrhotic Patients

Participants
Jin Wang, MD, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

High-risk esophageal varices (HREVs) pose a greater threat to life than low-risk esophageal varices (LREVs) in patients with liver cirrhosis. Non-invasive prediction of HREVs among cirrhotic patients is of utmost importance. The aim of this study was to assess the value of multifrequency MR elastography (MRE) to predict HREVs in patients with cirrhosis.*Methods and Materials This retrospective study received institutional review board approval, and informed consent was waived. From March 2018 to August 2020, 97 patients with liver cirrhosis who performed multifrequency MRE within 6 months before or after gastroscopy were retrospective included. The liver shear stiffness (G*), storage modulus (G'), shear loss modulus (G?) and damping ratio (?) were measured by multifrequency MRE at 30Hz, 40Hz and 60Hz. The presence of esophageal varices grade II and III were classified as HREVs while no varices and grade I were classified as LREVs. Logistic regression analysis was used to identify independent risk factors for predicting HREVs in cirrhotic patients by using clinical and multi-parametric information.*Results According to gastroscopy, forty-five (46.39%, 45/97) patients were classified HREVs and fifty-two (53.61%, 52/97) patients were classified as LREVs. Low platelet count(PLT)(P=0.011; odds ratio=0.979, 95% CI, 0.963-0.995), 60Hz G?(P=0.018; odds ratio=2.369, 95% CI, 1.162-4.828) and 40Hz G?(P=0.029; odds ratio=2.970, 95% CI, 1.116-7.904) were independent risk factors for predicting HREVs. Combination of PLT and 40Hz G? had sensitivity of 59.3% and specificity of 82.8% with AUC of 0.762, combination of PLT and 60Hz G? had sensitivity of 78.8% and specificity of 69.0% with AUC of 0.766, combination of PLT, 40Hz G? and 60Hz G? had sensitivity of 77.8% and specificity of 69.0% with AUC of 0.770 for prediction of HREVs.*Conclusions Combination of platelet count, 60Hz G? and 40Hz G? can perform well in the prediction of HREV in cirrhotic patients.*Clinical Relevance/Application The combination of laboratory biomarkers and quantitative measurements from multifrequency MRE may be a useful method to identify cirrhotic patients with HREVs, helpful for clinical management and follow-up strategies.

RESULTS

According to gastroscopy, forty-five (46.39%, 45/97) patients were classified HREVs and fifty-two (53.61%, 52/97) patients were classified as LREVs. Low platelet count(PLT)(P=0.011; odds ratio=0.979, 95% CI, 0.963-0.995), 60Hz G?(P=0.018; odds ratio=2.369, 95% CI, 1.162-4.828) and 40Hz G?(P=0.029; odds ratio=2.970, 95% CI, 1.116-7.904) were independent risk factors for predicting HREVs. Combination of PLT and 40Hz G? had sensitivity of 59.3% and specificity of 82.8% with AUC of 0.762, combination of PLT and 60Hz G? had sensitivity of 78.8% and specificity of 69.0% with AUC of 0.766, combination of PLT, 40Hz G? and 60Hz G? had sensitivity of 77.8% and specificity of 69.0% with AUC of 0.770 for prediction of HREVs.

CLINICAL RELEVANCE/APPLICATION

The combination of laboratory biomarkers and quantitative measurements from multifrequency MRE may be a useful method to identify cirrhotic patients with HREVs, helpful for clinical management and follow-up strategies.

SDP-GI-101 Assessment Of Two Quantification Techniques For Measuring Small Bowel Motility With Cine-MRI

Participants
Kyra Van Rijn, MD, Amsterdam, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

Cine-MRI motility measurements are increasingly used in different populations, some with dilated small bowel loops. Usually, this automated technique calculates an average motility score within a region of interest (ROI). In subjects with dilated bowel loops, the lumen may cover a large part of the ROI and may therefore have a disproportionate influence on the motility score. Our aim was to evaluate the effect of bowel dilation on cine-MRI small bowel motility measurements, by comparing a MRI motility score that includes both bowel walls and luminal content with a bowel wall-specific motility score in healthy and diseased populations.*Methods and Materials Four populations were included: 10 Crohn's patients with a stricture and pre stricture dilation for segmental motility analysis, and 14 mannitol-prepared healthy volunteers, 15 fasted healthy volunteers and 8 chronic intestinal pseudo-obstruction (CIPO) patients (characterized by dilated bowel loops) for global small bowel motility analysis. All subjects underwent a cine-MRI scan from which two motility scores were calculated: a conventional score that included both bowel walls and luminal content and a small bowel wall-specific motility score. The difference between the two scores was calculated per population and was compared between the populations with an ANOVA and Tukey-Kramer post hoc analysis.*Results In Crohn's patients the median (IQR) change between the conventional and wall-specific motility score was 0% (-2 to +4%) in the stricture and 0% (-1 to +7%) for the pre stricture dilation. For the global small bowel, in mannitol-prepared healthy volunteers this was -1% (-5 to 0%), in healthy fasted subjects -2% (-6 to +2%) and in CIPO patients +14% (+6 to +20%). The ANOVA showed a significant difference between the populations (P<0.001*), post hoc analysis showed that CIPO patients were different from the other populations.*Conclusions The conventional small bowel motility score appears to be robust in Crohn's patients and healthy subjects. In CIPO patients with globally and grossly dilated bowel loops a clear difference was detected, therefore a bowel-wall specific motility score may give a better representation of small bowel motility.*Clinical Relevance/Application Cine-MRI small bowel motility measurements appear to be robust in Crohn's patients and healthy subjects, but globally dilated bowel loops affect motility measurements, needing a tailored approach.

RESULTS

In Crohn's patients the median (IQR) change between the conventional and wall-specific motility score was 0% (-2 to +4%) in the

In Crohn's patients the median (IQR) change between the conventional and wall-specific motility score was 0% (-2 to +4%) in the stricture and 0% (-1 to +7%) for the pre stricture dilation. For the global small bowel, in mannitol-prepared healthy volunteers this was -1% (-5 to 0%), in healthy fasted subjects -2% (-6 to +2%) and in CIPO patients +14% (+6 to +20%). The ANOVA showed a significant difference between the populations (P<0.001*), post hoc analysis showed that CIPO patients were different from the other populations.

CLINICAL RELEVANCE/APPLICATION

Cine-MRI small bowel motility measurements appear to be robust in Crohn's patients and healthy subjects, but globally dilated bowel loops affect motility measurements, needing a tailored approach.

SDP-GI-102 Impact Of Spleen Volume On Prediction Of Clinical Outcome After Open Abdominal Aortic Repair In Elderly Patients

Participants
Hiroki Horinouchi, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Spleen volume is reported to be an independent prognostic factor for patients with cancer or infectious diseases. However, the relationship between spleen volume and clinical outcomes in patients with cardiovascular diseases has rarely been studied or addressed. In elderly patients, open abdominal aortic repair (OAR) carries a significantly higher risk of operative mortality and perioperative complications. The purpose of this study was to investigate whether preoperative spleen volume was associated with clinical outcomes in elderly patients undergoing elective OAR.*Methods and Materials We retrospectively reviewed our institutional data to identify all elderly patients (age = 80 years) who underwent elective OAR between 2007 and 2020. Patients with emergency procedure or insufficient data were excluded. Clinical outcomes were hospital length of stay (LOS) and overall survival (OS) after OAR. Spleen volume was measured on preoperative computed tomography scans. Patient characteristics, intraprocedural variables, and imaging findings including spleen volume were analyzed using stepwise multiple regression and multivariable analysis to determine predictors of LOS and OS.*Results We identified 90 elderly patients (median age, 82 years) who underwent OAR. The median preoperative spleen volume was 95.9 (interquartile range (IQR): 72.0-129.5) mL. The median LOS was 14 (IQR: 12-17) days. The overall survival rate was 82% at five years. Pneumonia, heart disease, cancer, and stroke were the most common causes of death, and no deaths occurred due to aneurysm rupture. Stepwise multiple regression analysis demonstrated that preoperative spleen volume (B coefficient, 0.213; 95% confidence interval (CI), 0.000348-0.0443; p = 0.047) and age (B coefficient, 0.381; 95% CI, 0.385-1.207; p = 0.0002) were associated with prolonged postoperative LOS. There was no association between OS and the spleen volume (p = 0.17).*Conclusions Preoperative spleen volume can be an independent prognostic factor for prolonged postoperative LOS after elective OAR in elderly patients.*Clinical Relevance/Application Spleen volume was associated with prolonged hospital length of stay after open abdominal aortic repair in elderly patients. Spleen volume may predict outcomes in patients with cardiovascular diseases.

RESULTS

We identified 90 elderly patients (median age, 82 years) who underwent OAR. The median preoperative spleen volume was 95.9 (interquartile range (IQR): 72.0-129.5) mL. The median LOS was 14 (IQR: 12-17) days. The overall survival rate was 82% at five years. Pneumonia, heart disease, cancer, and stroke were the most common causes of death, and no deaths occurred due to aneurysm rupture. Stepwise multiple regression analysis demonstrated that preoperative spleen volume (B coefficient, 0.213; 95% confidence interval (CI), 0.000348-0.0443; p = 0.047) and age (B coefficient, 0.381; 95% CI, 0.385-1.207; p = 0.0002) were associated with prolonged postoperative LOS. There was no association between OS and the spleen volume (p = 0.17).

CLINICAL RELEVANCE/APPLICATION

Spleen volume was associated with prolonged hospital length of stay after open abdominal aortic repair in elderly patients. Spleen volume may predict outcomes in patients with cardiovascular diseases.

SDP-GI-103 Inter-reader Agreement Of Adequacy And Visualization Scores Of Gadoxetate-enhanced Abbreviated Mri (amri) And Liver Ultrasound (us) For Hepatocellular Carcinoma (hcc) Screening/surveillance

Participants
Guilherme M. Cunha, MD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

Abbreviated MRI (AMRI) protocols for HCC surveillance have been proposed as more sensitive alternatives to ultrasound (US) in high-risk patients (1, 2). Both AMRI and US may be limited in some patients due to factors such as body habitus, severity of cirrhosis, and suboptimal contrast uptake (2, 3). A standardized approach to communicating limitations is needed to allow for adaptive alternative surveillance strategies. We aimed to assess and compare inter-reader agreement for LI-RADS US visualization score and novel US and AMRI adequacy scoring systems.*Methods and Materials Data from a prospective study of gadoxetate-AMRI/US surveillance was available for analysis in 62 patients, reviewed and scored by 3 independent readers according to the LI-RADS visualization score, as well as additional adequacy scoring indices on both US and AMRI. Inter-reader agreement was computed using intra-class correlation (ICC). Bootstrap comparison was performed between AMRI and US visualization scores*Results 27 (44%) patients were men (age: 60±10, BMI: 30 ±7) and 40 (64.5%) had liver cirrhosis. The ICC for US LI-RADS visualization score was 0.19 (95%CI: 0.02 - 0.38), and ranged from 0.08 (0.08 - 0.30), 0.11 (0.04 - 0.29), 0.36 (0.19 - 0.53), 0.64 (0.51, 0.76) and 0.51 (0.35 - 0.66) for the other US metrics. The ICC for AMRI visualization score was 0.721 (95% CI: 0.598, 0.82), significantly higher than US visualization score (p<0.001), and 0.749 (0.631, 0.842) and 0.578 (0.419, 0.716) for contrast uptake and parenchymal heterogeneity indexes, respectively.*Conclusions The ICC for assessment of adequacy of HBP-AMRI was high, while the US LI-RADS visualization score and other indices showed poor agreement.*Clinical Relevance/Application Further refinements in the US adequacy metrics are needed to standardize communication in a reliable way. AMRI adequacy scores may direct potential need for alternative surveillance imaging.

RESULTS

27 (44%) patients were men (age: 60±10, BMI: 30 ±7) and 40 (64.5%) had liver cirrhosis. The ICC for US LI-RADS visualization score was 0.19 (95%CI: 0.02 - 0.38), and ranged from 0.08 (0.08 - 0.30), 0.11 (0.04 - 0.29), 0.36 (0.19 - 0.53), 0.64 (0.51, 0.76) and 0.51 (0.35 - 0.66) for the other US metrics. The ICC for AMRI visualization score was 0.721 (95% CI: 0.598, 0.82), significantly higher than US visualization score (p<0.001), and 0.749 (0.631, 0.842) and 0.578 (0.419, 0.716) for contrast uptake and parenchymal heterogeneity indexes, respectively.

Further refinements in the US adequacy metrics are needed to standardize communication in a reliable way. AMRI adequacy scores may direct potential need for alternative surveillance imaging.

SDP-GI-104 Correlating Quantitative Para-aortic Node CT Parameters With FDG PET For Cervical Cancer Staging: Possible Solution For Resource Constrained Countries

Participants
Paul D'Cunha, BS, Dallas, Texas (*Presenter*) Nothing to Disclose

PURPOSE

To determine the most accurate quantitative morphological parameters on CT that correlate with FDG-avid PANs in patients with cervical cancer.*Methods and Materials A single institution retrospective evaluation was preformed of women with cervical cancer who underwent pretreatment PET/CT and radiotherapy therapy planning CT between 2009 and 2020. A node-by-node correlation between pretreatment CT and PET/CT was performed for the reference standard of FDG-avidity for short and long axes diameters, volume, and long/short-axes ratio (L/S). Nodal volume was manually contoured and calculated using the radiation treatment program. FDG-avid PANs were defined as PET positive and non FDG-avid PANs from patients without PET determined PAN metastasis were defined as PET negative. Area under the receiver operator curve (AUC) was calculated to access diagnostic accuracy of the different quantitative parameters. Three specificity set points of 0.85, 0.90, and 0.95 were used to calculate various cutoffs and compare sensitivity between parameters.*Results A total of 94 women (mean age ± standard deviation, 52 years ± 13) with cervical cancer were included. Forty-seven patients had PET positive PANs (181 PET positive PANs) and 47 patients had no PET positive PANs (141 PET negative PANs). The AUC for PAN volume (0.945) was significantly greater (P < 0.001) than that of short-axis diameter (0.895), long-axis diameter (0.885), and L/S (0.583). For all three specificity set points, 0.85, 0.90, and 0.95, nodal volume sensitivity was significantly higher than that of short-axis diameter (P < 0.001, P = 0.001, and P = 0.005, respectively), long-axis diameter (P < 0.001, P = 0.002, P < 0.001, respectively), and L/S ratio (P < 0.001 for all specificity set points). At a specificity set point of 0.90 (127/141 PANs), the cutoff for volume was = 0.443 cm3 (0.85 sensitivity [154/181 PAN]) and for short-axis diameter was = 5.9 mm (0.75 sensitivity [135/181 PAN]).*Conclusions Para-aortic lymph node volume demonstrated improved node-by-node correlation between CT and PET/CT compared to short-axis diameter, long-axis diameter, and L/S and is an alternative to improve detection of PAN suspicious for metastatic disease for cervical cancer patients in locations without access to PET/CT.*Clinical Relevance/Application Our CT quantitative parameter cutoffs provide improved sensitivity, without much compromise in specificity, compared to literature CT criteria for detection of para-aortic nodes suspicious for metastatic disease in cervical cancer patients, which is useful for sites without access to PET/CT.

RESULTS

A total of 94 women (mean age ± standard deviation, 52 years ± 13) with cervical cancer were included. Forty-seven patients had PET positive PANs (181 PET positive PANs) and 47 patients had no PET positive PANs (141 PET negative PANs). The AUC for PAN volume (0.945) was significantly greater (P < 0.001) than that of short-axis diameter (0.895), long-axis diameter (0.885), and L/S (0.583). For all three specificity set points, 0.85, 0.90, and 0.95, nodal volume sensitivity was significantly higher than that of short-axis diameter (P < 0.001, P = 0.001, and P = 0.005, respectively), long-axis diameter (P < 0.001, P = 0.002, P < 0.001, respectively), and L/S ratio (P < 0.001 for all specificity set points). At a specificity set point of 0.90 (127/141 PANs), the cutoff for volume was = 0.443 cm3 (0.85 sensitivity [154/181 PAN]) and for short-axis diameter was = 5.9 mm (0.75 sensitivity [135/181 PAN]).

CLINICAL RELEVANCE/APPLICATION

Our CT quantitative parameter cutoffs provide improved sensitivity, without much compromise in specificity, compared to literature CT criteria for detection of para-aortic nodes suspicious for metastatic disease in cervical cancer patients, which is useful for sites without access to PET/CT.

SDP-GI-11 Evaluation Of Dual-energy CT Derived Radiomics Signatures In Predicting Outcomes In Patients With Advanced Gastric Cancer After Neoadjuvant Chemotherapy

Participants
Yong Chen, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the prognostic value of dual-energy CT (DECT) based radiomics to predict disease-free survival (DFS) and overall survival (OS) for patients with advanced gastric cancer (AGC) after neoadjuvant chemotherapy (NAC).*Methods and Materials From January 2014 to December 2018, a total of 156 AGC patients were enrolled and randomly allocated into a training cohort and a testing cohort at a ratio of 2:1. Volume of interest of primary tumor was delineated on eight image series. Four feature sets derived from pre-NAC and delta radiomics were generated for each survival arm. Random survival forest was used for generating the optimal radiomics signature (RS). Statistical metrics for model evaluation included Harrell's concordance index (C-index) and the average cumulative/dynamic AUC throughout follow-up. A clinical model and a combined Rad-clinical model were built for comparison.*Results The pre-IU (derived from iodine uptake images before NAC) RS performed best for DFS and OS in the testing cohort (C-indices, 0.784 and 0.698; the average cumulative/dynamic AUCs, 0.80 and 0.77). When compared with the clinical model, the radiomics model had significantly higher C-indices to predict DFS in both cohorts (0.822 vs. 0.651, p < 0.001; 0.784 vs. 0.635, p < 0.001), but no statistical significance was found for OS prediction in either the training or the testing cohorts (0.724 vs. 0.728, p = 0.899; 0.698 vs. 0.680, p = 0.473).*Conclusions The DECT radiomics model serves as a promising non-invasive biomarker to predict survival for AGC patients after NAC, providing an opportunity of transforming proper treatment.*Clinical Relevance/Application Compared with conventional CT images, iodine uptake maps before neoadjuvant chemotherapy may provide more insight into heterogeneity of gastric cancer to predict survival.

RESULTS

The pre-IU (derived from iodine uptake images before NAC) RS performed best for DFS and OS in the testing cohort (C-indices, 0.784 and 0.698; the average cumulative/dynamic AUCs, 0.80 and 0.77). When compared with the clinical model, the radiomics model had significantly higher C-indices to predict DFS in both cohorts (0.822 vs. 0.651, p < 0.001; 0.784 vs. 0.635, p < 0.001), but no statistical significance was found for OS prediction in either the training or the testing cohorts (0.724 vs. 0.728, p = 0.899; 0.698 vs. 0.680, p = 0.473).

CLINICAL RELEVANCE/APPLICATION

Compared with conventional CT images, iodine uptake maps before neoadjuvant chemotherapy may provide more insight into heterogeneity of gastric cancer to predict survival.

SDP-GI-13 Application Of Basis Material Decomposition Technique With Spectral CT In Quantitatively Evaluating The Staging Of Chronic Hepatitis B Liver Fibrosis Using Histopathology As The Reference Standard

Participants
Liu Xianwang, Lanzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the application value of basis material decomposition technique with spectral CT in the quantitative assessment of chronic hepatitis B liver fibrosis staging.*Methods and Materials This prospective study included patients with chronic liver disease who were scheduled to undergo multiphase abdominal CT(including portal phase dual-energy scanning) and liver biopsy from January 2018 to December 2020. The area of interest (ROI) was drawn in the area that approximately matched the area of biopsy on the right lobe, and another ROI was placed on the abdominal aorta at the level of the celiac trunk to calculate the normalized iodine concentration of liver (LNIC). One-way analysis of variance (ANOVA) and least significant difference method (LSD) were used to compare the differences of LNIC with the METAVIR fibrosis stage (ranging from F0 to F4). Spearman correlation analysis was used to evaluate the correlation between chronic hepatitis B liver fibrosis stage and LNIC. Diagnostic performance of the LNIC was assessed by using areas under the receiver operating characteristic curve (AUCs).*Results A total of 36 participants (mean age, 45.61 years ± 9.03 ; 16 women) and 20 control subjects (mean age, 38.30 years ±11.02; 11 men) were evaluated. There are differences in LNIC among different stages of chronic hepatitis B liver fibrosis (F=39.778, P<0.001). The RNIC showed strong nagative correlation with METAVIR stage (Spearman r=-0.830, P<0.001). The AUC values of LNIC in the diagnosis of chronic hepatitis B liver fibrosis staging are all >0.9, which has high diagnostic value. The AUC, sensitivity, specificity of LNIC distinguishes ?F1, ?F2, and ?F3+4 were 0.926, 86.11%, 95%; 0.922, 91.62%, 81.25%; 0.982, 100%, 90.7%, respectively.*Conclusions Basis material decomposition technique with spectral CT can be used to quantitatively assess the staging of chronic hepatitis B hepatic fibrosis and provide more evidence for the early diagnosis of chronic hepatitis B liver fibrosis staging.*Clinical Relevance/Application The basis material decomposition technique with energy spectral CT is helpful for the evaluation of chronic hepatitis B hepatic fibrosis.

RESULTS

A total of 36 participants (mean age, 45.61 years ± 9.03 ; 16 women) and 20 control subjects (mean age, 38.30 years ±11.02; 11 men) were evaluated. There are differences in LNIC among different stages of chronic hepatitis B liver fibrosis (F=39.778, P<0.001). The RNIC showed strong nagative correlation with METAVIR stage (Spearman r=-0.830, P<0.001). The AUC values of LNIC in the diagnosis of chronic hepatitis B liver fibrosis staging are all >0.9, which has high diagnostic value. The AUC, sensitivity, specificity of LNIC distinguishes ?F1, ?F2, and ?F3+4 were 0.926, 86.11%, 95%; 0.922, 91.62%, 81.25%; 0.982, 100%, 90.7%, respectively.

CLINICAL RELEVANCE/APPLICATION

The basis material decomposition technique with energy spectral CT is helpful for the evaluation of chronic hepatitis B hepatic fibrosis.

SDP-GI-14 In Vivo Quantitative Proton MR Spectroscopy For Predicting The Presence Of Esophageal Varices Needing Treatment In Patients With Liver Cirrhosis

Participants
Sang Soo Shin, MD, Gwangju, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the metabolic change and its correlation with clinical characteristics to predict the presence of esophageal varices needing treatment (VNT) in patients with liver cirrhosis using in vivo quantitative proton magnetic resonance spectroscopy (1H-MRS).*Methods and Materials This prospective study consisted of 40 cirrhotic patients (M:F = 20:20, 59±21.45 years of age) without VNT including negative red color sign and 40 cirrhotic patients (M:F = 20:20, 63±22.9 years of age) with VNT including positive red color sign, which were classified by conventional endoscopy. 1H-MRS with single-voxel localization was performed in cirrhotic liver parenchyma at a 3-T MR scanner (Magnetom TimTrio). Blood cell counts and liver function were measured as blood-based biomarkers using a routine clinical chemistry analyzer. Also, the spleen diameter was measured on MR images as an imaging biomarker. Data were statistically analyzed using independent two-sample t-tests to compare clinical variables and analysis of covariance (ANCOVA) with adjustments for age and sex to compare the metabolic levels between the two groups. A multiple linear regression analysis was used to analyze the significant factors affecting cellular alterations of hepatic metabolism.*Results Cirrhotic patients with VNT had lower platelet counts, lower levels of serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT), higher total bilirubin, lower serum albumin levels, longer spleen diameters, and lower ratios of platelet count to spleen diameter than those without VNT. Except for AST and ALT levels, these clinical variables were all significantly different between the two groups (P < 0.05). Also, the metabolite levels of lactate+triglyceride (TG) and choline in cirrhotic patients with VNT were significantly higher as compared to those of cirrhotic patients without VNT (P < 0.05). Additionally, in cirrhotic patients with VNT, older age, longer spleen diameter, lower platelet counts, and lower ratios of platelet count/spleen diameter were significantly and independently associated with an increase in both lactate+TG and choline metabolites in the presence of esophageal VNT (except age, which was not significantly associated with choline).*Conclusions The higher values of lactate+TG and choline at 1H-MRS were associated with the presence of esophageal VNT. Those metabolic changes were correlated with longer spleen diameters, lower platelet counts, and lower ratios of platelet count to spleen diameter.*Clinical Relevance/Application 1H-MRS could be effectively used for predicting the presence of esophageal varices needing treatment in cirrhotic patients.

RESULTS

Cirrhotic patients with VNT had lower platelet counts, lower levels of serum aspartate aminotransferase (AST) and alanine aminotransferase (ALT), higher total bilirubin, lower serum albumin levels, longer spleen diameters, and lower ratios of platelet count to spleen diameter than those without VNT. Except for AST and ALT levels, these clinical variables were all significantly different between the two groups (P < 0.05). Also, the metabolite levels of lactate+triglyceride (TG) and choline in cirrhotic patients with VNT were significantly higher as compared to those of cirrhotic patients without VNT (P < 0.05). Additionally, in cirrhotic patients with VNT, older age, longer spleen diameter, lower platelet counts, and lower ratios of platelet count/spleen diameter were significantly and independently associated with an increase in both lactate+TG and choline metabolites in the presence of esophageal VNT (except age, which was not significantly associated with choline).

SDP-GI-15   Confounders Of Liver Ultrasound Positive Predictive Value In Hepatocellular Carcinoma Screening

Participants
Nadine Zeidan, MD, Dallas, Texas (*Presenter*) Nothing to Disclose

PURPOSE

Liver ultrasound (US) is recommended for hepatocellular carcinoma (HCC) surveillance by professional society guidelines including the American Association for the Study of Liver Disease (AASLD). Prior studies suggest patient-related factors, such as obesity and non-viral liver disease, are associated with worse visualization; however, their impact on diagnostic performance has not been reported. Therefore, we evaluated whether patient-related factors are associated with US exam-level specificity for HCC detection.*Methods and Materials This retrospective cohort study at two academic centers included patients with chronic liver disease, at risk for HCC, who had a screen-positive US exam per US LI-RADS (US-3) during 01/2016-06/2019. Patients were categorized as True Positive (TP) or False Positive (FP) by a composite reference standard of histology or diagnostic CT/MRI demonstrating HCC, or no clinical diagnosis of HCC =2 years after index US, respectively. Patients who were lost to follow-up prior to 2 years and duplicate US exams were excluded. We used logistic regression analysis to evaluate associations between US positivity and Visualization Score (A; B; C), Body Mass Index (BMI) >30 kg/m2, and viral vs. nonviral liver disease etiology.*Results Of 310 patients with US-3 exams, 37 patients (12%) were lost to follow-up. Of the remaining 273, 34% were TP and 66% were FP. Factors associated with FPR are summarized in Table 1. Higher FPR was significantly associated with BMI >30 kg/m2 (OR 2.17, p=0.004), nonviral cirrhosis (OR 2.38, p<0.001), and age younger than 60 years (OR 0.38, p<0.001). Notably, US Visualization Score was not significantly associated with FPR.*Conclusions Our results show a higher false positive rate in screening US liver exams in obese patients, and in those with nonviral cirrhosis, independent of Visualization Score. This suggests alternative surveillance strategies may be needed in these populations to reduce unnecessary harms associated with a false positive screen.*Clinical Relevance/Application We found two-thirds of screen-positive liver US (i.e., US-3) are false positive results, with a higher FPR in obese patients and in those with nonviral cirrhosis. False positive US results can lead to unnecessary invasive biopsies, additional costly and inconvenient follow-up imaging, and patient anxiety. This is concerning given the increasing prevalence of obesity and nonviral cirrhosis due to nonalcoholic steatohepatitis (NASH), suggesting this will become more problematic in the future. Our data highlight a clear need for alternative surveillance modalities, with increased diagnostic performance, for these patients.

RESULTS

Of 310 patients with US-3 exams, 37 patients (12%) were lost to follow-up. Of the remaining 273, 34% were TP and 66% were FP. Factors associated with FPR are summarized in Table 1. Higher FPR was significantly associated with BMI >30 kg/m2 (OR 2.17, p=0.004), nonviral cirrhosis (OR 2.38, p<0.001), and age younger than 60 years (OR 0.38, p<0.001). Notably, US Visualization Score was not significantly associated with FPR.

CLINICAL RELEVANCE/APPLICATION

We found two-thirds of screen-positive liver US (i.e., US-3) are false positive results, with a higher FPR in obese patients and in those with nonviral cirrhosis. False positive US results can lead to unnecessary invasive biopsies, additional costly and inconvenient follow-up imaging, and patient anxiety. This is concerning given the increasing prevalence of obesity and nonviral cirrhosis due to nonalcoholic steatohepatitis (NASH), suggesting this will become more problematic in the future. Our data highlight a clear need for alternative surveillance modalities, with increased diagnostic performance, for these patients.

SDP-GI-16   Two-section Formula Based On Axial+Coronal CT In The Discrimination Of Siewert Types Of Adenocarcinoma Of Esophagogastric Junction

Participants
Yiting Liu, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To build an easy-handled formula to judge the Siewert type of AEG on CT images, through the comparison with the pathological findings.*Methods and Materials A total of 62 patients with AEG were enrolled. All patients underwent preoperative enhancement CT and had postoperative Siewert type. Siewert type on CT was performed by two radiologists on venous phase. On the coronal CT image, find the angular notch (the anatomical junction of the esophagus and the greater curvature of stomach, A in the figure) and the counterpart point on the lesser curvature (B in the figure). Connect the two points with a smooth arc to get the EGJ line. The midpoint of the line on axial image equals to EGJ layer. Then we judge Siewert type using the layer numbers on axial images with two-section formula (TSF): formula 1. Positive values signified as Siewert III, and negative ones will use formula 2 to further discriminate Siewert I and II, the positive values will be determined as Siewert II, and negative as Siewert I. (The formula will be shown in PDF attachment.)*Results The interobserver agreement was good (kappa value=0.737). TSF method and pathological findings reached consensus in 56 patients: type I 11 in 15, type II 43 in 44, and type III 2 in 3. The Siewert type difference between pathology and TSF was not statistically significant different (p >0.05), and the agreement was good (kappa value=0.759).*Conclusions Two-section formula using axial combing with coronal CT information provided a potential method in the preoperative judgement of the Siewert type of AEG.*Clinical Relevance/Application Two-section formula might be applied to gastric cancer structured report for more convenient calculation in daily report writing.

RESULTS

The interobserver agreement was good (kappa value=0.737). TSF method and pathological findings reached consensus in 56 patients: type I 11 in 15, type II 43 in 44, and type III 2 in 3. The Siewert type difference between pathology and TSF was not statistically significant different (p >0.05), and the agreement was good (kappa value=0.759).

CLINICAL RELEVANCE/APPLICATION

Two-section formula might be applied to gastric cancer structured report for more convenient calculation in daily report writing.

SDP-GI-17   **The Role Of Preoperational Imaging Traits In Selecting Surgical Resection Or Radiofrequency Ablation For Single <= 5cm Hepatocellular Carcinoma**

Participants
Mengchao Wei, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Current treatment selection method for single = 5 cm hepatocellular carcinoma (HCC) gives inadequate attention on inter-tumor biological heterogeneity. Imaging traits including non-smooth tumor margins, internal arteries, peritumoral enhancement and absence of hypodense halos can reflect tumor aggressiveness preoperatively and may affect treatment selection. Therefore, our study aimed to explore the role of these four imaging traits in treatment selection between surgical resection (SR) and radiofrequency ablation (RFA) for patients with single = 5 cm HCC.*Methods and Materials 381 patients with single = 5 cm HCC who underwent SR (n=202) or RFA (n=179) in our hospital from April 2010 to December 2019 were retrospectively enrolled. The efficacy of SR and RFA in patients with the imaging traits that significantly influenced recurrence-free survival (RFS) or overall survival (OS) was compared and analyzed.*Results 381 patients with a median age of 56 years (interquartile range: 47-64 years) were evaluated. There were 330 men and 51 women. Multivariable Cox regression analysis identified albumin (P = 0.02), platelet (P = 0.02) and internal arteries (P = 0.001) were independent influencing factors for RFS, while prothrombin time (P < 0.001), internal arteries (P = 0.005) and peritumoral enhancement (P = 0.001) were independent influencing factors for OS. In patients with internal arteries, subgroup analysis based on tumor size demonstrated that both RFS and OS of SR were superior to those of RFA in patients with 3-5 cm HCC (RFS, P = 0.02; OS, P = 0.02). In patients with peritumoral enhancement, both RFS and OS of SR were superior to those of RFA (RFS, P = 0.02; OS, P = 0.04).*Conclusions Surgical resection might be the first choice for patients with single 3-5 cm hepatocellular carcinoma having internal arteries and patients with single = 5 cm hepatocellular carcinoma having peritumoral enhancement.*Clinical Relevance/Application Current treatment selection method gives inadequate attention on inter-tumor biological heterogeneity. As a consequence, doctors are unable to differentiate tumors with distinct aggressiveness. To tackle the challenge, our study adopted preoperative imaging traits as a surrogate of biological heterogeneity to illustrate its role in treatment selection of HCC and we successfully found a non-invasive, maneuverable and repeatable therapeutic selection method based on internal arteries and peritumoral enhancement. These traits are usually easily acquired and it would be convenient for doctors to apply the method in clinical practice.

RESULTS

381 patients with a median age of 56 years (interquartile range: 47-64 years) were evaluated. There were 330 men and 51 women. Multivariable Cox regression analysis identified albumin (P = 0.02), platelet (P = 0.02) and internal arteries (P = 0.001) were independent influencing factors for RFS, while prothrombin time (P < 0.001), internal arteries (P = 0.005) and peritumoral enhancement (P = 0.001) were independent influencing factors for OS. In patients with internal arteries, subgroup analysis based on tumor size demonstrated that both RFS and OS of SR were superior to those of RFA in patients with 3-5 cm HCC (RFS, P = 0.02; OS, P = 0.02). In patients with peritumoral enhancement, both RFS and OS of SR were superior to those of RFA (RFS, P = 0.02; OS, P = 0.04).

CLINICAL RELEVANCE/APPLICATION

Current treatment selection method gives inadequate attention on inter-tumor biological heterogeneity. As a consequence, doctors are unable to differentiate tumors with distinct aggressiveness. To tackle the challenge, our study adopted preoperative imaging traits as a surrogate of biological heterogeneity to illustrate its role in treatment selection of HCC and we successfully found a non-invasive, maneuverable and repeatable therapeutic selection method based on internal arteries and peritumoral enhancement. These traits are usually easily acquired and it would be convenient for doctors to apply the method in clinical practice.

SDP-GI-18   **Delta Radiomics On Dual-energy CT For Gastric Cancer With Neoadjuvant Chemotherapy: A Preliminary Study**

Participants
Yong Chen, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a radiomics signature to evaluate tumor regression grade (TRG) for locally advanced gastric cancer (GC) after neoadjuvant chemotherapy (NAC) and assess prognostic value.*Methods and Materials One hundred and three GC patients treated with NAC were retrospectively recruited from April 2018 to December 2019 and were randomly allocated into a training cohort (n = 69) and a validation cohort (n = 34). Delineation was performed on both mix and iodine uptake images on portal venous and delayed phases based on dual-energy CT (DECT). A total of 4094 radiomics features were extracted from pre-NAC, post-NAC and delta feature sets. Spearman correlation and the least absolute shrinkage and selection operator were used for robust analysis and dimensionality reduction. Multivariable logistic regression was used for TRG evaluation and generated the optimal radiomics signature. Kaplan-Meier survival analysis with log-rank test was implemented in an independent cohort of 40 patients for validating the prognostic value of the optimal radiomics signature.*Results Three, five and six radiomics features were finally selected for pre-NAC, post-NAC and delta feature sets. The delta model was demonstrated best performance assessing TRG both in the training and the validation cohorts (AUCs, 0.91 and 0.76, respectively, p > 0.1). The optimal radiomics signature from the delta model showed significant capability to predict DFS and OS in the independent cohort (p =0.027 and 0.014, respectively).*Conclusions Delta radiomics based on DECT images serves as a potential biomarker of TRG evaluation and shows potential prognostic values for GC patients with NAC.*Clinical Relevance/Application Delta radiomics based on dual-energy CT can serve as an alternative noninvasive tool for evaluating tumor regression grade for locally advanced gastric cancer after neoadjuvant chemotherapy.

RESULTS

Three, five and six radiomics features were finally selected for pre-NAC, post-NAC and delta feature sets. The delta model was demonstrated best performance assessing TRG both in the training and the validation cohorts (AUCs, 0.91 and 0.76, respectively, p > 0.1). The optimal radiomics signature from the delta model showed significant capability to predict DFS and OS in the independent cohort (p =0.027 and 0.014, respectively).

CLINICAL RELEVANCE/APPLICATION

Delta radiomics based on dual-energy CT can serve as an alternative noninvasive tool for evaluating tumor regression grade for locally advanced gastric cancer after neoadjuvant chemotherapy.

Predictive Value Of Gd-eob-dtpa Enhanced MRI With Adc : Microvaseular Invasion In Hepatocellular

Min Du, Xuzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Microvascular invasion (MVI) is one of the factors related to the prognosis of HCC. This study aims to explore the diagnostic value of clinical factors and Gd-EOB-DTPA enhanced MRI combined with ADC for HCC MVI.*Methods and Materials From September 2018 to December 2020, a total of 94 patients with 117 tumor were enrolled, who had complete information and didn't underwent any preoperative treatment. However, patients with recurrent HCC or other malignant tumors were excluded. Finally, the imaging of the patients were collected, including the peritumoral enhancement, peritumoral hypointensity, tumor maximum diameter, and tumor apparent diffusion coefficient (ADC) value, ADC ratio (the ratio of tumor ADC value to normal liver parenchymal ADC value), mismatch between diffusion-weighted imaging (DWI) and T2-weighted image (T2WI). Gender, age, alpha- fetoprotein (AFP), Protein induced by vitamin K absence or antagonist-II (PIVKA-II). These factors are divided into two groups: MVI positive (+) and MVI negative (-). Univariate analyses are performed in clinical and imaging factors and also logistic regression analyses. The receiver operating characteristic (ROC) curve is used to evaluate the diagnostic value of various factors for HCC MVI.*Results In the clinical factors, PIVKA-II was an independent predictor for HCC MVI The area of under the ROC curve (AUC) is 0.853, the sensitivity and specificity are 80.0% and 78.3%respectively, and the cut-off value is = 255 mAu/ml. AFP, gender, number of lesions and age groups are not correlated with HCC MVI. In the imaging factors, logistic regression analyses revealed peritumoral enhancement, peritumor hypointensity are independent predictors for MVI ,but largest tumor diameter and mismatch between DWI and T2WI are not independent predictors for MVI. However, the difference of the largest tumor diameter and mismatch between DWI and T2WI in groups are statistically significant. ROC curve analysis showed that the AUC of the peritumoral enhancement is the largest.However, these four factors united has highest AUC of 0.824, and has good sensitivity (79.4%) and specificity (77.1%).*Conclusions PIVKA-II is an independent predictor for HCC MVI with high diagnostic value. At the same time, peritumoral enhancement in the artery phase and peritumor hypointensity in the hepatobiliary phase are independent risk factors for HCC MVI. The maximum diameter of the tumor and the shape of the tumor are related to HCC MVI. The combination of the four factors has the highest value in the diagnose of HCC MVI. ADC value and ADC ratio and mismatch between DWI and T2WI have limited value in the diagnose of HCC MVI.*Clinical Relevance/Application Helping predict HCC MVI in advance and helping doctors choose appropriate treatments to improve prognosis

RESULTS

In the clinical factors, PIVKA-II was an independent predictor for HCC MVI The area of under the ROC curve (AUC) is 0.853, the sensitivity and specificity are 80.0% and 78.3%respectively, and the cut-off value is = 255 mAu/ml. AFP, gender, number of lesions and age groups are not correlated with HCC MVI. In the imaging factors, logistic regression analyses revealed peritumoral enhancement, peritumor hypointensity are independent predictors for MVI ,but largest tumor diameter and mismatch between DWI and T2WI are not independent predictors for MVI. However, the difference of the largest tumor diameter and mismatch between DWI and T2WI in groups are statistically significant. ROC curve analysis showed that the AUC of the peritumoral enhancement is the largest.However, these four factors united has highest AUC of 0.824, and has good sensitivity (79.4%) and specificity (77.1%).

CLINICAL RELEVANCE/APPLICATION

Helping predict HCC MVI in advance and helping doctors choose appropriate treatments to improve prognosis

SDP-GI-2   Dynamic CT and Gadoxetic Acid-Enhanced MR Imaging Characteristics of P53-Mutated Hepatocellular Carcinoma

Participants
Azusa Kitao, MD, Kanazawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To clarify the imaging characteristics of P53-mutated hepatocellular carcinoma (HCC) correlated with clinical features, pathology, and prognosis.*Methods and Materials Institutional review board approval was obtained, and informed consent was waived. One hundred forty-nine patients with 175 HCCs who were diagnosed by surgical resection at our institution from January 2015 to May 2018 were enrolled. Cases were classified as HCC with P53 mutation (n=28) and HCC without P53 mutation (n=147) by immunostaining. Dynamic CT and gadoxetic acid-enhanced MR imaging (MRI) findings, clinical features, pathological findings, and prognosis were compared. P53 and organic anion-transporting polypeptide (OATP) 1B3 expression detected by immunochemistry was semiquantitatively evaluated.*Results P53-mutated HCC showed significantly higher serum alpha fetoprotein (AFP) (median 34 ng/ml vs 6 ng/ml; P=0.0001) and AFP-L3 fraction (7.15% vs 0.5%; P=0.001). P53-mutated HCC was often poorly differentiated (75.0% vs 17.0%; P<0.0001). In the arterial phase of dynamic CT, P53-mutated HCC showed poorly enhanced areas (57.1% vs 32.0%; P=0.003) and dilated arteries (35.7% vs 10.2%; P=0.002). In the hepatobiliary phase of gadoxetic acid-enhanced MRI, irregular tumor margin (39.3% vs 18.4%; P=0.05), peritumoral hypointensity (28.6% vs 9.5%; P=0.01), relative enhancement ratio (1.34 vs 1.70; P=0.04), and lower tumor/liver signal intensity ratio (0.46 vs 0.60; P=0.004) were common in P53-mutated HCC. In multivariate regression analysis, low signal intensity ratio in the hepatobiliary phase was an independent predictor of P53-mutated HCC (P=0.008, OR=0.02). Area under the curve of receiver operating characteristic curve was 0.68 and the cut-off value was 0.50. There was a significantly positive correlation between OATP1B3 expression and signal intensity ratio in the hepatobiliary phase (P<0.0001, R=0.41), and an inverse correlation between OATP1B3 expression and P53 expression (P=0.002, R=-0.23). Overall survival was worse in P53-mutated HCC than in HCC without P53 mutation (P=0.02).*Conclusions P53-mutated HCC is a biologically aggressive subtype with higher serum tumor marker expression, poorer differentiation grade, and worse survival. A lower signal intensity ratio in the hepatobiliary phase is useful for predicting P53-mutated HCC.*Clinical Relevance/Application Imaging findings, especially lower signal intensity ratio in the hepatobiliary phase, will help to predict P53-mutated HCC with aggressive features.

RESULTS

P53-mutated HCC showed significantly higher serum alpha fetoprotein (AFP) (median 34 ng/ml vs 6 ng/ml; P=0.0001) and AFP-L3 fraction (7.15% vs 0.5%; P=0.001). P53-mutated HCC was often poorly differentiated (75.0% vs 17.0%; P<0.0001). In the arterial phase of dynamic CT, P53-mutated HCC showed poorly enhanced areas (57.1% vs 32.0%; P=0.003) and dilated arteries (35.7% vs 10.2%; P=0.002). In the hepatobiliary phase of gadoxetic acid-enhanced MRI, irregular tumor margin (39.3% vs 18.4%; P=0.05), peritumoral hypointensity (28.6% vs 9.5%; P=0.01), relative enhancement ratio (1.34 vs 1.70; P=0.04), and lower tumor/liver signal intensity ratio (0.46 vs 0.60; P=0.004) were common in P53-mutated HCC. In multivariate regression analysis, low signal intensity ratio in the hepatobiliary phase was an independent predictor of P53-mutated HCC (P=0.008, OR=0.02). Area under the curve of receiver operating characteristic curve was 0.68 and the cut-off value was 0.50. There was a significantly positive correlation between OATP1B3 expression and signal intensity ratio in the hepatobiliary phase (P<0.0001, R=0.41), and an inverse correlation

between OATP1B3 expression and P53 expression (P=0.002, R=-0.23). Overall survival was worse in P53-mutated HCC than in HCC without P53 mutation (P=0.02).

CLINICAL RELEVANCE/APPLICATION

Imaging findings, especially lower signal intensity ratio in the hepatobiliary phase, will help to predict P53-mutated HCC with aggressive features.

SDP-GI-20 Usefulness Of Contrast-enhanced Ultrasound LI-RADS Version 2017: Diagnostic Accuracy And Inter-reader Agreement For Differentiating Hepatocellular Carcinoma From Other Malignancies

Participants
Rushuang Mao, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to explore the diagnostic accuracy of contrast-enhanced ultrasound (CEUS) Liver Imaging Reporting and Data System (LI-RADS) version 2017 for differentiating hepatocellular carcinoma (HCC) from non-HCC malignancies in high-risk patients, and to determine the inter-reader agreement (IRA) between the expert and novice reader for CEUS features and the final categories.*Methods and Materials Patients with chronic hepatitis B virus infection and at least one US-detected liver observation between 2006 and 2019 were enrolled in this retrospective study. Eventually, 517 patients with 517 pathologically proven observations (384 HCC, 78 intrahepatic cholangiocarcinoma, 50 combined hepatocellular cholangiocarcinoma, 5 metastases) evaluated at CEUS were included. A novice reader (R1) and an experienced reader (R2) independently assessed CEUS features and assigned an LI-RADS category for each observation.*Results The LR-5 category yielded a high specificity (R1, 92.48%; R2, 93.98%) and high PPV (R1, 96.48%; R2, 97.18%) for diagnosing HCC. For identifying non-HCC malignancies, the LR-M category had high sensitivity and high NPV for both readers (R1, 92.48%, and 96.63%; R2, 93.98%, and 97.30%). The inter-reader agreement for individual features and the overall LI-RADS algorithm were substantial to almost perfect (enhancement, ?=0.829; onset of washout, ?=0.835; degree of washout, ?=0.857; overall LI-RADS algorithm, ?=0.828).*Conclusions The CEUS LI-RADS had brilliant diagnostic accuracy for distinguishing HCC from non-HCC malignancies, and substantial to almost perfect inter-reader agreement was obtained between the expert and novice radiologists for both individual features and LI-RADS categories.*Clinical Relevance/Application Applying CEUS LI-RADS in clinical practice can effectively distinguish the HCC from non-HCC malignancies, and can help improve the diagnostic performance of novice radiologists.

RESULTS

The LR-5 category yielded a high specificity (R1, 92.48%; R2, 93.98%) and high PPV (R1, 96.48%; R2, 97.18%) for diagnosing HCC. For identifying non-HCC malignancies, the LR-M category had high sensitivity and high NPV for both readers (R1, 92.48%, and 96.63%; R2, 93.98%, and 97.30%). The inter-reader agreement for individual features and the overall LI-RADS algorithm were substantial to almost perfect (enhancement, ?=0.829; onset of washout, ?=0.835; degree of washout, ?=0.857; overall LI-RADS algorithm, ?=0.828).

CLINICAL RELEVANCE/APPLICATION

Applying CEUS LI-RADS in clinical practice can effectively distinguish the HCC from non-HCC malignancies, and can help improve the diagnostic performance of novice radiologists.

SDP-GI-21 A CT-based Radiomics Nomogram For Prediction Of Preoperative Pathological Grading Of Advanced Gastric Cancer

Participants
xiaolei wang I, BS,BS, BengBu, China (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to establish and validate the the radiomics nomogram constructed based on the radiomics signature of enhanced CT images combined with clinical features in the preoperative pathological grading of advanced gastric cancer.*Methods and Materials A retrospective analysis of 260 patients with pathologically confirmed gastric cancer obtained from two centers (176 in the training cohort, 44 in the internal testing cohort, and 40 in the external testing cohort) was performed to outline the region of interests (ROIs) and extract radiomics signature on arterial phase and venous phase CT images, respectively. The least absolute shrinkage and selection operator regression and iterative screening features were applied for feature selection and radiomics signature construction. An external testing cohort was used to verify the stability of arterial model, and finally the arterial phase radiomics signature were combined with clinical independent risk factors to establish the combined model and radiomics nomogram using support vector machine (SVM) and multiple logistic regression, respectively. The utility of the proposed model was evaluated using the ROC, area under ROC curve (AUC), calibration curve, and decision curve analysis (DCA).*Results Arterial model with 8 feature combinations (training cohort: AUC = 0.827; testing cohort: AUC = 0.827), The efficacy was higher than that of the venous model (Training cohort: AUC = 0.803; Testing cohort: AUC = 0.799). External validation demonstrated the stability of the arterial model (Training cohort: AUC = 0.809; Testing cohort: AUC = 0.792), and after single-factor and multi-factor logistic regression screening, the independent clinical correlates were used to contracted a clinical model (Training cohort: AUC = 0.639; Testing cohort: AUC = 0.659). Three independent predictors of radiomics signature, gender and enhancement degree were finally selected to construct the combined model (Training cohort: AUC = 0.869; Testing cohort: AUC = 0.851) and the radiomics nomogram model (Training cohort: AUC = 0.877; Testing cohort: AUC = 0.854) were constructed respectively. The efficacy of the radiomics nomogram was higher than that of the combined model. The calibration curve and DCA demonstrated the clinical usefulness of the radiomics nomogram.*Conclusions The radiomics nomogram model constructed in this study is more effective than other models and can be useful in predicting the preoperative pathological grading of advanced gastric cancer.*Clinical Relevance/Application The application of AI method such as radiomics nomogram constructed based on the radiomics signature of CT images combined can provide higher level.

RESULTS

Arterial model with 8 feature combinations (training cohort: AUC = 0.827; testing cohort: AUC = 0.827), The efficacy was higher than that of the venous model (Training cohort: AUC = 0.803; Testing cohort: AUC = 0.799). External validation demonstrated the stability of the arterial model (Training cohort: AUC = 0.809; Testing cohort: AUC = 0.792), and after single-factor and multi-factor logistic regression screening, the independent clinical correlates were used to contracted a clinical model (Training cohort: AUC = 0.639; Testing cohort: AUC = 0.659). Three independent predictors of radiomics signature, gender and enhancement degree were finally selected to construct the combined model (Training cohort: AUC = 0.869; Testing cohort: AUC = 0.851) and the radiomics

nomogram model (Training cohort: AUC = 0.877; Testing cohort: AUC = 0.854) were constructed respectively. The efficacy of the radiomics nomogram was higher than that of the combined model. The calibration curve and DCA demonstrated the clinical usefulness of the radiomics nomogram.

CLINICAL RELEVANCE/APPLICATION

The application of AI method such as radiomics nomogram constructed based on the radiomics signature of CT images combined can provide higher level.

SDP-GI-22   A Deep Learning Risk Prediction Model Based On Residual CNN For Overall Survival In Patients With Advanced Gastric Cancer

Participants
Wenjuan Zhang, Lanzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Gastric cancer is one of the most common malignant tumors of the digestive tract. Predicting the probability of survival accurately before surgery, stratifying the risk, are the key steps to individualized treatment of gastric cancer. This study aimed to construct and validate a survival risk prediction deep learning (DL) model based on the widely recognized residual convolutional neural network (Residual CNN).*Methods and Materials We retrospectively collected 337 patients from Lanzhou University Second Hospital, which were divided into a training cohort (n=237) and an external validation cohort (n=100). We developed an end-to-end DL model based on the architecture of Residual CNN, and augmented the size of training dataset by image transformations to avoid overfitting. Cox regression for univariable and multivariable analysis were used to develop a clinical model. Meanwhile, a comprehensive prediction model was constructed by combining the DL model and the clinical model, and then, nomogram was constructed. We calculated the Harrell's concordance index (C-index) and hazard ratio (HR) to evaluate the performance of the three models. Calibration curves and decision curve analysis (DCA) was also applied to verify the prognostic value of these prediction models.*Results Totally 5688 CT images were prepared by data augmentation and fed into DL model. The DL model significantly classified patients into high-risk and low-risk groups in training cohort (C-index: 0.70, HR: 2.88, P<0.002) and validation cohort (C-index:0.64, HR: 4.32, P<0.002,). The clinical model was developed with three significant clinical variables (P <0.05). The comparison illustrated the combined model (DL+ Clinical) had the best performance for risk prediction of OS according to the C-index (training: combined model vs DL vs Clinical =0.74 vs 0.72 vs 0.70, validation: 0.67 vs 066 vs 0.64). The DL model also had the highest HR both in training and validation cohort. The calibration curve analysis shows that the predicted 1, 2 and 3 year survival probability based on the integrated prediction model is in good agreement with the actual OS. The DCA also proved that the comprehensive prediction model had the best net benefit than other models for the patients.*Conclusions The DL model constructed based on the Residual CNN in this study is a good survival risk assessment model and has good application value for the early prediction of OS in AGC patients.*Clinical Relevance/Application The new AI technology is expected to effectively supplement the existing prognostic evaluation system and may become a potential tool to guide the personalized treatment of AGC.

RESULTS

Totally 5688 CT images were prepared by data augmentation and fed into DL model. The DL model significantly classified patients into high-risk and low-risk groups in training cohort (C-index: 0.70, HR: 2.88, P<0.002) and validation cohort (C-index:0.64, HR: 4.32, P<0.002,). The clinical model was developed with three significant clinical variables (P <0.05). The comparison illustrated the combined model (DL+ Clinical) had the best performance for risk prediction of OS according to the C-index (training: combined model vs DL vs Clinical =0.74 vs 0.72 vs 0.70, validation: 0.67 vs 066 vs 0.64). The DL model also had the highest HR both in training and validation cohort. The calibration curve analysis shows that the predicted 1, 2 and 3 year survival probability based on the integrated prediction model is in good agreement with the actual OS. The DCA also proved that the comprehensive prediction model had the best net benefit than other models for the patients.

CLINICAL RELEVANCE/APPLICATION

The new AI technology is expected to effectively supplement the existing prognostic evaluation system and may become a potential tool to guide the personalized treatment of AGC.

SDP-GI-23   Comparison Of Volumetric Liver Fat Measurement Method And Conventional Method Of Drawing Of Region Of Interest

Participants
Hyun Ji Lee, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the feasibility of volumetric liver fat measurement methods (Fvol) compared to conventional multiple region of interest drawing methods (Froi)*Methods and Materials Sixty-seven patients who underwent liver MRI with fat quantification from August to September 2020 were included in this retrospective study. Two experienced radiologists measured proton density fat fraction (PDFF) of the liver twice in the mDIXON-Quant sequence using two methods: Fvol, PDFF was measured volumetrically using dedicated program and Vroi, 3 ROIs were drawn on each segment (total of 24) and the averaged value was calculated. PDFF measurement was performed twice with each method with at least 4 weeks interval to avoid recall bias. Measurement times were recorded for the comparison between the two methods. The intra-class correlation coefficient (ICC) were calculated between the observer and method. Inter-observer variability was also evaluated between the two measurements of the same method. P values less than 0.05 were considered as statistically significant.*Results The measurement times were significantly shorter in Fvol (127±46s and 64±18s for reviewer 1 and 2) compared to Froi (209±55s and 191±31s, P<0.05). ICC for the same methods in each reviewer were excellent (R1: 0.998, 95% confidence interval 0.998-0.999 and R2: 0.999, 0.999-1.000 for Froi; R1: 0.999, 0.999-1.000 and R2: 1.000, 1.000-1.000 for Fvol). ICC between reviewers (0.999, 0.998~0.999 for Froi and 1.000, 0.999~1.000 for Fvol) and between measurement methods (0.998, 0.996-0.999) for reviewer 1 and 0.995, 0.991-0.997 for reviewer 2) were also excellent.*Conclusions The measurement time of PDFF could be significantly reduced using Fvol compared to Froi, while maintaining the consistency of the measurement values.*Clinical Relevance/Application Volumetric measurement method of PDFF can reduce the measurement time with maintaining the consistency of the measured value

RESULTS

The measurement times were significantly shorter in Fvol (127±46s and 64±18s for reviewer 1 and 2) compared to Froi (209±55s and 191±31s, P<0.05). ICC for the same methods in each reviewer were excellent (R1: 0.998, 95% confidence interval 0.998-0.999 and R2: 0.999, 0.999-1.000 for Froi; R1: 0.999, 0.999-1.000 and R2: 1.000, 1.000-1.000 for Fvol). ICC between reviewers (0.999,

0.998~0.999 for Froi and 1.000, 0.999~1.000 for Fvol) and between measurement methods (0.998, 0.996-0.999) for reviewer 1 and 0.995, 0.991-0.997 for reviewer 2) were also excellent.

CLINICAL RELEVANCE/APPLICATION

Volumetric measurement method of PDFF can reduce the measurement time with maintaining the consistency of the measured value

SDP-GI-25   Application Of Iodine Concentration Quantitative Analysis Based On Energy Spectrum CT In Evaluating The Degree Of Differentiation Of Gastric Adenocarcinoma

Participants
Lu Ye, Tianjin, China (*Presenter*) Nothing to Disclose

PURPOSE

To determine the application value of iodine concentration (IC) for the pathological differentiation degree of gastric adenocarcinoma, and to compare their diagnostic efficacy.*Methods and Materials A retrospective analysis of 64 patients' clinical and imaging data with pathologically confirmed gastric adenocarcinoma was conducted by measuring the IC of arterial phase and portal venous phase of contrast-enhanced CT, including 21 patients with moderate/highly differentiated adenocarcinoma, 21 patients with moderately poorly differentiated adenocarcinoma, and 22 patients with poorly differentiated adenocarcinoma. The correlation with gastric adenocarcinoma differentiation were performed, receiver operating characteristic (ROC) curve analysis was further performed to explore their diagnostic efficiency for the values with statistical significance.*Results ICAP values of moderate/highly differentiated, moderately poorly differentiated and poorly differentiated gastric adenocarcinoma were 1.06±0.44 mg/mL, 1.48±0.51 mg/mL, 1.72±0.54 mg/mL, respectively,nICAP values was 0.15±0.05, 0.18±0.05, 0.22±0.09, and ICPP values were 2.81±0.59 mg/mL, 3.17±0.80 mg/mL, 3.64±0.79 mg/mL, respectively. The values of nICPP were 0.43±0.13, 0.55±0.13, 0.65±0.17, among which the nICPP value of poorly differentiation and moderately poorly differentiation group, the ICAP, nICAP, nICPP value of moderate/highly differentiation and moderately poorly differentiation group, the ICAP, nICAP, ICPP and nICPP values of moderate/highly differentiation and poorly differentiation group were statistically significant(p<0.05). Classified moderately poorly and poorly differentiation as poorly differentiation, the values of ICAP, nICAP, ICPP, nICPP were 1.61±0.53 mg/mL, 0.20±0.07, 3.41±0.82 mg/mL, 0.60±0.16 respectively. The AUC was 0.791, 0.749, 0.721, and 0.814 respectively. When the diagnostic threshold was 0.507, nICPP had the highest diagnostic efficiency for poorly differentiated gastric adenocarcinoma, with a sensitivity of 69.8% and a specificity of 81.0%.*Conclusions The quantitative analysis of IC of energy spectrum CT can determine the pathological differentiation degree of advanced gastric adenocarcinoma, and the nICPP value was most effective.*Clinical Relevance/Application IC and nIC of energy spectrum CT in arterial and venous phases have great potential in predicting the differentiation of gastric adenocarcinoma, and can provide a new index for preoperative evaluation.

RESULTS

ICAP values of moderate/highly differentiated, moderately poorly differentiated and poorly differentiated gastric adenocarcinoma were 1.06±0.44 mg/mL, 1.48±0.51 mg/mL, 1.72±0.54 mg/mL, respectively,nICAP values was 0.15±0.05, 0.18±0.05, 0.22±0.09, and ICPP values were 2.81±0.59 mg/mL, 3.17±0.80 mg/mL, 3.64±0.79 mg/mL, respectively. The values of nICPP were 0.43±0.13, 0.55±0.13, 0.65±0.17, among which the nICPP value of poorly differentiation and moderately poorly differentiation group, the ICAP, nICAP, nICPP value of moderate/highly differentiation and moderately poorly differentiation group, the ICAP, nICAP, ICPP and nICPP values of moderate/highly differentiation and poorly differentiation group were statistically significant(p<0.05). Classified moderately poorly and poorly differentiation as poorly differentiation, the values of ICAP, nICAP, ICPP, nICPP were 1.61±0.53 mg/mL, 0.20±0.07, 3.41±0.82 mg/mL, 0.60±0.16 respectively. The AUC was 0.791, 0.749, 0.721, and 0.814 respectively. When the diagnostic threshold was 0.507, nICPP had the highest diagnostic efficiency for poorly differentiated gastric adenocarcinoma, with a sensitivity of 69.8% and a specificity of 81.0%.

CLINICAL RELEVANCE/APPLICATION

IC and nIC of energy spectrum CT in arterial and venous phases have great potential in predicting the differentiation of gastric adenocarcinoma, and can provide a new index for preoperative evaluation.

SDP-GI-26   CT Texture Features In The Prediction Of Overall Survival In Patients With Her2+ Stage IV Gastric Cancer

Participants
Lei Tang, MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Non-invasive evaluation of target therapy for gastric cancer remains an urgent clinical need. We intend to determine whether CT texture features (CTTA) could become potential biomarkers for the prognosis in HER2+ stage IV gastric cancer patients treated by trastuzumab.*Methods and Materials 71 HER2+ stage IV gastric cancer patients were retrospectively enrolled into this study. 107 quantitative features, including histogram features, fractal features and high-level texture features, were extracted from each of the regions of interest (ROI) on arterial and venous phases, respectively. After intra-class correlation coe&9;cient (ICC) calculation and consistency test evaluating the reader agreement on feature extraction, Cox proportional hazard analysis and Kaplan-Meier analysis were used to determine the association of texture features and clinicopathological factors with overall survival (OS).*Results The median overall survival was 16.95 months. On multivariate Cox analysis, diffuse or mixed Lauren type (hazard ratio [HR]=8.074, 95 % confidence interval [CI]=3.335-19.574), BMI (HR=1.145, CI=1.027-1.276), CEA level (HR=1.002, CI=1.001-1.003) and two of key texture features, Arterial_GrayLevelDependenceMatrix_DependenceNonUniformityNormalized (A_GLDM_DNUN) (HR=1.953, CI=1.281-2.976) and V_GLDM_DNUN(HR=1.775, CI=1.148-2.744), were independently and significantly potential prognostic factors for overall survival. On Kaplan-Meier survival analysis of CT texture features parameters, A_GLDM_DNUN of more than -0.43 and V_GLDM_DNUN of more than -1.04 show more adverse overall survival (p<0.001 and p=0.002, log-rank test)*Conclusions For HER2+ stage IV gastric cancer patients treated with trastuzumab, the CT-guided radiomics signatures have the potential to be the non-invasive surrogates for the prediction of OS.*Clinical Relevance/Application We intend to expand the sample size and establish an external validation cohort to further explore the potential connection between prognosis and imaging biomarkers, for future applying it in clinical decision-making as soon as possible.

RESULTS

The median overall survival was 16.95 months. On multivariate Cox analysis, diffuse or mixed Lauren type (hazard ratio [HR]=8.074, 95 % confidence interval [CI]=3.335-19.574), BMI (HR=1.145, CI=1.027-1.276), CEA level (HR=1.002, CI=1.001-1.003) and two of key texture features, Arterial_GrayLevelDependenceMatrix_DependenceNonUniformityNormalized (A_GLDM_DNUN) (HR=1.953,

CI=1.281-2.976) and V_GLDM_DNUN(HR=1.775, CI=1.148-2.744), were independently and significantly potential prognostic factors for overall survival. On Kaplan-Meier survival analysis of CT texture features parameters, A_GLDM_DNUN of more than -0.43 and V_GLDM_DNUN of more than -1.04 show more adverse overall survival (p<0.001 and p=0.002, log-rank test)

CLINICAL RELEVANCE/APPLICATION

We intend to expand the sample size and establish an external validation cohort to further explore the potential connection between prognosis and imaging biomarkers, for future applying it in clinical decision-making as soon as possible.

SDP-GI-27 The Effect Of Deep Learning-based CT Image Reconstruction On The Image Quality Of The Biliary System

Participants
Jia Xu, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the effects of a deep learning reconstruction (DLR) method on the clear visibility of biliary system in patients with biliary system disease on abdominal CT images, in comparison with different iterative reconstruction (IR) algorithms (hybrid IR [AIDR3D], forward projected model-based IR [FIRST]) and conventional filtered back projection (FBP).*Methods and Materials This retrospective study included the imaging data of all the 30 consecutive patients who underwent clinically indicated contrast-enhanced abdominal imaging at our hospital between March and April 2021 with bile-duct dilatation caused by different biliary diseases (such as bile ducted stone, cholangitis, bile duct wall thickening). The portal phases were reconstructed using four different algorithms (DLR, FBP, AIDR3D and FIRST) separately. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of the biliary system, as well as image noise (which was calculated as the SD of the CT values for anterior subcutaneous fat) were compared among the four datasets. In subjective analyses, two radiologists independently ordered images (1, poor; 4, excellent) based on the visual image quality of the biliary system. Numerical data are expressed as means ± standard deviations. Qualitative variables were expressed as mean (minimum; maximum). The Friedman and the Dunn-Bonferroni post-hoc tests were used for comparison.*Results DLR images yielded significant higher CNR (4.4±0.87) than FBP (2.2±1.0), AIDR3D (2.8±0.91) and FIRST (2.5±1.2) images (all P<0.05), higher SNR (1.39±0.85) than FBP (0.86±0.63) and FIRST (1.0±0.61) images (all P<0.05), and showed lower image noise (10.5±3.5) than FBP (24.1±3.9), AIDR3D (15.7±2.4) and FIRST (21.5±19.6) images (all P<0.05). AIDR3D showed significant higher SNR (1.17±0.74), CNR (2.8±0.91) and lower image noise (15.7±2.4) than FBP (0.86±0.63, 2.2±1.0, 24.1±3.9, SNR, CNR and image noise respectively) images (all P<0.05). There were no significant differences in SNR and CNR between FIRST and AIDR3D images (all P>0.05). DLR images obtained higher score (4) than FPB (4), AIDR3D [2.85 (2;3)]and FIRST [2.15 (2;3)] (all P<0.05).*Conclusions DLR images yield significant lower the image noise, higher CNR compared to FBP, AIDR3D and FIRST images. DLR images showed the best visual image quality of the biliary system.*Clinical Relevance/Application DLR method can improve the image quality, resulted in a better observation of the structure of the biliary system.

RESULTS

DLR images yielded significant higher CNR (4.4±0.87) than FBP (2.2±1.0), AIDR3D (2.8±0.91) and FIRST (2.5±1.2) images (all P<0.05), higher SNR (1.39±0.85) than FBP (0.86±0.63) and FIRST (1.0±0.61) images (all P<0.05), and showed lower image noise (10.5±3.5) than FBP (24.1±3.9), AIDR3D (15.7±2.4) and FIRST (21.5±19.6) images (all P<0.05). AIDR3D showed significant higher SNR (1.17±0.74), CNR (2.8±0.91) and lower image noise (15.7±2.4) than FBP (0.86±0.63, 2.2±1.0, 24.1±3.9, SNR, CNR and image noise respectively) images (all P<0.05). There were no significant differences in SNR and CNR between FIRST and AIDR3D images (all P>0.05). DLR images obtained higher score (4) than FPB (4), AIDR3D [2.85 (2;3)]and FIRST [2.15 (2;3)] (all P<0.05).

CLINICAL RELEVANCE/APPLICATION

DLR method can improve the image quality, resulted in a better observation of the structure of the biliary system.

SDP-GI-28 Deep Learning Based Spectral CT Imaging For Quantifying Contrast Medium Enhancement And Washout In Hepatocellular Carcinomas: Comparison Of Iodine Maps And Virtual Monochromatic Images

Participants
Keigo Narita, Hiroshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

The typical characteristics of hepatocellular carcinoma (HCC) images include arterial-phase hyperenhancement and washout in the portal venous- and equilibrium phases. Deep learning (DL) based spectral CT imaging (DL-SCTI), a novel rapid kV-switching dual-energy technique, facilitates robust material decomposition analysis because the exact spatial and temporal alignment of high and low kV views yielded by the DL technique results in good energy separation. We compared iodine maps generated from hepatic arterial- and equilibrium phase DL-SCTI scans with virtual monochromatic images at 70 keV to assess their clinical applicability for the quantification of the contrast uptake and washout in HCC.*Methods and Materials Fifty-two patients with 61 hypervascular HCCs which vascularity was confirmed with CT during hepatic arteriography were evaluated with dynamic DL-SCTI scans. Virtual monochromatic images at 70 keV served as the conventional images. Iodine maps were reconstructed using three-material decomposition (fat, healthy liver tissue, iodine). A radiologist measured the image noise represented by the standard deviation of the attenuation measured in the paraspinal muscle and calculated the contrast-to-noise ratio (CNR) using the equation CNR = (ROIT- ROIL)/N, where ROIL is the mean attenuation of the liver parenchyma, ROIT the mean tumor attenuation, and N the noise.*Results In the arterial phase, the CNR for HCCs was significantly higher on iodine maps (3.34) than on 70 keV images (2.39) (p = 0.03). While only one HCC had a negative CNR on iodine maps, 6 had a negative CNR on 70 keV images. In the equilibrium phase, the CNR for HCCs was significantly lower on 70 keV images (-0.71) than on iodine maps (-0.05) (p < 0.01). Fewer HCCs had a negative CNR (washout) on iodine maps than on 70 keV images (32 vs 47).*Conclusions Iodine maps generated from DL-SCTI scans help in the assessment of HCCs for their arterial vascularity but not for washout in the equilibrium phase.*Clinical Relevance/Application Iodine maps generated from DL-SCTI scans were useful for evaluating the arterial hypervascularity of HCCs but not for evaluating washout in the equilibrium phase.

RESULTS

In the arterial phase, the CNR for HCCs was significantly higher on iodine maps (3.34) than on 70 keV images (2.39) (p = 0.03). While only one HCC had a negative CNR on iodine maps, 6 had a negative CNR on 70 keV images. In the equilibrium phase, the CNR for HCCs was significantly lower on 70 keV images (-0.71) than on iodine maps (-0.05) (p < 0.01). Fewer HCCs had a negative CNR

(washout) on iodine maps than on 70 keV images (32 vs 47).

CLINICAL RELEVANCE/APPLICATION

Iodine maps generated from DL-SCTI scans were useful for evaluating the arterial hypervascularity of HCCs but not for evaluating washout in the equilibrium phase.

SDP-GI-29 Evaluation Of Pancreatic Fibrosis: Extracellular Volume Fraction (ECV) Measurements Using Contrast-enhanced CT And Its Relation To Pancreatic Cancer

Participants
Hideyuki Fukui, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Pancreatic cancer is one of the fatal neoplasms, which is challenging to diagnose at an early stage. Recent studies show pancreatic fibrosis plays a pivotal role in pancreatic carcinogenesis. However, the clinically relevant methods have not yet to be derived for pancreatic fibrosis detection. This study aimed to assess the relationship between pancreatic fibrosis measured by extracellular volume fraction (ECV) using contrast-enhanced CT and histological pancreatic fibrosis and investigate the relationship between pancreatic fibrosis and pancreatic cancer presence.*Methods and Materials The study included 96 consecutive patients (54 males and 42 females; median age, 69 years; range, 17-89 years). Among these patients, 53 had pancreatic cancer, 43 had other diseases. Fifty-two cases were evaluated pathologically for pancreatic fibrosis to assess whether CT could be used to detect pancreatic fibrosis. The histological pancreatic fibrosis was quantified by using image analysis software (BZ-X analyzer; Keyence, Osaka, Japan) in nontumorous pancreatic tissue at the resection stump using 2-μm thick Azan-stained slides. A board-certified radiologist measured ECV by generating the largest possible spherical region of interest in the pancreatic parenchyma at an estimated transaction line to match the measurement point on CT with the area of pathological assessment. We investigated the correlation between histological pancreatic fibrosis and ECV and determined the optimal ECV cutoff value for detecting pancreatic cancer. We then investigated whether the ECV value could be used as a biomarker for pancreatic cancer.*Results The histological pancreatic fibrosis, ranged from 4.0% to 78.0% (median, 16.0%; interquartile range, 11.0%-30.8%), were significantly correlated with the ECV, ranged from 22.4% to 57.5% (median, 34.0%; interquartile range, 11.2%- 39.7%) (r=0.689, P<0.01). The pancreatic fibrosis evaluated by ECV was higher in the pancreatic cancer patients than other disease patients (P<0.01). Receiver operating characteristics analysis indicated that the ECV had good diagnostic accuracy for pancreatic cancer diagnosis (cutoff value 36.0; sensitivity 0.81, specificity 0.69). The pancreatic fibrosis evaluated by ECV was identified in the multivariate analysis as an independent risk factor for pancreatic cancer (odds ratio 0.82; P<0.01).*Conclusions Pancreatic fibrosis, which was associated with pancreatic cancer, could be accurately quantified by ECV.*Clinical Relevance/Application ECV can be an imaging predictor for estimating the probability of developing pancreatic cancer.

RESULTS

The histological pancreatic fibrosis, ranged from 4.0% to 78.0% (median, 16.0%; interquartile range, 11.0%-30.8%), were significantly correlated with the ECV, ranged from 22.4% to 57.5% (median, 34.0%; interquartile range, 11.2%- 39.7%) (r=0.689, P<0.01). The pancreatic fibrosis evaluated by ECV was higher in the pancreatic cancer patients than other disease patients (P<0.01). Receiver operating characteristics analysis indicated that the ECV had good diagnostic accuracy for pancreatic cancer diagnosis (cutoff value 36.0; sensitivity 0.81, specificity 0.69). The pancreatic fibrosis evaluated by ECV was identified in the multivariate analysis as an independent risk factor for pancreatic cancer (odds ratio 0.82; P<0.01).

CLINICAL RELEVANCE/APPLICATION

ECV can be an imaging predictor for estimating the probability of developing pancreatic cancer.

SDP-GI-3 Classification Of Malignant Features Of IPMNs: Interobserver Agreement Of CT Diagnosis

Participants
Eisuke Mukaida, MD, Morioka, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the interobserver agreement of malignant predictors and subtypes of intraductal papillary mucinous neoplasm (IPMN) on preoperative CT, and determine whether the radiologist's experience level affects evaluation.*Methods and Materials This retrospective study included patients who were pathologically diagnosed with IPMN postoperatively, from September 2007 to June 2020, and had undergone dynamic contrast-enhanced CT preoperatively. Four radiologists (more experienced, n=2; less experienced, n=2) reviewed the CT images and malignant factors of IPMN presented in the international guidelines, "high risk stigmata: HRS," and "worrisome features: WFs" on a three-point scale. Interobserver agreements were determined for all reviewers and their subgroups, stratified according to experience (more vs. less) using Fleiss and weighted k statistics. We then assigned a score to each malignant prognostic factor (each WF =1 point, each HRS=5 point), calculated the sensitivity and specificity of each reader's results for the pathological diagnosis, and performed a ROC analysis.*Results A total of 61 patients (mean age, 68.5±8.4; 40 males) were evaluated. Overall, interobserver agreements were poor to moderate for HRS and WFs (k for HRS = 0.37-0.68, k for WFs = 0.14-0.59). The k value of "enhancing mural nodule < 5 mm" was low for both more experienced and less experienced reviewers (k=0.21 vs. 0.11, respectively). As opposed to less experienced reviewers, more experienced reviewers demonstrated higher agreement in "thickened/enhancing cyst walls" (k=0.10 vs. 0.51, respectively). In the more experienced reviewers, the highest AUC was obtained with a total score of four (AUC=0.668). In the less experienced reviewers, the highest AUC was obtained with a total score of 3-4 (AUC=0.582).*Conclusions "Thickened/enhancing cyst walls" on dynamic contrast-enhanced CT may be dependent on the years of clinician experience. The "enhancing mural nodule < 5 mm" criteria is less consistently reproducible.*Clinical Relevance/Application IPMNs, one of the most common pancreatic cystic diseases, are easily detected incidentally due to advances in diagnostic imaging. CT is the primary imaging modality for cystic pancreatic lesions in the guideline. There are many predictors of malignancy listed in the guidelines, and the ability to identify malignant predictors will affect the treatment strategy. However, the interobserver agreement for malignant predictors varies among reports. We thought that the reason for this was related to the number of years of experience of the observer, and by clarifying this, we could re-examine the clinical significance of malignant prognostic factors.

RESULTS

A total of 61 patients (mean age, 68.5±8.4; 40 males) were evaluated. Overall, interobserver agreements were poor to moderate for HRS and WFs (k for HRS = 0.37-0.68, k for WFs = 0.14-0.59). The k value of "enhancing mural nodule < 5 mm" was low for both more experienced and less experienced reviewers (k=0.21 vs. 0.11, respectively). As opposed to less experienced reviewers, more

experienced reviewers demonstrated higher agreement in "thickened/enhancing cyst walls" (k=0.10 vs. 0.51, respectively). In the more experienced reviewers, the highest AUC was obtained with a total score of four (AUC=0.668). In the less experienced reviewers, the highest AUC was obtained with a total score of 3-4 (AUC=0.582).

CLINICAL RELEVANCE/APPLICATION

IPMNs, one of the most common pancreatic cystic diseases, are easily detected incidentally due to advances in diagnostic imaging. CT is the primary imaging modality for cystic pancreatic lesions in the guideline. There are many predictors of malignancy listed in the guidelines, and the ability to identify malignant predictors will affect the treatment strategy. However, the interobserver agreement for malignant predictors varies among reports. We thought that the reason for this was related to the number of years of experience of the observer, and by clarifying this, we could re-examine the clinical significance of malignant prognostic factors.

SDP-GI-30   Enhanced CT Radiomics For The Prediction Of Kit Exon 11 Mutations In Gastrointestinal Stromal Tumors

Participants
Xiaofei Yue, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

To construct and evaluate radiomics models based on enhanced CT for preoperative prediction of KIT exon 11 mutations in gastrointestinal stromal tumors (GIST).*Methods and Materials 122 patients with GIST (66 patients with KIT exon 11 mutations and 60 patients without KIT exon 11 mutations) who performed preoperative enhanced CT and postoperative pathologically confirmed were involved in this study. GISTs were segmented manually using ITK-SNAP (www.itksnap.org) in the artery phase (AP) and the portal venous phase (PVP) images of enhanced CT. 1218 radiomics features were extracted using Anaconda Prompt (version 4.2.0) importing the feature package of pyradiomics (github.com/Radiomics/pyradiomics). Patients were randomized to training and test sets in a 5:5 ratio. The algorithms of mRMR and LASSO were used to select the feature. Then, Radiomics models were constructed based on AP, PVP, and AP+PVP by LASSO. Statistics were carried out using R 3.6.1 (http://www.Rproject.org). The ROC curve was used to compare the predictive capabilities between three radiomics (AP, PVP, and AP+PVP) and pure clinical models, and the differences between them were compared by using the DeLong test. The DCA curve was used to compare the clinical benefits between four models.*Results All the radiomics signatures (Radscores) showed favorable abilities to predict KIT exon 11 mutations. The area under the curves (AUCs) of the three Radscores (AP, PVP, and AP+PVP) were 1.00, 1.00, and1.00 in training sets, and 0.99, 1.00, and1.00 in test sets, respectively. The clinical features were also analyzed, and the poor predictive performance was found in the training and test cohorts (with the AUCs of 0.87 and 0.63, respectively). The predictabilities among the three Radscores showed no significant differences (P > 0.05), but there were significant differences (P < 0.05) between the clinical model and either of the Radscores. The results of DCA indicated the clinical benefits of Radscores were far better than the clinical results.*Conclusions The Radiomics models based on enhanced CT achieve a good predictive performance to predict KIT exon 11 mutations and are not affected by phases. Compared to two-phases, a single-phase (either AP or PVP could be selected) is recommended for the reasons of the same good predictability and time- and labor-savings.*Clinical Relevance/Application KIT exon 11 mutations in gastrointestinal stromal tumors (GIST) often indicate a poor prognosis. The Radiomics analysis can help clinicians to develop better personalized treatment plans.

RESULTS

All the radiomics signatures (Radscores) showed favorable abilities to predict KIT exon 11 mutations. The area under the curves (AUCs) of the three Radscores (AP, PVP, and AP+PVP) were 1.00, 1.00, and1.00 in training sets, and 0.99, 1.00, and1.00 in test sets, respectively. The clinical features were also analyzed, and the poor predictive performance was found in the training and test cohorts (with the AUCs of 0.87 and 0.63, respectively). The predictabilities among the three Radscores showed no difference (P > 0.05), but there were significant differences (P < 0.05) between the clinical model and either of the Radscores. The results of DCA indicated the clinical benefits of Radscores were far better than the clinical results.

CLINICAL RELEVANCE/APPLICATION

KIT exon 11 mutations in gastrointestinal stromal tumors (GIST) often indicate a poor prognosis. The Radiomics analysis can help clinicians to develop better personalized treatment plans.

SDP-GI-31   Iodine Density Calculation Based On The Double Probe Spectrum Ct Of Ecv Research To The Diagnosis Of Colorectal Cancer Nerve Vascular Infiltration

Participants
Wenxia zheng, Lanzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the feasibility and diagnostic efficacy of the extracellular volume (ECV) in the assessment of neurovascular infiltration in colorectal cancer based on dual detector spectral CT iodine density measurement.*Methods and Materials The basic data of 64 patients diagnosed with colorectal cancer in Gansu Provincial People's Hospital from July 20 to February 21 were collected, including 10 cases of colorectal cancer and 54 cases of colorectal cancer.All patients underwent dual-layerspectral CT (DLCT) enhanced examination. Before examination, hematocrit was collected. Iodine density (IC) in venous phase and delayed phase and IC values in abdominal aorta or iliac vessels of the same plane were measured after scanning, and extracellularvolume (ECV) score was calculated.To analyze the feasibility of ECV in evaluating neurovascular infiltration in colorectal cancer, and to analyze the diagnostic efficacy by ROC curve.*Results There was no significant difference in ECV value between CD31, D2-40 and S100 positive and negative immunohistochemical groups based on spectral CT during venous phase (all P > 0.05).There were significant differences between delayed ECV and immunohistochemical CD31, D240, S100 positive and negative groups (all P < 0.001).Comparison of two stages of ECV between colorectal cancer and normal intestinal wall indicated that ECV of colorectal cancer was significantly increased.*Conclusions ECV score based on delayed iodine density measurement of spectral CT can reflect the neurovascular infiltration in patients with colorectal cancer, which provides a new preoperative evaluation method for clinical practice.*Clinical Relevance/Application Preliminary studies have shown that ECV can reflect the infiltration of nerve vessels in colorectal cancer, and can distinguish cancer tissue from normal intestinal wall.It is hoped that ECV will provide more value in the diagnosis and differential diagnosis of colorectal diseases, lymphatic metastasis and prognosis with the continuous follow-up of studies.

RESULTS

There was no significant difference in ECV value between CD31, D2-40 and S100 positive and negative immunohistochemical groups

based on spectral CT during venous phase (all P > 0.05).There were significant differences between delayed ECV and immunohistochemical CD31, D240, S100 positive and negative groups (all P < 0.001).Comparison of two stages of ECV between colorectal cancer and normal intestinal wall indicated that ECV of colorectal cancer was significantly increased.

CLINICAL RELEVANCE/APPLICATION

Preliminary studies have shown that ECV can reflect the infiltration of nerve vessels in colorectal cancer, and can distinguish cancer tissue from normal intestinal wall.It is hoped that ECV will provide more value in the diagnosis and differential diagnosis of colorectal diseases, lymphatic metastasis and prognosis with the continuous follow-up of studies.

SDP-GI-32 Preoperative CT Imaging Findings Of Arterial Invasion In Patients With Pancreatic Ductal Adenocarcinoma: What Is The Best Diagnostic Finding?

Participants
Yoshihumi Noda, MD,PhD, Gifu, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the diagnostic performance of preoperative computed tomographic (CT) imaging findings for diagnosing arterial invasion in pancreatic ductal adenocarcinoma (PDAC) and to determine the best imaging criterion.*Methods and Materials This retrospective study was composed of patients with PDAC who underwent preoperative contrast-enhanced CT from January 2008 to July 2020. Five board-certified radiologists (7-13 years of experience [more experienced]) and four fellows (3-5 years of experience [less experienced]) independently assessed arterial invasions for celiac, superior mesenteric, splenic, and common hepatic arteries using a 6-point score: 1, no tumor contact; 2, hazy attenuation =180°; 3, hazy attenuation >180°; 4, soft-tissue contact =180°; 5, soft-tissue contact >180°; and 6, contour irregularity. Receiver-operating-characteristic (ROC) analysis was conducted to evaluate the diagnostic performances of each score and to determine the best criterion for diagnosing arterial invasion which was confirmed by pathological or intraoperative findings. Interobserver agreements between more and less experienced reviewers were determined by Fleiss ? statistics.*Results In 128 patients (71 ± 9 years, 73 men) who were evaluated, 45 had been received neoadjuvant treatment. For both patients treated with and without neoadjuvant treatment, soft-tissue contact =180° demonstrated the highest diagnostic performance for arterial invasion (sensitivity, 100% and 100%; specificity, 90% and 93%; and area under the ROC curve, 0.96 and 0.98 in patients treated with and without neoadjuvant treatment, respectively). Interobserver agreements in less experienced reviewers were not inferior to more experienced reviewers (? = 0.61 vs 0.61; P = .39 and ? = 0.59 vs 0.51; P < .001 in patients treated with and without neoadjuvant treatment, respectively).*Conclusions Presence of soft-tissue contact =180° demonstrated the highest performance for diagnosing arterial invasion in pancreatic ductal adenocarcinoma.*Clinical Relevance/Application We revealed the best imaging criterion of soft-tissue contact =180° for diagnosing arterial invasion in pancreatic ductal adenocarcinoma. This imaging finding is useful to determine the candidate for surgical resection.

RESULTS

In 128 patients (71 ± 9 years, 73 men) who were evaluated, 45 had been received neoadjuvant treatment. For both patients treated with and without neoadjuvant treatment, soft-tissue contact =180° demonstrated the highest diagnostic performance for arterial invasion (sensitivity, 100% and 100%; specificity, 90% and 93%; and area under the ROC curve, 0.96 and 0.98 in patients treated with and without neoadjuvant treatment, respectively). Interobserver agreements in less experienced reviewers were not inferior to more experienced reviewers (? = 0.61 vs 0.61; P = .39 and ? = 0.59 vs 0.51; P < .001 in patients treated with and without neoadjuvant treatment, respectively).

CLINICAL RELEVANCE/APPLICATION

We revealed the best imaging criterion of soft-tissue contact =180° for diagnosing arterial invasion in pancreatic ductal adenocarcinoma. This imaging finding is useful to determine the candidate for surgical resection.

SDP-GI-34 The Contrast-enhanced Portal Vein-to-liver Ratio: A New, Simple, And Accurate Parameter For Diagnosis Of Fatty Liver On Contrast-enhanced Computed Tomography.

Participants
Hadeer Al-Ali, MBBS, Doha, Qatar (*Presenter*) Nothing to Disclose

PURPOSE

To assess the value of contrast-enhanced portal vein-to-liver ratio as a new, simple, and accurate parameter for diagnosis of fatty liver on contrast-enhanced computed tomography.*Methods and Materials Three hundred ninety-one consecutive unenhanced and portal-phase contrast enhanced CT from the daily work have been included in the study after exclusion of patients with focal liver lesions, cirrhosis, heart failure, and diseases of the bile ducts, pancreas, and spleen and patients with poor technical quality examination and poorly timed portal-phase contrast enhanced CT. Attenuation value of the liver parenchyma, portal vein, aorta, and spleen were measured by manually placed region-of-interest on the unenhanced and contrast-enhanced CT. On the contrast-enhanced CT, two parameters were calculated: the portal vein/liver (P/L) ratio and the blood-subtracted liver attenuation, defined as [L - 0.3 x (0.75 x P + 0.25 x A)]/0.7, where L, P and A represent the attenuation of the liver, main portal vein and abdominal aorta, respectively. Area under the Receiver-Operator Characteristic Curve (AUCROC) was calculated for the two parameters at different cut-off values.*Results In comparison to the gold standard of an attenuation value ratio between the liver and the spleen of 0.8 or less on the unenhanced CT for the diagnosis of fatty liver. P/L ratio was found to have specificity, sensitivity, and accuracy of 96%, 69%, and 92% respectively at a cut-off value of 2, while the blood-subtracted attenuation of the liver had corresponding values of 96%, 73%, and 93% at the cut-off value of 55. AUC-ROC has been 0.93 for P/L ratio and 0.92 for the blood-subtracted attenuation parameter.*Conclusions A portal vein-to-liver ratio of 2 or more is accurate for the diagnosis of fatty liver on contrast-enhanced CT. This newly described parameter is easier to use compared to the previously described blood-subtracted attenuation which is also accurate but needs more sophisticated calculations.*Clinical Relevance/Application On direct contrast-enhanced CT of the liver not preceded by an unenhanced CT, diagnosis of fatty liver can still be made if the attenuation value of the portal vein is double (or more than double) that of the liver. This can be done during the reporting session without the need of sophisticated calculations.

RESULTS

In comparison to the gold standard of an attenuation value ratio between the liver and the spleen of 0.8 or less on the unenhanced CT for the diagnosis of fatty liver. P/L ratio was found to have specificity, sensitivity, and accuracy of 96%, 69%, and 92% respectively at a cut-off value of 2, while the blood-subtracted attenuation of the liver had corresponding values of 96%, 73%, and 93% at the cut-off value of 55. AUC-ROC has been 0.93 for P/L ratio and 0.92 for the blood-subtracted attenuation parameter.

CLINICAL RELEVANCE/APPLICATION

On direct contrast-enhanced CT of the liver not preceded by an unenhanced CT, diagnosis of fatty liver can still be made if the attenuation value of the portal vein is double (or more than double) that of the liver. This can be done during the reporting session without the need of sophisticated calculations.

SDP-GI-35   Conventional And Volumetric Response Assessment In Chemotherapy For Patients With Pancreatic Adenocarcinoma

Participants
Azarakhsh Baghdadi, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

RECIST 1.1 and WHO are the most commonly used response assessment criteria for systemic therapies in PDAC, however response to treatment may not be fully reflected through conventional response assessment criteria. We aimed to compare the performance of RECIST, WHO, total and viable tumor volume for evaluation of response to systemic chemotherapy in patients with PDAC.*Methods and Materials This retrospective study was HIPAA compliant and approved by the IRB, waiver of consent was granted. We conducted a retrospective review of patients receiving systemic chemotherapy for PDAC at the Johns Hopkins Hospital from 2017-2021. Patients were included if they had received systemic chemotherapy as standard of care and at least 6 months of follow-up, with corresponding contrast enhanced CT at baseline and at the end of treatment. Manual contouring of tumor volume was performed. Thresholds for tumor viability on venous CT scans were identified based on pathologic correlation. The above-mentioned threshold was used to derive viable tumor volume from total tumor volume which was reported as percentage of total tumor volume. Percent change in total and viable tumor volume for all patients was calculated. Reduction of 66% in viability and 50% in total tumor volume were deemed as response to treatment. Anatomic (RECIST, and WHO) and functional (total and viable tumor volume) imaging parameters were evaluated at baseline and at the end of treatment.*Results Twenty-seven patients with the mean age of 67 years old, fulfilled our inclusion criteria and were included in our imaging assessment. Mean change in the sum of bidimensional measurements based on WHO criteria was 28%. Fifteen patients went into surgery. Overall mean change in RECIST was 15.5%. On imaging assessment of post-treatment scans, viable volume assessment yielded higher response rates (42%), than RECIST (25%) and WHO(25%).*Conclusions Viable tumor volume identifies more responders with chemotherapy in PDAC than conventional imaging modalities. Further prospective studies are needed to validate viable tumor volume as a predictor of response in chemotherapy for PDAC.*Clinical Relevance/Application Our data is useful to lay the groundwork for future larger prospective studies to assess response in patients with PDAC.

RESULTS

Twenty-seven patients with the mean age of 67 years old, fulfilled our inclusion criteria and were included in our imaging assessment. Mean change in the sum of bidimensional measurements based on WHO criteria was 28%. Fifteen patients went into surgery. Overall mean change in RECIST was 15.5%. On imaging assessment of post-treatment scans, viable volume assessment yielded higher response rates (42%), than RECIST (25%) and WHO(25%).

CLINICAL RELEVANCE/APPLICATION

Our data is useful to lay the groundwork for future larger prospective studies to assess response in patients with PDAC.

SDP-GI-36   Impact Of COVID-19 Pandemic On Liver Multidisciplinary Cancer Clinic In A Tertiary Referral Center

Participants
Azarakhsh Baghdadi, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

In 2020, the COVID-19 pandemic upended the delivery of medical care across all specialties, but the impact of the COVID-19 pandemic on the delivery of cancer care has not been comprehensively assessed. We performed a retrospective review of patient care in the Johns Hopkins Multidisciplinary Liver Cancer Clinic (MDLC) in 2020, as compared to 2019, to determine how the pandemic influenced the presentation and management of multidisciplinary liver cancer care for biliary tract cancers (BTC) or hepatocellular carcinoma (HCC).*Methods and Materials A retrospective review was conducted using data from JHH between January 2019 and December 2020. The inclusion criteria for the study were as follows: (1) new patients who were evaluated at the MDLC, (2) HCC diagnosed by radiographic or histologic confirmation or BTC (CCA, gallbladder cancer) by histologic confirmation, and (3) age = 18 years. The study protocol was approved by the Johns Hopkins Institutional Review Boards (IRB00231803).*Results Patient consultations took place exclusively over telemedicine for 17 weeks beginning on 3/25/2020 and a mix of in person and telemedicine for most of the remaining year. A total of 188 patients were evaluated in MDLC in 2019 and 189 patients were evaluated in MDLC in 2020. As compared to 2019 when patient consultations took place in person, there was no significant change in the median number of specialties that patients met with during in MDLC (median of 2 specialties in 2019, 2 specialties in 2020). The percentage of BTC patients presenting with disease that was determined in MDLC to be resectable decreased from 8% in 2019 to 4% in 2020. The percentage of HCC patients presenting with resectable disease decreased from 4.8% in 2019 to 1% in 2020.*Conclusions Coordinated expert multidisciplinary care was feasible during the COVID19 pandemic, but a significantly lower number of patients presenting to MDLC had resectable disease potentially reflecting delays in cancer diagnosis.*Clinical Relevance/Application The implications of these changes on the clinical outcomes of patients with primary liver cancers warrants further investigation.

RESULTS

Patient consultations took place exclusively over telemedicine for 17 weeks beginning on 3/25/2020 and a mix of in person and telemedicine for most of the remaining year. A total of 188 patients were evaluated in MDLC in 2019 and 189 patients were evaluated in MDLC in 2020. As compared to 2019 when patient consultations took place in person, there was no significant change in the median number of specialties that patients met with during in MDLC (median of 2 specialties in 2019, 2 specialties in 2020). The percentage of BTC patients presenting with disease that was determined in MDLC to be resectable decreased from 8% in 2019 to 4% in 2020. The percentage of HCC patients presenting with resectable disease decreased from 4.8% in 2019 to 1% in 2020.

CLINICAL RELEVANCE/APPLICATION

The implications of these changes on the clinical outcomes of patients with primary liver cancers warrants further investigation.

SDP-GI-37   Baseline Imaging Features Associated With Progression In Patients With Hepatocellular Carcinoma Listed For Liver Transplantion

Participants
Azarakhsh Baghdadi, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to assess baseline imaging features that are associated with waitlist dropout due to progression of disease in patients with hepatocellular carcinoma (HCC) who are listed for liver transplantation.*Methods and Materials This retrospective study was HIPAA compliant and approved by the IRB. 102 patients who were listed for liver transplant with HCC between 2013-2018 were reviewed. Patients with HCC with adequate baseline MRI, who were able to receive liver transplantation or those who were delisted due to HCC progression beyond transplant criteria were included in the study (n=91). HCC treatment history, transplant listing date, waitlist dropout or transplantation dates were retrieved from electronic medical records. All baseline scans were independently reviewed and analyzed by a radiologist. Tumor margin (well- vs ill-defined), presence of capsule bulging, lesion size and number of lesions were included in the analysis. Volumetric analysis was performed using MR Multiparametric Tool (Siemens Healthineers) software. Logistic regression and ROC analyses were used to predict disease progression and to investigate the difference in waitlist time between categories. P<0.05 was considered significant.*Results 87 patients met our inclusion criteria and were included in the analysis. In univariate analysis, following variables were significantly associated with disease progression; number of lesions, diameter of the dominant lesion, sum of diameters of all lesions, lesion bulging outside of liver capsule, tumor volume at baseline and AFP level. The final logistic model was developed based on the clusters of patients who were either within or outside Milan criteria. In multivariable analysis, having >1 HCC lesion (OR=2.34, p=0.005), tumor bulging outside of liver capsule (OR=1.20, p = 0.038), ill-defined margin (OR=4.86, p = <0.001) and larger tumor diameter (OR=3.24 per 1 cm, p<0.001) were independent predictors of disease progression while on transplant waitlist. This model had a predictive performance of 83%.*Conclusions In HCC patients who were listed for liver transplant, baseline imaging parameters that are predictors of waitlist dropout are as follows, >1 HCC lesion, ill-defined tumor margin, tumor causing liver capsule bulging, and lesion diameter =3.24 cm. These imaging features correlated with earlier progression of disease. Volumetric evaluations show a positive trend and may also be prognostic in larger studies.*Clinical Relevance/Application Imaging findings such as tumor margin and bulging of liver capsule can augment current liver transplant criteria such as Milan and improve their performance.

RESULTS

87 patients met our inclusion criteria and were included in the analysis. In univariate analysis, following variables were significantly associated with disease progression; number of lesions, diameter of the dominant lesion, sum of diameters of all lesions, lesion bulging outside of liver capsule, tumor volume at baseline and AFP level. The final logistic model was developed based on the clusters of patients who were either within or outside Milan criteria. In multivariable analysis, having >1 HCC lesion (OR=2.34, p=0.005), tumor bulging outside of liver capsule (OR=1.20, p = 0.038), ill-defined margin (OR=4.86, p = <0.001) and larger tumor diameter (OR=3.24 per 1 cm, p<0.001) were independent predictors of disease progression while on transplant waitlist. This model had a predictive performance of 83%.

CLINICAL RELEVANCE/APPLICATION

Imaging findings such as tumor margin and bulging of liver capsule can augment current liver transplant criteria such as Milan and improve their performance.

SDP-GI-38   **Motion Compensation Method For Non-periodic In-plane And Out-of-plane Motion In 2d Contrast-enhanced Ultrasound Of Focal Liver Lesions**

Participants
Thodsawit Tiyarattanachai, Bangkok, Thailand (*Presenter*) Nothing to Disclose

PURPOSE

While the use of contrast-enhanced ultrasound (CEUS) in hepatic applications is increasing, quantification of perfusion remains a challenge due to motion artifacts during the dynamic contrast enhanced cine. Thus, development of advanced motion compensation (MC) algorithms is necessary to advance quantification of perfusion parameters in the clinic. Motion can result from periodic respiration, or from non-periodic movements, such as probe movement, large diaphragm movement after long breath holding, patient movement and talking. Previous reports have described MC methods for periodic motion. In this study, we proposed a novel MC method that works for both periodic and non-periodic motion in 2D CEUS of focal liver lesions.*Methods and Materials We developed a MC algorithm based on iterative local search. The algorithm receives as input a user-defined reference region of interest (ROI) on the lesion in B-mode window in only 1 frame. The algorithm then tracks the lesion on B-mode and translates the corresponding coordinates to the contrast-enhanced window. The in-plane tracking works by iteratively searching for the area with maximum normalized correlation coefficient with the reference ROI. The search is confined within a local region, which updates based on prior information from previously tracked frames. Finally, frames with out-of-plane motion are eliminated by applying a correlation threshold, which is automatically determined during the iterative tracking process. We applied the MC algorithm on 20 CEUS videos of focal liver lesions, collected at Stanford University. Performance of the algorithm was evaluated by fitting time-intensity curve (TIC) using the lognormal model. The root mean square error (RMSE) and coefficient of determination (R2) of pre-MC and post-MC TICs were compared.*Results The MC algorithm significantly improved TICs. Median RMSE significantly decreased from 0.031 to 0.025 (p=0.037). Median R2 significantly increased from 0.83 to 0.93 (p=0.037). Overall, we found that the MC algorithm worked well on lesions with various characteristics, and on cases with either periodic or non-periodic motion.*Conclusions The MC algorithm can compensate for both periodic and non-periodic, in-plane and out-of-plane motion, ultimately improving quality of perfusion analysis of focal liver lesions by CEUS.*Clinical Relevance/Application Motion during acquisition of CEUS negatively impacts quality of perfusion analysis of focal liver lesions. Our novel MC algorithm can compensate for both periodic and non-periodic motion in CEUS cine.

RESULTS

The MC algorithm significantly improved TICs. Median RMSE significantly decreased from 0.031 to 0.025 (p=0.037). Median R2 significantly increased from 0.83 to 0.93 (p=0.037). Overall, we found that the MC algorithm worked well on lesions with various characteristics, and on cases with either periodic or non-periodic motion.

CLINICAL RELEVANCE/APPLICATION

Motion during acquisition of CEUS negatively impacts quality of perfusion analysis of focal liver lesions. Our novel MC algorithm can compensate for both periodic and non-periodic motion in CEUS cine.

SDP-GI-39   **Ultrasound Liver Imaging Reporting And Data System (US LI-RADS) Visualization Score: Stability Of**

Visualization Score Over Time

Participants
Thodsawit Tiyarattanachai, Bangkok, Thailand (*Presenter*) Nothing to Disclose

PURPOSE

The Ultrasound Liver Imaging Reporting and Data System (US LI-RADS) Visualization Score conveys the expected level of sensitivity of the screening/surveillance examination in patients at risk for hepatocellular carcinoma (HCC). The Visualization Score depends on patient's liver condition, body habitus and radiologist's interpretation. We sought to determine how often the Visualization Score changes during repeated evaluation.*Methods and Materials 6998 consecutive ultrasound HCC screening and surveillance studies in 3115 patients from 2017 to 2020 were retrospectively reviewed. Of these, 6154 (87.9%) studies were Visualization A (No or minimal limitations), 709 (10.1%) were Visualization B (Moderate limitations), and 135 (1.9%) were Visualization C (Severe limitations). Conditional probabilities of Visualization Score transition, given preceding examination(s), were calculated, along with 95% confidence intervals (CI).*Results The median time interval between examinations in patients with Visualization A, B and C were 191 (interquartile range, IQR 69), 199 (IQR 131.5) and 203 (IQR 111) days, respectively. Visualization A remained stable with high probability of 0.95 (1349/1426, CI 0.93-0.96) and 0.96 (865/898, CI 0.95-0.98) after 1 and 2 consecutive Visualization A's, respectively.For Visualization B, the probability of remaining stable increased from 0.51 (122/240, CI 0.45-0.57) after 1 examination, to 0.61 (37/61, CI 0.48-0.73) after 2 consecutive Visualization B examinations. The probabilities of transition from Visualization B to A were 0.45 (108/240, CI 0.39-0.51) and 0.34 (21/61, CI 0.23-0.46); B to C were 0.04 (10/240, CI 0.02-0.07) and 0.05 (3/61, CI 0-0.10) after 1 and 2 consecutive Visualization B's, respectively.For Visualization C, the probability of remaining stable increased from 0.49 (17/35, CI 0.32-0.65) after 1 examination, to 0.67 (6/9, CI 0.36-0.98) after 2 consecutive Visualization C examinations. The probabilities of transition from Visualization C to A were 0.17 (6/35, CI 0.05-0.30) and 0 (0/9, CI 0-0.34); C to B were 0.34 (12/35, CI 0.19-0.50) and 0.33 (3/9, CI 0.03-0.64) after 1 and 2 consecutive Visualization C's, respectively.*Conclusions Patients with Visualization B or C may benefit from repeated evaluation as Visualization Scores may change in approximately 50% of patients on subsequent examination(s). After 2 consecutive B or C Visualization Scores, change is less likely and at that point the decision for alternative imaging may be made on a case-by-case basis.*Clinical Relevance/Application Our findings of Visualization Score dynamics helps support rationale in choosing an appropriate imaging modality for HCC screening and surveillance in each patient.

RESULTS

The median time interval between examinations in patients with Visualization A, B and C were 191 (interquartile range, IQR 69), 199 (IQR 131.5) and 203 (IQR 111) days, respectively. Visualization A remained stable with high probability of 0.95 (1349/1426, CI 0.93-0.96) and 0.96 (865/898, CI 0.95-0.98) after 1 and 2 consecutive Visualization A's, respectively.For Visualization B, the probability of remaining stable increased from 0.51 (122/240, CI 0.45-0.57) after 1 examination, to 0.61 (37/61, CI 0.48-0.73) after 2 consecutive Visualization B examinations. The probabilities of transition from Visualization B to A were 0.45 (108/240, CI 0.39-0.51) and 0.34 (21/61, CI 0.23-0.46); B to C were 0.04 (10/240, CI 0.02-0.07) and 0.05 (3/61, CI 0-0.10) after 1 and 2 consecutive Visualization B's, respectively.For Visualization C, the probability of remaining stable increased from 0.49 (17/35, CI 0.32-0.65) after 1 examination, to 0.67 (6/9, CI 0.36-0.98) after 2 consecutive Visualization C examinations. The probabilities of transition from Visualization C to A were 0.17 (6/35, CI 0.05-0.30) and 0 (0/9, CI 0-0.34); C to B were 0.34 (12/35, CI 0.19-0.50) and 0.33 (3/9, CI 0.03-0.64) after 1 and 2 consecutive Visualization C's, respectively.

CLINICAL RELEVANCE/APPLICATION

Our findings of Visualization Score dynamics helps support rationale in choosing an appropriate imaging modality for HCC screening and surveillance in each patient.

SDP-GI-40 **Pancreatic MRI For Surveillance Of Cystic Neoplasms: Comparison Of The Diagnostic Value Of Breath Hold Versus Respiratory-gated T2-weighted Coronal Sequences**

Participants
Tom Gibson, MBBCHIR, Romsey, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

A limited pancreatic cyst surveillance protocol has been advocated using respiratory-gated (RG) T2-weighted axial and coronal imaging. The objective was to assess whether breath hold (BH) coronal T2-weighted imaging instead of RG could be used to further reduce scanning time.*Methods and Materials This retrospective study included 55 consecutive patients with working-diagnosis of PCN and available MRI/MRCP. 10 patients were excluded due to absence of the necessary sequences (5), recent lesion resection/resolution (3), or extensive pancreatic cystic disease precluding reliable re-evaluation (2). The images were anonymised. Two radiologists independently evaluated axial HASTE, BH, and RG T2-weighted sequences for each patient at spaced intervals and with randomisation. The baseline PCN surveillance protocol included: unenhanced T1-weighted imaging, axial T2 HASTE, RG PACE, and BH and RG T2 coronal [total acquisition time (AT)?~?10 min]. For RG vs BH T2-weighted coronal sequences specifically, AT ~ 3 min 20 s vs 1 min 4 s, respectively. Intra- and inter-observer reliability were determined. Mean values of largest cyst/main pancreatic duct diameter (DC/DMPD) were compared. The presence/absence of pancreatic parenchymal or extra-pancreatic abnormalities was also assessed.*Results Both intra- and inter-observer reliability were high (intraclass correlation coefficient (ICC) = 0.97-0.99 and ICC = 0.96, respectively). For DC and DMPD, mean values with BH/RG were 19.76/20.0 mm and 3.62/3.54 mm, while mean differences BH-RG were 0.2 mm (p?=?0.75) and 0.08 mm (p?=?0.14), respectively. Additional pancreatic parenchymal or extra-pancreatic findings in 10/45 (22.2%) patients were all visible on both RG and BH sequences.*Conclusions For PCN surveillance, a non-gated breath hold coronal T2-weighted sequence demonstrates no statistically significant difference to a respiratory-gated version in the measurement of cystic and MPD dimensions and in the identification of additional local and distant abnormalities, with the advantage of being more time efficient.*Clinical Relevance/Application MRI surveillance of pancreatic cystic lesions is increasingly utilised due to incidental diagnosis. Cumulatively, this becomes burdensome in time and cost. Refining scan acquisition time (and hence cost) whilst maintaining diagnostic capability is therefore key.

RESULTS

Both intra- and inter-observer reliability were high (intraclass correlation coefficient (ICC) = 0.97-0.99 and ICC = 0.96, respectively). For DC and DMPD, mean values with BH/RG were 19.76/20.0 mm and 3.62/3.54 mm, while mean differences BH-RG were 0.2 mm (p?=?0.75) and 0.08 mm (p?=?0.14), respectively. Additional pancreatic parenchymal or extra-pancreatic findings in 10/45 (22.2%) patients were all visible on both RG and BH sequences.

CLINICAL RELEVANCE/APPLICATION

MRI surveillance of pancreatic cystic lesions is increasingly utilised due to incidental diagnosis. Cumulatively, this becomes

burdensome in time and cost. Refining scan acquisition time (and hence cost) whilst maintaining diagnostic capability is therefore key.

SDP-GI-41   Discrepancies Of On-call Radiology Residents' Interpretations In Abdominal Imaging: Risk Factor Evaluation

Participants
Su Jeong Yang, MD, Incheon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To report discrepancy for examinations interpreted by on-call residents, and to investigate risk factors for discrepancies and characteristics of major finding discrepancies in abdominal radiology*Methods and Materials A total of 1132 consecutive patients for examinations interpreted by on-call residents from February 2016 to September 2019 in abdominal radiology. The images were initially interpreted by on-call residents, compared with final interpretations including abdominal radiologists and clinical data. Interpreted data were analyzed regarding specific organs, examination types, resident grade, discrepancy rates, and major discrepancies. Multiple logistic regression analysis was used to evaluate specific features for risk factors of discrepancy interpretations by on-call residents.*Results Of 1132, bowel (564, 49.8%) was the most common organ interpreted by on-call residents, and followed by gallbladder/bile duct/pancreas (139, 12.3%) and liver (118, 10.4%). Sixty-four (5.6%) showed discrepancies and 26 (2.3%) major finding discrepancies consisted of 14 active bleeding, 6 bowel obstruction, 4 rupture of organ, and 2 etc. Resident grade 2 (odd ratio [OR]; 2.23, 95% confidence interval [CI]: 1.34-3.72, P =.002) and bowel obstruction (OR; 2.89, 95% CI: 1.17-7.13, P =.02) revealed significant risk factors for discrepancy on-call interpretations.*Conclusions The overall discrepancy rate between interpretations by on-call residents and final decisions showed low in abdominal radiology. However, residents should be aware of the relatively high rate of missed bowel obstruction and one of the most on-call interpretations was bowel section.*Clinical Relevance/Application We suggest that abdominal radiology staff inform residents about the relatively high rate of missed bowel obstructions and instruct them to interpret carefully bowel obstruction cases. Before starting night duty, additional education for residents must be needed about the higher rate of previous missing cases among the major discrepancies in abdominal radiology.

RESULTS

Of 1132, bowel (564, 49.8%) was the most common organ interpreted by on-call residents, and followed by gallbladder/bile duct/pancreas (139, 12.3%) and liver (118, 10.4%). Sixty-four (5.6%) showed discrepancies and 26 (2.3%) major finding discrepancies consisted of 14 active bleeding, 6 bowel obstruction, 4 rupture of organ, and 2 etc. Resident grade 2 (odd ratio [OR]; 2.23, 95% confidence interval [CI]: 1.34-3.72, P =.002) and bowel obstruction (OR; 2.89, 95% CI: 1.17-7.13, P =.02) revealed significant risk factors for discrepancy on-call interpretations.

CLINICAL RELEVANCE/APPLICATION

We suggest that abdominal radiology staff inform residents about the relatively high rate of missed bowel obstructions and instruct them to interpret carefully bowel obstruction cases. Before starting night duty, additional education for residents must be needed about the higher rate of previous missing cases among the major discrepancies in abdominal radiology.

SDP-GI-42   Using Machine Learning Methods To Detect Imaging Features In Crohn's Disease

Participants
Ashish Wasnik, MD, Ann Arbor, Michigan (*Presenter*) Royalties, Reed Elsevier;Research Grant, Sequana Medical NV;Royalties, Applied Morphomics Inc;Patent agreement, Applied Morphomics Inc

PURPOSE

Explore machine learning methods for detecting and localizing qualitative CT imaging features of Crohn's disease (CD)*Methods and Materials In this retrospective, IRB approved study, CD patients with CT enterography between 2014-2018 identified. Inclusion criteria: at least 5 cm of terminal ileal disease, Age > 18 years. Exclusion criteria: only colonic disease, penetrating disease, or ileostomy. Two body radiologists localized CD features on CT using a customized electronic interface: mural hyperenhancement, bowel wall thickening, mural stratification, stenosis, and mesenteric fat stranding. Two models were generated to predict presence and location of CD findings (1) random forest (RF) model using automatically extracted radiologist-defined features, 2) unassisted convolution neural network (CNN) using self-generated source CTE features. Model area under the curve (AUC), accuracy, sensitivity, and specificity used to describe model performance. Agreement between radiologists and between models and adjudicated radiologist ground truth was assessed using Cohen's kappa statistic.*Results 165 patients included. Median length of segmented bowel was 25.9 cm with 5,979 points evaluated for each of the 5 qualitative features rendering 29,895 individual annotations. Agreement between radiologists on presence and localization of findings was very good (k=0.72, 95% CI 0.70-0.74). Reviewer agreement on individual qualitative CD findings: very good for degree of mural enhancement (k=0.73) and presence of bowel wall thickening (k=0.71), good for stricture localization (k=0.66) and mural stratification (k=0.67), and poor for mesenteric fat stranding (k=0.47). RF model performance was excellent with an average AUROC of 0.905 across all qualitative findings, with an accuracy, sensitivity, and specificity of 84.2%, 0.81 and 0.85, respectively. Agreement between RF prediction and localization of findings with radiologists nearly matched the agreement between paired radiologists (Table 1). CNN model performed equally well with an average AUROC, accuracy, sensitivity, and specificity across all qualitative findings of 0.906, 0.83%, 0.79, and 0.85, respectively. Time spent on image analysis: Radiologist (25-30 min) versus machine learning models (near instantaneous).*Conclusions ML methods can detect and localize qualitative findings of CD with performance similar to experienced radiologist and the potential to improve reproducibility, objectivity and efficiency.*Clinical Relevance/Application ML approaches to image analysis in CD have the ability to standardize and reproduce reporting for traditional imaging feature, with capability to extract quantifiable features that can potentially impact clinical decision making.

RESULTS

165 patients included. Median length of segmented bowel was 25.9 cm with 5,979 points evaluated for each of the 5 qualitative features rendering 29,895 individual annotations. Agreement between radiologists on presence and localization of findings was very good (k=0.72, 95% CI 0.70-0.74). Reviewer agreement on individual qualitative CD findings: very good for degree of mural enhancement (k=0.73) and presence of bowel wall thickening (k=0.71), good for stricture localization (k=0.66) and mural stratification (k=0.67), and poor for mesenteric fat stranding (k=0.47). RF model performance was excellent with an average AUROC of 0.905 across all qualitative findings, with an accuracy, sensitivity, and specificity of 84.2%, 0.81 and 0.85, respectively. Agreement between RF prediction and localization of findings with radiologists nearly matched the agreement between paired radiologists (Table 1). CNN model performed equally well with an average AUROC, accuracy, sensitivity, and specificity across all

qualitative findings of 0.906, 0.83%, 0.79, and 0.85, respectively. Time spent on image analysis: Radiologist (25-30 min) versus machine learning models (near instantaneous).

CLINICAL RELEVANCE/APPLICATION

ML approaches to image analysis in CD have the ability to standardize and reproduce reporting for traditional imaging feature, with capability to extract quantifiable features that can potentially impact clinical decision making.

SDP-GI-43   Multiparametric Magnetic Resonance Imaging Improves The Prognostic Outcomes In Patients With Intrahepatic Cholangiocarcinoma After Curative-intent Resection

Participants
Qian Li, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

To characterise patients with intrahepatic cholangiocarcinoma (ICC) into different clinical phenotypes using multiomics-based clustering analysis, and to further identify the clinical phenotypes associated with the prognostic outcomes.*Methods and Materials A retrospective study comprised of 256 patients undergoing only dynamic enhanced CT scan (CT group) and 31 patient undergoing both mpMRI and CT (CT+MR group) scan. Inverse probability treatment weighting (IPTW) and propensity score matching (PSM) were used to minimize potential selection bias and confounding effects. The rates of overall survival (OS) and recurrence-free survival (RFS) of the two groups were compared.*Results More nodules (n=6), additional biliary dilation (n=4) and peritumoral parenchymal arterial phase hyperenhancement (n=18) were found with the additional mpMRI scan, and led to the treatment modification. Multivariate analysis revealed a survival advantage of additional mpMRI imaging (OS: HR 0.390, 95%CI 0.236-0.646, P<0.001, IPTW HR 0.465, 95%CI 0.263-0.823, P=0.008, PSM HR 0.415, 95%CI 0.216-0.800, P=0.009; RFS: HR 0.545, 95%CI 0.344-0.863, P=0.010, IPTW HR 0.486, 95%CI 0.279 -0.849, P=0.011, PSM HR 0.686, 95%CI 0.301-0.939, P=0.048).*Conclusions Additional mpMRI has the potential to select better treatment options and lower the risk of tumor recurrence, and improve overall survival.*Clinical Relevance/Application The prognosis of patients with intrahepatic cholangiocarcinoma (ICC) is dismal. The additional multi-parametric magnetic resonance imaging (mpMRI) enabled to find more tumor lesions, biliary dilation and peritumoral parenchymal arterial phase hyperenhancement. Consequently, it would help ICC patients to receive additional treatment in time. and patients undergoing both CT and mpMRI scan achieved better overall survival and recurrence-free survival than those undergoing CT scan only.

RESULTS

More nodules (n=6), additional biliary dilation (n=4) and peritumoral parenchymal arterial phase hyperenhancement (n=18) were found with the additional mpMRI scan, and led to the treatment modification. Multivariate analysis revealed a survival advantage of additional mpMRI imaging (OS: HR 0.390, 95%CI 0.236-0.646, P<0.001, IPTW HR 0.465, 95%CI 0.263-0.823, P=0.008, PSM HR 0.415, 95%CI 0.216-0.800, P=0.009; RFS: HR 0.545, 95%CI 0.344-0.863, P=0.010, IPTW HR 0.486, 95%CI 0.279 -0.849, P=0.011, PSM HR 0.686, 95%CI 0.301-0.939, P=0.048).

CLINICAL RELEVANCE/APPLICATION

The prognosis of patients with intrahepatic cholangiocarcinoma (ICC) is dismal. The additional multi-parametric magnetic resonance imaging (mpMRI) enabled to find more tumor lesions, biliary dilation and peritumoral parenchymal arterial phase hyperenhancement. Consequently, it would help ICC patients to receive additional treatment in time. and patients undergoing both CT and mpMRI scan achieved better overall survival and recurrence-free survival than those undergoing CT scan only.

SDP-GI-44   Multiparametric MRI-based Radiomics Signature For Predicting Overall Survival In Intrahepatic Cholangiocarcinomaafter Partial Hepatectomy

Participants
Yang Yang, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop radiomics signature using multiparametric MRI images to predict overall survival in patients with intrahepatic cholangiocarcinoma (ICC) and to investigate its incremental value for disease stratification.*Methods and Materials In this retrospective study, quantitative radiomics features (n=4998) were extracted from the multiparametric MRI of 163 patients with ICC (allocated to a training and validation set, 7:3 ratio). Radiomics model was built based on LASSO algorithm. The clinicopathologic-radiologic (CPR) model and the combined model integrating the radiomics signature with the CPR risk factors were developed with multivariate cox regression model. The Kaplan-Meier method and log-rank test were used to estimate the efficacy of risk stratification of the above models. Net Reclassification Index (NRI) and Integrate Discrimination Improvement (IDI) were used to analyze the reclassification ability of the combined model compared with CPR model.*Results The radiomics signature achieved significant stratification of overall survival (OS) and disease-free survival (DFS) in both training (p<0.0001, p<0.001, respectively) and validation set (p<0.001,p=0.0036, respectively). The C-index of the radiomics signature for predicting OS in training and validation sets were 0.680 (95%CI 0.618-0.742) and 0.698 (95%CI 0.583-0.814), which was comparable to CPR model (training set: 0.705, 95%CI: 0.634-0.777; validation set: 0.674, 95%CI: 0.555-0.792) (p=0.486, p=0.752, respectively). The C-index of the combined model integrating radiomics signature and CPR risk factors were 0.750 (95%CI 0.680-0.819) and 0.723 (95%CI 0.624-0.822), with no improvement in prognostic performance compared with that of CPR model in both sets (p=0.109, p=0.214; respectively). The combined model showed increased ability to stratify prognosis over the CPR model (validation set: p=0.028 vs p=0.058). In reclassification analyses, incorporating radiomics signature into CPR model significantly improved the prognostic accuracy(validation set: NRI and IDI of 1-year OS were 0.325, and 0.081;NRI and IDI of 2-year OS were 0.343 and 0.129;NRI and IDI of 3-year OS were 0.414 and 0.162).*Conclusions Multiparametric MRI-based radiomics signature is a potential biomarker for preoperative prognostic stratification.*Clinical Relevance/Application Multiparametric MRI-based radiomics signature is a powerful tool for prognostic assessment, and potentially serves as an individualized recommender for decision-making in ICC patients.

RESULTS

The radiomics signature achieved significant stratification of overall survival (OS) and disease-free survival (DFS) in both training (p<0.0001, p<0.001, respectively) and validation set (p<0.001,p=0.0036, respectively). The C-index of the radiomics signature for predicting OS in training and validation sets were 0.680 (95%CI 0.618-0.742) and 0.698 (95%CI 0.583-0.814), which was comparable to CPR model (training set: 0.705, 95%CI: 0.634-0.777; validation set: 0.674, 95%CI: 0.555-0.792) (p=0.486, p=0.752, respectively). The C-index of the combined model integrating radiomics signature and CPR risk factors were 0.750 (95%CI 0.680-0.819) and 0.723 (95%CI 0.624-0.822), with no improvement in prognostic performance compared with that of CPR model in both

sets (p=0.109, p=0.214; respectively). The combined model showed increased ability to stratify prognosis over the CPR model (validation set: p=0.028 vs p=0.058). In reclassification analyses, incorporating radiomics signature into CPR model significantly improved the prognostic accuracy(validation set: NRI and IDI of 1-year OS were 0.325, and 0.081;NRI and IDI of 2-year OS were 0.343 and 0.129;NRI and IDI of 3-year OS were 0.414 and 0.162).

CLINICAL RELEVANCE/APPLICATION

Multiparametric MRI-based radiomics signature is a powerful tool for prognostic assessment, and potentially serves as an individualized recommender for decision-making in ICC patients.

SDP-GI-45 Clinical Validation Of Ultrasound Backscatter Statistics For Assessment Of Liver Steatosis With Possible Concomitant Hepatitis

Participants
Chih Hao Lin, MD, Taoyuan, Taiwan (*Presenter*) Nothing to Disclose

PURPOSE

Hepatic steatosis is becoming the leading cause for hepatitis and liver fibrosis. Ultrasonography is widely used to grade hepatic steatosis. However, concomitant hepatitis may reduce the accuracy of grayscale evaluation of steatosis. This study compared backscatter statistics and echogenicity in ultrasound grading of hepatic steatosis in case of co-existing hepatitis.*Methods and Materials A total of 236 surgical patients were prospectively enrolled. Surgical specimen was used to determine the histologic diagnosis of hepatic steatosis. Ultrasound radio-frequency (RF) data of right side of liver were collected using the Terason t3000 ™ (convex array) system pre-operatively. An FDA-cleared backscatter analysis tool (AmCAD-US) was used to analyze the echogenicity and backscatter signals. The median of the echogenicity level (env), the median Nakagami (m) and the median histogram (h) backscatter statistics were calculated. ANOVA and Receiver Operating Characteristic (ROC) curve analysis were performed to compare ultrasonic and histologic severity of steatosis.*Results There were 93 grade 0 (<5%), 100 grade 1 (5~33%), 30 grade 2 (34~66%), and 13 grade 3 (>66%) steatosis cases and 70 had hepatitis with an elevated serum alanine aminotransferase level (>41 U/L). The area under ROC curve (AUC) showed a significant discriminant power of the liver steatosis by each of the three ultrasound statistics env, m and h: grade 0 versus grade 1-3, AUC= 0.643, 0.817, 0.817 (p-value<0.001); grade 0-1 versus grade 2-3, AUC= 0.837, 0.855, 0.863 (p-value<0.001); and grade 0-2 versus grade 3, AUC=0.899, 0.897, 0.907 (p-value<0.001), respectively. The two-way ANOVA showed that the steatosis grade was severely confounded by hepatitis in the echogenicity level with significant inflammation (p-value=0.003) as well as interaction effects (p-value=0.028). Whereas the backscatter statistics' discriminant power of the steatosis severity was not affected by hepatitis*Conclusions Given the highly variable echogenicity in liver parenchyma with concomitant liver disease, the use of backscatter statistics may improve the current ultrasonic capacity in diagnosis and staging of fatty liver disease.*Clinical Relevance/Application Fatty liver disease may cause hepatitis and further evolve into fibrosis. However, with conventional gray-scale image, co-existing hepatitis may largely compromise the accuracy of ultrasonic estimation of fatty liver disease. This study demonstrated backscatter signal analysis and its statistics may be a better clinical tool in assessing fatty liver disease, particularly when there were concomitant hepatitis and liver fibrosis.

RESULTS

There were 93 grade 0 (<5%), 100 grade 1 (5~33%), 30 grade 2 (34~66%), and 13 grade 3 (>66%) steatosis cases and 70 had hepatitis with an elevated serum alanine aminotransferase level (>41 U/L). The area under ROC curve (AUC) showed a significant discriminant power of the liver steatosis by each of the three ultrasound statistics env, m and h: grade 0 versus grade 1-3, AUC= 0.643, 0.817, 0.817 (p-value<0.001); grade 0-1 versus grade 2-3, AUC= 0.837, 0.855, 0.863 (p-value<0.001); and grade 0-2 versus grade 3, AUC=0.899, 0.897, 0.907 (p-value<0.001), respectively. The two-way ANOVA showed that the steatosis grade was severely confounded by hepatitis in the echogenicity level with significant inflammation (p-value=0.003) as well as interaction effects (p-value=0.028). Whereas the backscatter statistics' discriminant power of the steatosis severity was not affected by hepatitis

CLINICAL RELEVANCE/APPLICATION

Fatty liver disease may cause hepatitis and further evolve into fibrosis. However, with conventional gray-scale image, co-existing hepatitis may largely compromise the accuracy of ultrasonic estimation of fatty liver disease. This study demonstrated backscatter signal analysis and its statistics may be a better clinical tool in assessing fatty liver disease, particularly when there were concomitant hepatitis and liver fibrosis.

SDP-GI-46 Risk Prediction Models For Screening High-risk Esophageal Varices With MR-Elastography In Patients With Advanced Liver Disease

Participants
Safa Hoodeshenas, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To explore the role of MR elastography (MRE) in stratifying portal hypertension (PHTN) severity and predicting high-risk varices (HRV) by using esophagogastroduodenoscopy (EGD) as the reference standard.*Methods and Materials We retrospectively identified 1,167 patients who had MRE-assessed liver stiffness measurement (LSM) =5 kPa; 457 of them had EGD within one year of the MRE exam. LSM, spleen stiffness measurement (SSM), spleen size and platelet count (PLT) were identified as four predictors to assess PHTN severity. Data for all four predictors were available in 211 patients. The severity of esophageal varices was classified into four grades based on the EGD findings and variceal bleeding history: Grade 0 (No varices), Grade1 (small varices), Grade 2 (large varices or high-risk small varices), Grade 3 (active or prior variceal bleeding). Grades 0 and 1 were considered as a low-risk group, while grades 2 and 3 as a high-risk group .The models were constructed with Logistic regression analyses and trained with Leave-one-out cross-validation. To facilitate predicting the chance of having HRV for each patient, we designed a nomogram based on the most predictive model.*Results The model using all four predictors showed significantly higher performance compared to the model based on LSM plus PLT alone in predicting HRV (P-value=0.002) or stratifying variceal severity grades (P-value <0.05). SSM showed the most significant role among four predictors in predicting HRV (|odds ratio - 1| = 30.96%) .It had almost a doubled effect than LSM (|odds ratio - 1| =16.79%) and sixty times than PLT (|odds ratio - 1|=0.52%). We found weak correlation (Spearman ? =0.11; P < 0.06) between LSM and SSM in our study cohort. As all patients in our cohort had LSM=5.0 kPa, we extended our evaluation to a larger range of LSM in our database. We found strong correlation between LSM and SSM (0.51 < ? = 0.69 < 0.82 at 99.5% confidence) for LSM < 5kPa and weak correlation (-0.02 < ? = 0.15 < 0.31 at 99.5% confidence) for LSM = 5kPa. The correlation in all patients was also significant (0.31 < ? = 0.43 < 0.55 at 99.5% confidence).*Conclusions MRE-based

assessment of the shear stiffness of the spleen shows promise for predicting the absence of HRV in patients with advanced liver disease and is more accurate than measurement of liver stiffness and platelet count alone, allowing for use of fewer endoscopies in management of these patients.*Clinical Relevance/Application The multiparametric predictive model developed in this study has potential to reduce unnecessary endoscopy procedures and improve longitudinal management of patients with portal hypertension.

RESULTS

The model using all four predictors showed significantly higher performance compared to the model based on LSM plus PLT alone in predicting HRV (P-value=0.002) or stratifying variceal severity grades (P-value <0.05). SSM showed the most significant role among four predictors in predicting HRV (|odds ratio - 1| = 30.96%) .It had almost a doubled effect than LSM (|odds ratio - 1| =16.79%) and sixty times than PLT (|odds ratio - 1|=0.52%). We found weak correlation (Spearman ? =0.11; P < 0.06) between LSM and SSM in our study cohort. As all patients in our cohort had LSM=5.0 kPa, we extended our evaluation to a larger range of LSM in our database. We found strong correlation between LSM and SSM (0.51 < ? = 0.69 < 0.82 at 99.5% confidence) for LSM < 5kPa and weak correlation (-0.02 < ? = 0.15 < 0.31 at 99.5% confidence) for LSM = 5kPa. The correlation in all patients was also significant (0.31 < ? = 0.43 < 0.55 at 99.5% confidence).

CLINICAL RELEVANCE/APPLICATION

The multiparametric predictive model developed in this study has potential to reduce unnecessary endoscopy procedures and improve longitudinal management of patients with portal hypertension.

SDP-GI-47 Preliminary Application Of Spectral CT In Preoperative Evaluation Of Esophageal High-grade Intraepithelial Neoplasia And Pathological Grades Of The Squamous Cell Carcinoma

Participants
Yi Wang, Taizhou, China (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study is to investigate the value of spectral CT in the quantitative assessment of esophageal high-grade intraepithelial neoplasia (EHGIEN) and esophageal squamous cell carcinoma (ESCC) with different degrees of differentiation.*Methods and Materials There were 221 patients with proven EHGIEN or ESCC who underwent enhanced spectral CT from July 2017 to March 2021 retrospectively enrolled. These patients were divided into four groups based on pathological results: HGIEN, well differentiated ESCC, moderately differentiated ESCC and poorly differentiated ESCC. Iodine concentration (IC), water concentration (WC), effective atomic number (Eff-Z) and the slope of the spectral curve (?HU) of the arterial phase (AP) and venous phase (VP) were measured or calculated. The quantitative parameters of four groups were compared by using one-way ANOVA and pairwise comparison were performed with LSD. Receiver operating characteristic (ROC) analysis was used to evaluate the diagnostic performance of these parameters on EHGIEN and ESCC.*Results There were significant differences in IC, WC, Eff-Z, and ?HU in AP and VP among the four groups (all p < 0.001). The IC and Eff-Z in the poorly differentiated group were significantly higher than those in other three groups in VP (all p < 0.001), while the IC and Eff-Z in the HGIEN group were significantly lower than those in other three groups in VP (all p<0.05). In the ROC analysis, IC performed the best in the identification of EHGIEN group and ESCC group (AUC = 0.828, Sensitivity = 0.628 and Specificity = 0.933 under the threshold of 20.745).*Conclusions The quantitative parameters of spectral CT performed decently in the differential diagnosis between EHGIEN and ESCC with different degrees of differentiation before operation.*Clinical Relevance/Application Quantitative parameters of spectral CT, especially IC and Eff-Z in venous phase, could be helpful in the differential diagnosis of EHGIEN and ESCC with different degrees of differentiation.

RESULTS

There were significant differences in IC, WC, Eff-Z, and ?HU in AP and VP among the four groups (all p < 0.001). The IC and Eff-Z in the poorly differentiated group were significantly higher than those in other three groups in VP (all p < 0.001), while the IC and Eff-Z in the HGIEN group were significantly lower than those in other three groups in VP (all p<0.05). In the ROC analysis, IC performed the best in the identification of EHGIEN group and ESCC group (AUC = 0.828, Sensitivity = 0.628 and Specificity = 0.933 under the threshold of 20.745).

CLINICAL RELEVANCE/APPLICATION

Quantitative parameters of spectral CT, especially IC and Eff-Z in venous phase, could be helpful in the differential diagnosis of EHGIEN and ESCC with different degrees of differentiation.

SDP-GI-48 Dynamic Enhanced Computed Tomography Features Predict Pancreatic Neuroendocrine Neoplasm With Ki-67 Index Less Than 5%

Participants
Haopeng Yu, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

Patients with Ki67 index less than 5% had better prognosis after curative surgery. Based on preoperative dynamic enhanced computed tomography (CT), this study aimed to investigate imaging characteristics eligible to discriminate Ki67of =5% group from Ki67 of >5% group of nonmetastatic pancreatic neuroendocrine neoplasm (PanNEN).*Methods and Materials Patients with pathologically diagnosed PanNEN and preoperative multiphase CT were enrolled. Their Ki67 index was calculated and grouped according to the 5% cutoff value. Various CT imaging characteristics and some serum biomarkers were assessed between the two groups: the diameter, location, tumor margin, calcification, pancreatic atrophy, distal pancreatic duct dilation, vessel involvement, and enhancement pattern characteristics of both arterial phase (AP) and portal vein phase (PVP).*Results A total of 142 patients with PanNEN were enrolled in this study, comprising 104 in the long (Ki67, 1%-5%) and 38 in the high index group (Ki67, >5%). Alpha fetoprotein (AFP) and cancer antigen 125 (CA125) were significant between the two groups (P-values, 0.030 and 0.049, respectively). The diameter (P=0.000), margin (P=0.003), distal main ductal dilation (P=0.021), vessel involvement (P=0.002), AP hypoenhancement (P=0.000), PVP hypoenhancement (P=0.003), AP ratio (P=0.000), and PVP ratio (P=0.000) manifested significant difference between low and high index groups. The area under the curve of multivariate logistic regression model is 0.853.*Conclusions This study found several radiological differences in nonmetastatic PanNENs between the Ki67 index >5% group and lower Ki67 index group with preoperative enhanced CT.*Clinical Relevance/Application The findings of this study may affect the decision on PanNEN patients as to whether surgery is more beneficial or if postoperative surveillance should be more intensive.

RESULTS

A total of 142 patients with PanNEN were enrolled in this study, comprising 104 in the long (Ki67, 1%-5%) and 38 in the high index

A total of 142 patients with PanNEN were enrolled in this study, comprising 104 in the long (Ki67, 1%-5%) and 38 in the high index group (Ki67, >5%). Alpha fetoprotein (AFP) and cancer antigen 125 (CA125) were significant between the two groups (P-values, 0.030 and 0.049, respectively). The diameter (P=0.000), margin (P=0.003), distal main ductal dilation (P=0.021), vessel involvement (P=0.002), AP hypoenhancement (P=0.000), PVP hypoenhancement (P=0.003), AP ratio (P=0.000), and PVP ratio (P=0.000) manifested significant difference between low and high index groups. The area under the curve of multivariate logistic regression model is 0.853.

CLINICAL RELEVANCE/APPLICATION

The findings of this study may affect the decision on PanNEN patients as to whether surgery is more beneficial or if postoperative surveillance should be more intensive.

SDP-GI-49 Visceral Adiposity As A Risk Factor For Lean Nonalcoholic Fatty Liver Disease In Potential Living Liver Donors

Participants
Sunyoung Lee, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to investigate the relationship between hepatic steatosis (HS) evaluated by biopsy and visceral adiposity assessed by CT in lean living liver donor candidates and to determine the risk factors for lean nonalcoholic fatty liver disease (NAFLD).*Methods and Materials This retrospective study included 250 lean (body mass index, <23 kg/m2) potential living liver donors (mean age, 31.1±8.6 years; 141 men) who had undergone liver biopsy and abdominal CT between 2017 and 2018. Anthropometry, laboratory parameters, body composition, and the degree of HS were evaluated. Logistic regression was used to identify independent predictors of lean NAFLD.*Results The visceral fat area (VFA) was significantly correlated with the degree of HS in men (r=0.408; P<0.001) and women (r=0.360; P<0.001). The subcutaneous fat area (SFA) was significantly correlated with the degree of HS in men (r=0.398; P<0.001), but not in women. The skeletal muscle area did not correlate with the degree of HS in either men or women. In the multivariable logistic regression analysis, the VFA (odds ratio [OR], 1.028; 95% confidence interval [CI], 1.013-1.004; P<0.001) and SFA (OR, 1.016; 95% CI, 1.004-1.028; P=0.009) were independent risk factors for lean NAFLD in men, and the VFA (OR, 1.036; 95% CI, 1.013-1.059; P=0.002) was an independent risk factor for lean NAFLD in women.*Conclusions The severity of nonalcoholic fatty liver was positively correlated with visceral fat accumulation in a lean Asian population. Visceral adiposity may be a risk factor for lean NAFLD in potential living liver donors.*Clinical Relevance/Application Visceral adiposity may be a risk factor for lean NAFLD in potential living liver donors.

RESULTS

The visceral fat area (VFA) was significantly correlated with the degree of HS in men (r=0.408; P<0.001) and women (r=0.360; P<0.001). The subcutaneous fat area (SFA) was significantly correlated with the degree of HS in men (r=0.398; P<0.001), but not in women. The skeletal muscle area did not correlate with the degree of HS in either men or women. In the multivariable logistic regression analysis, the VFA (odds ratio [OR], 1.028; 95% confidence interval [CI], 1.013-1.004; P<0.001) and SFA (OR, 1.016; 95% CI, 1.004-1.028; P=0.009) were independent risk factors for lean NAFLD in men, and the VFA (OR, 1.036; 95% CI, 1.013-1.059; P=0.002) was an independent risk factor for lean NAFLD in women.

CLINICAL RELEVANCE/APPLICATION

Visceral adiposity may be a risk factor for lean NAFLD in potential living liver donors.

SDP-GI-5 Relationship Between Pancreatic Parenchyma Loss And Medium-and Long-term Blood Glucose In Patients With Benign Pancreatic Diseases

Participants
Wen Kan, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the relationship between pancreatic parenchyma loss and type 3c diabetes mellitus (T3cDM).*Methods and Materials A total of 105 patients with benign pancreatic tumors or chronic pancreatitis, whose preoperative fasting blood glucose (FBG) was normal and who underwent partial pancreatectomy were included. The pancreatic resection volume ratios (PRV) was measured by CT imaging. The patients were followed up for 18 months (3 months, 6 months, 9 months, 12 months and 18 months after operation). The content of the follow-up was the FBG value of the patients. According to WHO criteria, patients were divided into diabetes mellitus group (DM group), impaired fasting blood glucose group (IFG group) and normal blood glucose group (NG group). The differences of blood glucose at different time points after operation in the three groups were compared. The sex, age, BMI, hypertension, hyperlipidemia, surgery type were compared between non-diabetic group (IFG+NG) and DM group. Exploring the best cutoff value of resection volume ratio to predict new-onset diabetes after operation.*Results (1) A total of 13 patients with new-onset diabetes mellitus were found during the 18-month observation period, and the incidence was 12.38% (13/105). (2) The blood glucose of NG group returned to normal 3 months after operation. The blood glucose of the IFG group and the DM group also decreased 3 months after operation, but it was still higher than normal value. There was no significant difference between the FBG at 6, 9, 12 and 18 months postoperatively and those at 3 months postoperatively in the three groups (P > 0.05). (3) There was significant difference in age and PRV between non-DM group and DM group (P<0.05), and there was no significant difference in sex, hypertension, hyperlipidemia, BMI, surgery type between the two groups (P > 0.05). (4) ROC curve analysis showed the best cutoff value of the PRV between the DM group and non-DM group was 52.60%, AUC = 0.727, the sensitivity was 76.92%, and the specificity was 77.27%.*Conclusions Patients with PRV = 52.60% have a higher risk of developing T3cDM after operation. In addition, age are also associated with postoperative diabetes mellitus. The occurrence of T3cDM may be a multifactor process. Therefore, it is necessary to follow up the patients who have undergone partial pancreatectomy for a long time, especially the elderly patients whose PRV is greater than 52.60%.*Clinical Relevance/Application After partial pancreatectomy, the loss of pancreatic parenchyma must mean the loss of endocrine cells and function, but the compensatory ability of pancreas has not been reached. The purpose of this study was to explore the relationship between pancreatic parenchyma loss and type 3c diabetes mellitus (T3cDM).

RESULTS

(1) A total of 13 patients with new-onset diabetes mellitus were found during the 18-month observation period, and the incidence was 12.38% (13/105). (2) The blood glucose of NG group returned to normal 3 months after operation. The blood glucose of the IFG group and the DM group also decreased 3 months after operation, but it was still higher than normal value. There was no

significant difference between the FBG at 6, 9, 12 and 18 months postoperatively and those at 3 months postoperatively in the three groups (P > 0.05). (3) There was significant difference in age and PRV between non-DM group and DM group (P<0.05), and there was no significant difference in sex, hypertension, hyperlipidemia, BMI, surgery type between the two groups (P > 0.05). (4) ROC curve analysis showed the best cutoff value of the PRV between the DM group and non-DM group was 52.60%, AUC = 0.727, the sensitivity was 76.92%, and the specificity was 77.27%.

CLINICAL RELEVANCE/APPLICATION

After partial pancreatectomy, the loss of pancreatic parenchyma must mean the loss of endocrine cells and function, but the compensatory ability of pancreas has not been reached. The purpose of this study was to explore the relationship between pancreatic parenchyma loss and type 3c diabetes mellitus (T3cDM).

SDP-GI-50   Is There Clinically Significant Liver Injury In Acute COVID-19 And Post-COVID Period: Multimodal Imaging Approach

Participants
Maija Radzina, MD,PhD, Riga, Latvia (*Presenter*) Speakers Bureau, Canon Medical Systems Corporation;Speakers Bureau, Bayer AG;Speakers Bureau, Medtronic plc;Speakers Bureau, Bracco Group

PURPOSE

This study takes a multimodal imaging approach to evaluate liver injury during and after Covid-19 in the setting of a varying patient population and clinical outcomes.*Methods and Materials 1117 patients were enrolled: 1027 with acute Covid-19 had a thoracic computed tomography (CT) scan performed, in which liver density and abdominal ratio (AR) was measured. 56 patients with previous Covid-19 infection had a multiparametric ultrasound (mpUS) examination performed to evaluate liver elasticity, viscosity and attenuation, with same-day thoracic CT and abdominal magnetic resonance (MR) scans. The remaining 34 patients were a clinically healthy control group. Imaging findings were correlated with markers of liver injury and inflammation, the clinical course and outcomes of Covid-19.*Results 76% of acute patients had diffusely decreased liver density, corresponding to increased liver markers (p<0.001). Increased liver fattiness was more common among hospitalised patients (p=0.001, F=10.5) and in mild-moderate cases (p<0.001, F=13.8), but did not influence ICU admission or mortality. Increased AR correlated with steatosis on CT (r = 0.4, p<0.01), however, AR was slightly decreased in cases of lethal outcome when compared to survivors (p=0.002). Patients after Covid-19 had significantly different fibrosis, steatosis and viscosity scores on mpUS compared to the control group (p<0.001). Increased liver stiffness correlated with increased liver markers, but CT and MR did not (p>0.05). Patients with higher BMI had more severe disease (p<0.001) and had higher stiffness and steatosis values (p=0.016). Hospitalised patients were 9 times more likely to have increased steatosis values (p<0.01). Patients who had indicators of steatosis on MR were more likely to have had experienced moderate or severe disease (p=0.01).*Conclusions Biochemical and imaging signs of liver injury were observed in patients during and after Covid-19. Diffusely decreased liver density on CT predicted hospitalisation rates and moderate disease but did not influence lethality. Reduced AR possibly signified increased risk of a lethal outcome. Biochemically evident liver injury was more common 3-9 months after Covid-19 when compared to a control group: this was mirrored by altered mpUS findings, especially increased liver stiffness. MpUS findings were more sensitive to altered biochemical markers of liver injury than CT or MR.*Clinical Relevance/Application Easy measurements on thoracic CT scans such as liver density or the abdominal ratio could aid predicting the need for hospitalisation, development of severe disease, or indicate risk of a lethal outcome. In clinical practice, lasting effect on the liver from Covid-19 could be evaluated by mpUS, which is sensitive to liver injury.

RESULTS

76% of acute patients had diffusely decreased liver density, corresponding to increased liver markers (p<0.001). Increased liver fattiness was more common among hospitalised patients (p=0.001, F=10.5) and in mild-moderate cases (p<0.001, F=13.8), but did not influence ICU admission or mortality. Increased AR correlated with steatosis on CT (r = 0.4, p<0.01), however, AR was slightly decreased in cases of lethal outcome when compared to survivors (p=0.002). Patients after Covid-19 had significantly different fibrosis, steatosis and viscosity scores on mpUS compared to the control group (p<0.001). Increased liver stiffness correlated with increased liver markers, but CT and MR did not (p>0.05). Patients with higher BMI had more severe disease (p<0.001) and had higher stiffness and steatosis values (p=0.016). Hospitalised patients were 9 times more likely to have increased steatosis values (p<0.01). Patients who had indicators of steatosis on MR were more likely to have had experienced moderate or severe disease (p=0.01).

CLINICAL RELEVANCE/APPLICATION

Easy measurements on thoracic CT scans such as liver density or the abdominal ratio could aid predicting the need for hospitalisation, development of severe disease, or indicate risk of a lethal outcome. In clinical practice, lasting effect on the liver from Covid-19 could be evaluated by mpUS, which is sensitive to liver injury.

SDP-GI-51   Screening Of Radiotracer For Diagnosis Of Colorectal Cancer Liver Metastasis Based On Macc1Spon2

Participants
Huijie Jiang, PhD, MS, Harbin, China (*Presenter*) Nothing to Disclose

PURPOSE

Metastasis-associated in colon cancer 1 (MACC1) and Spondin2 (SPON2) are newly discovered oncogenes,but little is known about their role in colorectal cancer(CRC) liver metastases. PET has become an important molecularimaging technology due to its high sensitivity and quantifability. In particular, its targeted, specifc molecular probes can detect biological behaviors. This study was designed to evaluate the diferent biological properties of 18F-FDG, 18F-FLT, and 18F-FMISO PET. The value of the CRC liver metastasis model explores the correlation and potential mechanisms of three tracers uptakes with tumor-related biological characteristics.*Methods and Materials Human CRC cell lines(LoVo and HCT8), were cultured for in vitro radionuclide uptake experiments to compare the molecular imaging features of colorectal cancer cells with diferent metastatic potentials. Two kinds of cells wereinjected into the spleen of nude mice to establish a liver metastasis model. After the tumor formation, three kinds of tracer PET images were performed to evaluate the characteristics of live PET imaging of high and low liver metastasis colorectal cancer models. The expression levels of MACC1 and SPON2 in tissues were detected by immunohistochemistry and Westernblot. Correlation between tracer uptake and expression of MACC1 and SPON2 in liver metastases was assessed by linear regression analysis.*Results The uptake rate of in vitro three tracers uptake experiments was LoVo>HCT8. Micro-PET scan showed no significant diference between the 18F-FDG SUV values of the two cells (P>0.05); there was signifcant diference between the18F-FLT and 18F-FMISO SUV values (P<0.05). All in vivo FLT and FMISO SUV values were signifcantly higher in LoVo tumors than in HCT8 tumors. The results of Western blot and immunohistochemistry showed that the expression levels of MACC1 and SPON2 in

LoVo liver metastasis were higher than those in HCT8 (P<0.05). The 18F-FLT SUVmax ratio was signifcantly correlated with the expression of MACC1 and SPON2 in hepatic metastases (r=0.737, P=0.0026; r=0.842,P=0.0002). The 18F-FMISO SUVmax ratio was only signifcantly correlated with the expression of MACC1 in hepatic metastasis (r=0.770, P=0.0013).*Conclusions Early screening with 18F-FLT and 18F-FMISO tracers has important clinical value for the efcient diagnosis and treatment of colorectal cancer liver metastases.*Clinical Relevance/Application a

RESULTS

The uptake rate of in vitro three tracers uptake experiments was LoVo>HCT8. Micro-PET scan showed no significant diference between the 18F-FDG SUV values of the two cells (P>0.05); there was signifcant diference between the18F-FLT and 18F-FMISO SUV values (P<0.05). All in vivo FLT and FMISO SUV values were signifcantly higher in LoVo tumors than in HCT8 tumors. SDP-GI-52 Non-enhanced CT Images Based Deep Learning Analysis For The Severity Prediction Of Acute Pancreatitis At The Early Stage: A Pilot Study

Participants
Yi Wang, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

This study aims to develop a lightweight network-structured deep learning (DL) model based on non-enhanced CT (NECT) images for the severity prediction of acute pancreatitis (AP) at the early stage.*Methods and Materials A total of 978 AP patients in a single center from July 2016 to August 2019 were retrospectively recruited, and the severity of AP was determined according to the Revised Atlanta Classification. The NECT images within 72 hours of onset were collected, and clinical factors selected by multivariate logistic regression were used to develop the clinical model via decision tree method. Two MobileNetV2-backbone based DL models were constructed by using CT images (image model) or both CT images and clinical factors (combined model), respectively. All models were trained and fine-tuned in the development cohort (n = 783) and their performance were evaluated in the independent testing dataset (n = 195). Confusion matrix was used to evaluate the efficacy of the models in the classification of AP severity.*Results Clinical factors including WBC, NLR, CRP, Ca2+, LDH, Cr, 24h SIRS and 48h SIRS were significantly related to the severity of AP (all p values less than 0.05) and used for model development. In the independent testing dataset, the accuracy in predicting severe AP (SAP) of clinical model was only 29.0%, while those of image model and combined model were 64.5% and 74.2%, respectively. The accuracy of clinical model, image model and combined model for moderately severe AP (MSAP) prediction were 43.2%, 27.0% and 32.4%, respectively, and for mild AP (MAP) prediction were 80.0%, 76.7% and 90.0%, respectively. The overall prediction accuracy of the combined model was 65.6%, which was higher than those of the clinical model (57.9%, p = 0.118) and the imaging model (55.9%, p = 0.049). The combined model had achieved AUCs of 0.820 (95% CI, 0.759~0.871) and 0.920 (95% CI, 0.873~0.954) in diagnosing MAP and SAP, separately.*Conclusions The combined deep learning model which integrated clinical and image information achieved favorable performance for early prediction of AP severity, providing a basis for risk stratification of patients in early clinical stage.*Clinical Relevance/Application Early and accurate assessment of the severity of AP is of great significance in guiding timely clinical intervention, so as to improve the therapeutic effect and reduce the mortality.The clinical and image information-based deep learning model predicts AP severity with an overall accuracy of 65.6%, which might help risk stratification of patients in early clinical stage.

RESULTS

Clinical factors including WBC, NLR, CRP, Ca2+, LDH, Cr, 24h SIRS and 48h SIRS were significantly related to the severity of AP (all p values less than 0.05) and used for model development. In the independent testing dataset, the accuracy in predicting severe AP (SAP) of clinical model was only 29.0%, while those of image model and combined model were 64.5% and 74.2%, respectively. The accuracy of clinical model, image model and combined model for moderately severe AP (MSAP) prediction were 43.2%, 27.0% and 32.4%, respectively, and for mild AP (MAP) prediction were 80.0%, 76.7% and 90.0%, respectively. The overall prediction accuracy of the combined model was 65.6%, which was higher than those of the clinical model (57.9%, p = 0.118) and the imaging model (55.9%, p = 0.049). The combined model had achieved AUCs of 0.820 (95% CI, 0.759~0.871) and 0.920 (95% CI, 0.873~0.954) in diagnosing MAP and SAP, separately.

CLINICAL RELEVANCE/APPLICATION

Early and accurate assessment of the severity of AP is of great significance in guiding timely clinical intervention, so as to improve the therapeutic effect and reduce the mortality.The clinical and image information-based deep learning model predicts AP severity with an overall accuracy of 65.6%, which might help risk stratification of patients in early clinical stage.

SDP-GI-53 Evaluation Of Pancreatic Ductal Adenocarcinoma Resectability Using 80 Kvp 1mm Thickness CT: A Prospective Multicenter Study

Participants
Dong Ho Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Low kVp CT can provide better iodine contrast than 120 kVp standard CT, and 1mm thin-section CT provides high spatial resolution which would be helpful for the evaluation of vascular invasion by pancreatic ductal adenocarcinoma (PDAC). In this multicenter prospective study, we aimed to evaluate the diagnostic accuracy of 80 kVp 1mm section CT in assessing resectability of pancreatic cancer*Methods and Materials From April 2019 to October 2020, we prospectively enrolled patients who were candidates of surgical resection for PDAC at six-tertiary referral hospitals in South Korea. All participants underwent contrast enhanced pancreas protocol CT. Both late arterial phase and portal venous phase images were obtained using 80kVp with reference mAs of 325 mAs, and reconstructed every 1mm with iterative reconstruction algorithm (i.e., ADMIRE level 2). The PDAC resectability was evaluated using NCCN guideline at each center. The PDAC resectability was also assessed using 5-point scale: 1, definitely resectable; 2, probably resectable; 3, indeterminate; 4, probably unresectable; and 5, definitely unresectable. After pancreatic resection, the rate of R0 resection was assessed using histopathologic analysis as well as operative findings. To evaluate the diagnostic accuracy of 80 kVp

1mm thickness CT in assessing PDAC resectability, ROC analysis was used.*Results During the study period, 124 patients were enrolled in this study. Pancreatic resection was done in 115 patients, and R0 resection was achieved in 92 patients (74.2%, 92/124). According to the 80 kVp 1mm thickness CT and NCCN guideline, 69 patients were classified as having resectable PDC, 43 patients as having borderline resectable, and 12 patients as having unresectable, The R0 resection rate was 89.9% (62/69) for 69 patients with resectable, 65.1% (28/43) for borderline resectable, and 16.7% (2/12) for unresectable PDAC. The area-under-ROC curve of 80 kVp 1mm thickness CT in predicting R0 resection was 0.800 (P<0.001). When categories 1, 2, and 3 were considered to indicate R0 resection, the sensitivity, specificity, and accuracy of 80 kVp 1mm thickness CT in predicting R0 resection was 90.2% (83/92), 53.1% (17/32), and 80.6% (100/124), respectively.*Conclusions The 80 kVp 1mm thickness pancreas protocol CT provided good diagnostic performance in assessing PDAC resectability with accuracy of 80.6%, particularly in predicting R0 resection for resectable PDAC patients (89.9%, 62/69).*Clinical Relevance/Application The 80 kVp 1mm thickness pancreas protocol CT is useful for the evaluation of pancreatic cancer resectability with good diagnostic accuracy.

RESULTS

During the study period, 124 patients were enrolled in this study. Pancreatic resection was done in 115 patients, and R0 resection was achieved in 92 patients (74.2%, 92/124). According to the 80 kVp 1mm thickness CT and NCCN guideline, 69 patients were classified as having resectable PDC, 43 patients as having borderline resectable, and 12 patients as having unresectable, The R0 resection rate was 89.9% (62/69) for 69 patients with resectable, 65.1% (28/43) for borderline resectable, and 16.7% (2/12) for unresectable PDAC. The area-under-ROC curve of 80 kVp 1mm thickness CT in predicting R0 resection was 0.800 (P<0.001). When categories 1, 2, and 3 were considered to indicate R0 resection, the sensitivity, specificity, and accuracy of 80 kVp 1mm thickness CT in predicting R0 resection was 90.2% (83/92), 53.1% (17/32), and 80.6% (100/124), respectively.

CLINICAL RELEVANCE/APPLICATION

The 80 kVp 1mm thickness pancreas protocol CT is useful for the evaluation of pancreatic cancer resectability with good diagnostic accuracy.

SDP-GI-54 Predicting T And N Staging Of Resectable Gastric Cancer According Towhole Tumor Histogram Analysisabout A Non-cartesian K-space Acquisitiondce-mri: Afeasibility Study

Participants
Yan Liangliang, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the feasibility of the whole tumor histogram analysis parameters derived from dynamic contrast-enhanced MRI (DCE-MRI) based on stack-of stars (StarVIBE) to predict T and N staging of resectable gastric cancer(GC).*Methods and Materials Eighty-seven patients confirmed as GC by histopathology were enrolled in this prospective study. DCE-MRI were performed before surgery, and quantitative DCE parameters (Ktrans, Kep, Ve) and histogram metrics (Skewness, Kurtosis and Entropy) were measured by Omni-Kinetics software. Intraclass correlation coefficient (ICC) testing was used to determine the consistency of Ktrans, Kep and Ve values and histogram metrics values between two radiologists using Bland-Altman analysis. The quantitative DCE parameters or histogram metrics values between T stage or N stage were compared using ANOVA or Kruskal-Wallis testing. Receiver operating characteristic (ROC) analyses was performed to find out the best parameters for identifying T and N staging.*Results There were statistically difference in Ktrans, Kep, Ve and entropy to identify T staging (P=0.015, 0.033, <0.001, and 0.007, respectively), and in pairwise comparisons of Ve values showed statistically difference between T1+2 and T3 group (P<0.001), T1+2 and T4 group (P<0.001) . There were statistically differences in Ve to identify N staging (P=0.041). In ROC analysis, Ve was the best parameter for identifying T staging (AUC: 0.788, the sensitivity and specificity was 0.929 and 0.578, respectively) and N staging (AUC: 0.590, the sensitivity and specificity was 0.714 and 0.899, respectively).*Conclusions The whole tumor histogram analysis parameters derived from StarVIBE DCE-MRI may be able to quantitatively evaluate T and N staging of GC.*Clinical Relevance/Application The whole tumor histogram analysis parameters derived from DCE-MRI may be able to quantitatively evaluate T and N staging of GC, so as to help clinical treatment decision optimization.

RESULTS

There were statistically difference in Ktrans, Kep, Ve and entropy to identify T staging (P=0.015, 0.033, <0.001, and 0.007, respectively), and in pairwise comparisons of Ve values showed statistically difference between T1+2 and T3 group (P<0.001), T1+2 and T4 group (P<0.001) . There were statistically differences in Ve to identify N staging (P=0.041). In ROC analysis, Ve was the best parameter for identifying T staging (AUC: 0.788, the sensitivity and specificity was 0.929 and 0.578, respectively) and N staging (AUC: 0.590, the sensitivity and specificity was 0.714 and 0.899, respectively).

CLINICAL RELEVANCE/APPLICATION

The whole tumor histogram analysis parameters derived from DCE-MRI may be able to quantitatively evaluate T and N staging of GC, so as to help clinical treatment decision optimization.

SDP-GI-55 Qualitative Assessment Of Fontan Associated Liver Disease Using Gd-EOB-DTPA-MRI: Correlation With Serum Liver Fibrosis Markers

Participants
Reiko Sakai, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

In patients undergoing Fontan procedure for congenital single ventricle, Fontan-associated liver disease (FALD) has been reported as a sequela in approximately 40% of patients, which leads to a fatal outcome. The present study aims to quantify FALD using uptake analysis of Gd-EOB-DTPA MRI with 1.5T and 3T scanners, and verify its association with serum hepatic fibrosis markers.*Methods and Materials 60 examinations of Gd-EOB-DTPA MRI for 31 patients (mean age; 28 years) after Fontan procedure was retrospectively analyzed. Of these, 44 examinations of 27 patients were scanned with a 1.5 tesla scanner, and 16 examinations of 13 patients were scanned with a 3 tesla MR scanner. The increase rate of liver-to-spleen signal intensity ratio (LSR-increasing-ratio) on the hepatobiliary phase after 15 minutes of Gd-EOB-DTPA administration was used as an assessment of FALD, and the correlation with serum liver fibrosis markers hyaluronic acid and Fib-4 index was examined. When liver fibrosis was defined as Fib-4 index 2.67 or higher, the diagnostic ability was examined by ROC curved analysis.*Results LSR-increasing-ratio was decreased significantly as hyaluronic acid (1.5 tesla and 3 tesla; Pearson r -0.57 and -0.59, p<0.05) and Fib-4 index (1.5 tesla and 3 tesla; Pearson r -0.71 and -0.83, p<0.0001) increased. Using the optimal threshold for LSR-increasing-ratio, the diagnostic performance of liver fibrosis at 1.5 tesla and 3 tesla was threshholds 0.14 and 0.29, areas under the curve 0.89 and 0.93,

sensitivity 80% and 100%, and specificity 91% and 91%.*Conclusions LSR-increasing-ratio as a quantitative index of FALD correlated significantly with serum liver fibrosis markers and could be used to detect liver fibrosis noninvasively.*Clinical Relevance/Application Gd-EOB-DTPA MRI can simultaneously evaluate liver fibrosis and the presence or absence of tumors, and it is a helpful tool for FALD management.

RESULTS

LSR-increasing-ratio was decreased significantly as hyaluronic acid (1.5 tesla and 3 tesla; Pearson r -0.57 and -0.59, p<0.05) and Fib-4 index (1.5 tesla and 3 tesla; Pearson r -0.71 and -0.83, p<0.0001) increased. Using the optimal threshold for LSR-increasing-ratio, the diagnostic performance of liver fibrosis at 1.5 tesla and 3 tesla was threshholds 0.14 and 0.29, areas under the curve 0.89 and 0.93, sensitivity 80% and 100%, and specificity 91% and 91%.

CLINICAL RELEVANCE/APPLICATION

Gd-EOB-DTPA MRI can simultaneously evaluate liver fibrosis and the presence or absence of tumors, and it is a helpful tool for FALD management.

SDP-GI-56   Deep Learning 3D Convolutional Neural Network For Noninvasive Evaluation Of Pathologic Grade Of Hepatocellular Carcinoma Using Contrast-enhanced Magnetic Resonance Imaging

Participants
Ying Zhao JR, Dalian, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the diagnostic performance of three-dimensional convolutional neural network (3D-CNN) model for the differentiation of the pathologic grade of hepatocellular carcinoma (HCC) based on contrast-enhanced (CE)-MR images.*Methods and Materials This retrospective study enrolled 113 patients who underwent preoperative CE-MR examinations and were pathologically confirmed as HCC, including 60 poorly-differentied (PD) HCCs and 53 non-PD (well-differentied (WD) and moderately-differentied (MD)) HCCs. The samples were randomly divided into the training set (n = 90) and the testing set (n = 23) at ratio of 8:2. Figure 1 shows the flowchart of the multimodal fusion model. On the arterial (A), venous (V) and delayed (D) phase images, two radiologists manually outlined the regions of interest (ROIs) which enclosed the boundary of the lesions. We set the size of the normalized HCC slice as 224 × 224 to input into the network. ResNet-50 was used to extract senior semantic features based on each phase images. Figure 2 shows the feature extraction process of ResNet-50. We used the parameters of ResNet-50 model trained on ImageNet dataset to initialize our three ResNet-50 model. In order to make the ResNet-50 network on different phase images to better learn to express the characteristics of HCC differentiation, we deleted the last full connected layer of each ResNet-50, and then added two fully connected layers with 2048 and two neurons respectively. Finally, we added two fully connected layers followed by the three models (A, V and D). These two fully connected layers were used to fuse the senior semantic features of different phase MR images for the HCC classification task. ROC analysis was used to evaluate the diagnostic performance for differentiation of pathologic grade of HCC.*Results The multimodal fusion model showed prior performance (AUC = 0.889) compared with the single-modal model (A model: AUC = 0.579; V model: AUC: 0.793; D model: AUC = 0.681), were shown in Table 1.*Conclusions 3D-CNN model may be valuable for the noninvasive evaluation of the pathologic grade of HCC.*Clinical Relevance/Application In this study, we proposed a 3D-CNN model to preoperatively identify HCC grading, which will provide more prognostic information and facilitate clinical management.

RESULTS

The multimodal fusion model showed prior performance (AUC = 0.889) compared with the single-modal model (A model: AUC = 0.579; V model: AUC: 0.793; D model: AUC = 0.681), were shown in Table 1.

CLINICAL RELEVANCE/APPLICATION

In this study, we proposed a 3D-CNN model to preoperatively identify HCC grading, which will provide more prognostic information and facilitate clinical management.

SDP-GI-57   MRI-based Radiomic Model For Predicting Treatment Response To First Transarterial Chemoembolization In Intermediate-stage Hepatocellular Carcinoma

Participants
huanyi zhu, Nanjing, China (*Presenter*) Nothing to Disclose

PURPOSE

This article aims to construct and validate a radiomic model to predict the first-month objective treatment response of patients with intermediate-stage hepatocellular carcinoma (HCC) who received first transarterial chemoembolization (TACE), on the basis of preoperative MRI image data and clinic data.*Methods and Materials All subjects enrolled in a single-arm multicentre prospective clinical trial 'A Study of Tandem Microspheres in Localized Hepatocellular Carcinoma' were analyzed in this study. The patients were all diagnosed with intermediate-stage HCC and accepted Tandem Microspheres TACE as the first-line therapy. The demographics and laboratory test results of the subjects were collected. All patients received Tandem Microspheres TACE within 14 days after the acquisition of baseline contrast-enhanced abdominal MRI. Follow-up MRI were performed one month after the treatment. Region of interests (ROIs) were drew at the central level of the tumor on the fat-saturated T2-weighted sequence, late arterial and portal venous phase images. All lesions were separated into training and testing group randomly in the ratio of 7:3. High-throughput extraction of image features were performed with python. According to the modified Response Evaluation Criteria in Solid Tumors (mRECIST), all lesions were divided into CR group (complete response) and non-CR group (partial response / stable disease / progressive disease). Lasso regression were performed to build radiomic model, and receiver operating characteristic curve (ROC) was used to evaluate the performance of the model.*Results 109 subjects (mean age, 60.3 ± 14.7 years old) from 10 centres were included in the study and 160 lesions were analyzed. A total of 3218 radiomic features were extracted for each lesion. After dimension reduction, 10 image features were selected for radiomic model construction. The areas under the curve (AUCs) of the model were 0.748 and 0.675 in the training and the testing group, respectively. Among all features, Wavelet-LLL GLRLM Long Run Low Gray Level Emphasis from portal venous phase MR image demonstrated the greatest contribution in the model.*Conclusions The MRI-based radiomic model had a good performance in predicting the objective response after the initial TACE in patients with intermediate-stage HCC.*Clinical Relevance/Application The MRI-based radiomic model may have potential in guiding personalized TACE treatment in patients with intermediate-stage HCC.

RESULTS

109 subjects (mean age, 60.3 ± 14.7 years old) from 10 centres were included in the study and 160 lesions were analyzed. A total of 3218 radiomic features were extracted for each lesion. After dimension reduction, 10 image features were selected for radiomic model construction. The areas under the curve (AUCs) of the model were 0.748 and 0.675 in the training and the testing group, respectively. Among all features, Wavelet-LLL GLRLM Long Run Low Gray Level Emphasis from portal venous phase MR image demonstrated the greatest contribution in the model.

CLINICAL RELEVANCE/APPLICATION

The MRI-based radiomic model may have potential in guiding personalized TACE treatment in patients with intermediate-stage HCC.

SDP-GI-58 Development Of A CT-based Binary Radiological Prediction Model For Lauren Classification Of Gastric Adenocarcinoma

Participants
Jiejin Yang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to develop and compare different radiomics models (with/without clinical information) for differentiating the Lauren classification of gastric adenocarcinoma.*Methods and Materials A total of 259 portal-venous-phase CT images with Lauren classification confirmed gastric adenocarcinoma was retrospectively collected and were randomly assigned to the training set (intestinal type/non-intestinal type = 59/123) and test set (intestinal type/non-intestinal type=25/52) at a ratio of 7:3. Three kinds of clinical information were used to participate in the construction of the model, including the patient's gender, age, and tumor location. The manually segmented 3D gastric cancer label in portal venous phase CT images was used as the region of interest. After extracting features of the ROI, normalization, feature reduction, and feature selection, a simple radiomics model of Lauren classification with radiomics features and a radiomics model combining clinical information were established respectively. 5-fold cross-validation were both used in the training sets of the two models. Receiver operating characteristic (ROC) curves, accuracy, sensitivity, and specificity were used to validate the capability of the radiomics models on both the training and test cohorts. Furthermore, the decision curve analysis (DCA) was used to compare the predictive performance of the two models.*Results The DCA showed that the radiomics model combined with clinical information had better performance in predicting the Lauren classification of gastric cancer. In the test set, the model had an AUC of 0.808, and accuracy, sensitivity, and specificity of 77.9%, 84.0%, and 75.0%, respectively.*Conclusions The radiomics model combined with clinical information had better performance in predicting the Lauren classification of gastric cancer than the simple radiomics model. The patient's age, gender, and tumor location information were potentially helpful to improve the predictive performance of the Lauren classification binary radiomics model.*Clinical Relevance/Application The Lauren classification of gastric adenocarcinoma is a simple and powerful histological classification method and is widely accepted and adopted by pathologists and clinicians. Preoperative prediction of Lauren classification of gastric adenocarcinoma is of great significance for tumor treatment and prognostic evaluation. Establishing the radiomics model of differentiating Lauren classification of gastric adenocarcinoma by deeply explore CT image characteristics, could provide more information for tumor treatment, and improve the value of imaging reports.

RESULTS

The DCA showed that the radiomics model combined with clinical information had better performance in predicting the Lauren classification of gastric cancer. In the test set, the model had an AUC of 0.808, and accuracy, sensitivity, and specificity of 77.9%, 84.0%, and 75.0%, respectively.

CLINICAL RELEVANCE/APPLICATION

The Lauren classification of gastric adenocarcinoma is a simple and powerful histological classification method and is widely accepted and adopted by pathologists and clinicians. Preoperative prediction of Lauren classification of gastric adenocarcinoma is of great significance for tumor treatment and prognostic evaluation. Establishing the radiomics model of differentiating Lauren classification of gastric adenocarcinoma by deeply explore CT image characteristics, could provide more information for tumor treatment, and improve the value of imaging reports.

SDP-GI-59 Differentiation Of T2- And T3-stage Rectal Cancer Using Whole-tumor CT Radiomics Signatures

Participants
Takeshi Nakaura, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Diagnosis of the depth of rectal cancer is important in deciding the indication for preoperative chemotherapy and surgery, but it is often difficult to perform, even with endoscopy and CT. Radiomics analysis using contrast-enhanced CT has recently been found useful for tumor differentiation, malignant diagnosis, and prediction of various parameters such as gene expression. In this study, we evaluated the usefulness of CT radiomics analysis in the differentiation of T2- and T3-stage rectal cancer.*Methods and Materials Total 166 rectal cancer resections performed at our hospital from April 2019 to March 2021 were included in the study, with 87 patients placed in the training group and 29 patients in the test group. Volumes of interest of the whole tumors were manually contoured in preoperative portal-phase CT examinations, and total 115 radiomics features (14 shape features, 18 &7;rst-order intensity statistics features, and 73 texture features) were extracted. Signi&7;cant features for the differentiation of T2- and T3-stage rectal cancer were selected using the Random Forest and Boruta algorithms. Radiomics signatures were built and validated with the selected features in the training group using five-fold cross-validation. The performance of the radiomics signature was evaluated using the receiver operating characteristics curve and area under the curve (AUC) and compared with the diagnostic performance of the combination of CT and rectal endoscopy performed by two radiologists.*Results Nine radiomics factors ("Sphericity," "SurfaceArea," "Flatness," "LeastAxis," "DependenceNonUniformity," "Energy," "TotalEnergy," "RunLengthNonUniformity," and "GrayLevelNonUniformity") were extracted by variable selection using Boruta. In the test group, the AUC of the model using these parameters was 0.81, which was significantly higher (p < 0.01) than the AUCs of the radiologists using the CT (Reader 1, 0.56; Reader 2, 0.55) and the endoscope (Reader 1, 0.47; Reader 2, 0.53).*Conclusions Whole-tumor CT radiomics signatures may be a useful tool for the differentiation between T2- and T3-stage rectal cancer.*Clinical Relevance/Application Whole-tumor CT radiomics signatures can differentiate between T2- and T3-stage rectal cancer using preoperative contrast-enhanced CT with high diagnostic accuracy.

RESULTS

Nine radiomics factors ("Sphericity," "SurfaceArea," "Flatness," "LeastAxis," "DependenceNonUniformity," "Energy," "TotalEnergy,"

"RunLengthNonUniformity," and "GrayLevelNonUniformity") were extracted by variable selection using Boruta. In the test group, the AUC of the model using these parameters was 0.81, which was significantly higher (p < 0.01) than the AUCs of the radiologists using the CT (Reader 1, 0.56; Reader 2, 0.55) and the endoscope (Reader 1, 0.47; Reader 2, 0.53).

CLINICAL RELEVANCE/APPLICATION

Whole-tumor CT radiomics signatures can differentiate between T2- and T3-stage rectal cancer using preoperative contrast-enhanced CT with high diagnostic accuracy.

SDP-GI-6   Extracellular Volume Fraction With Equilibrium Contrast-enhanced MRI For Predicting Chemotherapy Response In Pancreatic Ductal Adenocarcinoma: Comparison With DCE-MRI

Participants
Yoshihiko Fukukura, MD, PhD, Kagoshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Tumor extracellular volume (ECV) fraction determined with equilibrium contrast-enhanced CT has been reported to be a useful imaging biomarker to predict the treatment response and survival of patients with pancreatic ductal adenocarcinoma (PDAC) after chemotherapy. However, the clinical relevance of ECV fraction determined with equilibrium contrast-enhanced MRI as an imaging biomarker for cancer patients has not been reported. Moreover, the exact underlining mechanisms in the association between ECV fraction and treatment response to chemotherapy in PDAC remain unclear. Therefore, this study aimed to assess the feasibility of ECV fraction with equilibrium contrast-enhanced MRI for prediction of treatment response to chemotherapy in PDAC in comparison with DCE-MRI and to clarify the association between ECV fraction and dynamic contrast-enhanced (DCE) MRI-derived parameters.*Methods and Materials This retrospective study included 34 consecutive patients (22 men, 12 women; mean age, 68.0 years; range, 47-82) with histologically confirmed PDAC who underwent DCE-MRI before systemic chemotherapy. Tumor pharmacokinetic parameters including the volume transfer coefficient (Ktrans), rate constant (kep), and extracellular extravascular volume fraction (ve) of DCE-MRI, and ECV fraction quantified with equilibrium contrast-enhanced MRI were calculated using ROI measurements within PDAC. These parameters were compared between the response (complete or partial response) and nonresponse groups (stable or progressive disease). The correlation of tumor ECV fraction with each DCE-MRI-derived parameter was examined using Spearman's rank correlation coefficient.*Results Tumor Ktrans (P=0.004), ve (P <0.001), and ECV fraction (P <0.001) were significantly higher in the response group than in the non-response group, whereas no significant difference was found in kep (P=0.190). Tumor ECV fraction showed the highest AUC of 0.910, with a sensitivity of 87.5%, specificity of 88.9%, and accuracy of 88.2% (cut off, >34.8%). The ECV fraction showed a significant positive correlation with Ktrans (Spearman's coefficient=0.68, P <0.001) and ve (Spearman's coefficient=0.82, P <0.001).*Conclusions ECV fraction determined with equilibrium contrast-enhanced MRI was as useful as DCE-MRI-derived parameters for predicting treatment response to chemotherapy in patients with PDAC.*Clinical Relevance/Application ECV fraction could offer an alternative imaging biomarker to DCE-MRI for predicting the response to chemotherapy in patients with PDAC.

RESULTS

Tumor Ktrans (P=0.004), ve (P <0.001), and ECV fraction (P <0.001) were significantly higher in the response group than in the non-response group, whereas no significant difference was found in kep (P=0.190). Tumor ECV fraction showed the highest AUC of 0.910, with a sensitivity of 87.5%, specificity of 88.9%, and accuracy of 88.2% (cut off, >34.8%). The ECV fraction showed a significant positive correlation with Ktrans (Spearman's coefficient=0.68, P <0.001) and ve (Spearman's coefficient=0.82, P <0.001).

CLINICAL RELEVANCE/APPLICATION

ECV fraction could offer an alternative imaging biomarker to DCE-MRI for predicting the response to chemotherapy in patients with PDAC.

SDP-GI-60   Development And Validation Of Radiomics Signatures To Predict Kras Mutation Subtypes Based On Enhanced Computed Tomography In Patients With Colorectal Cancer

Participants
Yuntai Cao, MS,MS, Xining, China (*Presenter*) Nothing to Disclose

PURPOSE

Recent accumulating evidence indicates different KRAS mutation subtypes have different anti-EGFR therapeutic efficacy in colorectal cancer (CRC) patients. This retrospective study was designed to investigate whether a computed tomography (CT)-based radiomic features can be non-invasively predicting KRAS mutation subtypes.*Methods and Materials Our study included 447 patients with CRCs, who underwent preoperative contrast-enhanced CT examinations and performed the KRAS mutations analysis. 1037 radiomic features were extracted from the delayed phase CT images of each patient. Three tasks (task 1, Prediction of KRAS G13D mutation; task 2, Prediction of other KRAS mutation; task 3, differentiating KRAS G13D mutation from other KRAS mutation) were performed in the current study to explore the capability of radiomic features for predicting KRAS mutation subtypes. Univariate analysis and Boruta method were used to select the key features for KRAS mutation subtypes. Radiomic models were built using the random forest (RF) analysis, and the ROC curve and corresponding AUC value, calibration curve and decision curve were used to evaluate the predictive performance and clinical usefulness of each model.*Results After removed irrelevant features, 8 radiomics features were retained as the final signatures for the prediction of KRAS G13D mutation, while 9 radiomics features were final signatures for the prediction of other KRAS mutation. Moreover, 3 features demonstrated a statistically significant in the discrimination of KRAS G13D mutation and other KRAS mutation. Based on these relevant features, this study constructed 3 radiomics models for analyzing KRAS mutation subtypes. The constructed radiomic models showed promising performance in predicting KRAS mutation subtypes. Task 1 had the AUCs of 0.759 (95CI, 0.673-0.846) and 0.790 (95CI, 0.679-0.901) in training cohort and validation cohort, respectively. Task 2 had the AUCs of 0.753 (95CI, 0.697-0.810) and 0.715 (95CI, 0.614-0.815) two cohorts, respectively. Task 3 had the AUCs of 0.785 (95CI, 0.693-0.876) and 0.773 (95CI, 0.639-0.907) in two cohorts, respectively.*Conclusions The radiomics model based on enhanced CT has promising performance for predicting KRAS mutation subtypes of CRC, and the constructed model has been effectively verified on the internal validation cohort.*Clinical Relevance/Application Our models can be used as an auxiliary tool for preoperative non-invasive detection of KRAS mutation subtypes, to achieve precise targeted therapy stratification, and help to develop effective personalized treatment strategies for patients with CRC.

RESULTS

After removed irrelevant features, 8 radiomics features were retained as the final signatures for the prediction of KRAS G13D mutation, while 9 radiomics features were final signatures for the prediction of other KRAS mutation. Moreover, 3 features demonstrated a statistically significant in the discrimination of KRAS G13D mutation and other KRAS mutation. Based on these relevant features, this study constructed 3 radiomics models for analyzing KRAS mutation subtypes. The constructed radiomic models showed promising performance in predicting KRAS mutation subtypes. Task 1 had the AUCs of 0.759 (95CI, 0.673-0.846) and 0.790 (95CI, 0.679-0.901) in training cohort and validation cohort, respectively. Task 2 had the AUCs of 0.753 (95CI, 0.697-0.810) and 0.715 (95CI, 0.614-0.815) two cohorts, respectively. Task 3 had the AUCs of 0.785 (95CI, 0.693-0.876) and 0.773 (95CI, 0.639-0.907) in two cohorts, respectively.

CLINICAL RELEVANCE/APPLICATION

Our models can be used as an auxiliary tool for preoperative non-invasive detection of KRAS mutation subtypes, to achieve precise targeted therapy stratification, and help to develop effective personalized treatment strategies for patients with CRC.

SDP-GI-61   Comparison Analysis Of Ivim And 4d Flow-MRI In Patients With Liver Cirrhosis

Participants
Nan Wang, Dalian, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the correlation between liver IVIM quantitative parameters and portal vein 4D flow quantitative parameters in patients with liver cirrhosis.*Methods and Materials This study has been approved by the institutional IRB. 11 patients were recruited with informed consent acquired from each subject. All patients were scanned using a 3.0 T MR scanner (Ingenia CX, Philips Healthcare, the Netherlands) with a 16-channel abdominal array coil. The MR protocols include T1WI, T2WI, DWI, IVIM, 4D Flow and DYNAMIC sequence. For 4D Flow imaging, a 2D phase-contrast scan was performed first to measure the flow velocity in the portal vein, as a reference for velocity encodings (VENC). The 4D Flow sequence with 8-fold compressed sensing acceleration was scanned with the following parameters: axial, TR/TE = 5.0/3.2 ms, FOV = 300×350 mm2, resolution = 2.5×2.5×2.5 mm3, PC direction = RL-AP-FH, VENC = 30 cm/s, scan time = 4min37s. The detailed parameters for all the other sequences were listed in Table 1. After the MR scan is completed, the 4D flow images were processed on CVI42 package (Canada Circle Cardiovascular Imaging)by an experienced radiologist to obtain the 3D angiogram. Four planes were manually placed vertical on the targeted vessel segments to measure the flow direction,the flow rate (cm/s), the axial-wall shear stress (WSS, Pa), and the pressure gradient (mmHg). Three planes were placed at the proximal, middle, and distal of the main portal vein and one at the splenic vein confluence as reference (Figure1). The images of other sequences were analyzed on a post-processing ISP workstation (Intelli Space Portal, Philips Healthcare) to measure IVIM parameters included: sADC, D, D* and F (Figure2). Spearman test (SPSS 22.0) was used to analyze the correlation between IVIM parameters and 4D flow-MRI parameters.*Results sADC and D values were negatively correlated with the proximal Flow rate (r=0.626, P<0.05) and the middle Flow rate (r=0.709, P<0.05), respectively. D* value was positively correlated with the middle Flow and proximal Flow rate (r=0.900, P=0.037). There was no correlation among the other parameters (P>0.05).*Conclusions The changes in portal blood flow during the development of liver cirrhosis were associated with the variation of the signals in intrahepatic blood flow. There is a certain correlation among sADC and D values measured by IVIM and flow rate in 4D flow sequences. The mechanism behind this correlation need the further investigation and may shed light on the disease assessment and the development of novel therapies.*Clinical Relevance/Application The changes in portal blood flow during the development of liver cirrhosis were associated with the variation of the signals in intrahepatic blood flow.

RESULTS

sADC and D values were negatively correlated with the proximal Flow rate (r=0.626, P<0.05) and the middle Flow rate (r=0.709, P<0.05), respectively. D* value was positively correlated with the middle Flow and proximal Flow rate (r=0.900, P=0.037). There was no correlation among the other parameters (P>0.05).

CLINICAL RELEVANCE/APPLICATION

The changes in portal blood flow during the development of liver cirrhosis were associated with the variation of the signals in intrahepatic blood flow.

SDP-GI-62   Estimation Of Liver Steatosis In Patients With Non Alcoholic Fatty Liver Disease With A New Parameter Lisa That Calculates The Attenuation Of Ultrasound B-mode Acoustic Signal.

Participants
Petros Drazinos, PhD,MSc, Kifissia, Greece (*Presenter*) Nothing to Disclose

PURPOSE

Non Alcoholic Fatty Liver Disease (NAFLD) is one the most widespread type of chronic liver disease in the Western Countries. NAFLD may lead to Non Alcoholic Steatohepatitis (NASH) and, if not opposed, to Cirrhosis and liver failure. Ultrasound (US) is widely used for the disease diagnosis and staging as it is a low cost and radiation-free non invasive method. One of the US B-Mode imaging methods developed for NAFLD diagnosis is the calculation of signal attenuation. Several studies suggest that ultrasonic wave attenuation is faster in livers with increased fat content. Acoustic attenuation parameters may, therefore, contribute to fat liver content quantification. An established parameter for calculation of attenuation and hence steatosis estimation is offered by Fibroscan, known as Controlled Attenuation Parameter (CAP). CAP is measured without a visual placement of a ROI in the B-Mode acoustic window. Recently a new attenuation parameter was developed, Liver Ultrasound Attenuation (LiSA) which is similar to CAP with the addition of visual ROI placement through B-Mode imaging for attenuation measurement. Our purpose is the evaluation of the LiSA performance in Liver Steatosis Estimation using MRI-PDFF examinations as 'gold-standard'.*Methods and Materials 159 consecutive NAFLD patients were included in the study with mean age of 59 years (range: 24-85) and a mean BMI of 28.09 (range 17.3-45.6). An MRI-PDFF examination for liver steatosis quantification and an US B-Mode examination and a LiSA measurement was performed an all subjects in the study.*Results The median (IQR) values of MRI-PDFF and LiSA were 4.9% (11.2%) and 246 (71.75) db/m. The Pearson Correlation Coefficient was calculated, PCC = 0.80 with a p-value = 3.21*10-36 (<<0.05). Using regression analysis we obtained the following equation for MRI-PDFF calculation using a LiSA measurement with a Mean Absolute Error of 4.39%. MRI-PDFF=0.14*LiSA-27.79*Conclusions The attenuation parameter LiSA presented a good correlation with the liver fat percentage as measured with an MRI-PDFF examination. We can quantify liver fat content using LiSA with a mean error of 4.39%. More subjects should be included in the future so LiSA can be further evaluated as a valuable non-invasive tool estimating liver steatosis in a fatty liver.*Clinical Relevance/Application A new attenuation parameter LiSA similar to Fibroscan/CAP was evaluated in liver steatosis estimation using MRI-PDFF examinations as reference.

RESULTS

The median (IQR) values of MRI-PDFF and LiSA were 4.9% (11.2%) and 246 (71.75) db/m. The Pearson Correlation Coefficient was calculated, PCC = 0.80 with a p-value = 3.21*10-36 (<<0.05). Using regression analysis we obtained the following equation for MRI-PDFF calculation using a LiSA measurement with a Mean Absolute Error of 4.39%. MRI-PDFF=0.14*LiSA-27.79

CLINICAL RELEVANCE/APPLICATION

A new attenuation parameter LiSA similar to Fibroscan/CAP was evaluated in liver steatosis estimation using MRI-PDFF examinations as reference.

SDP-GI-63   Diagnosis Of Gastric Cancer Serosa Invasion Using A Radiomics Model Focusing On Localized Stomach Wall And Peritumoral Tissue Texture Features In Dual-Energy Computed Tomography(DECT)

Participants
Junyi Sun, Shijiazhuang, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the performance of a localized radiomics model derived from the dual-energy computed topoghapy (DECT) iodine and mixed images for the serosa invasion discriminating in patients with gastric cancer.*Methods and Materials This study retrospectively reviewed 231 patients who had postoperative pathology confirmed gastric adenocarcinoma. All patients underwent preoperative DECT scans and were randomly allocated into the developing (n= 132 for training cohort, n= 58 for test cohort) and validation cohort (n=41). The radiomics feature were extracted using a dedicated radiomics software (Frontier, Siemens). Instead of segmenting the intact volume of the lesion, ROI was placed on the most suspicious location which includes the lesion and peri-gastric fat within 5 mm at the maximum invasion layer. Meanwhile, ROI was also automatically synchronized to iodine map which can directly reflect the blood supply in that region. Intraclass correlation coefficient (ICC)>0.8 and Boruta were used to screen out the significant features for the radiomics model construction with Random Forest algorithm. Finally, a radiomics nomogram was developed by integrating the radiomics signatures and CT findings via multivariable logistic regression. The diagnostic performance between models (clinical, radiomics, and combined model) was evaluated by receiver operating characteristic (ROC) curve analysis and decision curve analysis(DCA).*Results 631 features with ICC>0.8 and the top 200 vital features from the Boruta feature selection were selected for the model construction. The radiomics model performed well in train (AUC and 95%CI, 0.9[0.84-0.95]), test (0.90[0.81-0.98]) and the validation cohort (0.849 [0.728-0.969]).The nomogram consisted of radiomics scores and the CT findings(haziness of the perigastric fat, lymph node and location)showed higher discrimination accuracy (AUC and 95%CI for training:0.92[0.87-0.97],testing:0.93[0.87-0.99],validation:0.90, [0.81-0.99]) compared to clinical model(P<0.05, AUC and 95%CI for training:0.786 [0.70- 0.86], testing:0.78 [0.65-0.91], validation:0.79 [0.66-0.93]). The DCA curves indicated the combined model was superior to the clinical model alone in terms of clinical usefulness.*Conclusions Radiomic model derived from localized tumor and peritumoral features in DECT showed an incremented diagnostic value for the identification of serosa invasion.*Clinical Relevance/Application Preoperative precise identification of serosa invasion in clinical remains a challenge. The integration of DECT image with radiomics and CT clinical finding shows great potential for discriminating of serosa invasion in gastric cancer patient.

RESULTS

631 features with ICC>0.8 and the top 200 vital features from the Boruta feature selection were selected for the model construction. The radiomics model performed well in train (AUC and 95%CI, 0.9[0.84-0.95]), test (0.90[0.81-0.98]) and the validation cohort (0.849 [0.728-0.969]).The nomogram consisted of radiomics scores and the CT findings(haziness of the perigastric fat, lymph node and location)showed higher discrimination accuracy (AUC and 95%CI for training:0.92[0.87-0.97],testing:0.93[0.87-0.99],validation:0.90, [0.81-0.99]) compared to clinical model(P<0.05, AUC and 95%CI for training:0.786 [0.70- 0.86], testing:0.78 [0.65-0.91], validation:0.79 [0.66-0.93]). The DCA curves indicated the combined model was superior to the clinical model alone in terms of clinical usefulness.

CLINICAL RELEVANCE/APPLICATION

Preoperative precise identification of serosa invasion in clinical remains a challenge. The integration of DECT image with radiomics and CT clinical finding shows great potential for discriminating of serosa invasion in gastric cancer patient.

SDP-GI-64   The Role Of Gadoxetic Acid-enhanced MRI In Predicting Severe Microvascular Invasion Of Hepatocellular Carcinoma

Participants
Jae Seok Bae, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the role of gadoxetic acid-enhanced MRI (GA-MRI) in predicting severe microvascular invasion (MVI) of hepatocellular carcinoma (HCC).*Methods and Materials We retrospectively analyzed 247 consecutive treatment-naïve patients (median age, 63 years [range, 56-69]) who underwent GA-MRI before hepatic resection for single HCC between July 2014 and December 2017. When MVI was detected on surgical specimens, the number of tumor cells and the number of invaded vessels were analyzed to identify severe-MVI. When the number of tumor cells = 50 and the number of invaded vessels = 5, the MVI was considered severe-MVI that may have a higher prognostic impact over any degree of MVI. Two radiologists independently GA-MRI images and reached a consensus for the presence of the four following imaging features that have been reported to be associated with MVI: arterial peritumoral enhancement, non-smooth tumor margin, peritumoral hypointensity on hepatobiliary phase, and satellite nodule. Logistic regression analysis was performed to identify GA-MRI imaging features that are associated with severe-MVI. Sensitivity and specificity of imaging features for detecting severe-MVI were calculated. In addition, the area under the curve of each imaging feature for detecting severe-MVI were calculated by using receiver operating characteristics curve analysis.*Results On histopathologic examination, any degree of MVI and severe-MVI were found in 88 (34%) and 54 (21%) patients, respectively. Among the GA-MRI imaging features, non-smooth tumor margin (Odds ratio [OR], 4.09; 95% confidence interval [CI], 1.32-12.74) and satellite nodule (OR, 4.27; 95% CI, 1.41-12.98) were independently associated with severe-MVI. For predicting severe-MVI, non-smooth tumor margin demonstrated a high sensitivity of 92.9% and satellite nodule demonstrated a high specificity of 96.9%. However, the areas under the curve of non-smooth tumor margin and satellite nodule for the detection of severe-MVI were 0.658 and 0.609, respectively.*Conclusions Although non-smooth tumor margin and satellite nodule were associated with severe-MVI, their diagnostic performances for predicting severe-MVI were at best modest.*Clinical Relevance/Application Considering the limited diagnostic performance of GA-MRI imaging features to detect severe-MVI, caution is needed when preoperatively predicting severe-MVI using GA-MRI.

RESULTS

On histopathologic examination, any degree of MVI and severe-MVI were found in 88 (34%) and 54 (21%) patients, respectively. Among the GA-MRI imaging features, non-smooth tumor margin (Odds ratio [OR], 4.09; 95% confidence interval [CI], 1.32-12.74) and satellite nodule (OR, 4.27; 95% CI, 1.41-12.98) were independently associated with severe-MVI. For predicting severe-MVI, non-smooth tumor margin demonstrated a high sensitivity of 92.9% and satellite nodule demonstrated a high specificity of 96.9%. However, the areas under the curve of non-smooth tumor margin and satellite nodule for the detection of severe-MVI were 0.658 and 0.609, respectively.

CLINICAL RELEVANCE/APPLICATION

Considering the limited diagnostic performance of GA-MRI imaging features to detect severe-MVI, caution is needed when preoperatively predicting severe-MVI using GA-MRI.

SDP-GI-65   Validation Of Liver Imaging Reporting And Data System Tumor In Vein Category Using CT And Hepatobiliary Agent-enhanced MR Imaging

Participants
Jae Seok Bae, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To assess the diagnostic performances of the LR-TIV category in detecting macroscopic tumor in vein (TIV) on CT and hepatobiliary contrast agent-enhanced MRI (HBA-MRI) using pathologic results as the reference standard.*Methods and Materials Between January 2010 and December 2019, 1322 consecutive patients with (n=101) or without (n=1221) macroscopic TIV who underwent both CT and HBA-MRI before hepatic resection or liver transplantation were retrospectively included. Three radiologists independently assessed the LR-TIV features of 'enhancing soft tissue in vein' and features suggestive of TIV (FSTIV), and reached a consensus. Macroscopic TIV on pathologic examination served as the reference standard. Sensitivities and specificities of the LR-TIV category without and with FSTIV were calculated, and the added value of FSTIV was evaluated using the McNemar test. Interobserver agreements were calculated using Fleiss ?.*Results In the 1322 total patients (median age, 64 years; 1053 men), without considering FSTIV, the sensitivity and specificity of 'enhancing soft tissue in vein' in detecting macroscopic TIV on pathology were 64.4% (65/101) and 99.8% (1218/1221) with CT and 62.4% (63/101) and 99.8% (1218/1221) with HBA-MRI, respectively. When considering FSTIV, the sensitivity and specificity of the LR-TIV category became 67.3% (68/101) and 99.7% (1217/1221) on both CT and HBA-MRI. There was no significant difference between measurements without and with FSTIV (P values = .18). Interobserver agreements for the LR-TIV category were nearly perfect for CT and substantial for HBA-MRI (?=0.82 and 0.75, respectively).*Conclusions The Liver Imaging Reporting and Data System tumor in vein category showed moderate sensitivity and high specificity in detecting macroscopic tumors in veins on both CT and hepatobiliary contrast agent-enhanced MRI using pathology as the reference standard.*Clinical Relevance/Application The high specificity of the LI-RADS tumor in vein category would be desirable for transplant candidates who have a sufficient enough waiting period to confirm the presence or absence of macroscopic TIV.

RESULTS

In the 1322 total patients (median age, 64 years; 1053 men), without considering FSTIV, the sensitivity and specificity of 'enhancing soft tissue in vein' in detecting macroscopic TIV on pathology were 64.4% (65/101) and 99.8% (1218/1221) with CT and 62.4% (63/101) and 99.8% (1218/1221) with HBA-MRI, respectively. When considering FSTIV, the sensitivity and specificity of the LR-TIV category became 67.3% (68/101) and 99.7% (1217/1221) on both CT and HBA-MRI. There was no significant difference between measurements without and with FSTIV (P values = .18). Interobserver agreements for the LR-TIV category were nearly perfect for CT and substantial for HBA-MRI (?=0.82 and 0.75, respectively).

CLINICAL RELEVANCE/APPLICATION

The high specificity of the LI-RADS tumor in vein category would be desirable for transplant candidates who have a sufficient enough waiting period to confirm the presence or absence of macroscopic TIV.

SDP-GI-66   Contrast-enhanced Ultrasound Liver Imaging Reporting And Data System Category M: A Systematic Review And Meta-analysis

Participants
Jaeseung Shin, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

We performed a meta-analysis to determine the proportion of identifying contrast-enhanced ultrasound (CEUS) Liver Imaging Reporting and Data System (LI-RADS) category M (LR-M) in hepatocellular carcinomas (HCCs) and non-HCC malignancies and to determine the frequency of individual CEUS LR-M imaging features.*Methods and Materials MEDLINE and EMBASE databases were searched from inception to July 23, 2020, for studies reporting the proportion of CEUS LR-M in HCC and non-HCC malignancies. The meta-analytic pooled proportions of HCC and non-HCC malignancies in the CEUS LR-M category were calculated. The meta-analytic frequencies of CEUS LR-M imaging features in non-HCC malignancies were also determined. Risk of bias and applicability were evaluated using the Quality Assessment of Diagnostic Accuracy Studies-2 tool.*Results A total of twelve studies were identified reporting the diagnostic performance of the CEUS LR-M category and seven studies reporting the frequencies of individual CEUS LR-M imaging features. The pooled proportions of HCC and non-HCC malignancies in the CEUS LR-M category were 54% (95% confidence interval [CI], 44%-65%) and 40% (95% CI, 28%-53%), respectively. The pooled frequencies of individual CEUS LR-M imaging features in non-HCC malignancies were 30% (95% CI, 17%-45%) for rim arterial phase hyperenhancement, 79% (95% CI, 66%-90%) for early (<60 s) washout, and 42% (95% CI, 21%-64%) for marked washout.*Conclusions For observations categorized as CEUS LR-M, 94% were malignancies, with HCCs representing 54% and non-HCC malignancies representing 40%. The frequencies of individual CEUS LR-M imaging features were variable, with early washout showing the highest frequency for non-HCC malignancies.*Clinical Relevance/Application Along with high proportion of overall malignancies, substantial proportion of CEUS LR-M is HCC with atypical imaging features as well as non-HCC malignancy. Therefore, the accurate diagnosis with biopsy is required for nodules with CEUS LR-M to deploy appropriate management.

RESULTS

A total of twelve studies were identified reporting the diagnostic performance of the CEUS LR-M category and seven studies reporting the frequencies of individual CEUS LR-M imaging features. The pooled proportions of HCC and non-HCC malignancies in the

CEUS LR-M category were 54% (95% confidence interval [CI], 44%-65%) and 40% (95% CI, 28%-53%), respectively. The pooled frequencies of individual CEUS LR-M imaging features in non-HCC malignancies were 30% (95% CI, 17%-45%) for rim arterial phase hyperenhancement, 79% (95% CI, 66%-90%) for early (<60 s) washout, and 42% (95% CI, 21%-64%) for marked washout.

CLINICAL RELEVANCE/APPLICATION

Along with high proportion of overall malignancies, substantial proportion of CEUS LR-M is HCC with atypical imaging features as well as non-HCC malignancy. Therefore, the accurate diagnosis with biopsy is required for nodules with CEUS LR-M to deploy appropriate management.

SDP-GI-67   Diagnostic Value Of The 2017 US Li-Rads Algorithm: Results From An Academic Medical Center In British Columbia

Participants
Rohith Bhargavan, MD, Vancouver, British Columbia (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the 2017 US LI-RADS standardized reporting system and assess sensitivity and specificity in the detection of hepatocellular carcinoma in at risk patients.*Methods and Materials 720 patients meeting LI-RADS criteria for screening US examination were assessed over a 2.5 year period from July 2017. All examinations were performed by trained sonographers. Results of screening and surveillance examinations were recorded using the 2017 US LI-RADS categories for findings and liver visualization score using a standardized proforma. Examinations were reported by fellowship trained abdominal radiologists. All follow up imaging was reviewed for occurrence of HCC defined as LR4/5 findings on contrast enhanced CT or MR imaging.*Results 347 patients were female (48.2%), mean age at first examination 59 years (range 19-94 years). 347 patients had Hepatitis B +/- cirrhosis (67.5%) and 117 patients had Hepatitis C (16.3%), while only 21 patients had alcohol-related liver disease (2.9%). Initial US findings were US1A 491, US1B 123, US1C 20 (total US1 634). US2A 37, US2B 9, US2C 2 (total US2 48). US3A 25, US3B 10, US3C 3 (total US3 38). 170 were lost to follow-up following initial examination. Mean length of follow up was 366 days (range 2-994 days). Positive predictive value of US3 for the subsequent diagnosis of HCC/LRM was 18%. Negative predictive value of US1/2 for subsequent diagnosis of HCC/LRM was 99%. The overall sensitivity of US3 results for the diagnosis of HCC was 50% (6/12) and the specificity was 95% (511/538). Specificity was 95% in US-A, 93.5% in US-B, and 91.7% in US-C.*Conclusions LIRADS US categories provide a clinically useful screening tool for the detection of HCC in at risk patients, with high specificity and negative predictive value.*Clinical Relevance/Application In the assessment of rare occurrences of HCC in surveillance populations, US-LIRADS remains a cost-effective screening tool to increase early detection and treatment for HCC in both cirrhotic and non-cirrhotic patients.

RESULTS

347 patients were female (48.2%), mean age at first examination 59 years (range 19-94 years). 347 patients had Hepatitis B +/- cirrhosis (67.5%) and 117 patients had Hepatitis C (16.3%), while only 21 patients had alcohol-related liver disease (2.9%). Initial US findings were US1A 491, US1B 123, US1C 20 (total US1 634). US2A 37, US2B 9, US2C 2 (total US2 48). US3A 25, US3B 10, US3C 3 (total US3 38). 170 were lost to follow-up following initial examination. Mean length of follow up was 366 days (range 2-994 days). Positive predictive value of US3 for the subsequent diagnosis of HCC/LRM was 18%. Negative predictive value of US1/2 for subsequent diagnosis of HCC/LRM was 99%. The overall sensitivity of US3 results for the diagnosis of HCC was 50% (6/12) and the specificity was 95% (511/538). Specificity was 95% in US-A, 93.5% in US-B, and 91.7% in US-C.

CLINICAL RELEVANCE/APPLICATION

In the assessment of rare occurrences of HCC in surveillance populations, US-LIRADS remains a cost-effective screening tool to increase early detection and treatment for HCC in both cirrhotic and non-cirrhotic patients.

SDP-GI-68   Clinical Staging Of Mass-forming Intrahepatic Cholangiocarcinoma: CT Versus MRI

Participants
Yeun-Yoon Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To compare the performance of CT and MRI for preoperative clinical staging of mass-forming intrahepatic cholangiocarcinoma (iCCA) using the 8th American Joint Committee on Cancer (AJCC) system.*Methods and Materials This retrospective, multicenter, cohort study consecutively identified patients who underwent partial hepatectomy for mass-forming iCCA and had preoperative CT and MRI performed from January 2009 to December 2015. CT and MRI imaging characteristics were used to determine clinical stage based on the 8th AJCC system. Performances of CT and MRI for clinical T and N staging were compared using generalized estimating equations.*Results In 334 patients (median age, 63 years; 221 men), MRI sensitivities were significantly higher than CT sensitivities for detecting T1b or higher stages (91.0% vs 80.5%, P <0.001), T2 or higher stages (89.1% vs 73.8%, P <0.001), and T3 or T4 stage (77.8% vs 58.0%, P <0.001). MRI was also more sensitive at identifying multiple tumors than CT (66.7% vs 50.0%, respectively, P = 0.026), without a significant difference in specificity (78.1% vs 80.1%, respectively, P = 0.342). Sensitivities were comparable between CT and MRI for determination of size >5 cm (i.e., T1b for single tumor), and extrahepatic organ invasion (i.e., T4). Sensitivities of CT and MRI were not different for N stage (65.0% vs 64.0%, respectively, P = 0.808), but the specificity of CT was significantly higher than that of MRI (80.7% vs 72.9%, respectively, P = 0.001) when using a composite reference standard.*Conclusions MRI showed superior sensitivity to CT for diagnosing T2 and T3 stages, particularly multiple tumors. CT and MRI had comparable sensitivity for N staging, but CT provided higher specificity than MRI.*Clinical Relevance/Application MRI can more sensitively detect multiple tumors than CT in patients with iCCA, without impaired specificity, and may help decide patient eligibility for curative resection.

RESULTS

In 334 patients (median age, 63 years; 221 men), MRI sensitivities were significantly higher than CT sensitivities for detecting T1b or higher stages (91.0% vs 80.5%, P <0.001), T2 or higher stages (89.1% vs 73.8%, P <0.001), and T3 or T4 stage (77.8% vs 58.0%, P <0.001). MRI was also more sensitive at identifying multiple tumors than CT (66.7% vs 50.0%, respectively, P = 0.026), without a significant difference in specificity (78.1% vs 80.1%, respectively, P = 0.342). Sensitivities were comparable between CT and MRI for determination of size >5 cm (i.e., T1b for single tumor), and extrahepatic organ invasion (i.e., T4). Sensitivities of CT and MRI were not different for N stage (65.0% vs 64.0%, respectively, P = 0.808), but the specificity of CT was significantly higher than that of MRI (80.7% vs 72.9%, respectively, P = 0.001) when using a composite reference standard.

CLINICAL RELEVANCE/APPLICATION

MRI can more sensitively detect multiple tumors than CT in patients with iCCA, without impaired specificity, and may help decide patient eligibility for curative resection.

SDP-GI-69 Deep Learning Reconstruction (DLR): Comparison For Image Quality And Diagnostic Performance For IPMN On 3D MRCPs By Conventional Parallel Imaging, Compressed Sensing And Multiple Slice Encoding In TR (Fast 3D Mode Multiple)

Participants
Takahiro Matsuyama, Toyoake, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To compare the capability of deep learning reconstruction (DLR) for image quality and diagnostic performance improvements on 3D MRCP by conventional parallel imaging (PI), compressed sensing (CS) and multiple slice encoding in TR (Fast 3D mode multiple: i.e. Fast 3Dm) methods in patients with IPMN.*Methods and Materials 32 consecutive IPMN patients underwent 3D MRCPs by PI, CS and Fast 3Dm methods, surgical resections, and pathological examinations. Then, each MRCP data was reconstructed with and without DLR. Standard reference for IPMN was determined by pathological examination results. Examination time for each MRCP was recorded. Then, signal-to-noise ratio (SNR) and contrast ratio (CR) between pancreas and liver were assessed by ROI measurements. In addition, overall image quality and lesion depiction were assessed by 5-point scales by consensus of two readers. Moreover, IPMN types were also evaluated by consensus of two readers. Examination time, SNR and CR were compared among all MRCP data set by Tukey's HSD test. Moreover, all qualitative indexes were compared among all data set by Wilcoxon signed-rank test. Agreement for IPMN type evaluation between each MRCP data and standard reference was determined by ? statistics with ?2 test. Finally, diagnostic accuracy for IPMN evaluation was compared each other by McNemar's test.*Results Examination times of CS and Fast 3Dm were significantly shorter than that of PI (p<0.05). All image quality indexes of each method with DLR were significantly higher than those without DLR (p<0.05). In addition, each index of PI and Fast 3Dm with and without DLR showed significantly higher than those of CS with and without DLR (p<0.05). Agreements of all MRCP data except CS without DLR were substantial (0.64<?<0.79, p<0.0001), although CS without DLR was moderate (?=0.46, p<0.0001). For diagnostic performance of IPMN, all MRCP data except CS without DLR (78%<AC<88%) were significantly accurate than CS without DLR (65.5%, p<0.05).*Conclusions DLR is able to improve image quality and diagnostic performance of 3D MRCP in patients with IPMN and would be better to be applied CS rather than others in routine clinical practice.*Clinical Relevance/Application DLR is able to improve image quality and diagnostic performance in patients with IPMN and would be better to be applied CS rather than PI and Fast 3Dm.

RESULTS

Examination times of CS and Fast 3Dm were significantly shorter than that of PI (p<0.05). All image quality indexes of each method with DLR were significantly higher than those without DLR (p<0.05). In addition, each index of PI and Fast 3Dm with and without DLR showed significantly higher than those of CS with and without DLR (p<0.05). Agreements of all MRCP data except CS without DLR were substantial (0.64<?<0.79, p<0.0001), although CS without DLR was moderate (?=0.46, p<0.0001). For diagnostic performance of IPMN, all MRCP data except CS without DLR (78%<AC<88%) were significantly accurate than CS without DLR (65.5%, p<0.05).

CLINICAL RELEVANCE/APPLICATION

DLR is able to improve image quality and diagnostic performance in patients with IPMN and would be better to be applied CS rather than PI and Fast 3Dm.

SDP-GI-7 Liver Fibrosis: Staging With MR Elastography And Extracellular Volume Fraction Analysis With Contrast-enhanced CT

Participants
Keigo Yano, MD, Osaka, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To compare the accuracy of staging liver fibrosis by MR elastography and extracellular volume fraction (fECV) analysis with contrast-enhanced CT.*Methods and Materials Sixty-one consecutive patients, who underwent both liver MR imaging including MR elastography and contrast-enhanced CT before hepatic surgery, constituted the study population. Liver fibrosis stages were histopathologically confirmed with surgical specimens. Two radiologists (R1 and R2) measured liver stiffness on MR elastography and fECV with CT images, independently. Correlations between liver stiffness or fECV and pathological liver fibrosis stage were evaluated by using Spearman rank correlation coefficient [rs]. Subgroup analyses classified with pathological inflammation grade (A0, A1, and A2) were also assessed. Accuracy of liver stiffness and fECV analysis for staging liver fibrosis was assessed with receiver operating characteristic (ROC) analysis and the results were compared using the method of DeLong et al.*Results Correlation of liver stiffness with liver fibrosis stage (rs = 0.69, 0.67) was significantly superior to that of fECV (0.26, 0.30) for each radiologist (P < .01, respectively). The areas under the ROC curves for MR elastography for each stage differentiation (0.84 for F0 vs F1-4, 0.87 for F0-1 vs F2-4, 0.86 for F0-2 vs F3-4, and 0.84 for F0-3 vs F4 for R1 and 0.81, 0.87, 0.86, 0.83 for R2) were higher than those for fECV analysis with CT (0.64, 0.61, 0.61, and 0.69; P = .06, < .005, < .005, and = .06 for R1, 0.69, 0.63, 0.61, and 0.69; P = 0.2, < .01, < .005, and = 0.1 for R2, respectively). In the subgroup analyses, the correlation coefficients between liver stiffness and liver fibrosis in A0, A1 and A2 group (0.673, 0.641 and 0.622 for R1, 0.691, 0.66 and 0.56 for R2, respectively) were significantly higher than those between fECV and liver fibrosis (0.28, 0.272 and 0.199 for R1, 0.299, 0.306 and 0.012 for R2, respectively, and P < .05 for all comparisons).*Conclusions MR elastography allows more accurate liver fibrosis staging compared with fECV analysis with CT. In addition, MR elastography was less affected by the inflammatory state than fECV analysis.*Clinical Relevance/Application MR elastography is recommended over extracellular volume fraction analysis with CT for the noninvasive evaluation of the liver fibrosis stage.

RESULTS

Correlation of liver stiffness with liver fibrosis stage (rs = 0.69, 0.67) was significantly superior to that of fECV (0.26, 0.30) for each radiologist (P < .01, respectively). The areas under the ROC curves for MR elastography for each stage differentiation (0.84 for F0 vs F1-4, 0.87 for F0-1 vs F2-4, 0.86 for F0-2 vs F3-4, and 0.84 for F0-3 vs F4 for R1 and 0.81, 0.87, 0.86, 0.83 for R2) were higher than those for fECV analysis with CT (0.64, 0.61, 0.61, and 0.69; P = .06, < .005, < .005, and = .06 for R1, 0.69, 0.63, 0.61, and 0.69; P = 0.2, < .01, < .005, and = 0.1 for R2, respectively). In the subgroup analyses, the correlation coefficients between liver stiffness and liver fibrosis in A0, A1 and A2 group (0.673, 0.641 and 0.622 for R1, 0.691, 0.66 and 0.56 for R2, respectively) were significantly higher than those between fECV and liver fibrosis (0.28, 0.272 and 0.199 for R1, 0.299, 0.306 and 0.012 for R2, respectively, and P < .05 for all comparisons).

MR elastography is recommended over extracellular volume fraction analysis with CT for the noninvasive evaluation of the liver fibrosis stage.

SDP-GI-70   Establishment Of Automatic Segmentation Model Of Gastric Tumor-like Lesions Based On 3D U-Net

Participants
Jiejin Yang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Establish and validate a 3D U-Net-based automatic segmentation model of stomach tumor-like lesions using abdominal enhanced CT.*Methods and Materials To establish a segmentation model of gastric tumor-like lesions, a total of 584 portal-phase thin-layer CT images of patients with gastric tumor-like lesions diagnosed before 2019 were retrospectively collected, including 389 cases of diffuse tumor-like lesions and 195 cases of focal tumor-like lesions. According to the ratio of 8:1:1, all the data were randomly allocated to the training set (n=465), the validation set (n=60), and the test set (n=59). For external verification of the model, a total of 70 consecutive cases of gastric diffuse tumor-like lesions (35 cases) and focal tumor-like lesions (35 cases) were retrospectively collected. The 3D U-Net network architecture was adopted by the segmentation model. Using the 3D stomach wall label as a mask, and artificially outlined gastric tumor-like lesion label as the gold standard, a 3D U-Net-based gastric tumor-like lesion segmentation model was established. The accuracy of the model segmentation results was evaluated from the following three aspects: qualitative (accuracy, sensitivity), quantitative (corrected Dice correlation coefficient, and Hausdorff distance) and comprehensive evaluation (comprehensive rating table).*Results In the external validation set, with lesions as the unit, the accuracy and sensitivity of the model's qualitative evaluation were 80.5% and 94.3%, respectively. The average corrected DSC and the average corrected HD were 0.752, 20.354mm, respectively. The average corrected HD of diffuse gastric lesions was slightly worse than that of focal lesions, and the difference was statistically significant. In the comprehensive evaluation aspect, 55.7% of the cases with the subjective rating of the model prediction result above A-.*Conclusions The automatic segmentation model of gastric tumor-like lesions based on 3D U-Net has satisfactory segmentation performance.*Clinical Relevance/Application The segmentation of gastric tumor-like lesions can obtain the diameter and volume of the lesion, and provide important information for the estimation of the scope of surgical resection, the calculation of the radiation field, and the dose of tumor radiotherapy. It is also an important basis for lesion location, differential diagnosis, and staging. By using this model in conjunction with the basic gastric segmentation and classification model, the radiology department can efficiently provide more vivid lesion images and quantitative measurement information for tumor treatment, reducing the work pressure of imaging physicians.

RESULTS

In the external validation set, with lesions as the unit, the accuracy and sensitivity of the model's qualitative evaluation were 80.5% and 94.3%, respectively. The average corrected DSC and the average corrected HD were 0.752, 20.354mm, respectively. The average corrected HD of diffuse gastric lesions was slightly worse than that of focal lesions, and the difference was statistically significant. In the comprehensive evaluation aspect, 55.7% of the cases with the subjective rating of the model prediction result above A-.

CLINICAL RELEVANCE/APPLICATION

The segmentation of gastric tumor-like lesions can obtain the diameter and volume of the lesion, and provide important information for the estimation of the scope of surgical resection, the calculation of the radiation field, and the dose of tumor radiotherapy. It is also an important basis for lesion location, differential diagnosis, and staging. By using this model in conjunction with the basic gastric segmentation and classification model, the radiology department can efficiently provide more vivid lesion images and quantitative measurement information for tumor treatment, reducing the work pressure of imaging physicians.

SDP-GI-72   Evaluation Of Body Composition Measurements From Preoperative CT Using Convolutional Neural Network For Prediction Of Pancreatic Fistula And Overall Survival After Pancreaticoduodenectomy For Pancreatic Ductal Adenocarcinoma

Participants
Jeongin Yoo, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate whether body composition measurements acquired using convolutional neural network (CNN) from preoperative CT images could predict postoperative pancreatic fistula (POPF) and overall survival (OS) after pancreaticoduodenectomy in patients with pancreatic ductal adenocarcinoma (PDAC).*Methods and Materials A total of 149 patients (M:F=100:49, mean age ± standard deviation, 64.0 ± 9.1 years) who underwent pancreaticoduodenectomy for PDAC were included in this retrospective study. All patients underwent contrast-enhanced abdominal CT scan. The body composition measurements were based on CNN trained to segment portal venous phase images into skeletal muscle area, abdominal visceral fat (AVF), and subcutaneous fat (SF). Skeletal muscle area, AVF, and SF were standardized by body surface area. Electronic medical records and national registry data were reviewed to determine the diagnosis of POPF and death. POPF severity was classified into three grades (grade A, biochemical leak; grade B that requires drains either left in place >3 weeks or repositioned; and grade C that requires reoperation or lead to single or multiple organ failure and/or mortality) according to the 2016 International Study Group guideline. The independent risk factors for POPF were determined using a multivariate logistic regression model and the prognostic factors for OS were assessed using Cox proportional hazards regression analyses.*Results Among the 149 patients, 34 (22.8%) patients had POPF (grade A [n=18], grade B [n=15], and grade C [n=1]). Standardized AVF (odds ratio [OR]=1.01, p=0.001) and main pancreatic diameter (OR=0.72, p=0.028) were independent prognostic factors for POPF grade B or C (n=16). During the mean follow-up period of 29.7 months, 126 (84.6%) patients died. For prediction of OS, skeletal muscle area (hazard ration [HR]=0.56, p=0.048) and SF (HR=1.68, p=0.007) were significant factors, along with N stage (HR=1.63, p=0.017), vascular invasion (HR=1.76, p=0.005) and CA 19-9 level (HR=1.01, 0.006).*Conclusions Standardized AVF was significantly associated with POPF, while skeletal muscle area and SF were independent predictors for OS.*Clinical Relevance/Application Body composition measurements acquired using CNN from preoperative CT images could predict POPF and OS in patients who underwent pancreaticoduodenectomy for PDAC.

RESULTS

Among the 149 patients, 34 (22.8%) patients had POPF (grade A [n=18], grade B [n=15], and grade C [n=1]). Standardized AVF (odds ratio [OR]=1.01, p=0.001) and main pancreatic diameter (OR=0.72, p=0.028) were independent prognostic factors for POPF grade B or C (n=16). During the mean follow-up period of 29.7 months, 126 (84.6%) patients died. For prediction of OS, skeletal

muscle area (hazard ration [HR]=0.56, p=0.048) and SF (HR=1.68, p=0.007) were significant factors, along with N stage (HR=1.63, p=0.017), vascular invasion (HR=1.76, p=0.005) and CA 19-9 level (HR=1.01, 0.006).

CLINICAL RELEVANCE/APPLICATION

Body composition measurements acquired using CNN from preoperative CT images could predict POPF and OS in patients who underwent pancreaticoduodenectomy for PDAC.

SDP-GI-73   Automatic Pancreatic Cystic Lesions Segmentation Using Deep Learning Method: Evaluation On Arterial, Portal And Dual-phase CT

Participants
Xiheng Wang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To present a novel deep learning method for automatic pancreas and pancreatic cystic lesions(PCLs) segmentation and evaluate segmentation performance on arterial, portal and dual-phase images.*Methods and Materials We present a multi-phase multi-scale segmentation network, a framework that integrates cross-phase information of the venous and arterial phases images for multi-phase pancreas and PCLs segmentation. The network is built upon a dual-path model in which each path is intended for one phase. Inter-phase contextual information is explored via interactive linear connections between the two paths. We further devise a cross-phase attention to exploring non-euclidean relationships between phases. Besides, to effectively integrate local and global information, we adopt the multi-scale segmentation strategy. 232 patients with preoperative CT images from our institution are retrospectively enrolled, and are successively divided 151 for training, 22 for validation and 59 for testing with both arterial and portal phase CT images according to the scanning date. Dice similarity coefficient(DSC) is the objective evaluation index. Wilcoxon signed-rank test is used to compare the segmentation results of single-phase and dual-phase, p<0.05 indicates the difference is statistically significant.*Results The training and validation set has 69 males and 104 females (60.12%), with the mean age of 50 years (range: 13-75 years), and there are 29 males and 30 females (50.85%) in the testing set, with the mean age of 51 years (range: 14-79 years). There are no significant differences either in gender or mean age of the two groups (p=0.101 and 0.213, respectively). The DSC of both pancreas and PCLs segmentation are highest on dual-phase (0.928 and 0.851, respectively), which is higher than that on arterial phase (0.873 and 0.764 respectively) and portal phase (0.906 and 0.770 respectively) (both p<0.001).*Conclusions We present a multi-phase multi-scale segmentation network for pancreas and PCLs segmentation. Experimental result shows good performance of segmentation on dual-phase CT.*Clinical Relevance/Application Reliable performance of pancreas segmentation and PCLs detection on dual-phase shows promise for the following PCLs' classification. Besides, the dual-phase provides additional information for the conventional single-phase images.

RESULTS

The training and validation set has 69 males and 104 females (60.12%), with the mean age of 50 years (range: 13-75 years), and there are 29 males and 30 females (50.85%) in the testing set, with the mean age of 51 years (range: 14-79 years). There are no significant differences either in gender or mean age of the two groups (p=0.101 and 0.213, respectively). The DSC of both pancreas and PCLs segmentation are highest on dual-phase (0.928 and 0.851, respectively), which is higher than that on arterial phase (0.873 and 0.764 respectively) and portal phase (0.906 and 0.770 respectively) (both p<0.001).

CLINICAL RELEVANCE/APPLICATION

Reliable performance of pancreas segmentation and PCLs detection on dual-phase shows promise for the following PCLs' classification. Besides, the dual-phase provides additional information for the conventional single-phase images.

SDP-GI-74   Performance Evaluation Of Artificial Intelligence Technology For Fast And Accurate Bolus-tracking Process In Abdomen Enhanced CT

Participants
Juan Yu, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Process of bolus-tracking scans before enhancement CT scanning usually include monitoring location selection and region-of-interest (ROI) placement to generate time-density curve (TDC) triggering the enhanced scanning. In this study we aimed to evaluate the performance of an artificial intelligence-based technology (SmartPlan, GE Healthcare) for fast and accurate bolus-tracking process compared with manual operation by technicians.*Methods and Materials Total of 27 abdominal enhanced CT scans performed using the SmartPrep triggering technique were prospectively enrolled. The monitoring location for placing ROI by CT technicians for dynamic contrast-enhancement monitoring in bolus-tracking scans and TDC generated in the ROI were collected and recorded as the control group; The scout scans and time-resolved images were then imported into the SmartPlan software to automatically determine the monitoring location for placing ROI and to generate TDC, and the results were recorded as the experimental group. The consistency and time consuming of the location selection and the peak value of TDC curve triggering the scan between the experimental and control groups were analyzed using paired sample t-test. P < 0.05 was considered statistically significant.*Results There was no significant difference in monitoring position between the experimental group (305.33±22.63mm) and control group (305.44±22.82mm) (P=0.840). Therefore, monitoring locations are consistent with physicians' personal judgement. There was no difference in the peak value of TDC curves between the experimental group (233.40±34.05) and the control group (228.54±30.57), (P=0.093).Time consuming were found significant decreased in the experimental group compared with the control group (26.26 vs 0.600), (P=0.000).*Conclusions The AI-based automatic bolus-tracking technique can simplify CT scan process and physician intervention to provide reliable information for automatically triggering enhancement CT scanning.*Clinical Relevance/Application The intelligent automatic bolus-tracking technique based on deep learning neural network may reduce the manual intervention and simplify the process of automatically triggering enhancement CT scanning.

RESULTS

There was no significant difference in monitoring position between the experimental group (305.33±22.63mm) and control group (305.44±22.82mm) (P=0.840). Therefore, monitoring locations are consistent with physicians' personal judgement. There was no difference in the peak value of TDC curves between the experimental group (233.40±34.05) and the control group (228.54±30.57), (P=0.093).Time consuming were found significant decreased in the experimental group compared with the control group (26.26 vs 0.600), (P=0.000).

CLINICAL RELEVANCE/APPLICATION

The intelligent automatic bolus-tracking technique based on deep learning neural network may reduce the manual intervention and simplify the process of automatically triggering enhancement CT scanning.

SDP-GI-75 Prediction Of Risk Grading Of Primary Gastric Gastrointestinal Stromal Tumors: Integration Of Semantic Features, Radiomics And Deep Learning Features Of CT

Participants
Jiamei Wu, Chongqing, China (*Presenter*) Nothing to Disclose

PURPOSE

To establish and evaluate risk grading prediction models based on semantic features, radiomics and deep learning features of CT for differentiating the malignant risk of primary gastric gastrointestinal stromal tumors (GISTs).*Methods and Materials A total of 193 patients with primary gastric GISTs were enrolled. 70% of the data were used for model training and validation, and 30% were used for model testing. Senior radiologists segmented the three-dimensional images of the tumor area manually, extracted radiomics features of the region of interest, and extracted deep learning features based on ResNet50. Recursive feature elimination and multivariate logistic regression were used for feature selection and model construction. Receiver operating characteristic (ROC) curve was used to evaluate the efficacy of models. The efficacy of the radiomics and deep learning features construction models of venous phase, arterial phase and two-phase (combination of arterial & venous phases) were compared. Finally, the combined model was constructed by adding semantic features to the two-phase model. The clinical application value of the combined model was determined through the decision curve analysis (DCA) and the net reclassification index (NRI) of the combined model was analyzed.*Results The area under the curve (AUC) of the model constructed from the radiomics and deep learning features of two-phase was 0.876, which was higher than that of the model of venous or arterial phase alone (0.813, 0.838, respectively). The combined model with semantic features was more powerful than the models above, with an AUC of 0.921 (95% CI: 0.874 - 0.953) (p = 0.012, Delongtest). DCA demonstrated that the combined model was clinically useful and NRI is 0.575 (95% CI: 0.357 - 0.891).*Conclusions This study presents a combined model that incorporates semantic features, the radiomics and deep learning features of two-phase, which can be used to facilitate the preoperative individualized prediction of malignancy in primary gastric GISTs.*Clinical Relevance/Application Tumor location in GISTs is closely related to risk stratification. GISTs are most common in the stomach (about 60%). Meanwhile, some semantic features on CT have shown improved performance for diagnosis of malignancy. However, these semantic features are derived using visual assessment which can lead to variations in diagnostic accuracy. Radiomics and deep learning features can capture relationships between image voxels that can not be perceived by the naked eye. So, this study combines semantic features, radiomics and deep learning features for the precise treatment and follow-up of patients with primary gastric GISTs.

RESULTS

The area under the curve (AUC) of the model constructed from the radiomics and deep learning features of two-phase was 0.876, which was higher than that of the model of venous or arterial phase alone (0.813, 0.838, respectively). The combined model with semantic features was more powerful than the models above, with an AUC of 0.921 (95% CI: 0.874 - 0.953) (p = 0.012, Delongtest). DCA demonstrated that the combined model was clinically useful and NRI is 0.575 (95% CI: 0.357 - 0.891).

CLINICAL RELEVANCE/APPLICATION

Tumor location in GISTs is closely related to risk stratification. GISTs are most common in the stomach (about 60%). Meanwhile, some semantic features on CT have shown improved performance for diagnosis of malignancy. However, these semantic features are derived using visual assessment which can lead to variations in diagnostic accuracy. Radiomics and deep learning features can capture relationships between image voxels that can not be perceived by the naked eye. So, this study combines semantic features, radiomics and deep learning features for the precise treatment and follow-up of patients with primary gastric GISTs.

SDP-GI-76 Predicting Therapeutic Response Using Peritumoral Radiomics Based On Contrast-enhanced MRI For Patients With HCC Treated With TACE

Participants
Ying Zhao JR, Dalian, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a contrast-enhanced (CE) MRI-based peritumoral radiomics to predict an early response to transarterial chemoembolization (TACE) in patients with hepatocellular carcinoma (HCC).*Methods and Materials Preoperative CE-MRI datasets of 89 HCC patients (45 objective response, 44 non-response) were collected and randomly divided into the training (n = 61) and validation cohorts (n = 28). Tumor segmentation was performed by manually delineating the region of interest (ROI) along the tumor contour on each axial slice of arterial phase (AP), portal venous phase (PVP), and delayed phase (DP) images. To capture radiomics features from the tumor periphery, the VOIperi3 and VOIperi5 were generated by automatically expanding 3 mm and 5 mm from the lesion border. The VOIplus3 and VOIplus5 were also generated with automatic tumor border expansion (3 mm and 5 mm) plus the VOI of intratumor regions (VOIintratumor), shown in Figure 1. Total 1206 radiomics features were extracted using AK software for VOIintratumor, VOIperi3, VOIperi5, VOIplus3 and VOIplus5. Five radiomics models based on intratumoral, peritumoral expansion (3 mm and 5 mm) and intratumoral plus peritumoral expansion (3 mm and 5 mm) were established using logistic regression analysis. Receiver operating characteristic curve (ROC) analysis was performed to evaluate the performance of each prediction model.*Results The radiomics models demonstrated favorable discrimination in the both cohorts (AUC: training 0.816 - 0.963, validation 0.801 - 0.903), and the radiomics model based on VOIplus3 showed the best predictive performance with the AUCs of 0.963 (95% CI, 0.921 - 1.000) and 0.903 (95% CI, 0.773 - 1.000) in the training and validation cohorts. ROC curves and discriminative performance of the five radiomics models in the two cohorts are shown in Figure 2A, 2B and Table 1. *Conclusions The radiomics approach based on peritumoral regions has potential to improve performance for response prediction using preoperative CE-MRI.*Clinical Relevance/Application In this study, we proposed a CE-MRI-based peritumoral radiomics strategy to preoperatively predict therapeutic response to TACE in HCC, which may guide further individualized surveillance and therapeutic option.

RESULTS

The radiomics models demonstrated favorable discrimination in the both cohorts (AUC: training 0.816 - 0.963, validation 0.801 - 0.903), and the radiomics model based on VOIplus3 showed the best predictive performance with the AUCs of 0.963 (95% CI, 0.921 - 1.000) and 0.903 (95% CI, 0.773 - 1.000) in the training and validation cohorts. ROC curves and discriminative performance of the five radiomics models in the two cohorts are shown in Figure 2A, 2B and Table 1.

In this study, we proposed a CE-MRI-based peritumoral radiomics strategy to preoperatively predict therapeutic response to TACE in HCC, which may guide further individualized surveillance and therapeutic option.

SDP-GI-77 Incidental Nonfunctioning Pancreatic Neuroendocrine Tumors: Contrast Enhanced Ultrasound Features In Diagnosis

Participants
Yi Dong, MD, PhD, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

More than 50% nonfunctioning pancreatic neuroendocrine tumors (pNETs) are incidental findings on cross-sectional imaging and most of these lesions are asymptomatic. We retrospectively reviewed the contrast enhanced ultrasound features of a series of pNETs, with the aim to identify the capability of preoperatively diagnosis of pNETs on the basis of their contrast enhancemennt pattern.*Methods and Materials In this retrospective study, 46 histologically proved pNETs lesions incidentally detected with ultrasound examination were included. Various ultrasound features such as size, echogenicity, presence of pancreatic duct dilation and CEUS enhancement features were evaluated and were correlated with histopathological results of tumors. Fifty-two patients with surgery and histopathologically proved pancreatic ductal adenocarcinoma (PDAC) lesions who underwent CEUS examination for pancreatic lesions were enrolled as control group.*Results After injection of ultrasound contrast agents, most pNETs lesions displayed focal hyperenhancement (40/46, 86.9 %) in the arterial phase. During the late phase, most pNETs lesions were hyper- (31/46, 67.4 %) or iso-enhancing (11/46, 23.9 %). Six patients showed vascular involvement by CEUS. Liver metastases were detected in 5 patients during the late phase scan of the whole liver. However, most of PDAC lesions showed hypoenhancement (50/52, 96.1%) during arterial phase and late phase (51/52, 98.1%) (P < 0.05).*Conclusions CEUS features may preoperatively allow the diagnosis of pNETs, assisting decisions about treatment.*Clinical Relevance/Application CEUS is helpful to differentiate pNETs from PDAC and to determine the potential of resectability.

RESULTS

After injection of ultrasound contrast agents, most pNETs lesions displayed focal hyperenhancement (40/46, 86.9 %) in the arterial phase. During the late phase, most pNETs lesions were hyper- (31/46, 67.4 %) or iso-enhancing (11/46, 23.9 %). Six patients showed vascular involvement by CEUS. Liver metastases were detected in 5 patients during the late phase scan of the whole liver. However, most of PDAC lesions showed hypoenhancement (50/52, 96.1%) during arterial phase and late phase (51/52, 98.1%) (P < 0.05).

CEUS is helpful to differentiate pNETs from PDAC and to determine the potential of resectability.

SDP-GI-78 Determination Of Reference Intervals Of Liver And Spleen Volumes Using Deep Learning CT Volumetry

Participants
Dong Wook Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To establish population-based and personalized reference intervals for liver volume, spleen volume, and liver-to-spleen volume ratio (LSVR).*Methods and Materials This retrospective study consecutively included healthy adult liver donors from 2001 to 2013 (reference group) and from 2014 to 2016 (healthy validation group) and patients with viral hepatitis from 2007 to 2017. Liver volume, spleen volume, and LSVR were measured by CT using a deep learning algorithm. In the reference group, the reference intervals for the volume indices were determined using the population-based (ranges encompassing the central 95% of donors) and personalized (quantile regression modeling of the 2.5th and 97.5th percentiles using age, sex, height, and weight) approaches. The validity of the reference intervals was evaluated in the healthy validation and the viral hepatitis group.*Results The reference and healthy validation groups had 2989 (30 years ± 9; 1828 men) and 472 (30 years ± 9; 334 men) donors, respectively. The viral hepatitis group had 158 patients (48 years ± 12; 95 men). The population-based reference intervals were 824.5-1700.0 cm3, 81.1-322.0 cm3, and 3.96-13.78 for liver volume, spleen volume, and LSVR, respectively. Formulae and a web calculator were presented to calculate the personalized reference intervals. In the healthy validation group, both the population-based and personalized reference intervals classified the volume indices of 94%-96% of the donors as falling within the normal ranges. In the viral hepatitis group, compared with the population-based reference intervals, the personalized reference intervals identified higher proportions of patients with volume indices outside the normal range, (liver volume, 21.5% vs 13.3%, P=.01; spleen volume, 29.1% vs 22.2%, P=.01; LSVR, 35.4% vs 26.6%, P<.001).*Conclusions The proposed reference intervals may enable evidence-based liver and spleen volume assessment.*Clinical Relevance/Application Deep learning-based automated CT volumetry would be implemented in the clinical practice based on the proposed reference intervals.

RESULTS

The reference and healthy validation groups had 2989 (30 years ± 9; 1828 men) and 472 (30 years ± 9; 334 men) donors, respectively. The viral hepatitis group had 158 patients (48 years ± 12; 95 men). The population-based reference intervals were 824.5-1700.0 cm3, 81.1-322.0 cm3, and 3.96-13.78 for liver volume, spleen volume, and LSVR, respectively. Formulae and a web calculator were presented to calculate the personalized reference intervals. In the healthy validation group, both the population-based and personalized reference intervals classified the volume indices of 94%-96% of the donors as falling within the normal ranges. In the viral hepatitis group, compared with the population-based reference intervals, the personalized reference intervals identified higher proportions of patients with volume indices outside the normal range, (liver volume, 21.5% vs 13.3%, P=.01; spleen volume, 29.1% vs 22.2%, P=.01; LSVR, 35.4% vs 26.6%, P<.001).

Deep learning-based automated CT volumetry would be implemented in the clinical practice based on the proposed reference intervals.

SDP-GI-79 Clinical Impact Of PET/MRI In Oligometastatic Colorectal Cancer

Participants

Felipe Furtado, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Oligometastatic colorectal cancer (CRC) is potentially curable and demands individualized strategies. This study investigated if positron emission tomography (PET)/magnetic resonance imaging (MR) had a clinical impact on oligometastatic CRC relative to the standard of care imaging (SCI).*Methods and Materials This single-center retrospective study included adult patients with oligometastatic CRC on SCI who also underwent PET/MR between 3/2016 and 3/2019. The exclusion criterion was lack of confirmatory standard of reference, either surgical pathology, intraoperative gross confirmation, or imaging follow-up. SCI consisted of contrast-enhanced (CE) computed tomography of the chest/abdomen/pelvis (CT), abdominal/pelvic CE-MR, and/or CE whole-body PET/CT with diagnostic-quality (i.e., standard radiation dose) CT. Follow-up was evaluated until 3/2020.*Results Thirty-one patients constituted the cohort, 16 (52%) male, median patient age was 53 years (interquartile range: 49-65 years). PET/MR and SCI results were divergent in 19% (95% CI 9%-37%) of the cases, with PET/MR leading to management changes in all of them. The diagnostic accuracy of PET/MR was 90±5%, versus 71±8% for SCI. In a pairwise analysis, PET/MR outperformed SCI when compared to the reference standard (p = 0.0412).*Conclusions These findings suggest the potential usefulness of PET/MR in the management of oligometastatic CRC.*Clinical Relevance/Application Oligometastatic disease is curable and demands individualized treatment. PET/MRI may aid in the clinical decision and potentially changes the management course.

RESULTS

Thirty-one patients constituted the cohort, 16 (52%) male, median patient age was 53 years (interquartile range: 49-65 years). PET/MR and SCI results were divergent in 19% (95% CI 9%-37%) of the cases, with PET/MR leading to management changes in all of them. The diagnostic accuracy of PET/MR was 90±5%, versus 71±8% for SCI. In a pairwise analysis, PET/MR outperformed SCI when compared to the reference standard (p = 0.0412).

CLINICAL RELEVANCE/APPLICATION

Oligometastatic disease is curable and demands individualized treatment. PET/MRI may aid in the clinical decision and potentially changes the management course.

SDP-GI-8   Diagnostic Performance Of Contrast Enhanced MRI In T- Restaging Of Locally Advanced Rectal Cancer Following Neoadjuvant Chemoradiotherapy

Participants
Qiaoyuan Lu, MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of our study was to determine the value of contrast enhenced(ceMRI) in distinguishing between ypT0-1 and non-ypT0-1 rectal cancer following NCRT,and to compare the accuracy of restaging by ceMRI to that of the conventional combination of T2WI and DWI for the selection of Local excision candidates .*Methods and Materials This retrospective study included 334 patients with locally advanced rectal cancer evaluated from january 2014 to October 2018.All baseline and post-NCRT MRI features(mrT,mrEMVI,mrMRF, ratio of tumor involvement in the circumference of intestinal lumen and tumor location) were evaluated by two experienced radiologists. The post-NCRT T stage(ymrT) were evaluated on high b-value (b1000) DWIs together with the T2WI in the first round(named as"T2DWI Protocol"), and was evaluated again on the third series of ceMRI (named as"ceMRI Protocol")at least two weeks after completion of the first round. All patients were divided into ymrT0-1 group and non-ymrT0-1 group by 2 Protocols respectively. Pathological results(ypT0-1 and non-ypT0-1)were regarded as the gold standard. The diagnostic accuracies for the differentiation of ypT0-1tumors from non-ypT0-1 tumors with 2 protocols were compared. Multivariate regression analysis was used to explore the independent predictors of ypT0-1 lesions.*Results From January 2014 to October 2018, a total of 334 patients (231 males [69%]; mean age 57 years ± 10 [standard deviation]) were enrolled. The AUC of ceMRI protocol to predict ypT0-1 was 0.81 (95% CI, 0.75-0.88), which was better than that of T2DWI protocol (0.651) (95% CI, 0.58-0.72; P< 0.001). Multivariate logistic regression analysis revealed that ymrT on ceMRI was the independent predictor of ypT0-1 lesions(P< 0.001).*Conclusions The conventional approach of T2WI plus DWI is not applicable for the restaging of rectal cancer patients following NCRT. We found that ceMRI could distinguish residual tumor from fibrosis by their different enhancement characteristics, significantly improving the accuracy of T-restaging.*Clinical Relevance/Application The capability of ceMRI in restaging rectal cancer can provide improved individualized treatment strategies, particularly in organ-saving surgery.

RESULTS

From January 2014 to October 2018, a total of 334 patients (231 males [69%]; mean age 57 years ± 10 [standard deviation]) were enrolled. The AUC of ceMRI protocol to predict ypT0-1 was 0.81 (95% CI, 0.75-0.88), which was better than that of T2DWI protocol (0.651) (95% CI, 0.58-0.72; P< 0.001). Multivariate logistic regression analysis revealed that ymrT on ceMRI was the independent predictor of ypT0-1 lesions(P< 0.001).

CLINICAL RELEVANCE/APPLICATION

The capability of ceMRI in restaging rectal cancer can provide improved individualized treatment strategies, particularly in organ-saving surgery.

SDP-GI-80   Early Changes Of DCE-MRI Biomarkers May Predict Survival Outcomes In Patents With Advanced Hepatocellular Carcinoma Treated With 2nd-line Targeted Therapy After Sorafenib Failure

Participants
Bang Bin Chen, MD, Taipei, Taiwan (*Presenter*) Nothing to Disclose

PURPOSE

To predict survival outcomes using DCE-MRI biomarkers in patients with advanced hepatocellular carcinoma (HCC) receiving 2nd-line targeted therapy after progression from 1st-line sorafenib treatment.*Methods and Materials Methods: This study included 74 participants (men/women = 64/10, mean age 60 ± 11.8) with advanced HCC who received 2nd-line targeted therapy (n= 41 with lenalidomide; n = 33 with axitinib) after sorafenib failure from two prospective phase II studies. Among them, all patients underwent DCE-MRI at baseline, on days 3 and day 14 of treatment. The relative changes (?) of DCE-MRI parameters, including ?Peak, ?AUC, and ?Ktrans, were derived from the largest hepatic tumor. The treatment response was evaluated by The Response Evaluation Criteria in Solid Tumors (RECIST 1.1). The Cox model was used to investigate the associations of the clinical variables and DCE-MRI biomarkers with progression-free survival (PFS) and overall survival (OS).*Results The objective response rate (ORR) was 10.8%

(8/74) and the disease control rate (DCR) was 58.1% (43/74). The median PFS and OS were 1.9 and 7.8 months, respectively. On day 3, participants with low reductions in ?Peak_D3 [hazard ratio (HR) 2.58, 95% confidence interval (CI) 1.1-6.07, P = 0.017] or ?AUC_D3 (HR 1.96, 95% CI 0.96-3.99, P = 0.043) were associated with shorter PFS. On day 14, participants with low reductions of ?Peak_D14 (HR 1.95, 95% CI 0.99-3.85, P < 0.032), ?AUC_D14 (HR 1.86, 95% CI 1.12-3.08, P = 0.009), or ?Ktrans_D14 (HR 4.56, 95% CI 2.1-9.9, P < 0.001) had shorter PFS than did those with high reduction values. Also, low reductions of ?AUC_D14 (HR 1.89, 95% CI 1.12-3.18, P = 0.016) or ?Ktrans_D14 (HR 2.13, 95% CI 1.02-4.42, P = 0.038) were associated with poor OS. Among clinical variables, ORR was associated with both PFS (P = 0.001) and OS (P= 0.005). DCR was associated with PFS (P = 0.002), but not OS (P= 0.089). Cox multivariable analysis revealed that ?Ktrans_D14 (P = 0.004) remained independent predictors of PFS after control for ORR and DCR.*Conclusions Early reduction of tumor perfusion detected by DCE-MRI biomarkers, especially on day 14, may predict survival outcomes in participants with HCC receiving 2nd-line targeted therapy after sorafenib failure.*Clinical Relevance/Application Post-treatment DCE-MRI biomarkers may predict survival outcomes as early as 14 days in participants with HCC receiving 2nd-line targeted therapy after sorafenib failure.

RESULTS

The objective response rate (ORR) was 10.8% (8/74) and the disease control rate (DCR) was 58.1% (43/74). The median PFS and OS were 1.9 and 7.8 months, respectively. On day 3, participants with low reductions in ?Peak_D3 [hazard ratio (HR) 2.58, 95% confidence interval (CI) 1.1-6.07, P = 0.017] or ?AUC_D3 (HR 1.96, 95% CI 0.96-3.99, P = 0.043) were associated with shorter PFS. On day 14, participants with low reductions of ?Peak_D14 (HR 1.95, 95% CI 0.99-3.85, P < 0.032), ?AUC_D14 (HR 1.86, 95% CI 1.12-3.08, P = 0.009), or ?Ktrans_D14 (HR 4.56, 95% CI 2.1-9.9, P < 0.001) had shorter PFS than did those with high reduction values. Also, low reductions of ?AUC_D14 (HR 1.89, 95% CI 1.12-3.18, P = 0.016) or ?Ktrans_D14 (HR 2.13, 95% CI 1.02-4.42, P = 0.038) were associated with poor OS. Among clinical variables, ORR was associated with both PFS (P = 0.001) and OS (P= 0.005). DCR was associated with PFS (P = 0.002), but not OS (P= 0.089). Cox multivariable analysis revealed that ?Ktrans_D14 (P = 0.004) remained independent predictors of PFS after control for ORR and DCR.

CLINICAL RELEVANCE/APPLICATION

Post-treatment DCE-MRI biomarkers may predict survival outcomes as early as 14 days in participants with HCC receiving 2nd-line targeted therapy after sorafenib failure.

SDP-GI-81 Predicting Microvascular Invasion In Hepatocellular Carcinoma: A Dual-institution Study Based On Gadoxetate Disodium-enhanced MRI

Participants
Hanyu Jiang, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

Microvascular invasion (MVI) is an independent risk factor for increased postoperative recurrence and worse survival in patients with hepatocellular carcinoma (HCC). This dual-institution study aimed to develop a predictive model for MVI and to evaluate its capacity in stratifying postoperative survival in HCC patients.*Methods and Materials From July 2015 to November 2020, this retrospective study enrolled consecutive patients with surgically confirmed HCC who underwent preoperative gadoxetate disodium-enhanced MRI from two tertiary care hospitals. All MR images were assessed centrally by three independent masked reviewers who were blinded to the outcomes. A predictive model for MVI encompassing significant clinical and imaging features was developed via logistic regression analysis in the training center and tested in the validation center. Model performances were evaluated using area under the receiver operating curve (AUC), sensitivity and specificity. Survival was analyzed in the training center by the Kaplan-Meier method and compared with log-rank test.*Results A total of 328 (267 men; 52.4 ± 11.6 years) and 105 (89 men; 55.5 ± 10.0 years) patients were included in the training and validation center, respectively. MVI was confirmed pathologically in 158 (48.2%) patients from the training center and in 50 (47.6%) patients from the validation center. In the training center, five imaging features were significantly predictive of MVI: non-smooth tumor margin (odds ratio [OR]=4.949, p<0.001), hepatobiliary phase peritumoral hypointensity (OR=2.952, p<0.001), internal artery (OR=2.915, p<0.001), marked restricted diffusion (OR=2.820, p<0.001) and number of lesions (OR=2.261, p=0.008). Based on these features, the predictive model for MVI demonstrated an AUC of 0.823 (95% confidence interval [CI]: 0.742-0.903), a sensitivity of 64.0% (95%CI: 49.2%-77.1%) and a specificity of 81.5% (95%CI: 68.6%-90.7%) in the validation center. Patients with MVI predicted by the model had significantly shorter progression free survival (median, 486 vs. 1522 days, p<0.001) and overall survival (mean, 1422 vs. 1869 days, p<0.001) compared with those without.*Conclusions A preoperative model based on five EOB-MRI features could help accurately predict MVI and stratify postoperative survival in patients with HCC.*Clinical Relevance/Application A preoperative model based on EOB-MRI features non-smooth tumor margin, hepatobiliary phase peritumoral hypointensity, internal artery, marked restricted diffusion and number of lesions could help accurately predict MVI and stratify postoperative survival in patients with HCC.

RESULTS

A total of 328 (267 men; 52.4 ± 11.6 years) and 105 (89 men; 55.5 ± 10.0 years) patients were included in the training and validation center, respectively. MVI was confirmed pathologically in 158 (48.2%) patients from the training center and in 50 (47.6%) patients from the validation center. In the training center, five imaging features were significantly predictive of MVI: non-smooth tumor margin (odds ratio [OR]=4.949, p<0.001), hepatobiliary phase peritumoral hypointensity (OR=2.952, p<0.001), internal artery (OR=2.915, p<0.001), marked restricted diffusion (OR=2.820, p<0.001) and number of lesions (OR=2.261, p=0.008). Based on these features, the predictive model for MVI demonstrated an AUC of 0.823 (95% confidence interval [CI]: 0.742-0.903), a sensitivity of 64.0% (95%CI: 49.2%-77.1%) and a specificity of 81.5% (95%CI: 68.6%-90.7%) in the validation center. Patients with MVI predicted by the model had significantly shorter progression free survival (median, 486 vs. 1522 days, p<0.001) and overall survival (mean, 1422 vs. 1869 days, p<0.001) compared with those without.

CLINICAL RELEVANCE/APPLICATION

A preoperative model based on EOB-MRI features non-smooth tumor margin, hepatobiliary phase peritumoral hypointensity, internal artery, marked restricted diffusion and number of lesions could help accurately predict MVI and stratify postoperative survival in patients with HCC.

SDP-GI-82 Radiomic Analysis Of Gadoxetic Acid-enhanced Mri Predicts Vessels Encapsulating Tumor Clusters And Outcome In Hepatocellular Carcinoma

Participants
Fangming Chen, Wuxi, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop a model integrating multi-scale clinical and imaging factors, especially radiomic features from gadoxetic acid-enhanced MRI, for vessels encapsulating tumor clusters (VETC) prediction in hepatocellular carcinoma (HCC), and to evaluate the model's ability to predict outcomes.*Methods and Materials This retrospective two-center study included a training cohort of 152 patients at center 1 and a validation cohort of 75 patients at center 2 from Jan 2015 to Dec 2018. All the patients underwent preoperative gadoxetic acid-enhanced MRI scan and curative hepatectomy for HCC. The VETC phenotype is confirmed when unequivocal immunoreactivity of a continuous lining around tumor clusters in the CD34-stained HCC tissue section was found under light microscopy (400×). VETC-related radiomic score (Radscore) was built using 8,470 radiomic features extracted from T2- and diffusion-weighted imaging, 4 consecutive contrast-enhanced dynamics, and hepatobiliary phase images. Six clinical variables, 11 radiologic features of aggressive HCCs, and the Radscore were integrated into a prediction model, the clinic-radiologic-radiomic (CRR) model, by using multivariate logistic regression.*Results VETC HCCs were pathologically confirmed in 26%(58/227) of whole cohorts. The Radscore, comprised of ten radiomic features related to tumor size and intratumoral heterogeneity, showed significant differences according to VETC status (P <0.001). Regression analysis identified 4 risk factors of VETC HCCs, including AFP level, tumor necrosis, mosaic enhancement, and the Radscore. The CRR model achieved an area under the curve (AUC) of 0.909 in the training cohort and 0.889 in the validation cohort. CRR-predicted VETC HCC was associated with early recurrence (hazard ratio [HR]: 1.38 [1.02-2.55], P = 0.033) and disease-free survival (HR: 1.45 [1.10-2.66], P = 0.002) at multivariable analysis.*Conclusions The proposed model integrating multi-scale clinical and imaging data, especially radiomic features from gadoxetic acid-enhanced MRI, accurately predicts VETC HCCs. The model-predicted VETC HCC is associated with early disease recurrence and poor disease-free survival.*Clinical Relevance/Application VETC, a newly proposed vascular growth pattern of HCC and characterized by the presence of CD34+ vessels completely encapsulating tumor clusters, is a powerful predictor of poor survival. To date, there is no single highly reliable factor to preoperatively predict VETC HCCs. A reliable preoperative VETC HCC prediction method may be useful for identifying patients less likely to obtain a durable benefit from hepatectomy.

RESULTS

VETC HCCs were pathologically confirmed in 26%(58/227) of whole cohorts. The Radscore, comprised of ten radiomic features related to tumor size and intratumoral heterogeneity, showed significant differences according to VETC status (P <0.001). Regression analysis identified 4 risk factors of VETC HCCs, including AFP level, tumor necrosis, mosaic enhancement, and the Radscore. The CRR model achieved an area under the curve (AUC) of 0.909 in the training cohort and 0.889 in the validation cohort. CRR-predicted VETC HCC was associated with early recurrence (hazard ratio [HR]: 1.38 [1.02-2.55], P = 0.033) and disease-free survival (HR: 1.45 [1.10-2.66], P = 0.002) at multivariable analysis.

CLINICAL RELEVANCE/APPLICATION

VETC, a newly proposed vascular growth pattern of HCC and characterized by the presence of CD34+ vessels completely encapsulating tumor clusters, is a powerful predictor of poor survival. To date, there is no single highly reliable factor to preoperatively predict VETC HCCs. A reliable preoperative VETC HCC prediction method may be useful for identifying patients less likely to obtain a durable benefit from hepatectomy.

SDP-GI-83   Ultra-low Dose Pancreatic Perfusion CT Without Requiring Additional Conventional CT: Value Of Deep Learning Reconstruction

Participants
Juan Li, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the value of deep learning reconstruction (DLR) to pancreatic perfusion CT in replacing the combination of perfusion CT with conventional CT.*Methods and Materials 33 patients underwent ultra-low dose (CTDIvol 1.1mGy for each phase, total effective dose was 6.405 mSv) pancreatic perfusion CT plus conventional CT for suspected pancreatic neuroendocrine tumor were prospectively included. DLR and statistical-based iterative reconstruction (SBIR) were used for perfusion image reconstruction. SBIR images were post-processed by temporal image technique. The objective image quality (SNR, CNR) and overall image quality based on 4-point scale were compared between the four groups (DLR, SBIR images based on temporal image technique, combination of the two, conventional CT). ANOVA and Friedman test were used to do analysis.*Results All quantitative image quality parameters of DLR and SBIR based on temporal image technique are higher than that of conventional CT (all p<0.001), except for the SNR of portal vein (p=0.234 and 0.290, respectively). The overall image quality of DLR and SBIR based on temporal image technique were lower than that of conventional CT (all p< 0.05). However, there was no significant difference of the overall image quality (all scores are 4(3,4)) between the combination of the two and conventional CT (p=0.234 and 0.061 for arterial phase and portal vein phase, respectively).*Conclusions DLR has additional value to temporal image technique in assisting perfusion CT to be used alone without the requiring for additional conventional CT.*Clinical Relevance/Application DLR could be used when the temporal images have significant motion artifacts or patients with multiple neuroendocrine tumors, especially when tumors are small or absent of significant contrast enhancement.

RESULTS

All quantitative image quality parameters of DLR and SBIR based on temporal image technique are higher than that of conventional CT (all p<0.001), except for the SNR of portal vein (p=0.234 and 0.290, respectively). The overall image quality of DLR and SBIR based on temporal image technique were lower than that of conventional CT (all p< 0.05). However, there was no significant difference of the overall image quality (all scores are 4(3,4)) between the combination of the two and conventional CT (p=0.234 and 0.061 for arterial phase and portal vein phase, respectively).

CLINICAL RELEVANCE/APPLICATION

DLR could be used when the temporal images have significant motion artifacts or patients with multiple neuroendocrine tumors, especially when tumors are small or absent of significant contrast enhancement.

SDP-GI-84   Contrast Enhanced Ultrasound Features With Sonazoid Of Hepatocellular Carcinoma In The Non-cirrhotic Liver

Participants
Yi Dong, MD, PhD, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

Current report on the role of contrast enhanced ultrasound (CEUS) with Sonazoid in diagnosis hepatocellular carcinoma (HCC) in non-cirrhotic patients is limited. The aim of this retrospective study was to analyze CEUS features of histologically proven HCC in patients with non-cirrhotic liver.*Methods and Materials 96 patients with histologically proven HCC lesions with non-cirrhotic liver were retrospectively reviewed regarding CEUS features. Two radiologists assessed the CEUS enhancement pattern and came to a consensus using the WFUMB (World Federation of Societies for Ultrasound in Medicine and Biology) guideline criteria.*Results Most of the lesions were heterogeneous but predominantly hypoechoic on B mode ultrasound (64.5 %, 62/96), with ill-defined margins and irregular shapes. During the arterial phase of CEUS, most of the HCC lesions with non-cirrhotic liver displayed a heterogeneous hyperenhancement (78.1 %, 75/96) compared to the surrounding liver parenchyma. Almost 30 % of HCC lesions (28.1 %, 27/96) showed early washout (< 60 seconds). All lesions showed washout and hypoenhancement in the late phase and Kupffer phase.*Conclusions Sonazoid enhanced CEUS features of HCC lesions in non-cirrhotic patients including typically hyperenhancement in the arterial phase and relatively rapid washout in the portal venous phase, which is different from HCC in cirrhotic livers and more similar to liver metastasis.*Clinical Relevance/Application Sonazoid (GE Healthcare, Waukesha, WI, USA), a second-generation contrast agent, shows the unique property of accumulation in the liver and spleen.

RESULTS

Most of the lesions were heterogeneous but predominantly hypoechoic on B mode ultrasound (64.5 %, 62/96), with ill-defined margins and irregular shapes. During the arterial phase of CEUS, most of the HCC lesions with non-cirrhotic liver displayed a heterogeneous hyperenhancement (78.1 %, 75/96) compared to the surrounding liver parenchyma. Almost 30 % of HCC lesions (28.1 %, 27/96) showed early washout (< 60 seconds). All lesions showed washout and hypoenhancement in the late phase and Kupffer phase.

CLINICAL RELEVANCE/APPLICATION

Sonazoid (GE Healthcare, Waukesha, WI, USA), a second-generation contrast agent, shows the unique property of accumulation in the liver and spleen.

SDP-GI-85   The Application Of LI-RADS In Liver Transplantation Candidates: Determination Of Transplantation Eligibility According To The Milan Criteria

Participants
Jae Seok Bae, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To assess the performance of Liver Imaging Reporting and Data System (LI-RADS) in diagnosing hepatocellular carcinoma (HCC) and in determining liver transplantation (LT) eligibility according to the Milan criteria in LT candidates.*Methods and Materials We retrospectively analyzed 136 consecutive patients (mean age, 54 years ± 8) who underwent CT before LT between January 2010 and December 2018. All patients were in LI-RADS target population and were treatment-naïve. Two radiologists independently evaluated CT images by using LI-RADS, and reached a consensus. The positive predictive value and sensitivity of each LI-RADS category for detecting HCC were calculated by using the explanted liver as a reference standard. The accuracy of LI-RADS in determining the patient's LT eligibility by using the Milan criteria was assessed based on pathological result.*Results On histopathologic examination of explanted liver, 163 HCCs were found in 80.1% (109/136) of the patients. The positive predictive values and sensitivities of LI-RADS for detecting HCC were 95.0% (96/101) and 58.9% (96/163) when only LR-5 was considered HCC, and were 89.7% (104/116) and 63.8% (104/163) when both LR-5 and LR-4 LR-5 were considered HCC, respectively. According to pathological examination, 100 patients (73.5%) met Milan criteria and 36 patients (26.5%) were beyond the Milan criteria. The accuracy of LI-RADS in determining LT eligibility based on the Milan criteria was 93.4% (127/136) when only LR-5 was considered HCC, whereas it was 94.1% (128/136) when both LR-5 and LR-4 were considered HCC.*Conclusions In LT candidates, the LR-5 category demonstrated a high positive predictive value for detecting HCC. LI-RADS was also accurate for assessing the Milan criteria in LT candidates.*Clinical Relevance/Application LI-RADS would be useful for determining LT eligibility based on Milan criteria owing to the high positive predictive value in detecting HCC on explanted liver.

RESULTS

On histopathologic examination of explanted liver, 163 HCCs were found in 80.1% (109/136) of the patients. The positive predictive values and sensitivities of LI-RADS for detecting HCC were 95.0% (96/101) and 58.9% (96/163) when only LR-5 was considered HCC, and were 89.7% (104/116) and 63.8% (104/163) when both LR-5 and LR-4 LR-5 were considered HCC, respectively. According to pathological examination, 100 patients (73.5%) met Milan criteria and 36 patients (26.5%) were beyond the Milan criteria. The accuracy of LI-RADS in determining LT eligibility based on the Milan criteria was 93.4% (127/136) when only LR-5 was considered HCC, whereas it was 94.1% (128/136) when both LR-5 and LR-4 were considered HCC.

CLINICAL RELEVANCE/APPLICATION

LI-RADS would be useful for determining LT eligibility based on Milan criteria owing to the high positive predictive value in detecting HCC on explanted liver.

SDP-GI-86   Advantages Of The Latest Deep Learning Reconstruction Algorithm In Ultra-high-resolution Computed Tomography For Pancreatic Cystic Neoplasms

Participants
Keitaro Sofue, MD, Kobe, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Ultra-high-resolution (UHR) CT substantially increases image noise caused by insufficient incident photons on smaller detectors, which deteriorates image quality especially in the abdomen. To improve the image quality, a new deep learning reconstruction algorithm (AiCE Body Sharp; Canon Medical Systems) has been recently implemented into UHR CT of the abdomen. The purpose of this study was to investigate the image quality and clinical utility of the latest deep learning reconstruction algorithm in UHR CT for pancreatic cystic neoplasms.*Methods and Materials This retrospective study included 32 patients (17men; mean age, 67 years; mean body mass index 21.6 kg/m2) with pancreatic cystic neoplasms who underwent contrast-enhanced CT with a UHR CT scanner (Aquilion Precision; Canon Medical Systems). Image data were reconstructed with a 1024 matrix and 0.25-mm section thickness using hybrid iterative (AIDR 3D) and the latest deep learning (AiCE Body Sharp) reconstruction algorithms. Image noise of the paraspinal muscle, contrast-to-noise ratio (CNR) between the liver, pancreas, artery, or portal vein and paraspinal muscle, and pancreas-to-lesion CNR were calculated on arterial and portal venous phase images. Overall image quality, image noise, sharpness, vessel conspicuity, and lesion delineation were evaluated using a 5-point scale (1= unacceptable to 5= excellent). Presence or

absence of continuity between the cystic lesion and pancreatic duct, and thickened wall or mural nodule were also assessed with refer to endoscopic ultrasound examination. Objective and subjective assessments were compared between the two reconstruction algorithms.*Results The mean CNRs of the liver, pancreas, artery, and portal vein, and pancreas-to-lesion CNR were significantly higher in UHR CT images with AiCE Body Sharp than those in UHR CT images with AIDR 3D (P<.001 for all). Overall image quality, image noise, sharpness, and vessel conspicuity were significantly superior in UHR CT images with AiCE Body Sharp (P<.01 for all), although lesion delineation was equivalent between the two reconstruction algorithms (P=.112). Accuracy of continuity between the cystic lesion and pancreatic duct, and thickened wall or mural nodule were superior in UHR CT images with AiCE Body Sharp (P=.157 and .083, respectively).*Conclusions UHR CT images with AiCE Body Sharp can provide less image noise and high image quality CT images, which may contribute to precise evaluation of the pancreatic cystic neoplasms.*Clinical Relevance/Application Ultra-high-resolution CT with the latest deep learning-based reconstruction algorithm may contribute to precise evaluation of the pancreatic cystic neoplasms and adjacent anatomical structures.

RESULTS

The mean CNRs of the liver, pancreas, artery, and portal vein, and pancreas-to-lesion CNR were significantly higher in UHR CT images with AiCE Body Sharp than those in UHR CT images with AIDR 3D (P<.001 for all). Overall image quality, image noise, sharpness, and vessel conspicuity were significantly superior in UHR CT images with AiCE Body Sharp (P<.01 for all), although lesion delineation was equivalent between the two reconstruction algorithms (P=.112). Accuracy of continuity between the cystic lesion and pancreatic duct, and thickened wall or mural nodule were superior in UHR CT images with AiCE Body Sharp (P=.157 and .083, respectively).

CLINICAL RELEVANCE/APPLICATION

Ultra-high-resolution CT with the latest deep learning-based reconstruction algorithm may contribute to precise evaluation of the pancreatic cystic neoplasms and adjacent anatomical structures.

SDP-GI-87   Feasibility Of Four-dimensional Flow MRI To Assess Collateral Vessels In The Portal Hypertension Of Liver Cirrhosis

Participants
Nan Wang, Dalian, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the feasibility of 4D flow MRI in assessing the patency of collateral vessels in the portal hypertension of liver cirrhosis.*Methods and Materials This study has been approved by the local IRB. 15 patients with clinically diagnosed liver cirrhosis were retrospectively selected for this study. Imaging was performed on a 3.0T MR scanner (Ingenia CX, Philips Healthcare, Netherlands) with a 16-channel abdominal array coil. The MR protocols included a 2D quantitative flow sequence to measure the flow velocity in the portal vein as a reference for velocity encodings and a 4D flow sequence with CS for hemodynamics quantification. VENC was set to 30 cm/s for the 4D flow sequence to slightly surpass the measured velocity and avoid phase wrapping. Combined with gastroscopy and imaging findings, patients with liver cirrhosis were divided into normal group and collateral circulation group. The acquired images were processed on CVI42 package by an experienced radiologist to obtain the 3D angiogram. Four cut planes were manually placed to measure the flow,the flow rate (cm/s), the axial-wall shear stress (WSS, Pa), and the pressure gradient (mmHg) in the targeted vessel segments. Three planes were placed at the proximal, middle, and distal of the main portal vein and one at the splenic vein confluence as reference (Figure 1). The Mann-Whitney U test was used to analyze the difference of flow, the flow rate, axial-wall shear stress, and pressure gradient measured from the normal group and the collateral circulation group on the platform of SPSS22.0 (IBM). ROC analysis was employed to evaluate the diagnostic performance of the flow and the pressure gradient in the middle portal vein on patency of collateral circulation.*Results The values of the flow and the pressure gradient in the middle portal vein of cirrhotic patients with collateral circulation were higher than those without collateral circulation, and the difference was statistically significant. There was no statistical difference in quantitative parameters from other parts of the portal vein (Table 1). The AUCs of flow, pressure gradient, and flow combined with pressure gradient were 0.911, 0.833, and 0.956 (Figure 2 and Table 2). The sensitivity was 88.9%, and the specificity was 100% when the joint use quantitative values of flow, pressure gradient.*Conclusions Portal vein hypertension could be measured noninvasively using 4D flow MRI, which helps diagnose whether the collateral circulation is open or not. This strategy provides a quantitative guidance on choosing proper medical interventions for patients with liver fibrosis.*Clinical Relevance/Application Portal vein hypertension could be measured noninvasively using 4D flow MRI, which helps diagnose whether the collateral circulation is open or not.

RESULTS

The values of the flow and the pressure gradient in the middle portal vein of cirrhotic patients with collateral circulation were higher than those without collateral circulation, and the difference was statistically significant. There was no statistical difference in quantitative parameters from other parts of the portal vein (Table 1). The AUCs of flow, pressure gradient, and flow combined with pressure gradient were 0.911, 0.833, and 0.956 (Figure 2 and Table 2). The sensitivity was 88.9%, and the specificity was 100% when the joint use quantitative values of flow, pressure gradient.

CLINICAL RELEVANCE/APPLICATION

Portal vein hypertension could be measured noninvasively using 4D flow MRI, which helps diagnose whether the collateral circulation is open or not.

SDP-GI-88   The Risk Stratification For Hypervascular Transformation Of Hepatobiliary Phase Hypointense Nodules Without Arterial Phase Hyperenhancement On Gadoxetic Acid-enhanced MRI

Participants
Na Li, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To establish a risk stratification scale based on the combination of imaging findings which enable to predict hypervascular transformation for Hepatobiliary phase hypointense (HBP) hypointense nodules without Arterial phase hyperenhancement (APHE).*Methods and Materials In this retrospective, single-institutional study during January 2015 to January 2017, a total of 55 HBP hypointense nodules without APHE in 35 patients with chronic liver disease were investigated. After reviewing the regular 3~6 months interval follow-up MRI examinations and analyzing the primary endpoint of the nodules: transformed to hypervascular HCC or not (remained stable, size decreased, or disappeared). Univariate and multivariate analysis with a Cox proportional hazard regression model were performed to identify imaging findings which enabled predicting the hypervascular transformation. Establish a

risk stratification scale based on combining the contributing imaging findings and evaluate its efficacy.*Results Two MR imaging features were independently associated with hypervascular transformation: diffusion weighted imaging (DWI) hyperintensity (odds ratio [OR] = 4.984; 95% confidence interval [CI]: 1.599, 15.538; p=0.006) and portal venous phase (PVP) hypointensity (OR = 4.079; 95% CI: 1.430, 11.639; p = 0.009). When two imaging findings were combined, the specificity was 100% (28/28) though the sensitivity was insufficient (37.03%, 10/27). When either DWI hyperintensity or PVP hypointensity was satisfied, the sensitivity was 88.89% (24/27) while the specificity was 67.86% (19/28). Based on the observation of nodules with both, either or none of these two findings, the risk for hypervascular transformation was divided into: high, intermediate and low, respectively. The area under the curve (AUC) of receiver operator characteristics (ROC) of the risk scale for transformation was 0.843 (95%CI, 0.739-0.948. The mean interval for transformation for nodules with high, intermediate and low risk was 329 (95% CI, 195-463), 1066 (95% CI, 743-1388) and 2258 (95% CI, 1738-2778) days, respectively (P<0.001).*Conclusions A combination of two findings in gadoxetic acid-enhanced MRI: DWI hyperintensity and PVP hypointensity, can be used as high-risk indicator for hypervascular transformation, while nodules with either finding should be followed-up closely for the intermediate potential for transformation.*Clinical Relevance/Application To establish a risk stratification scale based on the combination of imaging findings which enabled to predict hypervascular transformation for HBP hypointense nodules without APHE and to provide evidence for making more appropriate imaging diagnosis and next-step clinical allocation.

RESULTS

Two MR imaging features were independently associated with hypervascular transformation: diffusion weighted imaging (DWI) hyperintensity (odds ratio [OR] = 4.984; 95% confidence interval [CI]: 1.599, 15.538; p=0.006) and portal venous phase (PVP) hypointensity (OR = 4.079; 95% CI: 1.430, 11.639; p = 0.009). When two imaging findings were combined, the specificity was 100% (28/28) though the sensitivity was insufficient (37.03%, 10/27). When either DWI hyperintensity or PVP hypointensity was satisfied, the sensitivity was 88.89% (24/27) while the specificity was 67.86% (19/28). Based on the observation of nodules with both, either or none of these two findings, the risk for hypervascular transformation was divided into: high, intermediate and low, respectively. The area under the curve (AUC) of receiver operator characteristics (ROC) of the risk scale for transformation was 0.843 (95%CI, 0.739-0.948. The mean interval for transformation for nodules with high, intermediate and low risk was 329 (95% CI, 195-463), 1066 (95% CI, 743-1388) and 2258 (95% CI, 1738-2778) days, respectively (P<0.001).

CLINICAL RELEVANCE/APPLICATION

To establish a risk stratification scale based on the combination of imaging findings which enabled to predict hypervascular transformation for HBP hypointense nodules without APHE and to provide evidence for making more appropriate imaging diagnosis and next-step clinical allocation.

SDP-GI-89   Assessment Of Prognostic Value And Interreader Agreement Of Anali Scores In Patients With Primary Sclerosing Cholangitis

Participants
Aristeidis Grigoriadis, STOCKHOLM, Sweden (*Presenter*) Nothing to Disclose

PURPOSE

The aim of the study is two-fold, namely to both assess the interreader agreement between expert radiologists of the two ANALI scores and of the radiological parameters they utilize, and to test the performance of the scores in our population.*Methods and Materials Three radiologists evaluated MRIs of 98 PSC patients from a prospectively collected cohort with a median follow-up of 6.7 years. Each parameter of ANALI scores was assessed, and the scores were calculated. Interreader agreement was assessed with intraclass correlation coefficient (ICC). The prognostic value of the ANALI scores was assessed by means of Cox regression analysis, and outcome-free survival rates were evaluated by means of Kaplan-Meier estimates.*Results The ANALI score without gadolinium had poor to moderate interreader agreement (ICC=0.56, 95% CI, 0.42-0.68) and with gadolinium poor agreement (ICC=0.30, 95% CI, 0.16- 0.44). Liver deformity (ICC=0.28, 95% CI, 0.13-0.44)and parenchymal enhancement heterogeneity (ICC=0.24, 95% CI, 0.12-0.38) had poor agreement. Portal hypertension (ICC=0.48, 95% CI, 0.36-0.59) had poor to moderate agreement and dilatation of the intrahepatic ducts had moderate agreement (ICC=0.64, 95% CI, 0.54-0.73). Hazard ratios for liver-related death, transplantation or cirrhosis decompensation of the ANALI scores with and without gadolinium were 3.53 (95% CI, 1.40- 8.93) and 2.25 (95% CI, 1.56-3.24), respectively. Outcome-free survival was better for patients with low ANALI scores.*Conclusions The ANALI scores show poor to moderate agreement, which challenges their usefulness in clinical practice. They are associated with clinical outcomes, confirming the value of imaging in prognosis of PSC, but need further fine-optimization and multicenter evaluation.*Clinical Relevance/Application There is need for prognostic markers in primary sclerosing cholangitis (PSC). The two prognostic ANALI scores utilize magnetic resonance imaging (MRI); however, their reproducibility is unknown. In 98 PSC patients the interreader agreement between experienced radiologists for the ANALI scores and the radiological parameter they utilize was shown to be poor to moderate which challenges their usefulness in everyday clinical practice. On the other hand, imaging parameters seem to be good candidates as prognostic markers, as the current study shows good association of radiological parameters to clinical outcomes. MRI is well established for the diagnosis and detection of complications in PSC patents. However, for prognostication, including the ANALI scores, fine optimisation and multicenter validation is necessary before implementation in clinical practice.

RESULTS

The ANALI score without gadolinium had poor to moderate interreader agreement (ICC=0.56, 95% CI, 0.42-0.68) and with gadolinium poor agreement (ICC=0.30, 95% CI, 0.16- 0.44). Liver deformity (ICC=0.28, 95% CI, 0.13-0.44)and parenchymal enhancement heterogeneity (ICC=0.24, 95% CI, 0.12-0.38) had poor agreement. Portal hypertension (ICC=0.48, 95% CI, 0.36-0.59) had poor to moderate agreement and dilatation of the intrahepatic ducts had moderate agreement (ICC=0.64, 95% CI, 0.54-0.73). Hazard ratios for liver-related death, transplantation or cirrhosis decompensation of the ANALI scores with and without gadolinium were 3.53 (95% CI, 1.40- 8.93) and 2.25 (95% CI, 1.56-3.24), respectively. Outcome-free survival was better for patients with low ANALI scores.

CLINICAL RELEVANCE/APPLICATION

There is need for prognostic markers in primary sclerosing cholangitis (PSC). The two prognostic ANALI scores utilize magnetic resonance imaging (MRI); however, their reproducibility is unknown. In 98 PSC patients the interreader agreement between experienced radiologists for the ANALI scores and the radiological parameter they utilize was shown to be poor to moderate which challenges their usefulness in everyday clinical practice. On the other hand, imaging parameters seem to be good candidates as prognostic markers, as the current study shows good association of radiological parameters to clinical outcomes. MRI is well established for the diagnosis and detection of complications in PSC patents. However, for prognostication, including the ANALI scores, fine optimisation and multicenter validation is necessary before implementation in clinical practice.

SDP-GI-9   **The Added Value Of Virtual Monoenergetic Imaging With Dual-layer Spectral Detector CT To Conventional Polyenergetic Imaging For Detecting Small Pancreatic Ductal Adenocarcinoma**

Participants
Yoshihiko Fukukura, MD, PhD, Kagoshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Dual-layer spectral detector CT (DLCT) enables retrospective reconstruction of virtual monoenergetic imaging (VMI) in addition to conventional polyenergetic imaging (PEI) to optimize tumor conspicuity. However, no prior studies have investigated the potential added value of VMI in the detection of pancreatic ductal adenocarcinoma (PDAC). Therefore, the purpose of this study was to evaluate the benefit of adding VMI to PEI in the preoperative detection of small PDAC.*Methods and Materials This study included consecutive 82 patients with pathologically confirmed small PDAC (=30 mm; mean size, 22 mm; range, 7-30 mm) and 20 patients without a pancreas tumor who underwent three-phase contrast-enhanced DLCT. Three observers reviewed the two image sets, a 120kVp PEI set and a combined image set (120kVp PEI + 40 keV VMI) to evaluate the detection of small PDAC using receiver operating characteristic analysis. Tumors' visual attenuation on each phase and tumor-to-pancreas contrast-to-noise ratio (CNR) was compared between 120kVp PEI and 40 keV VMI.*Results Area under the receiver operating characteristic curve values for the three observers were 0.974, 0.965, and 0.960 for the PEI set and 0.992, 0.993, and 0.986 for the combined image set (P=0.017-0.029), respectively. The combined image set (89.0% [observer 1]; 93.9% [observer 2], 98.8% [observer 3]) yielded better sensitivity than the conventional image set (78.0% [observer 1]; 84.1% [observer 3], 85.4% [observer 3]) (P=0.001-0.023) without loss of specificity (all, P>0.999). Tumor-to-pancreas CNR of 40 keV VMI was approximately threefold higher than those of conventional 120 kVp PEI.*Conclusions The addition of 40 keV VMI to conventional PEI had better sensitivity for detecting small PDAC.*Clinical Relevance/Application In preoperative evaluation of small pancreatic adenocarcinoma, the addition of 40 keV virtual monoenergetic imaging to conventional polyenergetic imaging improves the sensitivity of cancer detection.

RESULTS

Area under the receiver operating characteristic curve values for the three observers were 0.974, 0.965, and 0.960 for the PEI set and 0.992, 0.993, and 0.986 for the combined image set (P=0.017-0.029), respectively. The combined image set (89.0% [observer 1]; 93.9% [observer 2], 98.8% [observer 3]) yielded better sensitivity than the conventional image set (78.0% [observer 1]; 84.1% [observer 3], 85.4% [observer 3]) (P=0.001-0.023) without loss of specificity (all, P>0.999). Tumor-to-pancreas CNR of 40 keV VMI was approximately threefold higher than those of conventional 120 kVp PEI.

CLINICAL RELEVANCE/APPLICATION

In preoperative evaluation of small pancreatic adenocarcinoma, the addition of 40 keV virtual monoenergetic imaging to conventional polyenergetic imaging improves the sensitivity of cancer detection.

SDP-GI-90   **Computed Tomography In Evaluating Gastroesophageal Varices In Patients With Liver Cirrhosis: A Systematic Review And Meta-analysis**

Participants
Jinkui Li, Lanzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

This systematic review and meta-analysis was designed to evaluate the accuracy of computed tomography (CT) as a noninvasive method for diagnosing gastroesophageal varices (GEV) and identifying high-risk varices in patients with liver cirrhosis in reference to esophagogastroduodenoscopy (EGD).*Methods and Materials A systemic literature search of PubMed, Embase, Cochrane Library, and Web of Science databases were conducted to identify eligible articles. The following indices were calculated: pooled sensitivity (SEN) and specificity (SPE), positive and negative likelihood ratio (PLR and NLR), diagnostic odds ratio (DOR), and area under receiver operating characteristics(AUC). Subgroup analyses were also carried out according to the location of varices, CT technique, and study design. All statistical analyses were conducted by STATA 15.0,Meta-Disc 1.4 and RevMan 5.4.*Results Finally, 26 eligible studies were included, including 17 articles evaluating the presence of high-risk varices. Data were presented based on patient in 25 articles, while only one was presented based on number of varices. Based on patients, the pooled SEN, SPE, PLR, NLR, DOR, and AUC of CT for predicting any size and high-risk GEV were 0.91/0.81/4.73/0.11/41.60/0.93 and 0.89/0.90/8.86/0.12/75.71/0.95, respectively. Subgroup analysis: 1) accuracy was found in predicting any size esophageal varices (AUC=0.93) alone than any size gastric varices alone (AUC=0.89) (P<0.05); 2) CT performed with = 16-slice scanner (AUC=0.95) showed significantly better accuracy for predicting any size GEV compared with imaging performed with < 16-slice scanner (AUC=0.81), and with 64-slice CT (SEN=0.97) might be more sensitive to detect any size GEV than 16-slice CT (SEN=0.92) (P<0.05); 3) prospective study showed better performance in identifying any size GEV(AUC=0.95) than retrospective studies (AUC=0.90) (P<0.05). In the subgroup analysis of the cut-off of high-risk esophageal varices, a cut-point of 3mm seems to have the best diagnostic performance (AUC=0.99). Five of the included studies suggested that most patients prefer undergoing CT scan instead of EGD for screening for varices. A Deek's funnel plot indicated a low probability for publication bias*Conclusions CT had both high diagnostic accuracy for evaluating any size and high-risk varices in cirrhotic patients. As a more tolerable modality, CT could potentially replace EGD as a primary screening method.*Clinical Relevance/Application Such a high diagnostic accuracy of CT scans for predicting varices is clinically meaningful for cirrhotic patients with portal hypertension. If high-risk varices is identified at CT scans, early intervention would be helpful to reduce the risk of variceal bleeding.

RESULTS

Finally, 26 eligible studies were included, including 17 articles evaluating the presence of high-risk varices. Data were presented based on patient in 25 articles, while only one was presented based on number of varices. Based on patients, the pooled SEN, SPE, PLR, NLR, DOR, and AUC of CT for predicting any size and high-risk GEV were 0.91/0.81/4.73/0.11/41.60/0.93 and 0.89/0.90/8.86/0.12/75.71/0.95, respectively. Subgroup analysis: 1) accuracy was found in predicting any size esophageal varices (AUC=0.93) alone than any size gastric varices alone (AUC=0.89) (P<0.05); 2) CT performed with = 16-slice scanner (AUC=0.95) showed significantly better accuracy for predicting any size GEV compared with imaging performed with < 16-slice scanner (AUC=0.81), and with 64-slice CT (SEN=0.97) might be more sensitive to detect any size GEV than 16-slice CT (SEN=0.92) (P<0.05); 3) prospective study showed better performance in identifying any size GEV(AUC=0.95) than retrospective studies (AUC=0.90) (P<0.05). In the subgroup analysis of the cut-off of high-risk esophageal varices, a cut-point of 3mm seems to have the best diagnostic performance (AUC=0.99). Five of the included studies suggested that most patients prefer undergoing CT scan instead of EGD for screening for varices. A Deek's funnel plot indicated a low probability for publication bias

CLINICAL RELEVANCE/APPLICATION

Such a high diagnostic accuracy of CT scans for predicting varices is clinically meaningful for cirrhotic patients with portal hypertension. If high-risk varices is identified at CT scans, early intervention would be helpful to reduce the risk of variceal bleeding.

SDP-GI-91 Deep Learning For The Automatic Detection Of The Adhesive-related Small Bowel ObstrucionTransition Zone

Participants
Quentin Vanderbecq, Paris, France (*Presenter*) Nothing to Disclose

PURPOSE

To train machine learning models to locate the transition zone of adhesive related small bowel obstruction (SBO) in CT scans.*Methods and Materials We used 562 CT examinations performed between January 2005 and July 2018 from 404 patients with diagnosis of adhesive related SBO. Annotation of the transition zone was performed by experimented radiologists and trained residents with bounding boxes. A pretrained model was used to extract abdominal and pelvic areas as a preprocessing. We modeled the localization problem of the transition zone as a binary classification problem by splitting the abdominal and pelvic area into 125 patches and trained a neural network model to classify each patch as containing or not a transition zone. We coupled this with a trained probabilistic estimation of the presence of a transition zone in each patch. The models were evaluated first using Area under the curve metric (AUC). Secondly, in order to evaluate the clinical benefit, we measured the ratio of abdomen volume classified as containing the transition zone for a given localization success rate.*Results SBO transition zone had a higher probability to locate in the hypogastric region. The coupled classification network and spatial probability estimation obtained an AUC of 0.94. For a 15% volume ratio classified as transition zone the probability to contain the transition zone is 92%.*Conclusions Modeling the SBO localization problem by coupling CNN classification and probabilistic localization estimation shows the way to a possible automatic detection of the transition zone, a complex radiological task with a high clinical impact.*Clinical Relevance/Application Help radiologists to detection of the SBO transition zone, to improve workflow and accuracy of this task.

RESULTS

SBO transition zone had a higher probability to locate in the hypogastric region. The coupled classification network and spatial probability estimation obtained an AUC of 0.94. For a 15% volume ratio classified as transition zone the probability to contain the transition zone is 92%.

CLINICAL RELEVANCE/APPLICATION

Help radiologists to detection of the SBO transition zone, to improve workflow and accuracy of this task.

SDP-GI-92 How Much Abdominal Fat Do Obese Patients Lose Short Term After Laparoscopic Sleeve Gastrectomy? A Quantitative Study Evaluated With MRI

Participants
Jing Sun, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to elucidate the changes in the amount of abdominal adipose tissue after laparoscopic sleeve gastrectomy in obese Chinese patients over a relatively short follow-up period. The differences in surgical effects between genders would also be analyzed.*Methods and Materials We enrolled 91 patients, including 18 males and 73 females, who underwent laparoscopic sleeve gastrectomy between November 2017 and November 2019. The areas of subcutaneous/visceral adipose tissue and the liver proton density fat fraction were calculated before and short term after surgery with upper abdominal magnetic resonance examinations.*Results Approximately 100 days after surgery, the median values of weight loss and body mass index reduction were 23.1 kg and 8.1 kg/m2, respectively. The patients achieved a greater absolute loss of subcutaneous adipose tissue index than of visceral adipose tissue index (3.2×10^{-3} vs 1.6×10^{-3}, p<0.001). The amounts of weight loss, body mass index loss and absolute/relative reduction in visceral adipose tissue index were much greater in males than in females (31.7 kg vs 21.7 kg, p<0.001; 9.8 kg/m2 vs 7.9 kg/m2, p=0.016; 2.5×10^{-3} vs 1.3×10^{-3}, p=0.007; 28.2% vs 20.9%, p=0.029). There was a correlation between decreased amounts in subcutaneous and visceral adipose tissue in sum and weight loss (r=0.282, p=0.032). The absolute/relative reduction in visceral adipose tissue index was also correlated with absolute/relative reduction in liver proton density fat fraction (r=0.283, p=0.013; r=0.372, p=0.001).*Conclusions The reductions in body weight and visceral fat were more significant in male patients. The sum of absolute reduction in subcutaneous and visceral fat depots was correlated with weight loss. For severely obese patients, an upper abdominal MR examination could assess the body tissue composition and how it changes after bariatric surgery.*Clinical Relevance/Application Clinicians are recommended the use of upper abdominal MR for the preoperative and postoperative evaluation of body tissue composition.

RESULTS

Approximately 100 days after surgery, the median values of weight loss and body mass index reduction were 23.1 kg and 8.1 kg/m2, respectively. The patients achieved a greater absolute loss of subcutaneous adipose tissue index than of visceral adipose tissue index (3.2×10^{-3} vs 1.6×10^{-3}, p<0.001). The amounts of weight loss, body mass index loss and absolute/relative reduction in visceral adipose tissue index were much greater in males than in females (31.7 kg vs 21.7 kg, p<0.001; 9.8 kg/m2 vs 7.9 kg/m2, p=0.016; 2.5×10^{-3} vs 1.3×10^{-3}, p=0.007; 28.2% vs 20.9%, p=0.029). There was a correlation between decreased amounts in subcutaneous and visceral adipose tissue in sum and weight loss (r=0.282, p=0.032). The absolute/relative reduction in visceral adipose tissue index was also correlated with absolute/relative reduction in liver proton density fat fraction (r=0.283, p=0.013; r=0.372, p=0.001).

CLINICAL RELEVANCE/APPLICATION

Clinicians are recommended the use of upper abdominal MR for the preoperative and postoperative evaluation of body tissue composition.

SDP-GI-93 Unenhanced CT For Non-invasive Diagnosis Of Hepatic Steatosis Using Low Tube Voltage CT

Participants
Yunjung Choi, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Unenhanced CT is reported to have high specificity for diagnosing moderate to severe hepatic steatosis. However, previous results are derived from 120 kVp scans. Lowering kVp affects the image contrast and CT attenuation values of low kVp CT is different from those of 120 kVp scans. The purposes of this study are to determine the diagnostic performance and to establish the reference range of low kVp unenhanced CT for the assessment of hepatic steatosis in liver transplantation donors using MRS as a reference standard*Methods and Materials This retrospective study included 165 potential donors (M:F=114:51, 36.5±12 years old) who underwent 100 kVp single slice unenhanced CT scan and MRS. The difference between hepatic and splenic attenuation (CTL-S) and liver-to-spleen attenuation ratio (CTL/S) were measured. Reference standard was the fat signal fraction measured by MR spectroscopy. The limits of agreement between CT measurements and the reference standard were calculated. Area under receiver operating curves (AUROC) of CTL-S and CTL/S were compared for diagnosing moderate to severe degree hepatic steatosis. The cut-off values of CTL-S and CTL/S that provided 1) a balance between sensitivity and specificity, and 2) the highest specificity using the lower limit of the reference range were calculated.*Results Eighty-seven subjects were confirmed to have non-steatotic liver. Sixty-one subjects had mild degree steatosis and 17 subjects with moderate to severe steatosis based on MR spectroscopy. CTL-S and CTL/S values showed negative correlation with the degree of the fat signal fraction (p<0.001) and the limits of agreement were -8.4% to 8.4% for CTL-S and -9.6% to 9.6% for CTL/S. AUROCs of CTL-S and CTL/S for diagnosing moderate to severe steatosis were 0.956 and 0.957, respectively. Cut-off values of CTL-S and CTL/S for diagnosis moderate to severe degree steatosis by the Youden index were -0.5 HU and 0.99 for CTL-S and CTL/S, respectively, with sensitivity and specificity of 100% and 84.46%, respectively. Reference ranges of non-steatotic liver were -6.90 to 31.40 HU for CTL-S and 0.89 to 1.77 for CTL/S. With -6.9 HU for CTL-S and 0.89 for CTL/S as the cut-off values, the sensitivity and specificity for diagnosing moderate to severe steatosis were 70.59 and 90.54% for CTL-S and 76.47% and 90.54% for CTL/S, respectively.*Conclusions Diagnosis performance of CTL-S and CTL/S for hepatic steatosis were similar and reliable. Low kVp unenhanced CT is robust technique for diagnosing hepatic steatosis with reduced radiation exposure.*Clinical Relevance/Application Low kVp unenhanced CT can be used for the diagnosis of hepatic steatosis and helpful for avoiding unnecessary biopsy and minimize radiation exposure.

RESULTS

Eighty-seven subjects were confirmed to have non-steatotic liver. Sixty-one subjects had mild degree steatosis and 17 subjects with moderate to severe steatosis based on MR spectroscopy. CTL-S and CTL/S values showed negative correlation with the degree of the fat signal fraction (p<0.001) and the limits of agreement were -8.4% to 8.4% for CTL-S and -9.6% to 9.6% for CTL/S. AUROCs of CTL-S and CTL/S for diagnosing moderate to severe steatosis were 0.956 and 0.957, respectively. Cut-off values of CTL-S and CTL/S for diagnosis moderate to severe degree steatosis by the Youden index were -0.5 HU and 0.99 for CTL-S and CTL/S, respectively, with sensitivity and specificity of 100% and 84.46%, respectively. Reference ranges of non-steatotic liver were -6.90 to 31.40 HU for CTL-S and 0.89 to 1.77 for CTL/S. With -6.9 HU for CTL-S and 0.89 for CTL/S as the cut-off values, the sensitivity and specificity for diagnosing moderate to severe steatosis were 70.59 and 90.54% for CTL-S and 76.47% and 90.54% for CTL/S, respectively.

CLINICAL RELEVANCE/APPLICATION

Low kVp unenhanced CT can be used for the diagnosis of hepatic steatosis and helpful for avoiding unnecessary biopsy and minimize radiation exposure.

SDP-GI-94   Deep Learning Analysis For The Diagnosis Of Acute Pancreatitis On Non-enhanced CT Images: A Pilot Study

Participants
Yi Wang, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

This study aims to develop a deep learning (DL) model using abdominal non-enhanced computed tomography (NECT) images and validate its feasibility of differentiating acute pancreatitis (AP) from non-AP (NAP) patients.*Methods and Materials Nine hundred and ninety AP patients underwent NECT scan within 72 hours of disease onset and 416 non-acute pancreatitis (NAP) people with NECT scan were enrolled in this retrospective study. Patients were divided to a training dataset (782 AP and 343 NAP) and an independent testing dataset (208 AP and 73 NAP). A DL system based on the lightweight network (modified 3D MobileNetV2) was proposed to process 3D pancreas-centered patches cropped from CT images and automatically predict pancreas status. Model performance was evaluated using the receiver operating characteristic (ROC) analysis and the decision curve analysis. The diagnostic performance of DL model was also compared with that of a junior and a senior radiologist in a dataset including atypical cases (106 AP and 106 NAP).*Results The DL model had achieved a sensitivity, specificity, and AUC of 80.82%, 81.34%, and 0.871 (95% CI, 0.850-0.890) in the training dataset, respectively. The sensitivity, specificity, and AUC of the DL model were 74.04%, 78.08%, and 0.810 (95% CI, 0.759-0.854) in the independent testing dataset, respectively. Decision curve analysis demonstrated the clinical usefulness of the DL model. The DL model showed non-inferior performance to the senior radiologist (p = 0.625) and outperformed the junior radiologist (p < 0.001) with a very fast diagnostic speed (0.15 sec per-case). The performance of the junior and senior radiologists improved after the assistance of DL model with accuracy increased from 62.23% and 79.25% to 94.81% and 97.22%, while the diagnostic time per-case was reduced from 14.34 sec and 8.92 sec to 4.43 sec and 3.17 sec, respectively.*Conclusions The lightweight network-based DL model has good feasibility in diagnosing AP on NECT images and can assist junior radiologists to achieve better performance, which could benefit clinical practice.*Clinical Relevance/Application The deep learning model shows good performance and can improve emergency efficiency and help inexperienced doctors diagnose AP on non-enhanced CT images.

RESULTS

The DL model had achieved a sensitivity, specificity, and AUC of 80.82%, 81.34%, and 0.871 (95% CI, 0.850-0.890) in the training dataset, respectively. The sensitivity, specificity, and AUC of the DL model were 74.04%, 78.08%, and 0.810 (95% CI, 0.759-0.854) in the independent testing dataset, respectively. Decision curve analysis demonstrated the clinical usefulness of the DL model. The DL model showed non-inferior performance to the senior radiologist (p = 0.625) and outperformed the junior radiologist (p < 0.001) with a very fast diagnostic speed (0.15 sec per-case). The performance of the junior and senior radiologists improved after the assistance of DL model with accuracy increased from 62.23% and 79.25% to 94.81% and 97.22%, while the diagnostic time per-case was reduced from 14.34 sec and 8.92 sec to 4.43 sec and 3.17 sec, respectively.

CLINICAL RELEVANCE/APPLICATION

The deep learning model shows good performance and can improve emergency efficiency and help inexperienced doctors diagnose AP on non-enhanced CT images.

SDP-GI-95   Non-invasive Assessment Of Hemodynamics In Portal Venous System Using 4d Flow MR Imaging: Association With Liver Fibrosis

Participants
Atsushi Higaki, MD, Kurashiki, Japan (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to evaluate the relationship between the degree of liver fibrosis and hemodynamic changes in the portal venous system using 4D flow MR imaging.*Methods and Materials A total of 81 patients with (n=49) and without (n=32) chronic liver disease underwent 4D flow MR imaging using a 3-T system (Figure 1). Quantitative indices such as forward flow (ml/s), backward flow (ml/s), sum of forward and backward flow (ml/s), and average velocity (cm/s) were measured in middle part of the portal trunk (PT), proximal part of the right and left portal veins (PV), the superior mesenteric vein (SMV), and the splenic vein (SV). Liver fibrosis was assessed by a combination of qualitative assessment by radiologists and quantitative assessment such as Fib-4 index and aspartate transaminase-to-platelet ratio index (APRI), and divided into three groups (A: normal (n=16), B: mild-to-moderate fibrosis (n=54), and C: severe fibrosis (n=11)). Statistical analysis was performed using the Kruskal-Wallis and Mann-Whitney U tests.*Results In the comparison between the three groups, there were significant differences in backward flow (p<0.001) and average velocity (p=0.002) for the PT, average velocity for the SMV (p=0.003), sum of forward and backward flow for the SV (p=0.018), and backward flow (p=0.002) and average velocity (p=0.008) for the right PV. These six indices had significant differences between Group A and Group C (p<0.001to p=0.006) and between Group B and Group C (p=0.001 to p=0.045), but no significant differences between group A and group B (Figure 2).*Conclusions Our study results suggest that the change of hemodynamics in the portal venous system accelerates when liver fibrosis progresses to some extent. At the advanced stage of liver fibrosis, the flow rate and/or the velocity of portal trunk, SMV, and right portal vein decrease, whereas the flow rate of SV increases. These observations might be associated with stenosis of the right PV caused by liver fibrosis, and subsequent formation of collateral circulation. In addition, the difference in hemodynamics between right PV and left PV may be a cause of morphological change of the liver in cirrhosis.*Clinical Relevance/Application The 4D flow MR imaging could non-invasively evaluate hemodynamics in the portal venous system.

RESULTS

In the comparison between the three groups, there were significant differences in backward flow (p<0.001) and average velocity (p=0.002) for the PT, average velocity for the SMV (p=0.003), sum of forward and backward flow for the SV (p=0.018), and backward flow (p=0.002) and average velocity (p=0.008) for the right PV. These six indices had significant differences between Group A and Group C (p<0.001to p=0.006) and between Group B and Group C (p=0.001 to p=0.045), but no significant differences between group A and group B (Figure 2).

CLINICAL RELEVANCE/APPLICATION

The 4D flow MR imaging could non-invasively evaluate hemodynamics in the portal venous system.

SDP-GI-96   Relationship Of Apparent Bowel Wall Thickness At CT And Bowel Intralumenal Attenuation: A Phantom Study

Participants
Mark Sugi, MD, San Francisco, California (*Presenter*) Consultant, Nextrast, IncAuthor with royalties, RELX

PURPOSE

Bowel wall thickness assessment is critical for bowel disease diagnosis at CT. We assess the effect of bowel lumen attenuation on measured bowel wall thickness in a CT phantom at dual-energy CT.*Methods and Materials 6 cm cylinders were affixed to a "bowel wall" plastic plate (Original Solid Water Sheets, Gammex, Middleton, WI) 2mm+/-0.2 mm thick, validated to 10 HU at across 80 to 140 kVp. The cylinders were filled with water, canola oil, Breeza™, VoLumen™, air, Omnipaque Oral Solution, Readi-Cat 2™, and 2 experimental Dark Borosilicate Contrast Materials (DBCM, which has FDA IND). This phantom was immersed in fat to simulate mesenteric fat, and scanned at 80, 100, 120 and 140 kVp on dual-energy CT scanners. CT image thickness of the bowel wall plate was measured at ImageJ by count of voxels within zero +/- 3 standard deviations of background noise across large ROIs. Bowel wall clarity for each agent was rated by two radiologist readers on a 3-point scale: 0=poor, 1= adequate, 2=clear.*Results At 120 kVp, the CT attenuation of the lumen contents were -3, -123, 11, 23, -1001, 264, 375, -85, and -169 HU for water, oil, Breeza™, VoLumen™, air, Omnipaque Oral Solution, and Readi-Cat 2™, and DBCM A (low concentration) and DBCM B (high concentration), respectively. The bowel wall thicknesses at 120 kVp were measured to be 4.35, 2.01, 4.53, 4.53, 1.09, 1.17, 1.12 mm, 2.43, and 2.01 mm, respectively. Bowel wall clarity was rated lowest for the lumens with lowest difference in HU value with the bowel wall (p<0.005).*Conclusions At CT, measured bowel wall thickness diverges substantially from true thickness depending on the lumen CT attenuation at CT. The CT attenuation of the bowel lumen to that of the bowel wall must be considered at CT imaging for accurate assessment of bowel wall thickness and possible bowel wall disease. The most accurate bowel wall thickness measurements were seen with moderate (~100-200HU), but not excessive (>300HU) differences in HU between the wall and contrast agent.*Clinical Relevance/Application The CT attenuation of the bowel lumen relative to that of the bowel wall must be considered at CT imaging for accurate assessment of bowel wall thickness and hence sensitivity for bowel wall disease.

RESULTS

At 120 kVp, the CT attenuation of the lumen contents were -3, -123, 11, 23, -1001, 264, 375, -85, and -169 HU for water, oil, Breeza™, VoLumen™, air, Omnipaque Oral Solution, and Readi-Cat 2™, and DBCM A (low concentration) and DBCM B (high concentration), respectively. The bowel wall thicknesses at 120 kVp were measured to be 4.35, 2.01, 4.53, 4.53, 1.09, 1.17, 1.12 mm, 2.43, and 2.01 mm, respectively. Bowel wall clarity was rated lowest for the lumens with lowest difference in HU value with the bowel wall (p<0.005).

CLINICAL RELEVANCE/APPLICATION

The CT attenuation of the bowel lumen relative to that of the bowel wall must be considered at CT imaging for accurate assessment of bowel wall thickness and hence sensitivity for bowel wall disease.

SDP-GI-97   CT Perfusion During Routine Staging And Restaging As A Potential Biomarker For Pancreatic Ductal Adenocarcinoma

Participants

Ryan O'Malley, MD, Seattle, Washington (*Presenter*) Research Grant, General Electric Company

PURPOSE

To evaluate the significance of perfusion parameters acquired in conjunction with routine multi-phase contrast-enhanced CT on a 160 mm wide-coverage 256-slice scanner in patients with pancreatic ductal adenocarcinoma (PDAC).*Methods and Materials 28 patients with PDAC naïve to prior treatment (15 male; median age, 67; median BMI, 25 kg/m2), underwent routine multiphase CT before and after chemoradiation therapy. CT perfusion was added to routine CT with 15 acquisitions obtained 5-42.5 sec after contrast administration, followed by standard pancreatic arterial and portal venous phases using the same IV contrast injection. Perfusion maps were generated and blood flow (BF), blood volume (BV), and permeability surface area product (PS) for tumor and uninvolved pancreas were calculated using deconvolution algorithms. 90 perfusion features were created: 5 distribution parameters (min, max, mean, standard deviation [SD], and coefficient of variation [CV or heterogeneity]) were measured over the 3 tissue-specific parameters (BF, BV, PS) in 6 ROIs (aorta, tumor center, tumor max, tumor rim, pancreas near tumor, normal pancreas). Ability of these features to discriminate patients who responded or did not respond to therapy (stable disease or partial response [n=18] vs. progressive disease [n=10], per RECIST 1.1) was evaluated, and those with AUC = 0.70 were retained. Further, logistic regression was used to assess association of select BL perfusion features with response to treatment. P-values were adjusted for multiple comparisons with BH procedure.*Results 9 of the initial 90 perfusion features were retained. Baseline BFCV, PSCV and BVCV in the tumor max ROI, and BVmean in tumor center, were significantly associated with treatment nonresponse (OR: 6.8, 4.4, 4.0, and 0.3 per SD?, respectively; adj. P = 0.047, for all); BFmin, BFmean and PSmax in tumor center, BVmean in tumor rim, and PSCV in normal pancreas were not significantly associated with the outcome (adj. P = 0.09-0.14).*Conclusions Using a single comprehensive multiphase pancreas perfusion CT, decreasing tumor-perfusion homogeneity and blood volume mean correlated with worse outcomes for patients with PDAC.*Clinical Relevance/Application Perfusion CT combined with standard multiphase CT is an efficient comprehensive examination for patients with PDAC with added information predicting response and very little downside. By combining perfusion CT with standard of care CT, this utilizes a single IV contrast injection, adds no time or cost to the patient, and simultaneously acquiring quantitative data and standard of care staging and restaging information.

RESULTS

9 of the initial 90 perfusion features were retained. Baseline BFCV, PSCV and BVCV in the tumor max ROI, and BVmean in tumor center, were significantly associated with treatment nonresponse (OR: 6.8, 4.4, 4.0, and 0.3 per SD?, respectively; adj. P = 0.047, for all); BFmin, BFmean and PSmax in tumor center, BVmean in tumor rim, and PSCV in normal pancreas were not significantly associated with the outcome (adj. P = 0.09-0.14).

CLINICAL RELEVANCE/APPLICATION

Perfusion CT combined with standard multiphase CT is an efficient comprehensive examination for patients with PDAC with added information predicting response and very little downside. By combining perfusion CT with standard of care CT, this utilizes a single IV contrast injection, adds no time or cost to the patient, and simultaneously acquiring quantitative data and standard of care staging and restaging information.

SDP-GI-98 T2-Weighted MRI Of The Liver: The Value Of Deep Learning Reconstruction Is Higher In High-Resolution Single-Shot Fast Spin-Echo Sequence Than In Conventional Fast Spin-Echo Sequence.

Participants
Kengo Kiso, Suita-city, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To compare the efficacy of deep leaning reconstruction (DLR) for high-resolution single-shot fast spin-echo (SSFSE) sequence with that for conventional fast spin-echo (FSE) sequence in T2-weighted MRI of the liver.*Methods and Materials Fifty-five patients with suspected focal liver lesions underwent liver MRI. Respiratory-triggered T2-weighted imaging was obtained with FSE and SSFSE at the same spatial resolution (5-mm thickness and 320×256 matrix). The mean acquisition time of FSE and SSFSE was 233 and 64 sec, respectively. For each sequence, conventional reconstruction (CR) and DLR were applied and two sets of imaging were generated. One radiologist measured the signal-to-noise-ratio (SNR) and the relative contrast. Two radiologists independently assessed the image quality. The results were compared using repeated-measures analysis of variance or Friedman's test.*Results The mean SNR of the liver parenchyma was 10.3, 12.9, 6.0, and 12.0 on FSE-CR, FSE-DLR, SSFSE-CR, and SSFSE-DLR, respectively. The SNR was significantly the lowest in SSFSE-CR, and the highest in SSFSE-DLR and FSE-DLR (P < .01). There was no significant difference in liver-to-focal liver lesion contrast among the four imaging sets. Qualitative analyses showed that DLR significantly improved noise (P < .05) but did not change motion artifacts both for FSE and SSFSE. Sharpness was significantly improved by DLR on FSE in one reader but was significantly diminished on SSFSE in both readers. Consequently, two readers assigned the worst noise to SSFSE-CR, the worst motion artifacts to FSE-CR and FSE-DLR, and the worst sharpness to SSFSE-DLR. Overall image quality was the lowest on SSFSE-CR in both readers, and the highest on SSFSE-DLR in one reader, and on SSFSE-DLR and FSE-DLR in the other reader (P < .05). Lesion conspicuity was the lowest in SSFSE-CR (P < .05), and equivalently high in SSFSE-DLR, FSE-CR, and FSE-DLR.*Conclusions Noise is the main problem in high-resolution SSFSE, which is efficiently reduced by DLR, whereas motion artifacts are the main problem in FSE, which is not resolved by DLR. As a result, the effect of DLR is greater in SSFSE than in FSE.*Clinical Relevance/Application In liver T2-weighted MRI, high-resolution SSFSE with DLR can be a powerful back-up sequence or even have a potential to replace the conventional FSE as it achieves high image quality in a short acquisition time.

RESULTS

The mean SNR of the liver parenchyma was 10.3, 12.9, 6.0, and 12.0 on FSE-CR, FSE-DLR, SSFSE-CR, and SSFSE-DLR, respectively. The SNR was significantly the lowest in SSFSE-CR, and the highest in SSFSE-DLR and FSE-DLR (P < .01). There was no significant difference in liver-to-focal liver lesion contrast among the four imaging sets. Qualitative analyses showed that DLR significantly improved noise (P < .05) but did not change motion artifacts both for FSE and SSFSE. Sharpness was significantly improved by DLR on FSE in one reader but was significantly diminished on SSFSE in both readers. Consequently, two readers assigned the worst noise to SSFSE-CR, the worst motion artifacts to FSE-CR and FSE-DLR, and the worst sharpness to SSFSE-DLR. Overall image quality was the lowest on SSFSE-CR in both readers, and the highest on SSFSE-DLR in one reader, and on SSFSE-DLR and FSE-DLR in the other reader (P < .05). Lesion conspicuity was the lowest in SSFSE-CR (P < .05), and equivalently high in SSFSE-DLR, FSE-CR, and FSE-DLR.

CLINICAL RELEVANCE/APPLICATION

In liver T2-weighted MRI, high-resolution SSFSE with DLR can be a powerful back-up sequence or even have a potential to replace

the conventional FSE as it achieves high image quality in a short acquisition time.

SDP-GI-99   A Combined Region And Pixel Based Deep Learning Approach For Abdominal Adipose Tissue Quantification Using Dixon Magnetic Resonance Imaging

Participants
Li-Yueh Hsu, Bethesda, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Dixon based Magnetic Resonance Imaging (MRI) offers an effective assessment of subcutaneous (SAT) and visceral (VAT) adipose tissues in the abdomen without exposure to ionizing radiation. Conventional computerized quantification relies on segmenting abdomen regions of interest for empirical thresholding. In contrast, deep learning approach classifies both tissues with distinct pixel labels. We propose a convolutional neural network (CNN) approach combining both region and pixel-based labels for SAT and VAT quantification.*Methods and Materials 475 abdomen scans acquired on a 3T Philips MRI scanner using a 3D Dixon SENSE sequence were included in this study. For each scan, fat-only axial images located at the L2/3 and L4/5 disc spaces were selected for the quantification. For each image, an outer and an inner region around the abdomen wall as well as SAT and VAT pixel masks were generated by expert readers using an in-house software. These four types of masks served as the reference labels for CNN training and testing. A standard U-Net architecture with generalized Wasserstein distance loss was used to train two models; one for region segmentation and one for fat pixel classification. The performance was evaluated using Dice Similarity Coefficient (DSC) with five-fold cross-validation, and by Pearson correlation and Student's t-test. A $p < 0.05$ was considered statistically significant.*Results Mean and standard deviation of DSC for the outer region, inner region, SAT, and VAT were 0.974 ± 0.026, 0.997 ± 0.003, 0.981 ± 0.025, and 0.932 ± 0.047. Pearson coefficients were 1.000 for both outer (p=0.999) and inner (p=0.944) regions; and 1.000 and 0.982 for SAT (p=0.978) and VAT (p=0.620) comparisons. These results showed our method not only provides excellent agreement with the reference SAT and VAT measurements, it also produces accurate abdominal region segmentation allowing the user to modify the automated results using alternative threshold-based approach if needed.*Conclusions The proposed four-label CNN approach offers a comprehensive and accurate SAT and VAT quantification which may ease clinical workflow integration.*Clinical Relevance/Application Dixon based Magnetic Resonance Imaging is an effective technique for measuring adipose tissue. This study presents an accurate hybrid deep learning approach for quantification of subcutaneous and visceral abdominal adipose tissue.

RESULTS

Mean and standard deviation of DSC for the outer region, inner region, SAT, and VAT were 0.974 ± 0.026, 0.997 ± 0.003, 0.981 ± 0.025, and 0.932 ± 0.047. Pearson coefficients were 1.000 for both outer (p=0.999) and inner (p=0.944) regions; and 1.000 and 0.982 for SAT (p=0.978) and VAT (p=0.620) comparisons. These results showed our method not only provides excellent agreement with the reference SAT and VAT measurements, it also produces accurate abdominal region segmentation allowing the user to modify the automated results using alternative threshold-based approach if needed.

CLINICAL RELEVANCE/APPLICATION

Dixon based Magnetic Resonance Imaging is an effective technique for measuring adipose tissue. This study presents an accurate hybrid deep learning approach for quantification of subcutaneous and visceral abdominal adipose tissue.

BR04-B1   Correlating Shear-wave Elastography Features With Molecular Subtype And Axillary Lymph Node Status In Breast Cancer

Participants
Hee Jeong Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Breast cancer is composed of distinct molecular subtypes that differ in etiology, treatment response, and prognosis. Different biological behavior of tumors may be related to the lesion stiffness measured by shear-wave elastography in US. The purpose of our study is to correlate shear-wave elastography features with molecular subtype and also with axillary lymph node status of breast cancer.*Methods and Materials We retrospectively included 691 consecutive women (mean age, 52.50 ± 10.94 years; range, 24-83) who underwent breast US including shear-wave elastography for preoperative evaluation of breast cancer at our center between Decemter 2019 and January 2021. Stiffness values (maximum stiffness value; Emax, mean stiffness value; Emean, and lesion-to-fat elasticity ratio; Eratio) and the maximum diameter of the lesion on US were recorded. Histopathologic findings including immunohistochemical profiles, size of invasive cancer, histologic type, histologic grade, Ki-67 proliferation index, and axillary lymph node status were used. The relationship between the stiffness values and the histopathologic findings was analyzed by using independent sample T-test or one-way ANOVA test with Tukey's post hoc test, as well as logistic regression analyses.*Results Large lesion size on US was associated with higher stiffness values in all three parameters (P < .001). Large size of invasive cancer (P < .001 for all three parameters), high histologic grade (P = 0.015 for Emax and 0.042 for Emean), high Ki-67 (P = 0.003 for Emax and 0.020 for Emean) and positive axillary lymph node metastasis (P = 0.002 for Emax, 0.001 for Emean, and 0.019 for Eratio) were associated with higher stiffness values. Emax and Emean were higher in the order of luminal A < HER2 < triple negative < luminal B subtype (P = 0.006 and 0.015, respectively) and Eratio was higher in the order of luminal A < HER2 < luminal B < triple negative subtype (P = 0.032). Lower Emax (P = 0.026) and Emean (P = 0.028) were found to be independently associated with low grade luminal A subtype breast cancer. Higher Emean was independently associated with axillary lymph node metastasis for lesions 20 mm or smaller on US (P = 0.041).*Conclusions Increased tumor stiffness on shear-wave elastography was associated with aggressive histopathologic features of breast cancer, while low stiffness values were associated with better prognostic features.*Clinical Relevance/Application Shear-wave elastography in the preoperative US may noninvasively provide prognostic information of the breast cancer.

RESULTS

Large lesion size on US was associated with higher stiffness values in all three parameters (P < .001). Large size of invasive cancer (P < .001 for all three parameters), high histologic grade (P = 0.015 for Emax and 0.042 for Emean), high Ki-67 (P = 0.003 for Emax and 0.020 for Emean) and positive axillary lymph node metastasis (P = 0.002 for Emax, 0.001 for Emean, and 0.019 for Eratio) were associated with higher stiffness values. Emax and Emean were higher in the order of luminal A < HER2 < triple negative < luminal B subtype (P = 0.006 and 0.015, respectively) and Eratio was higher in the order of luminal A < HER2 < luminal B < triple negative subtype (P = 0.032). Lower Emax (P = 0.026) and Emean (P = 0.028) were found to be independently associated with low grade luminal A subtype breast cancer. Higher Emean was independently associated with axillary lymph node metastasis for lesions 20 mm or smaller on US (P = 0.041).

CLINICAL RELEVANCE/APPLICATION

Shear-wave elastography in the preoperative US may noninvasively provide prognostic information of the breast cancer.

BR04-B2   Machine Learning Models Using Breast Ultrasound Radiomic And Clinical Features: Potential For Prediction Of Response To Neoadjuvant Chemotherapy At Baseline

Participants
Panagiotis Kapetas, Vienna, Austria (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate whether machine learning (ML) models using selected clinical and radiomics features acquired from pre-therapeutic, B-mode breast ultrasound (US) can predict response to neoadjuvant chemotherapy (NAC).*Methods and Materials 253 patients with histologically confirmed invasive breast cancer who underwent NAC were included in this retrospective, IRB-approved study. A representative B-mode US image of each tumor from the baseline examination was selected. Tumors were manually segmented (with and without inclusion of surrounding tissue) and overall 851 radiomic features were extracted using dedicated software. Two analysis approaches were followed: on the one hand, principal component analysis (PCA) was used for feature reduction and a multilayer perceptron (MLP) artificial neural network was trained using the remaining US radiomic and selected clinical features. 1/3 of the cases were withheld and used as an external validation set. The rest of the dataset was split into 75% and 25% for training and testing the model. On the other hand, a decision tree using the exhaustive chi-squared automatic interaction detection method with 10-fold cross validation was constructed. Postoperative histology was the reference standard. Pathological complete response (pCR) was defined as the lack of invasive tumor in the breast or metastases in the axillary lymph-nodes. Diagnostic performance of each method was evaluated by means of the area under the ROC-curve (AUC).*Results 104 patients (41.1%) achieved pCR. In the

first model, 69 radiomic features remained after PCA and were combined with clinical features to train the MLP. In the validation set, the combination of radiomic features, age and molecular subtype showed the highest AUC, both for the tumor containing ROI (0.715; 95%CI: 0.606-0.809) and for the ROI containing peritumoral tissue as well (0.709; 95%CI: 0.599-0.803; p>0.05). The model resulted in 66.3% of correct classifications only considering the tumor ROI and 55.4% using the ROI containing peritumoral tissue in the validation set. On the other hand, decision trees based on molecular subtype and 5-6 radiomic features showed AUCs of 0.852 (95%CI: 0.802-0.893) for the tumor-only ROI and 0.896 (95%CI: 0.852-0.931) for the ROI containing peritumoral tissue as well (p>0.05). The corresponding percentages of correct classifications were 83.4% and 82.6%.*Conclusions ML models based on radiomic features from baseline B-mode breast US examinations and simple clinical features have the potential to predict response to NAC.*Clinical Relevance/Application Machine learning using simple clinical and sonographic radiomic features from breast tumors may help predict response to neoadjuvant chemotherapy even before its initiation.

RESULTS

104 patients (41.1%) achieved pCR. In the first model, 69 radiomic features remained after PCA and were combined with clinical features to train the MLP. In the validation set, the combination of radiomic features, age and molecular subtype showed the highest AUC, both for the tumor containing ROI (0.715; 95%CI: 0.606-0.809) and for the ROI containing peritumoral tissue as well (0.709; 95%CI: 0.599-0.803; p>0.05). The model resulted in 66.3% of correct classifications only considering the tumor ROI and 55.4% using the ROI containing peritumoral tissue in the validation set. On the other hand, decision trees based on molecular subtype and 5-6 radiomic features showed AUCs of 0.852 (95%CI: 0.802-0.893) for the tumor-only ROI and 0.896 (95%CI: 0.852-0.931) for the ROI containing peritumoral tissue as well (p>0.05). The corresponding percentages of correct classifications were 83.4% and 82.6%.

CLINICAL RELEVANCE/APPLICATION

Machine learning using simple clinical and sonographic radiomic features from breast tumors may help predict response to neoadjuvant chemotherapy even before its initiation.

BR04-B6   Cortical Thickness Of Axillary Lymph Nodes As An Indicator For Lymph Node Metastases

Participants
Maximilian Moreth, Frankfurt am Main, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To determine the role of cortical thickness as an indicator for several scenarios of lymph node metastasis during axillary ultrasound (AUS).*Methods and Materials During four years, 593 breast cancer patients had received an axillary ultrasound during clinical work-up and were retrospectively included in this study. Lymph nodes were defined as suspicious whenever they showed a cortical thickness of > 3,0 mm at 11-15 MHz harmonic imaging ultrasound. As golden standard for lymph node involvement core needle biopsy (n = 115), sentinel node dissection or axillary dissection were used. Extensive axillary involvement (EAI) was diagnosed if more than two lymph nodes showed metastatic disease on histology.*Results In 353 out of 593 patients (59,5%), the axilla was correctly classified as N0. Pathological lymph nodes were detected by ultrasound in 140 of the 593 patients (23,6%). False positive ultrasound diagnoses were made in 22 cases (3,7%). In 78 patients (13%), the lymph node metastases were not described by ultrasound. Of these patients, extensive axillary involvement was detected in 14 (17,9%), transcapsular growth of the lymph node metastasis in 27 (34,6%) cases. Based on these data, AUS for detecting all lymph node metastases had a sensitivity (95% CI) of 64,2 % (57,5 - 70,6), a specificity (95% CI) of 94,1% (91,3 - 96,3) and a negative predictive value (95% CI) of 81,9 % (77,9 - 85,4). However, the resulting negative predictive value (95% CI) for transcapsular growth was 92,9% (89,8 - 95,3), and for extensive axillary spread 96,2% (93,7 - 97,9).*Conclusions Using cortical thickness as an indicator for lmpyh node metastasis in axillary ultrasound was moderately efficient for detecting all involved lymph nodes. It was, however, sufficiently efficient for ruling out extensive axillary involvement.*Clinical Relevance/Application Cortical thickness in AUS is a feasable and reliable tool to rule out EAI. It helps to reduce the number of classic axillary dissections and decreases relevant morbidity.

RESULTS

In 353 out of 593 patients (59,5%), the axilla was correctly classified as N0. Pathological lymph nodes were detected by ultrasound in 140 of the 593 patients (23,6%). False positive ultrasound diagnoses were made in 22 cases (3,7%). In 78 patients (13%), the lymph node metastases were not described by ultrasound. Of these patients, extensive axillary involvement was detected in 14 (17,9%), transcapsular growth of the lymph node metastasis in 27 (34,6%) cases. Based on these data, AUS for detecting all lymph node metastases had a sensitivity (95% CI) of 64,2 % (57,5 - 70,6), a specificity (95% CI) of 94,1% (91,3 - 96,3) and a negative predictive value (95% CI) of 81,9 % (77,9 - 85,4). However, the resulting negative predictive value (95% CI) for transcapsular growth was 92,9% (89,8 - 95,3), and for extensive axillary spread 96,2% (93,7 - 97,9).

CLINICAL RELEVANCE/APPLICATION

Cortical thickness in AUS is a feasable and reliable tool to rule out EAI. It helps to reduce the number of classic axillary dissections and decreases relevant morbidity.

BR04-B8   Mammographic Density, Its Changes Over Time And Risk Of Breast Cancer Among A Diverse Cohort Of Women Undergoing Mammography Screening

Participants
Aimilia Gastounioti, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Mammographic density (MD) is a strong risk factor for breast cancer. MD is also a dynamic trait that may change over time, with potential implications for breast cancer risk. However, few studies have assessed the associations between MD change and breast cancer, none focusing on racially diverse populations. This study investigates the relationships between MD and MD change and breast cancer risk in a large, racially diverse, screening cohort.*Methods and Materials We retrospectively analyzed data from 8,468 women (age: median 56 y; BMI: mean 29.2 kg/m2; race: 49.6% Black, 44.7% white, 5.7% other; 65.5% postmenopausal) who underwent = 2 mammographic screening exams at our institution in Sept. 2010 - Dec. 2014 (between-screening interval: median 1.1 years, IQR 1.0-1.5; 20,779 exams in total); 118 women were diagnosed with breast cancer 1-5 years after their screening. LIBRA (v1.0.4) was used to estimate breast percent density (PD) and dense tissue area (DA) from raw digital mammograms (Selenia Dimensions, Hologic Inc.). For each MD measure, we conducted Cox regression analyses to examine the associations between MD, between-screening MD change, and breast cancer risk, adjusting for age, menopausal status, BMI, and race, and accounting for multiple exams per woman.*Results PD at screening was significantly associated with breast cancer risk

(hazard ratio (HR) for PD = 1.04 (95% CI [1.02, 1.06], p < 0.0005), but change in PD was not associated with breast cancer risk (HR for PD change = 1.35 [0.69, 2.64], p = 0.4). Though we observed differences in PD and PD change between Black and White women (p = 0.009), race was not significantly associated with breast cancer risk. Results using DA were essentially identical.*Conclusions Using a large racially diverse cohort, we found no evidence for an association between short-term change in MD and risk of breast cancer, suggesting that MD change may not be a strong predictor for risk.*Clinical Relevance/Application Longitudinal short-term MD changes seem to be of lesser importance from a risk point of view compared to MD, suggesting that short-term MD changes might have minimal effect on breast cancer risk.

RESULTS

PD at screening was significantly associated with breast cancer risk (hazard ratio (HR) for PD = 1.04 (95% CI [1.02, 1.06], p < 0.0005), but change in PD was not associated with breast cancer risk (HR for PD change = 1.35 [0.69, 2.64], p = 0.4). Though we observed differences in PD and PD change between Black and White women (p = 0.009), race was not significantly associated with breast cancer risk. Results using DA were essentially identical.

CLINICAL RELEVANCE/APPLICATION

Longitudinal short-term MD changes seem to be of lesser importance from a risk point of view compared to MD, suggesting that short-term MD changes might have minimal effect on breast cancer risk.

NMMI02-A1 Clinical Utility Of 18F-fluciclovine Pet/ct In Recurrent Prostate Cancer With Very Low (0.3 Ng/ml) Prostate-specific Antigen Levels.

Participants
Charles Marcus, MD, Altanta, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

To assess 18F-fluciclovine PET/CT detection rates in the evaluation of biochemical recurrence in prostate cancer patients with very low (=0.3 ng/mL) serum prostate-specific antigen (PSA) levels following definitive treatment*Methods and Materials Prostate cancer patients with biochemical recurrence and very low serum PSA (=0.3 ng/mL) who underwent clinical 18F-fluciclovine PET/CT were included in this single-institution retrospective study. Data on patient demographics, Gleason scores, primary definitive treatment, and serum PSA at the time of the scan were collected. PET/CT clinical reports at the time of interpretation were reviewed and categorized as positive or negative. In patients who had further evaluation with imaging and/or biopsy, the results were recorded to determine the true detection rate*Results Of the 64 eligible patients with very low serum PSA (median serum PSA of 0.17 ng/mL), 57.8% (37/64) scans were categorized as positive. Stratified by PSA levels, positivity rates were 43.8% (7/16), 60.0% (15/25) and 65.2% (15/23) for PSA <0.1 ng/mL, 0.1-<0.2 ng/mL and 0.2-=0.3 ng/mL, respectively. The most common location of disease was the prostate bed (73%), followed by pelvic lymph nodes (22%) and distant disease (14%). In the small subset of patients who had further evaluation after a positive study (n = 7), all had confirmed disease with a positive predictive value of 100%*Conclusions In prostate cancer patients with biochemical recurrence, 18F-fluciclovine PET/CT is useful in patients with very low serum PSA of =0.3 ng/mL, with a 57.8% positivity rate, higher than previously reported. Though standard of truth could only be ascertained in 19% (7/37) of patients with a positive study, the positive predictive value was 100%*Clinical Relevance/Application Reports on 18F-fluciclovine PET/CT detection rates in patients with biochemical prostate cancer recurrence with very low serum PSA has been highly variable, ranging from 0-56%. Our study results demonstrate high detection rates, even in patients with very low serum PSA and shows that 18F-fluciclovine PET/CT is useful in the evaluation of this patient cohort.

RESULTS

Of the 64 eligible patients with very low serum PSA (median serum PSA of 0.17 ng/mL), 57.8% (37/64) scans were categorized as positive. Stratified by PSA levels, positivity rates were 43.8% (7/16), 60.0% (15/25) and 65.2% (15/23) for PSA <0.1 ng/mL, 0.1-<0.2 ng/mL and 0.2-=0.3 ng/mL, respectively. The most common location of disease was the prostate bed (73%), followed by pelvic lymph nodes (22%) and distant disease (14%). In the small subset of patients who had further evaluation after a positive study (n = 7), all had confirmed disease with a positive predictive value of 100%

CLINICAL RELEVANCE/APPLICATION

Reports on 18F-fluciclovine PET/CT detection rates in patients with biochemical prostate cancer recurrence with very low serum PSA has been highly variable, ranging from 0-56%. Our study results demonstrate high detection rates, even in patients with very low serum PSA and shows that 18F-fluciclovine PET/CT is useful in the evaluation of this patient cohort.

NMMI02-A3 Classification Of Mediastinal Lymph Node Metastasis Of Non-small Cell Lung Cancer: Improved Performance By Incorporating Primary Tumor Features

Participants
Stephan Blazis, Dordrecht, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

This study investigates and compares a range of prediction models and the incorporation of primary tumor features to differentiate between FDG-avid malignant and benign mediastinal lymph nodes that could possibly improve the preoperative staging of lung cancer patients.*Methods and Materials We performed a retrospective analysis of 173 patients from two hospitals aging from 43 to 89 years comprising 101 men and 72 women (mean age 68 years); who underwent FDG PET-CT for primary staging of pathologically confirmed non-small cell lung cancer (NSCLC). For the annotation and segmentation of the primary tumors and hilar lymph nodes in the PET-CT images, ROIs were manually drawn and the resulting dataset combined with the pathology findings was used as the "ground truth". Diagnostic features were extracted from the PET data only and consisted of the SUV (mean and max) and tumor size for both the primary tumors as the lymph nodes. The resulting dataset was used for training and testing the developed prediction models at a 70/30 ratio. A comparison was performed for four different prediction models: A simple thresholding model based on the maximal SUV value of the lymph nodes. The second model is a classical machine learning Random Forest model based on the diagnostic features of the lymph nodes only, which was extended to a third model by incorporating the primary tumor diagnostic features. Finally, a CNN model based on the segmented lymph nodes and extended with the primary tumor SUV mean and max values was trained. The performance of the prediction models was evaluated by the area under the curve operating characteristic (AUC) and the diagnostic accuracy (ACC) value. For clinical comparison, a performance point of human doctors from a similar study was added to the results.*Results The ACC values of the four evaluated models ranged from 0.62 to 0.92 and the AUC values from 0.83 to 0.94. A significant difference was found between the Random Forest model with and without primary tumor features (ACC 0.79-0.83 and AUC 0.86-0.94). The simple thresholding model performed similarly in AUC(0.83) to the CNN model

(0.84). but the CNN model showed a significantly higher accuracy (0.83-0.63).*Conclusions This study showed that incorporating the diagnostic features of the primary tumor can significantly improve performance for the classification of lymph node metastasis of NSLCL from PET-CT images.*Clinical Relevance/Application Incorporating diagnostic features of the primary tumor into the development of prediction models significantly improves the performance of model-based lymph node metastasis classification and could replace the use of costly and invasive procedures such as endobronchial ultrasound or mediastinoscopy procedures for NSCLC patients.

RESULTS

The ACC values of the four evaluated models ranged from 0.62 to 0.92 and the AUC values from 0.83 to 0.94. A significant difference was found between the Random Forest model with and without primary tumor features (ACC 0.79-0.83 and AUC 0.86-0.94). The simple thresholding model performed similarly in AUC(0.83) to the CNN model (0.84). but the CNN model showed a significantly higher accuracy (0.83-0.63).

CLINICAL RELEVANCE/APPLICATION

Incorporating diagnostic features of the primary tumor into the development of prediction models significantly improves the performance of model-based lymph node metastasis classification and could replace the use of costly and invasive procedures such as endobronchial ultrasound or mediastinoscopy procedures for NSCLC patients.

NMMI02-A4 68Ga PSMA PET Is A Better Imaging Modality Than Multiparametric Mr In Biochemical Recurrent Disease.

Participants
juana martinez, MD,MD, NEW YORK, New York (*Presenter*) Nothing to Disclose

PURPOSE

68Ga Prostate Specific Membrane Antigen (PSMA) positron emission tomography (PET) improved the detection rate of prostate cancer related lesions compared with conventional imaging. PSMA PET combined with magnetic resonance imaging (MRI) has the advantages of both PET and MRI modalities, is a promising technique in the evaluation of patients with prostate cancer. Here, we compare PSMA PET with concomitant multiparametric MRI in detecting lesions suspicious for biochemical recurrence. We hypothesize that PSMA PET is a more robust modality for biochemical recurrence with the potential of identifying small lesions which would otherwise be dismissed on MRI alone.*Methods and Materials A review of all patients with prostate cancer who prospectively enrolled in a HIPAA-compliant, IRB-approved clinical trial of 68Ga PSMA PET/MRI done at New York Presbyterian Hospital - Weill Cornell campus from April 2018 to January 2021 was performed. Per protocol, Nuclear Medicine physicians read the PSMA PET portion of the study while a radiologist with fellowship training in cancer imaging read the MRI of the skull base to thigh, independent of each other. Patient demographics, the indication for PSMA PET/MRI, and serum prostate specific antigen (PSA) levels closest to the PSMA PET/MRI (within 60 days before the study and 30 days after the study) were extracted from patient charts.*Results There were 165 patients who had a PSMA PET/MRI, of whom 109 where imaged for biochemical recurrence. From our findings, PSMA PET was able to detect more lesions suspicious for recurrence than MRI at all PSA levels (Figure 1). After subgrouping the sample to only include patients who had PSMA PET/MRI for biochemical recurrent disease, PSMA PET fared superiorly at all PSA levels in comparison to MRI (Figure 2). An example of PSMA PET/MRI where an abnormal lesion was detected on PET for benign morphology on MRI is depicted in Figure 3.*Conclusions 68Ga PSMA PET has high utility in detection of suspicious lesions in biochemically recurrent prostate cancer. When compared with MRI, PSMA PET is highly robust in identifying lesions which are otherwise deemed unremarkable.*Clinical Relevance/Application We recommend the use of 68Ga PSMA PET/MR for biochemical recurrent prostate cancer with potential to be the new standard of care for this indication.

RESULTS

There were 165 patients who had a PSMA PET/MRI, of whom 109 where imaged for biochemical recurrence. From our findings, PSMA PET was able to detect more lesions suspicious for recurrence than MRI at all PSA levels (Figure 1). After subgrouping the sample to only include patients who had PSMA PET/MRI for biochemical recurrent disease, PSMA PET fared superiorly at all PSA levels in comparison to MRI (Figure 2). An example of PSMA PET/MRI where an abnormal lesion was detected on PET for benign morphology on MRI is depicted in Figure 3.

CLINICAL RELEVANCE/APPLICATION

We recommend the use of 68Ga PSMA PET/MR for biochemical recurrent prostate cancer with potential to be the new standard of care for this indication.

HN01-B1 **CT-based Iterative Metal Artefact Reduction In Patients With Head And Neck Abscess**

Participants
Ibrahim Yel, MD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to evaluate the impact of a CT-based iterative metal artefact (iMAR) algorithm on image quality in patients with head and neck abscess and dental implants.*Methods and Materials A total of 80 patients with dental implants and head and neck abscess were retrospectively reconstructed with iMAR. Two senior radiologists specialized with 6 and 10 years of experience evaluated standard and iMAR reconstructed CT images for subjective and objective image quality, metal artefacts, and delineation of the abscess based on a 5-point-rating-scale. Interobserver agreement was calculated using the Cohens Kappa.*Results Compared with uncorrected images, iMAR showed a significant artefact reduction from -480 HU to 53 HU in all patients (P < 0.001). Subgroup analysis of 38 patients with abscess and metal artifacts on equivalent anatomic levels showed a significantly higher objective and subjective noise reduction for iMAR images (P =0.005 and P = 0.028). Furthermore, iMAR images were rated superior regarding image quality, artefact reduction, and lesion delineation. Interrater agreement was excellent for overall image quality (? = .88), artefact reduction (? = .91), and lesion delineation (? = .95).*Conclusions CT images using iMAR significantly improve image quality and lesion delineation of head and neck abscesses in patients with dental hardware.*Clinical Relevance/Application Implementation of an iterative metal artefact reduction algorithm for CT imaging of head and neck abscess in patients with dental implants improves image quality and diagnostic accuracy.

RESULTS

Compared with uncorrected images, iMAR showed a significant artefact reduction from -480 HU to 53 HU in all patients (P < 0.001). Subgroup analysis of 38 patients with abscess and metal artifacts on equivalent anatomic levels showed a significantly higher objective and subjective noise reduction for iMAR images (P =0.005 and P = 0.028). Furthermore, iMAR images were rated superior regarding image quality, artefact reduction, and lesion delineation. Interrater agreement was excellent for overall image quality (? = .88), artefact reduction (? = .91), and lesion delineation (? = .95).

CLINICAL RELEVANCE/APPLICATION

Implementation of an iterative metal artefact reduction algorithm for CT imaging of head and neck abscess in patients with dental implants improves image quality and diagnostic accuracy.

HN01-B2 **Comparison Study Of Spectral Energy Mode Scans And Non-spectral Energy Mode Scans Combined With Adaptive Statistical Iterative Reconstruction-veo Algorithm On Thyroid Scan**

Participants
Zhaorong Tian, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the effects of spectral energy mode scans and non-spectral energy mode scans combined with Adaptive Statistical Iterative Reconstruction-Veo (ASiR-V) on image quality and radiation dose in thyroid scan.*Methods and Materials Forty-six patients prepared for CT thyroid scan were collected prospectively. They were labeled as group A and group B . Group A was set as spectral energy scanning mode with tube voltage fast kV switch (80/140 kV). Group B was set as non-spectral energy scanning mode with tube voltage 120kVp. Two groups of ASiR-V images with different levels (1: 0%,2:20%, 3: 40%, 4: 60%, 5: 80% and6: 100%) were reconstructed for comparative analysis. Group A was divided into A1, A2, A3, A4, A5 and A6 according to different ASiR-V levels. Similarly, group B was divided into B1- B6. Region of interest(ROI)was delineated at the maximum level of thyroid parenchyma . CT values and background noise (SD) of ROI in twelve groups were measured and compared respectively. The dose length product (DLP) of each scan was recorded after scanning, and the value of effective dose (ED) was calculated according to the formula: ED(mSv)=k(mSv*mGy-1*cm-1)*DLP(mGy*cm). The subjective image scores were assessed blindly by two experienced physicians using a 5-point system. The differences of SD among different ASiR-V groups were compared by one-way analysis of variance, and the differences of subjective scoring were compared by Kappa test.*Results The SD values of group A1- A6 image were (35.98±8.23)HU, (30.65±5.57)HU, (27.25±7.28)HU, (22.93±7.09)HU, (19.14±7.10)HU, (15.78±7.70)HU, respectively. The SD values of group B1-B6 were (29.98±7.68) HU, (26.69±7.36) HU, (22.79±6.16) HU, (18.27±6.14) HU, (15.19±5.31) HU, (11.81±5.04) HU, respectively. There was statistically significant difference of SD value on same ASiR-V between energy spectrum and non-energy spectrum scan (P<0.05). DLP of energy spectrum and non-spectrum scanning were (279.16±39.08) mGy*cm and (305.92±62.84) mGy*cm, respectively. The energy spectral scans decreased by 9.59% compared with non-spectrum. Subjective scores showed that the optimal ASiR-V of energy spectrum scans and non-spectral scans was 80%, and the Kappa values of consistency between two observers were 0.56, respectively.*Conclusions Combined with subjective scores, this study concluded that 80% ASiR-V can significantly improve the image quality of thyroid on energy spectrum scans and non-spectrum scans, and the radiation dose of energy spectrum scans decreases by 9.59% compared with that of non-spectrum scans.*Clinical Relevance/Application The level of ASiR-V can be used to optimize the image quality of energy spectrum and non-spectrum scans,which can be used in clinical examiation.

RESULTS

The SD values of group A1- A6 image were (35.98±8.23)HU, (30.65±5.57)HU, (27.25±7.28)HU, (22.93±7.09)HU, (19.14±7.10)HU, (15.78±7.70)HU, respectively. The SD values of group B1-B6 were (29.98±7.68) HU, (26.69±7.36) HU, (22.79±6.16) HU, (18.27±6.14) HU, (15.19±5.31) HU, (11.81±5.04) HU, respectively. There was statistically significant difference of SD value on same ASiR-V between energy spectrum and non-energy spectrum scan (P<0.05). DLP of energy spectrum and non-spectrum scanning were (279.16±39.08) mGy*cm and (305.92±62.84) mGy*cm, respectively. The energy spectral scans decreased by 9.59% compared with non-spectrum. Subjective scores showed that the optimal ASiR-V of energy spectrum scans and non-spectral scans was 80%, and the Kappa values of consistency between two observers were 0.56, respectively.

CLINICAL RELEVANCE/APPLICATION

The level of ASiR-V can be used to optimize the image quality of energy spectrum and non-spectrum scans,which can be used in clinical examiation.

HN01-B3   Visualization Of The Saccule And Utricle With Non-contrast-enhanced Flair Sequences.

Participants
Hikaru Fukutomi, Kyoto, Japan (*Presenter*) Technical support, Canon Medical Systems Corporation

PURPOSE

3D-FLAIR sequence collected four hours after gadolinium injection can delineate the perilymphatic space (PLS) from the endolymphatic space (ELS) to capture endolymphatic hydrops, the pathological counterpart of Ménière's disease. However, satisfactory delineation without injection has not been reported in the literature yet. Because the PLS and ELS protein concentrations are different, we hypothesized that non-injected 3D-FLAIR using an optimal setting of imaging parameters would allow visualization of inner ear internal anatomy.*Methods and Materials Twenty-two healthy subjects (11 men, and 11 women), 22-42 years old (mean: 29), with no history of inner ear disorders were scanned on 3T MRI unit (Vantage Galan 3T/ZGO, Canon Medical Systems Corporation, Tochigi, Japan) with a 32-channel array head coil. All subjects were scanned with non-injected 3D-FLAIR with variable T2 preparations (T2Preps) (OFF, 200, 400, and 600 ms), variable inversion times (TIs) (from 224 to 5000 ms) and different resolution (intermediate: 1.0×1.0×1.5 mm3, high: 0.6×0.6×0.8 mm3 and higher: 0.6×0.6×0.6 mm3). For all images, we used a denoising approach with deep learning-based reconstruction. Relative contrast between PLS and ELS was assessed and compared with Welch's t-test on intermediate resolution. The saccule and utricle's visibility were assessed with signal curve analysis on the reference line cross the two structures and compared between high and higher resolution.*Results The PLS and ELS were only differentiated with T2Prep. The maximum relative contrast between them was larger with T2Prep of 400 ms than 200 or 600 ms (0.72±0.22 vs. 0.44±0.11, p=0.019; and 0.72±0.22 vs. 0.46±0.28, p=0.034, respectively). The saccule and utricle were best delineated in 87.5 % cases when using T2Prep of 400 ms and TI of 2100 ms at the higher resolution (0.6×0.6×0.6 mm3). The optimized non-injected 3D-FLAIR images were consistent with anatomical knowledge and looked very similar to the images from the literature when using an injected 3D-FLAIR.*Conclusions For inner ear exploration, combining a specific T2Prep and TI on a non-injected 3D-FLAIR could provide a high enough contrast to separate the PLS and ELS and even a good delineation of the saccule and utricle.*Clinical Relevance/Application The results of this study pave the way toward future application to diagnose Ménière's disease.

RESULTS

The PLS and ELS were only differentiated with T2Prep. The maximum relative contrast between them was larger with T2Prep of 400 ms than 200 or 600 ms (0.72±0.22 vs. 0.44±0.11, p=0.019; and 0.72±0.22 vs. 0.46±0.28, p=0.034, respectively). The saccule and utricle were best delineated in 87.5 % cases when using T2Prep of 400 ms and TI of 2100 ms at the higher resolution (0.6×0.6×0.6 mm3). The optimized non-injected 3D-FLAIR images were consistent with anatomical knowledge and looked very similar to the images from the literature when using an injected 3D-FLAIR.

CLINICAL RELEVANCE/APPLICATION

The results of this study pave the way toward future application to diagnose Ménière's disease.

NMMI03-C3 Correlation Of Functional MRI With Changes In Tumor Microenvironment Following Sorafenib And Immunotherapy In Hepatocellular Carcinoma

Participants
Yanqiao Ren, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

Previously, few studies have focused on the dynamic monitoring of the tumor microenvironment changes during anti-vascular therapy and immunotherapy. Here, we used serial multimodal structural and functional magnetic resonance imaging (MRI) dynamic early assessment of tumor microenvironmental changes in HCC after treatment with sorafenib and anti-PD-L1 antibody and elucidate the synergistic mechanism.*Methods and Materials Subcutaneous syngeneic HCC tumors were established in the right flanks of C57/BL6 mice. Mice were longitudinally scanned using T1/T2-weighted MRI, diffusion-weighted (DW) MRI, and magnetic resonance spectroscopy (MRS) 1 day before and on days 7, 14 and 21 after treatment initiation to determine tumor size, necrosis area, apparent diffusion coefficient (ADC) value, and tumor metabolites including lactate. At indicated days later, the tumor-bearing mice were euthanized, and tumor tissues were harvested for further analysis including western blotting and qPCR array, immunohistochemistry, and immunofluorescence.*Results We treated 6-week-old C57/BL6 mice with subcutaneous tumor volume of about 80-120mm3 with daily sorafenib (50mg/kg) gavage or intraperitoneal injection of anti-PD-L1 antibody (10mg/kg) every 3 days, and control mice with intraperitoneal injection of isotype-matched IgG antibody (10mg/kg) every 3 days (Fig. 1A). Compared to sorafenib or anti-PD-L1 antibody, combination therapy of sorafenib and anti-PD-L1 antibody markedly retarded tumor growth increased tumor necrosis area, and led to increases in ADC value (Fig. 2, A-C). However, T1 mapping showed no significant difference in T1 values between the four groups at different time points (Fig. 1, D-E). Excessive pruning of tumor vessels by sorafenib resulted in increased tumor hypoxia in the tumor microenvironment, and MRS showed an enhancement of lactate levels (Fig. 3, A-D). Hypoxia causes drug resistance and high expression of PD-L1 in tumor cells, leading to immunosuppressive microenvironment (Fig.3, C and E).*Conclusions These imaging methods serve as a unique and non-invasive MRI biomarker for the early dynamic evaluation of tumor microenvironment changes after anti-vascular treatment and immunotherapy for HCC.*Clinical Relevance/Application The findings of this study are conducive to the establishment of an accurate correlation between imaging features-microenvironment characteristics-tumor anti-vascular treatment and immunotherapy, and the realization of scientific and precise individualized treatment of HCC.

RESULTS

We treated 6-week-old C57/BL6 mice with subcutaneous tumor volume of about 80-120mm3 with daily sorafenib (50mg/kg) gavage or intraperitoneal injection of anti-PD-L1 antibody (10mg/kg) every 3 days, and control mice with intraperitoneal injection of isotype-matched IgG antibody (10mg/kg) every 3 days (Fig. 1A). Compared to sorafenib or anti-PD-L1 antibody, combination therapy of sorafenib and anti-PD-L1 antibody markedly retarded tumor growth increased tumor necrosis area, and led to increases in ADC value (Fig. 2, A-C). However, T1 mapping showed no significant difference in T1 values between the four groups at different time points (Fig. 1, D-E). Excessive pruning of tumor vessels by sorafenib resulted in increased tumor hypoxia in the tumor microenvironment, and MRS showed an enhancement of lactate levels (Fig. 3, A-D). Hypoxia causes drug resistance and high expression of PD-L1 in tumor cells, leading to immunosuppressive microenvironment (Fig.3, C and E).

CLINICAL RELEVANCE/APPLICATION

The findings of this study are conducive to the establishment of an accurate correlation between imaging features-microenvironment characteristics-tumor anti-vascular treatment and immunotherapy, and the realization of scientific and precise individualized treatment of HCC.

SDP-PH-1   A Phantom Prototype For The Quantitative Evaluation Of The Dynamic Performance Of Flat-panel Detectors

Participants
Kwan Wai Li, Hong Kong, Hong Kong (*Presenter*) Nothing to Disclose

PURPOSE

The phantoms and experimental setups for the quantitative evaluation of the static performance of digital radiographic detectors have been well established for a long time. Although instantaneous image lag artifact is common and important in fluoroscopy and cine acquisition, standard for the quantitative evaluation of this artifact is yet to be developed. In this study, an in-house fabricated phantom is used to address this issue.*Methods and Materials The phantom consisted of a brushed DC geared motor driven by a battery-powered pulse width modulation (PWM) DC motor speed controller and two circular acrylic discs with different test patterns that could be rotated by the motor interchangeably. The first test pattern had three clinically used guidewires of diameters 0.46 mm, 0.63 mm and 0.89 mm equally spaced at 60° from each other. The second pattern had eight rows of holes equally spaced at 45° from each other, drilled at depths of 1.5 mm, 2 mm, 2.5 mm, 3 mm, 3.5 mm, 4 mm, 5 mm and 5.5 mm representing different contrast ratios, with six holes of diameters from 1 mm to 6 mm at 1 mm intervals in each row. The phantom was tested using Siemens Artis zee with PURE multi-purpose system equipped with an indirect-conversion flat-panel detector for fluoroscopy and angiography. The phantom rotation speed could be adjusted manually by the knob on the PWM controller and was set at 3 rpm, 15 rpm and 30 rpm to simulate cardiac wall motion speed at different heart rates. The phantom was placed at the isocenter and its fluoroscopic and cine acquisition images were acquired using the default digital subtraction angiography body protocol provided by the manufacturer.*Results Image retention was observed in both patterns for some settings of the protocol at 15 rpm and 30 rpm due to residual signals from previous acquisitions and image processing such as recursive filtering which temporally averaged images. For the first pattern, ghosting was quantitatively evaluated by plotting the pixel intensity profile across the guidewires or measuring the widening of the guidewires. For the second pattern, ghosting was quantitatively evaluated by measuring the normalized pixel values of the regions-of-interest (ROIs) at each pulse and counting the number of pulses the residual signal faded completely, with the size of the ROIs covering 80% of the area of the low-contrast targets at the first pulse.*Conclusions We have developed a portable phantom and simple quantitative methods to fine-tune the image processing parameters of imaging protocols used in angiography where dynamic performance is important.*Clinical Relevance/Application The portable phantom can be used for the optimization of image processing parameters when setting up clinical imaging protocols during acceptance of angiography machines.

RESULTS

Image retention was observed in both patterns for some settings of the protocol at 15 rpm and 30 rpm due to residual signals from previous acquisitions and image processing such as recursive filtering which temporally averaged images. For the first pattern, ghosting was quantitatively evaluated by plotting the pixel intensity profile across the guidewires or measuring the widening of the guidewires. For the second pattern, ghosting was quantitatively evaluated by measuring the normalized pixel values of the regions-of-interest (ROIs) at each pulse and counting the number of pulses the residual signal faded completely, with the size of the ROIs covering 80% of the area of the low-contrast targets at the first pulse.

CLINICAL RELEVANCE/APPLICATION

The portable phantom can be used for the optimization of image processing parameters when setting up clinical imaging protocols during acceptance of angiography machines.

SDP-PH-10   Measurement Of Directional Task-based Modulation Transfer Function At Abdominal CT: A Phantom Study

Participants
Toru Higaki, PhD, Minami-ku, Hiroshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

A modulation transfer function (MTF) is an index of spatial resolution of CT images. MTFs depend on contrast of a target object in non-linear image reconstruction methods such as iterative reconstruction (IR), and task contrast-based modulation transfer function (TTF) have been proposed. TTF is generally measured by the circular edge method, but direction dependence is not taken into consideration. This study aimed to investigate the direction-dependency of the TTF using a 3D printed abdominal phantom.*Methods and Materials We made two phantoms, one was a simple cylindrical phantom, the other was a structured phantom that simulated abdominal CT (Fig. left). The outer size of each phantom was 200×200 mm and 300×200 mm, respectively. Each phantom harbored a simulated low-contrast tumor, which was filled with diluted iodine contrast medium with 4.0 mgI/ml.We scanned the phantoms with our standard abdominal scan protocol (tube voltage: 120 kV, tube current: automatic exposure control with preset image noise 12 HU) 200 times repeatedly. We reconstructed images using hybrid IR (AIDR 3D with FC13 kernel, Canon Medical Systems Corp). We generated an average image from 200 repeated scans to reduce image noise for each phantom. We measured directional TTF using the circular edge method on the simulated low-contrast lesion. We divided 360 degrees into 8 parts

every 45 degrees and recorded the average TTF for each part. We recorded 50, 20, 10 and 5% TTF values for each direction and created a radar chart.*Results The CTDIvol of the cylindrical and abdominal phantom were 4.9 and 9.5 mGy, respectively. The 50, 20, 10, and 5% TTF of the cylindrical phantom were 0.316±0.012 (mean ± standard deviation [SD]), 0.496±0.023, 0.603±0.026, and 0.697±0.026 cy/mm, respectively. The 50, 20, 10, and 5% TTF of the structured abdominal phantom were 0.303±0.019, 0.476±0.035, 0.577±0.044, and 0.667±0.051 cy/mm, respectively. The SD of the directional TTF values in the structured abdominal phantom were higher than that of the cylindrical phantom, and the radar chart also showed that it was highly directionally dependent (Fig. right).*Conclusions TTFs in asymmetrically shaped objects vary from direction to direction.*Clinical Relevance/Application Due to the orientation dependence of TTF in non-rotationally symmetric objects such as the human body, the appearance of tumors may differ from direction to direction.

RESULTS

The CTDIvol of the cylindrical and abdominal phantom were 4.9 and 9.5 mGy, respectively. The 50, 20, 10, and 5% TTF of the cylindrical phantom were 0.316±0.012 (mean ± standard deviation [SD]), 0.496±0.023, 0.603±0.026, and 0.697±0.026 cy/mm, respectively. The 50, 20, 10, and 5% TTF of the structured abdominal phantom were 0.303±0.019, 0.476±0.035, 0.577±0.044, and 0.667±0.051 cy/mm, respectively. The SD of the directional TTF values in the structured abdominal phantom were higher than that of the cylindrical phantom, and the radar chart also showed that it was highly directionally dependent (Fig. right).

CLINICAL RELEVANCE/APPLICATION

Due to the orientation dependence of TTF in non-rotationally symmetric objects such as the human body, the appearance of tumors may differ from direction to direction.

SDP-PH-11 Super-resolution Deep Learning Reconstruction At CT: A Phantom Study For Coronary CT Angiography

Participants
Toru Higaki, PhD, Minami-ku, Hiroshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

In this study, we newly developed a super-resolution deep learning reconstruction (SR-DLR), converting conventional- to high-resolution CT images. We evaluated the diagnostic potential of the SR-DLR using a coronary CT angiography (CCTA) phantom with a 3D printer.*Methods and Materials The SR-DLR was implemented using a super-resolution DCNN (SR-DCNN). It was trained with pairs of high-resolution- and conventional resolution images (Fig. left-top). The high-resolution images were acquired using an actual ultra-high-resolution CT scanner (Aquilion Precision, Canon Medical Systems Corp.: CMSC), and reconstructed with deep learning based reconstruction. In order to virtually generate conventional resolution images, firstly, the super-high-resolution sinograms were down-sized, and then they were reconstructed with a conventional reconstruction method. We made a CCTA phantom (Fig. left-bottom) using a 3D printer (Agilista-3200, Keyence). Outer diameter of the phantom was 350×250 mm. Iodine contrast medium diluted with 20 mgI/ml was filled to the simulated left ventricle and coronary arteries, and there was a 70% stenosis in the simulated coronary arteries. We scanned the CCTA phantom using a conventional CT scanner (Aquilion ONE GENESIS, CMSC) with standard CCTA protocol (tube voltage: 120 kV, tube current: automatic exposure control with SD 23 HU, rotation speed: 0.275 s/rot, ECG-gated volume scan). Images were reconstructed with the SR-DLR and conventional hybrid iterative reconstruction (IR) (Adaptive Iterative Dose Reduction 3D with FC14 kernel, CMSC). We measured image noise, noise power spectrum (NPS), and modulation transfer function (MTF).*Results The image noise of the images reconstructed with SR-DLR and hybrid IR were 16.5- and 24.4 HU. In NPS, low-frequency noise was reduced on the SR-DLR image (Fig. right-top). The spatial resolution of the SR-DLR image was superior to the hybrid IR, 10% MTF values were 1.09 and 0.67 cy/mm, respectively. Margin of the simulated stenosis was more clearly delineated in SD-DLR- than hybrid IR image (Fig. right-bottom).*Conclusions The SR-DLR improved not only spatial resolution but also image noise.*Clinical Relevance/Application The super-resolution deep learning reconstruction may improve the diagnostic ability of coronary CT angiography.

RESULTS

The image noise of the images reconstructed with SR-DLR and hybrid IR were 16.5- and 24.4 HU. In NPS, low-frequency noise was reduced on the SR-DLR image (Fig. right-top). The spatial resolution of the SR-DLR image was superior to the hybrid IR, 10% MTF values were 1.09 and 0.67 cy/mm, respectively. Margin of the simulated stenosis was more clearly delineated in SD-DLR- than hybrid IR image (Fig. right-bottom).

CLINICAL RELEVANCE/APPLICATION

The super-resolution deep learning reconstruction may improve the diagnostic ability of coronary CT angiography.

SDP-PH-12 Physical Characteristics Of A New Photon-counting Detector CT Scanner: Comparison Of The Contrast-to-noise Ratio And The Noise Power Spectrum With Those On Conventional Energy-integrated Detector CT

Participants
Toru Higaki, PhD, Minami-ku, Hiroshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

FUJIFILM Healthcare Corporation developed a photon-counting detector CT (PCD-CT) scanner that features a photon sensor was made of CdZnTe. It has two scan modes, multi-energy discrimination (MED) mode where 3x3 detector pixels are bundled [detector pixel pitch (DPP) 0.58x0.63 mm, the same as the conventional energy-integrated detector CT (EID-CT)]. It can obtain projection data from four energy bins. The other is the ultra-high resolution (UHR) mode where each detector pixel is used separately; it can obtain high spatial resolution images (DPP: 0.19x0.21 mm) with projection data of one energy bin. We compared the contrast-to-noise ratio (CNR) of virtual monochromatic images (VMIs) obtained with the MED mode of the PCD-CT- and the conventional 120 kV images of the EID-CT scanner.*Methods and Materials A prototype PCD-CT scanner was built on the platform of a conventional EID-CT scanner (SCENARIA View, FUJIFILM Healthcare Corporation). We used a home-made phantom for PCD-CT and EID-CT scanning. The scan parameters were scan field-of-view 42.6 cm, tube voltage 120 kV, tube current time product 300 mAs, tube focal spot 0.7x0.8 mm, view rate 2880 view/sec, slice thickness 1.25 mm, matrix size 512x512, reconstruction with filtered back projection (kernel: abdominal sharp) on both instruments. The number of energy bin of the PCD-CT was 4. The phantom consisted of a cylindrical acrylic 20-cm diameter background [54 Hounsfield units (HU)] and 1.5-cm diameter cylindrical modules filled with iodine solution (2-, 10-, 15-, and 40 mgI/ml). We measured the CNR of each module.*Results For all modules the CNR of the PCD-

CT was the largest (55 - 65 keV). The maximum CNR of the PCD-CT for modules with 2-, 10-, 15-, and 40 mgI/ml was 6.1, 58.6, 94.6, and 265.6, respectively; the corresponding CNR of the EID-CT was 1.1, 49.8, 80.3, and 231.3. The noise power spectrum of PCD-CT and EID-CT was almost identical.*Conclusions The CNR was better in the SR mode of the PCD-CT than the EID-CT.*Clinical Relevance/Application As contrast resolution is better in the SR mode of PCD-CT- than on EID-CT images, it may be superior for identifying soft tissue tumors such as liver tumors.

RESULTS

For all modules the CNR of the PCD-CT was the largest (55 - 65 keV). The maximum CNR of the PCD-CT for modules with 2-, 10-, 15-, and 40 mgI/ml was 6.1, 58.6, 94.6, and 265.6, respectively; the corresponding CNR of the EID-CT was 1.1, 49.8, 80.3, and 231.3. The noise power spectrum of PCD-CT and EID-CT was almost identical.

CLINICAL RELEVANCE/APPLICATION

As contrast resolution is better in the SR mode of PCD-CT- than on EID-CT images, it may be superior for identifying soft tissue tumors such as liver tumors.

SDP-PH-13 Deep-learning-based Lumen Extraction Method To Improve The Diagnostic Performance To Detect Significant Stenosis In Coronary CT Angiography With Severe Calcification

Participants
Hidekazu Inage, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance of a deep-learning-based lumen extraction method (DL-LEM) to detect significant stenosis on coronary CT angiography (CCTA) in patients with severe coronary calcification.*Methods and Materials DL-LEM was trained using 900 CCTA and non-contrast CT datasets to produce virtual non-contrast CT images. Lumen images were created by subtracting the virtual non-contrast CT images from the original CCTA images. We tested the DL-LEM images using datasets of 99 patients with severe coronary calcification who underwent invasive coronary angiography (ICA). One radiologist and one radiological technologist evaluated the stenosis severity of the DL-LEM images and the original CCTA images. We compared the diagnostic accuracy to detect significant stenosis (diameter stenosis =50%) between the two methods with ICA as the reference standard.*Results Of the 891 segments, 228 segments were determined as significant stenosis due to severe calcification in the original CCTA images. DL-LEM improved the per-segment diagnostic accuracy from 73.5% to 74.6%, and the AUC improved from 0.751 to 0.762 (p = 0.019). When analyzing the 228 segments that could not be evaluated due to severe calcification on the original CCTA images, DL-LEM improved the accuracy from 35.5% to 41.2%, and the AUC improved from 0.500 to 0.581 (p = 0.0009).*Conclusions DL-LEM might be useful to improve the diagnostic performance to detect significant stenosis in patients with severe calcification.*Clinical Relevance/Application This preliminary study suggests that patients with severe coronary calcification might defer catheter angiography if a deep-learning-based model confirms the lumen is not stenotic.

RESULTS

Of the 891 segments, 228 segments were determined as significant stenosis due to severe calcification in the original CCTA images. DL-LEM improved the per-segment diagnostic accuracy from 73.5% to 74.6%, and the AUC improved from 0.751 to 0.762 (p = 0.019). When analyzing the 228 segments that could not be evaluated due to severe calcification on the original CCTA images, DL-LEM improved the accuracy from 35.5% to 41.2%, and the AUC improved from 0.500 to 0.581 (p = 0.0009).

CLINICAL RELEVANCE/APPLICATION

This preliminary study suggests that patients with severe coronary calcification might defer catheter angiography if a deep-learning-based model confirms the lumen is not stenotic.

SDP-PH-14 Physical Image Quality Of Deep Learning-based Image Reconstruction In ECG-gated CT Imaging

Participants
Kaoru Kitagawa, Kobe, Japan (*Presenter*) Support, General Electric Company

PURPOSE

In recent years, CT imaging using deep learning-based image reconstruction method has been performed. The physical characteristics of DLIR have been reported using ECG-non-gated imaging at 120 kV. However, it is necessary to clarify the physical characteristics of ECG-gated, low-tube voltage imaging for coronary CTA. In the present study, we evaluated the physical characteristics of DLIR and compared them with those of filtered back projection (FBP) and hybrid iterative reconstruction (HIR) by varying the radiation dose while performing ECG-gated imaging using a phantom.*Methods and Materials All phantom measurements were performed with an ECG-gated scan at 60 bpm. For CNR measurements, the elliptical phantom made from a water-equivalent material with 12mgI/ml rod insertion was scanned at 70, 80, 100 and 120 kV with same radiation dose level (2.2 mGy). For NPS measurements, the water phantom with a 20 cm diameter was scanned at two radiation levels (CTDIvol 1.2 and 0.6 mGy) for 4 tube voltages. All data were reconstructed using FBP, HIR (ASiR-V70%), and three levels of DLIR (DLIR-low [L], medium [M], high [H], respectively). CNR and NPS were calculated and compared for each tube voltage and reconstruction method.*Results The CNR for FBP was 12.8 for 70 kV, 9.8 for 80 kV, 6.9 for 100 kV, and 5.1 for 120 kV, while DLIR-H showed the best values of 16.8 for 80 kV, 14.6 for 100 kV, and 11.6 for 120 kV. The DLIR-H showed the best values at 16.8 for 80 kV, 14.6 for 100 kV and 11.6 for 120 kV. However, at 70 kV, the HIR value was 20.2, which was higher than the DLIR-H of 17.3. In the NPS, when the CTDIvol was 1.2 mGy, the peak frequency was 0.25 mm-1 for FBP, DLIR-L, and DLIR-M, but 0.15 mm-1 for HIR and DLIR-H. When the CTDIvol was 0.6 mGy, the peak frequency was 0.2 mm-1 for FBP, DLIR-L, and DLIR-M, but 0.15 mm-1 for HIR and DLIR-H.*Conclusions The effect of DLIR on image quality depends on its own strength and the tube voltage at the time of imaging.*Clinical Relevance/Application In this study, we evaluated the effect of DLIR on image quality in ECG-gated CT. For NPS, the peak frequencies changed with increasing strength of DLIR.

RESULTS

The CNR for FBP was 12.8 for 70 kV, 9.8 for 80 kV, 6.9 for 100 kV, and 5.1 for 120 kV, while DLIR-H showed the best values of 16.8 for 80 kV, 14.6 for 100 kV, and 11.6 for 120 kV. The DLIR-H showed the best values at 16.8 for 80 kV, 14.6 for 100 kV and 11.6 for 120 kV. However, at 70 kV, the HIR value was 20.2, which was higher than the DLIR-H of 17.3. In the NPS, when the CTDIvol was 1.2 mGy, the peak frequency was 0.25 mm-1 for FBP, DLIR-L, and DLIR-M, but 0.15 mm-1 for HIR and DLIR-H. When the CTDIvol was 0.6 mGy, the peak frequency was 0.2 mm-1 for FBP, DLIR-L, and DLIR-M, but 0.15 mm-1 for HIR and DLIR-H.

In this study, we evaluated the effect of DLIR on image quality in ECG-gated CT. For NPS, the peak frequencies changed with increasing strength of DLIR.

SDP-PH-15 Automatic And Accurate Detection Of Lesions Across The Whole Body Using Multi-view Deep Learning Network

Participants
Yan Zhang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning methods have shown success in detecting lesions of a particular type. We aim at detecting various lesions from different parts of the body (universal lesions) from CT through an end-to-end convolutional neural network.*Methods and Materials A total of 32,120 axial CT slices including 32,735 lesion instances from the whole body were retrieved from the NIH DeepLesion dataset. We separated this dataset into independent training (70%), validation (15%), and testing (15%) cohorts.We proposed a multi-view attention-aware network to detect universal lesion. Inspired by clinical practice, we adopted different window widths and window levels (so-called multi-view) for CT reconstructions. We collected recommended window level and window width of each slice, then clustered these statistics using the k-means algorithm. Three representative windows were generated from cluster centers, which are [50, 449], [-505, 1980], [446, 1960] respectively. These windows approximately correspond to the ideal CT windows for soft-tissue, lung, and other tissues (bone, brain, and mediastinal). For better 3D context modeling, 9 z-axis slices were sampled as inputs. Features from different views were extracted by a shared three-pathway residual architecture. Afterward, we employed a channel-wise attention module for feature aggregation. Enlightened by manually window selection process, this module was designed to put different weights upon all the channels. Given outputs of the abovementioned structures, another neural network predicted lesion locations. We evaluated our network by the sensitivity at a series of false positives (FPs) per image.*Results The sensitivity at 0.5, 1, 2, 3, and 4 FPs per image reached 73.11%, 80.92%, 87.01%, 89.11%, and 90.09% respectively. With far less 3D context, our model surpassed previous state-of-the-art method which used 27 slices by a large margin (4.44% for FPs@4.0 and 10.63% for FPs@0.5). Case study visualized this gap intuitively, as shown in the figure.*Conclusions We developed an end-to-end automated network for universal lesion detection which could pick up most of the lesions while diminishing FPs effectively.*Clinical Relevance/Application Automated screening of whole-body lesions could assist clinical diagnosis of disease or trauma. The high accuracy of our detection algorithm brings light to the future implementation of the computer-aided lesion detection system.

RESULTS

The sensitivity at 0.5, 1, 2, 3, and 4 FPs per image reached 73.11%, 80.92%, 87.01%, 89.11%, and 90.09% respectively. With far less 3D context, our model surpassed previous state-of-the-art method which used 27 slices by a large margin (4.44% for FPs@4.0 and 10.63% for FPs@0.5). Case study visualized this gap intuitively, as shown in the figure.

CLINICAL RELEVANCE/APPLICATION

Automated screening of whole-body lesions could assist clinical diagnosis of disease or trauma. The high accuracy of our detection algorithm brings light to the future implementation of the computer-aided lesion detection system.

SDP-PH-16 Correlation Between CT Signs And The Volume Of Intraoperative Bleeding Of Carotid Body Tumor

Participants
Dongmei Zhou, Xining, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the application value of head and neck CT angiography(CTA) in the prediction of the volume of intraoperative bleeding(VIB) of carotid body tumor(CBT).*Methods and Materials Twenty-six patients with CBT undergoing head and neck CTA examination before CBT resection were enrolled. All patients accepted the same operation method. The transverse and longitudinal diameters of the tumor, the encased degree of carotid artery by tumor (EDCA), the number of blood supply arteries (NBSA) and VIB were measured or recorded. EDCA was divided into three levels:<90°;90°-180°;>180°. The correlation between tumor diameters, NBSA, EDCA and VIB were analyzed by Spearman Correlation.*Results The average age of 26 patients was 51.81(SD,±7.73)years old, including 3 males and 23 females. The mean values of the tumor transverse diameter(TTD), tumor longitudinal diameter(TLD),NBSA and VIB are(3.07±1.34)cm,(3.37±1.38)cm,(1.73±0.87)and(157.69±249.13)ml, respectively. VIB had strong positive correlation with TTD, TLD and EDCA (rho=0.778,0.669 and 0.663,respectively, all P<0.001) and moderate correlation with NBSA(rho=0.573, P=0.002).*Conclusions The transverse and longitudinal diameters of the tumor and EDCA are all strongly positively correlated with VIB. Among all measurements, tumor transverse diameter is the best indicator.*Clinical Relevance/Application The head and neck CT angiography images can evaluate the VIB of CBT and provide help for clinical surgical treatment.

RESULTS

The average age of 26 patients was 51.81(SD,±7.73)years old, including 3 males and 23 females. The mean values of the tumor transverse diameter(TTD), tumor longitudinal diameter(TLD),NBSA and VIB are(3.07±1.34)cm,(3.37±1.38)cm, (1.73±0.87)and(157.69±249.13)ml, respectively. VIB had strong positive correlation with TTD, TLD and EDCA (rho=0.778,0.669 and 0.663,respectively, all P<0.001) and moderate correlation with NBSA(rho=0.573, P=0.002).

CLINICAL RELEVANCE/APPLICATION

The head and neck CT angiography images can evaluate the VIB of CBT and provide help for clinical surgical treatment.

SDP-PH-18 Estimation Of Radiation Risk Of Third Trimester Pregnant Patients And Fetus In Chest CT

Participants
Zhuang Nie, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

to estimate the radiation dose and radiation-related cancer risks associated with single phase chest CT examinations of pregnant patients and fetus by using standard radiation risk estimation models.*Methods and Materials We retrospectively included 84 pregnant patients admitted to the obstetrics department of our hospital underwent chest CT scan for COVID-19 screening, with

age average of 31.9±4.2 years and age range of 24-43 years. Based on CT scan parameters (such as tube voltage, mAs, pitch, etc.) and CTDIvol, DLP, using the digital anthropomorphic model of pregnant patients from the Radimetrics platform and Monte Carlo simulation to estimate the patient's organ dose, effective dose, and fetal dose. Then use the risk model from the International Commission on Radiological Protection (ICRP) to estimate the effective risk of the patient and the radiation-related cancer induction risks of each organ.*Results The average values of CTDIvol, SSDE and DLP are 7.8 ± 2.4mGy, 10.4 ± 2.7mGy, 256.2 ± 78.9mGy*cm. Breast (12 ± 3.4 mGy), lungs (11.8 ± 3.2 mGy), and heart (10.7 ± 3 mGy) have the highest organ dose, and the doses of other organs were all below 10 mGy. The average effective dose is 6.2 ± 1.7 mSv, and the average effective radiation risk is 5.8 ± 1.6 (the number of cases per 10,000 people). The three organs with the highest radiation-related cancer risk are: breast (2.1±0.6 cases per 10,000 people), lung (1.6±0.4 cases per 10,000 people) and stomach (0.7±0.2 cases per 10,000 people). The average equivalent dose to the fetus is 0.77±0.3mSv.*Conclusions This study can provide a quantitative reference for the risk-benefit ratio for clinical decision-making on radiological examinations for pregnant patients, and improve medical staff's awareness of the potential risks of radiological examinations for pregnant patients.*Clinical Relevance/Application This study can provide a quantitative reference for the risk-benefit ratio for clinical decision-making on radiological examinations for pregnant patients, and improve medical staff's awareness of the potential risks of radiological examinations for pregnant patients.

RESULTS

The average values of CTDIvol, SSDE and DLP are 7.8 ± 2.4mGy, 10.4 ± 2.7mGy, 256.2 ± 78.9mGy*cm. Breast (12 ± 3.4 mGy), lungs (11.8 ± 3.2 mGy), and heart (10.7 ± 3 mGy) have the highest organ dose, and the doses of other organs were all below 10 mGy. The average effective dose is 6.2 ± 1.7 mSv, and the average effective radiation risk is 5.8 ± 1.6 (the number of cases per 10,000 people). The three organs with the highest radiation-related cancer risk are: breast (2.1±0.6 cases per 10,000 people), lung (1.6±0.4 cases per 10,000 people) and stomach (0.7±0.2 cases per 10,000 people). The average equivalent dose to the fetus is 0.77±0.3mSv.

CLINICAL RELEVANCE/APPLICATION

This study can provide a quantitative reference for the risk-benefit ratio for clinical decision-making on radiological examinations for pregnant patients, and improve medical staff's awareness of the potential risks of radiological examinations for pregnant patients.

SDP-PH-19 Intermanufacturer Comparison Of Dual-Energy CT Monochromatic Attenuation: A Phantom Study

Participants
Yong Chen, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To determine the accuracy of dual-energy computed tomography monochromatic image CT value in a phantom system by comparing 3 types of structure dual energy CT: fast kilovolt peak-switching, dual-source, and dual-layer detector systems.*Methods and Materials An iodine phantom (Gammex 472, Middleton, WI, USA) containing five iodine concentration (IC) (2, 2.5, 5, 7.5, 10 mg/mL) was scanned three times with five dual-energy CT systems with 20 mGy radiation dose. Monochromatic images (40, 70, 100 and 140 keV) were created through post reconstruction. Monochromatic attenuation for each insert and reconstruction energy level were recorded. The recorded monochromatic attenuation value was compared to the theoretic value calculated from National Institute of Standards and Technology (NIST) XCOM database. The mean percentage error bias between the recorded value and NIST value at four monochromatic energy level and five (IC) was calculated and compared.*Results One dual source paradigm had the lowest bias in all iodine concentration (IC) for 40 keV (from 0.2% to 11.1%). Fast kilovolt peak switching paradigms showed tendency to perform better in low IC (2, 2.5 and 5mg/mL) for 70 and 100 keV (bias from 0.6% to 8.6%), while dual source paradigms were prone to have lower bias in high IC (7.5 and 10mg/mL, from 1.5% to 5.0%). Dual-layered detector arrays showed poor performance in 40, 70 and 100 KeV but had the best performance for 140 keV in IC of 2, 2.5 and 5mg/mL (bias of 20.4%, 2.3% and 2.1%).*Conclusions Fast kilovolt peak switching and dual source systems showed higher accuracy in low-to-moderate monochromatic energy level while dual-layered detector performed better in high monochromatic energy level.*Clinical Relevance/Application The difference in accuracy of dual-energy CT could provide useful information for the clinical diagnosis.

RESULTS

One dual source paradigm had the lowest bias in all iodine concentration (IC) for 40 keV (from 0.2% to 11.1%). Fast kilovolt peak switching paradigms showed tendency to perform better in low IC (2, 2.5 and 5mg/mL) for 70 and 100 keV (bias from 0.6% to 8.6%), while dual source paradigms were prone to have lower bias in high IC (7.5 and 10mg/mL, from 1.5% to 5.0%). Dual-layered detector arrays showed poor performance in 40, 70 and 100 KeV but had the best performance for 140 keV in IC of 2, 2.5 and 5mg/mL (bias of 20.4%, 2.3% and 2.1%).

CLINICAL RELEVANCE/APPLICATION

The difference in accuracy of dual-energy CT could provide useful information for the clinical diagnosis.

SDP-PH-2 Improvement Of Low-contrast Detectability Using Novel Iterative Progressive Reconstruction With Multifrequency Processing In Brain Ct

Participants
Yoshinori Funama, PhD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Iterative progressive reconstruction with visual modeling (IPV) with a multifrequency process that focuses on improving low-contrast detectability (IPV-LCD) is newly introduced in brain computed tomography (CT) imaging. IPV-LCD with multifrequency processing can adaptively reduce image noise that varies according to the spatial frequency.The present study aimed to investigate the performance of IPV-LCD as compared with conventional IPV in terms of noise texture patterns and low-contrast detectability at different radiation doses.*Methods and Materials Helical scans were performed on a 64-detector CT scanner (SCENARIA View, FUJIFILM Healthcare Corporation, Tokyo, Japan) using a CCT189 MITA CT IQ phantom (low-contrast modules with a contrast of 3 HU and diameters of 10 mm [C3?10]). The tube voltage was set at 120 kVp, and the tube current-time product was changed from 120 to 360 mAs (seven types). All images were reconstructed at 5-mm thickness using FBP, IPV-LCD with eight strength levels, and conventional IPV with two strength levels. The noise power spectrum (NPS) was calculated. A model observer involving a channelized Hotelling observer model was applied using low-contrast modules in the phantom for evaluating low-contrast detectability.*Results The NPS for all IPV-LCD images showed similar curves as those for FBP images. For C3?10, the detectability indices were 5.6-12.1 at FBP, 6.7-15.2 at conventional IPV with standard level (STD), 8.8-16.3 at IPV-LCD with STD, 8.0-17.4 at

conventional IPV with strong level (STR), 9.5-19.7 at IPV-LCD with STR, respectively. For STD and STR, the low-contrast detectabilities with IPV-LCD were 6%-32% and 10%-35% higher than those with conventional IPV. The contrast-to-noise ratio at 210 mAs was 1.1 at FBP. Similarly, CNRs of IPV-LCD with standard and strong levels were 1.8 and 2.9, and those of IPV were 1.3 and 2.3, respectively.*Conclusions IPV-LCD images showed improved low-contrast detectability as compared with FBP and conventional IPV and a similar noise texture pattern as that of FBP images.*Clinical Relevance/Application The use of IPV-LCD with multifrequency processing provides better brain tissue visibility without a lack of image texture appearance in brain CT.

RESULTS

The NPS for all IPV-LCD images showed similar curves as those for FBP images. For C3?10, the detectability indices were 5.6-12.1 at FBP, 6.7-15.2 at conventional IPV with standard level (STD), 8.8-16.3 at IPV-LCD with STD, 8.0-17.4 at conventional IPV with strong level (STR), 9.5-19.7 at IPV-LCD with STR, respectively. For STD and STR, the low-contrast detectabilities with IPV-LCD were 6%-32% and 10%-35% higher than those with conventional IPV. The contrast-to-noise ratio at 210 mAs was 1.1 at FBP. Similarly, CNRs of IPV-LCD with standard and strong levels were 1.8 and 2.9, and those of IPV were 1.3 and 2.3, respectively.

CLINICAL RELEVANCE/APPLICATION

The use of IPV-LCD with multifrequency processing provides better brain tissue visibility without a lack of image texture appearance in brain CT.

SDP-PH-20　The Influence Of Dual-energy Data Reconstruction Parameters On The Monosodium Urate Detection Based On Dual-energy CT

Participants
Yan Zhang, Peking, China (*Presenter*) Nothing to Disclose

PURPOSE

To study the influence of dual-energy data reconstruction parameters on the monosodium urate (MSU) detection based on Dual-energy CT.*Methods and Materials A total of 46 patients with gout, who were undergone gout dual-energy CT scan, were included in this study. Four groups with different slice thicknesses and increments were reconstructed based on the same CT raw data, they were group A:0.6/0.3mm, group B:0.75/0.4mm, group C: 1.0/0.5mm,group D:1.5/0.8mm. The fields of display view and the central position in the four groups were the same. The MSU was detected by the software of Dual-Energy Gout based on the dual-energy data, and volumes of the MSU were calculated automatically by the software of Volume. The distribution and shape scores of the MSU were evaluated subjectively. Using SPSS22.0 software, and the x2 test and the rank test were used for statistical analysis.*Results The MSU volumes detected in four groups were (6.93+19.36), (6.49+18.26), (6.18+17.55),(5.42+15.18) mm3, the MSU distribution scores were (1.09+0.28), (1.00+0.00), (0.04+0.21),(0.04+0.21), and the MSU shape scores were (2.24+1.40), (2.15+1.49), (1.30+1.40), (1.23+1.41) respectively. There were statistical significant differences in the MSU volumes, distributions and shapes in four groups (P<0.05). There was significant statistical difference between group A (6.93+19.36) mm3and C(6.18+17.55) mm3 (P<0.05), group A (6.93+19.36) mm3 and D(5.42+15.18) mm3 (P<0.05)on the MSU volumes. Besides group A and B, group C and D, there were significant statistical differences on MSU distributions and shapes between the other two groups (P<0.0083).*Conclusions The setting of reconstruction slice thickness and increment of dual-energy data had an effect on the MSU detection based on Dual-energy CT.*Clinical Relevance/Application It was suggested that the slice thickness of dual-energy data should be less than 1mm.

RESULTS

The MSU volumes detected in four groups were (6.93+19.36), (6.49+18.26), (6.18+17.55),(5.42+15.18) mm3, the MSU distribution scores were (1.09+0.28), (1.00+0.00), (0.04+0.21),(0.04+0.21), and the MSU shape scores were (2.24+1.40), (2.15+1.49), (1.30+1.40), (1.23+1.41) respectively. There were statistical significant differences in the MSU volumes, distributions and shapes in four groups (P<0.05). There was significant statistical difference between group A (6.93+19.36) mm3and C(6.18+17.55) mm3 (P<0.05), group A (6.93+19.36) mm3 and D(5.42+15.18) mm3 (P<0.05)on the MSU volumes. Besides group A and B, group C and D, there were significant statistical differences on MSU distributions and shapes between the other two groups (P<0.0083).

CLINICAL RELEVANCE/APPLICATION

It was suggested that the slice thickness of dual-energy data should be less than 1mm.

SDP-PH-21　Comparison Of Threshold Contrast Detail Detectability Curves Of A Solid-state Flat-panel Detector And An Image Intensifier For Fluoroscopy And Digital Acquisition

Participants
Kwan Wai Li, Hong Kong, Hong Kong (*Presenter*) Nothing to Disclose

PURPOSE

Detective quantum efficiency (DQE) has been regarded as a key indicator of the overall imaing performance of x-ray image receptors, yet it only relates to the physical characteristics of the receptors. With the recent advances in image processing, image quality assessment on for-presentation images using threshold contrast detail detectability (TCDD) objects becomes more important. In this study, TCDD curves were compared between an image intensifier (II) and a solid-state flat-panel detector (FPD) which is commonly available in interventional systems nowadays.*Methods and Materials The two systems used for comparison were (i) Siemens Artis zee with PURE multi-purpose system equipped with a 30 cm x 40 cm indirect-conversion FPD made from amorphous silicon photodiode with CsI scintillator and (ii) GE OEC Elite surgical imaging C-arm equipped with a 9-inch II. Both systems provided three dose levels, corresponding to low, normal and high input air kerma rate (IAKR). An additional 1.5 mm copper filter was placed at the collimator. Leeds test objects TO10 and TO12 were placed on the entrance plane of the image receptors for fluoroscopy and digital acquisition, respectively. The test object images were acquired under automatic dose rate control (ADRC) without anti-scatter grid and then analyzed using AutoPIA software based on heuristic algorithms instead of human observers. Target object contrasts given in TO10 and TO12 specifications were interpolated and extrapolated to generate contrast curves for any kVp and copper filter combination. Threshold detection index (HT(A)) values were caculated at each detail area.*Results Fluoroscopy and digital acquisition HT(A) curves for both systems were compared. The two protocols (Siemens: Service; GE: General) were selected such that the IAKR or IAK for both systems were very close. The settings of the two protocols were left as default. The TCDD performance of the FPD system for digital acquisition was significantly better than that of the II system. However, it was inferior to that of the II system during fluoroscopy.*Conclusions The preliminary results of this study show that the use of FPD does not necessarily improve the TCDD performance compared with II which was commonly used in the past. Proper adjustements to the protocols in the FPD system, especially the parameters of the internal image processing algorithms like

I-Noise Reduction and Digital Density Optimization from Siemens Healthineers, should be made to boost the TCDD performance in each specific organ and clinical scenario.*Clinical Relevance/Application Robust hardware as well as carefully adjusted image processing parameters for clinical protocols are equally important for radiologists to better identify low-contrast lesions.

RESULTS

Fluoroscopy and digital acquisition HT(A) curves for both systems were compared. The two protocols (Siemens: Service; GE: General) were selected such that the IAKR or IAK for both systems were very close. The settings of the two protocols were left as default. The TCDD performance of the FPD system for digital acquisition was significantly better than that of the II system. However, it was inferior to that of the II system during fluoroscopy.

CLINICAL RELEVANCE/APPLICATION

Robust hardware as well as carefully adjusted image processing parameters for clinical protocols are equally important for radiologists to better identify low-contrast lesions.

Vishruta Dumane, PhD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Knowledge-based planning (KBP) in which a large number of accepted clinical plans for treatment are used to generate a model that would optimally produce a dosimetric result for the given anatomy is an approach to improving efficiency and reducing variability in treatment planning. The aim of this work was to determine if the Varian Rapidplan™ system can efficiently produce volumetric modulated arc therapy (VMAT) plans for the prostate and lymph nodes.*Methods and Materials A total of 91 patient plans treated at our institution with radiation using VMAT with two coplanar arcs and 6 MV photons was used to build the dose volume histogram (DVH) estimation model for organs at risk (OARs, namely the bladder, bladder wall, rectum, rectal wall, bowel and femoral heads. Prescription dose to the PTV was 45Gy. Dose constraints for the rectal wall and bladder wall were V40Gy < 30%, V30Gy < 50%, bowel maximum < 50Gy, femoral head maximum < 45Gy and V30Gy < 50%. Coverage to the planning target volume (PTV) was expected to be = 98%. The DVH estimation model was trained and tested using the knowledge-based planning software. Treatment plans for 20 patients generated clinically as well as using KBP were compared for dosimetric parameters using the Wilcoxon rank-sum test.*Results Comparison of dosimetric parameters for clinical versus KBP showed as much as a 12% reduction in bladder dose on average with KBP compared to the clinical plan. Specifically, the bladder wall V40 Gy was reduced by 6%, the V30 Gy by 9% and the V20 Gy by 13%. The rectal dose was reduced on average with KBP by as much as 8%. The rectal wall V40Gy was decreased by 3%, the V30Gy by 5% and the V20 Gy by 8%. All these results were found to be statistically significant (p<0.05). No significant differences were seen in the sparing of the bowel or the femoral heads for both planning techniques. Out of the plans tested for verification, 77% showed an improvement after using the KBP technique while 23% showed no significant difference.*Conclusions Despite meeting standard dose constraints for bladder and rectum, the toxicity cannot be ignored. Both the clinical and the KBP plans were able to meet these constraints, however, the bladder and rectum showed improved sparing with respect to doses in the range of 20Gy to 40Gy in the KBP plans also showing the potential to reduce treatment planning time.*Clinical Relevance/Application KBP has not only the potential to improve plan quality but to also improve organs sparing, thereby reduce toxicity to the organs at risk while improving speed and efficiency.

RESULTS

Comparison of dosimetric parameters for clinical versus KBP showed as much as a 12% reduction in bladder dose on average with KBP compared to the clinical plan. Specifically, the bladder wall V40 Gy was reduced by 6%, the V30 Gy by 9% and the V20 Gy by 13%. The rectal dose was reduced on average with KBP by as much as 8%. The rectal wall V40Gy was decreased by 3%, the V30Gy by 5% and the V20 Gy by 8%. All these results were found to be statistically significant (p<0.05). No significant differences were seen in the sparing of the bowel or the femoral heads for both planning techniques. Out of the plans tested for verification, 77% showed an improvement after using the KBP technique while 23% showed no significant difference.

CLINICAL RELEVANCE/APPLICATION

KBP has not only the potential to improve plan quality but to also improve organs sparing, thereby reduce toxicity to the organs at risk while improving speed and efficiency.

SDP-PH-25 Clinical Value Of Artifact Identification In Ankle Dual-energy CT For Gout Diagnosis

Participants
Yan Zhang, Peking, China (*Presenter*) Nothing to Disclose

PURPOSE

To study the clinical value of artifact identification in ankle dual-energy CT for gout diagnosis.*Methods and Materials A total of 58 patients with gout, who were definitely diagnosed in Peking University Third Hospital from December 2018 to May 2019, were included in the case group, which was composed of 57 men and 1 woman. And 37 individuals without gout were regarded as the control group, which was composed of 36 men and 1woman. DECT was performed for one foot, and the affected side or the more serious side was chosen in the case group. The dual-energy data were used in gout-recognition software to highlight the monosodium urate (MSU) with green-colored. And to compare the difference in MSU relevance ratio on the images of the toenail, submillimeter spots, skins, movements and vascular calcification between two groups*Results In the case group, 55 patients were revealed with MSU green-colored toenails(relevance ratio 94.8%), while 22 cases in the control groups(relevance ratio 59.5%). There was significant statistical difference in the mean toenails' numbers and the MSU distribution scores in the two groups (P<0.01).In the case group ,47 patients were revealed with green-colored submillimeter spots(relevance ratio 81%),while 5 cases in the control group(relevance ratio 13.5%). The relevance ratio of submillimeter spots on tendon and ligament in the case group and control group were 75.9%(44/58)and 13.5%(5/37).There was also significant statistical difference in the two groups on submillimeter spots(P<0.01). And there was no significant statistical difference in the two groups on MSU green-colored skins, movements and vascular calcification.*Conclusions The detection of green MSU on toenails and sub-millimeter spots has great value in the clinical diagnosis of gout and should not be simply judged as an artifact.*Clinical Relevance/Application For the clinical diagnosis of gout , skins, movements and vascular calcification artifacts could be defined easily in ankle dual-energy CT, but toenails and submillimeter spots detected as green MSU, should be considered seriously.

RESULTS

In the case group, 55 patients were revealed with MSU green-colored toenails(relevance ratio 94.8%), while 22 cases in the control groups(relevance ratio 59.5%). There was significant statistical difference in the mean toenails' numbers and the MSU distribution scores in the two groups (P<0.01).In the case group ,47 patients were revealed with green-colored submillimeter spots(relevance ratio 81%),while 5 cases in the control group(relevance ratio 13.5%). The relevance ratio of submillimeter spots on tendon and ligament in the case group and control group were 75.9%(44/58)and 13.5%(5/37).There was also significant statistical difference in the two groups on submillimeter spots(P<0.01). And there was no significant statistical difference in the two groups on MSU green-colored skins, movements and vascular calcification.

CLINICAL RELEVANCE/APPLICATION

For the clinical diagnosis of gout , skins, movements and vascular calcification artifacts could be defined easily in ankle dual-energy CT, but toenails and submillimeter spots detected as green MSU, should be considered seriously.

SDP-PH-26 Synthetic CT Images From Head Magnetic Resonance(MR) Images Based On Deep Learning Technique

Participants
ZHENG TANG, Shenzhen, China (*Presenter*) Nothing to Disclose

PURPOSE

To generate CT modality images from their corresponding T1-weighted MRI sequence, applying deep learning (DL) method.*Methods and Materials 10 patients scanned with both CT and MRI modality sequences were retrospectively enrolled. Data formed up our experimental dataset were acquired on different United Imaging Healthcare MRI and CT machines including, uMR588, uMR780, uCT780 and uCT960+. The MRI and CT sequences were acquired within different time intervals varied from 7 days to 20 days. Both sequences were acquired and reconstructed in the same slice thickness of 1.0mm in order to have accurate correspondence between two sequences in different modalities. MRI data was then aligned to the corresponding CT images using rigid registration method. Dataset constructed with patients head scanning sequences. ROIs of MRI sequences were selected by experienced radiologists manually and images in the same area were simultaneously implemented on corresponding CT images. After that, registered CT/MRI pairs in total of 3000 images were used to train a DL model based on U-Net structure. 100 randomly selected images pairs from our datasets were then sent into the well-trained model and quantitative measurement included PSNR, MAE, SSIM were then calculated.*Results Our results showed outstanding performance on generating realistic CT image from MRI data (PSNR = 60.85 +/- 3.19 dB, SSIM = 96.52 +/- 5.74 %, MAE = 0.49 +/- 0.13 e-4). Quantitative analysis results demonstrated that our generated CT images have very high structural similarity, high reconstruction quality and only minor difference from real CT images.*Conclusions We applied a novel deep learning model to generate head synthetic CT from routine T1-weighted MR images. This work demonstrated that excellent quality CT images can be generated from MR sequence using a deep learning based scheme based on corresponding MR and CT images data. The common issue of MRI-only implementing treatment was image distortion and accurate synthetic CT can be very significant. Our generated CT images demonstrated high diagnostic value from its high accuracy, sensitivity and outstanding quantitative analysis result.*Clinical Relevance/Application Deep learning method has the potential to generate CT images from MR data, which can avoid ionizing radiation to human flesh by generating CT result using DL scheme from the acquired MR sequence.

RESULTS

Our results showed outstanding performance on generating realistic CT image from MRI data (PSNR = 60.85 +/- 3.19 dB, SSIM = 96.52 +/- 5.74 %, MAE = 0.49 +/- 0.13 e-4). Quantitative analysis results demonstrated that our generated CT images have very high structural similarity, high reconstruction quality and only minor difference from real CT images.

CLINICAL RELEVANCE/APPLICATION

Deep learning method has the potential to generate CT images from MR data, which can avoid ionizing radiation to human flesh by generating CT result using DL scheme from the acquired MR sequence.

SDP-PH-27 Differentiating Between The Intracerebral Hematoma And Hemorrhage In Initial CT Image With Hierarchical Deep Learning Approach

Participants
Kazunori Oka, Himeji, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Extracting intracerebral hematoma (ICH) region in CT images is a quite difficult task in image processing because there are similar density areas such as intraventricular and subdural hemorrhage. This study aims to propose a novel method to automatically extract the ICH region in thick-slice initial CT images of emergency patients.*Methods and Materials Subjects used in this study were 33 patients who were transported to the emergency department for cerebral hemorrhage. For each subject, head CT images were acquired twice: at the time of emergency transport and after 24 hours. The subjects were collected by J-ASPECT study. This study was conducted with the approval of the Ethics Committee of Kyushu University. The proposed method extracts the ICH region with a hierarchical deep learning approach. At first, it segments the intracranial region with level set method from CT images, and extracts the high-density areas inside the intracranial region. Next, it classifies the high-density voxels into the ICH region and the others with a convolutional neural network (CNN). For each voxel of the high-density areas, neighboring 129 by 129 voxels are feed to the input layer. The network model consists of convolution layer with ReLU, max pooling, batch normalization, fully connected layer with ReLU, and Softmax. The output layer has two neurons that provide possibilities of the ICH and the others. The training data are synthesized from only high-density voxels inside the intracranial region. That is, the role of the network is to classify a high-density voxel into ICH class and non-ICH class. The teaching labels are assigned by using the annotated ICH region in CT images with some well-trained neurosurgeon. In 33 subjects, 27, 3, 3 cases were used for training, validation, and test, respectively. The performance of the model was evaluated using a confusion matrix.*Results The accuracy, recall, specificity, and precision of the model on the training data were 0.94, 0.92, 0.96, and 0.96, respectively. The accuracy, recall, specificity, and precision of the model on the validation data were 0.83, 0.76, 0.92, and 0.91, respectively. It confirmed that the method has a performance of extracting the ICH region from the high-density area.*Conclusions The hierarchical deep learning approach can overcome a problem to extract the ICH region from the high-density areas. Although some studies discuss the ICH region segmentation in CT images, all methods extract the high-density areas including not only ICH but also intraventricular hemorrhage and subdural hemorrhage.*Clinical Relevance/Application Accurate segmentation and volumetry of the ICH region excepting the hemorrhage region will support neurosurgeons to predict the ICH growing, and decide medical treatment planning.

RESULTS

The accuracy, recall, specificity, and precision of the model on the training data were 0.94, 0.92, 0.96, and 0.96, respectively. The accuracy, recall, specificity, and precision of the model on the validation data were 0.83, 0.76, 0.92, and 0.91, respectively. It confirmed that the method has a performance of extracting the ICH region from the high-density area.

CLINICAL RELEVANCE/APPLICATION

Accurate segmentation and volumetry of the ICH region excepting the hemorrhage region will support neurosurgeons to predict the ICH growing, and decide medical treatment planning.

SDP-PH-28 Automated Tooth Recognition In Panoramic Radiograph Using Deep Learning And Anatomical Priori Knowledge

Participants
Kota Motoki, Himeji, Japan (*Presenter*) Nothing to Disclose

PURPOSE

This study aims to develop a computer-aided diagnosis (CAD) system, which assists dentists by automatically recognizing teeth in dental panoramic radiographs based on faster R-CNN and optimization with anatomical priori knowledge.*Methods and Materials This study collected 200 panoramic radiographs acquired in multiple dental clinics. The mean and standard deviation (SD) of lost teeth was 3.01± 2.58. The tooth numbering follows universal tooth numbering (UTN) system. The method is based on two steps; (1) tooth candidate detection step, and (2) optimization based candidate selection step. The first step detects tooth candidates in a panoramic radiograph as much as possible. It is performed with is a faster R-CNN and which is a well-known object detection method based on deep learning. The different tooth numbers are treated as the different objects. The trained faster R-CNN using ImageNet called ResNet-100 is fine-tuned using panoramic radiographs with annotated teeth. That is, multiple candidates will be detected for each tooth, same candidate will be detected by the different tooth, and candidates will overlap each other.By selecting the most appropriate one from the candidates at the second step, the method recognizes the teeth. The selection can be formulated as an optimization problem whose optimization function evaluates the following conditions; (1) the selected candidates do not overlap with each other, (2) the relative relationship among the selected candidates follow the anatomical spatial relationship. The proposed method is validated by 10-fold-cross-validation test. The evaluation indices are precision, recall, and F1-score.*Results Figure 1 shows the recognized teeth from a panoramic radiograph. Red boxes show the detected teeth, and the number shows the tooth number (T1-T32) and the confidence value (0-1). For the training subjects, the proposed method achieved the high recognition performance; the precision was 96.28%, recall was 96.97%, and F1-score was 96.63%.*Conclusions The combination of the object detection method and anatomical priori knowledge optimization method is effective to recognize the teeth from panoramic radiographs.*Clinical Relevance/Application Interpretation of dental panoramic radiographs is required in all initial diagnosis at dental clinics. However, it takes a time, and is causing faults of teeth recognition. This study completely automates the dentists' interpretation, and will improve the quality of diagnosis.

RESULTS

Figure 1 shows the recognized teeth from a panoramic radiograph. Red boxes show the detected teeth, and the number shows the tooth number (T1-T32) and the confidence value (0-1). For the training subjects, the proposed method achieved the high recognition performance; the precision was 96.28%, recall was 96.97%, and F1-score was 96.63%.

CLINICAL RELEVANCE/APPLICATION

Interpretation of dental panoramic radiographs is required in all initial diagnosis at dental clinics. However, it takes a time, and is causing faults of teeth recognition. This study completely automates the dentists' interpretation, and will improve the quality of diagnosis.

SDP-PH-29 The Effect Of Different CT Reconstruction Methods In The Coronary Artery: A Combined Clinical And Phantom Study

Participants
Xiaowei Ruan, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the different reconstruction methods of the energy spectral CT coronary computed tomography angiography (CCTA) in heart stent impanted patients and phantom, respectively, to show the differences in coronary artery stents and whether the effects of stent cavity display are consistent.*Methods and Materials 1) Twenty-five patients with coronary artery stent implantation in our hosptital were collected . 2) At the same time, three different materials (Cypher, TSUNAMI, Cypher), different internal diameters (4mm, 3mm, 2mm) coronary artery stent model filled with contrast agent solution (concentration of 10mg/ml) were fixed to the water tank, and the coronary artery stent model was scanned using electrocardiogram mode to simulate 62 times/min heart rate on 256 row dector CT (CT, GE Healthcare) to simulate 62 times/min heart rate. 3) Common scan protocals: high-definition mode, tube voltage 100kVp, tube current automatic milliamps, NI 26, front ASiR-V40%. After the scanning, both sets of images are reconstructed in Stnd and Detail modes. Two sets of images were measured, the inner diameter of the bracket tube cavity, the middle section, the far bracket inner diameter and the CT value, and the average and average CT values of the inner diameter of the two sets of image bracket were calculated respectively. Paired T-tests were used to compare the difference between the average and CT means of the inner diameter of the bracket tube cavity.*Results Patient group: the internal diameter of Stnd and Detail of the reconstruction mode were 2.55±0.33 and 2.65±0.32 mm, the differences are statistically significant (P<0.05);the CT values were 382.65±72.25 and 381.64±73.4 HU with no statistical significance(P>0.05).Phantom group: the average diameter of the Stand and Detail reconstruction mode bracket tube cavity were 2.41±0.350 and 2.55±0.34 mm, the difference is statistically significant (P<0.01).);The CT values were 220.96±37.79 and 225.42±32.28 HU, respectively, the difference was not statistically significant(P>0.05).*Conclusions The HD Detail reconstruction mode in Revolutio CT was consistent in the clinical coronary artery scan and phantom study, which showed a consistentcy in the difference of coronary artery stent and the effect of the cavity display inside the stent.*Clinical Relevance/Application The HD CT Detail reconstruction mode improves the image quality of coronary artery stents and has important clinical application value in coronary artery stent image evaluation.

RESULTS

Patient group: the internal diameter of Stnd and Detail of the reconstruction mode were 2.55±0.33 and 2.65±0.32 mm, the differences are statistically significant (P<0.05);the CT values were 382.65±72.25 and 381.64±73.4 HU with no statistical

significance(P>0.05).Phantom group: the average diameter of the Stand and Detail reconstruction mode bracket tube cavity were 2.41±0.350 and 2.55±0.34 mm, the difference is statistically significant (P<0.01).);The CT values were 220.96±37.79 and 225.42±32.28 HU, respectively, the difference was not statistically significant(P>0.05).

CLINICAL RELEVANCE/APPLICATION

The HD CT Detail reconstruction mode improves the image quality of coronary artery stents and has important clinical application value in coronary artery stent image evaluation.

SDP-PH-3 The Evaluation Of Iron Quantification With Dual-energy CT For Liver Iron Deposition In Patients With Blood Transfusion Dependent Non-severe Aplastic Anemia

Participants
Xia Zhao, Jinan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the application value of DECT in the diagnosis of liver iron deposition in patients with blood transfusion dependent non-severe aplastic anemia, by analyzing the various parameters of dual energy CT and serum ferritin in the same period.*Methods and Materials This study retrospectively evaluated the dual energy CTs in 32 in-patients with blood transfusion dependent non-severe aplastic anemia between November 2020 and March 2021. All patients had the RBC input range of 6u~22u within the past 6 months. Patients all checked serum ferritin on the day of hospitalization, and the interval between CT scans was 0~2 days. The examinational protocol used dual-energy (DE, 80 and 140kVp) with a scanning range from the top of the lung to the bottom of the ribs. The effective tube currents were 195mA with 0.6s rotation time, 40% ASiR-V. The images were reconstructed in STND mode, 1.25mm thickness. A liver map was created using base material decomposition into water and iron. The specific processing was as follows: 1) Measure the Hounsfield unit of the liver and aorta by placing ROIs in the differennt lobes of liver and aorta at the level where the portal vein branches between 40 and 140KeV every 5KeV intervals, and calculate the mean CT value of liver; 2) Obtain the iron (water) content of liver, calculate the mean LIC and LIC/AIC; 3) Calculate the Slope, the calculation formula was: Slope= (mean CT value at 75KeV- mean CT value at 40KeV)/(75-40).*Results In the group, the mean LIC, LIC/AIC, the Slope and serum ferritin content were 2.71±1.46mg/cm3, 2.773±3.394, 0.845±0.433, 1159.07±1176.67ng/ml, respectively. Correlations between LIC, the slope and serum ferritin were assessed by using Pearson correlation analysis. The slope showed a strong positive correlation with serum ferritin (r=0.714; p=0.003), and LIC showed a strong positive correlation with serum ferritin (r = 0.761; p=0.001).*Conclusions LIC and the Slope determined based on DECT image data obtained with a routine examinational protocol and calculated with the proposed post-processing prototype shows strong correlation with serum ferritin. Therefore, non-contrast routine DECT exam could be used in the daily routine diagnosis for complementary evaluation of liver iron deposition in patients with blood transfusion dependent non-severe aplastic anemia.*Clinical Relevance/Application non-contrast routine DECT exam could be used in the daily routine diagnosis for complementary evaluation of liver iron deposition in patients with blood transfusion.

RESULTS

In the group, the mean LIC, LIC/AIC, the Slope and serum ferritin content were 2.71±1.46mg/cm3, 2.773±3.394, 0.845±0.433, 1159.07±1176.67ng/ml, respectively. Correlations between LIC, the slope and serum ferritin were assessed by using Pearson correlation analysis. The slope showed a strong positive correlation with serum ferritin (r=0.714; p=0.003), and LIC showed a strong positive correlation with serum ferritin (r = 0.761; p=0.001).

CLINICAL RELEVANCE/APPLICATION

non-contrast routine DECT exam could be used in the daily routine diagnosis for complementary evaluation of liver iron deposition in patients with blood transfusion.

SDP-PH-30 Evaluation Of Basic Performance Of CTDI And Dose Distribution Measurement Method Using Plastic Scintillator And Digital Camera

Participants
Hiroshi Yoshitani, Fukuoka, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To develop and evaluate the performance of a system that acquires the dose distribution of the cross section of the phantom in real time using a plastic scintillator and a CMOS camera.*Methods and Materials A disk-shaped plastic scintillator plate was installed next to the cylindrical PMMA phantom. The light emission of the scintillator was photographed using a CMOS camera from one-way irradiation localizer radiograph. The brightness of the four points at the center and the edge was measured from the luminescence image, and a graph of the relationship between the luminescence amount and the dose was created. Next, a helical scan was performed and the state of light emission was continuously photographed at a shutter speed of 0.1 s. The dose at each luminescence image was estimated from the relationship between the luminescence amount and the dose. CTDI is also estimated from the estimated dose in the central and marginal regions of the luminescent image as before. We compared the displayed values of CT equipment and CTDI derived from semiconductor dosimeters.*Results At the time of localizer radiograph, even when the phantom was irradiated and the scintillator was not directly irradiated with X-rays, weak light emission could be detected, and the influence of scattered rays could be detected. In addition, the amount of light emitted and the dose in the five-point region showed a proportional relationship. When the shutter speed was 0.1 s, the rotation of the X-ray tube in the helical scan could be visually grasped from the emission distribution including the scattered rays in the phantom. CTDI was estimated from the relationship and showed a value close to the measured value.*Conclusions High-sensitivity cameras and scintillators were able to estimate CTDI from the amount of light emitted. When the shutter speed was 0.1 s, the dose profile in the central region was close to the shape measured by an actual dosimeter.*Clinical Relevance/Application A scintillator can be used to estimate doses in any area of the cross section in a single scan. The distribution of scattered rays can also be grasped by using a high-sensitivity camera.

RESULTS

At the time of localizer radiograph, even when the phantom was irradiated and the scintillator was not directly irradiated with X-rays, weak light emission could be detected, and the influence of scattered rays could be detected. In addition, the amount of light emitted and the dose in the five-point region showed a proportional relationship. When the shutter speed was 0.1 s, the rotation of the X-ray tube in the helical scan could be visually grasped from the emission distribution including the scattered rays in the phantom. CTDI was estimated from the relationship and showed a value close to the measured value.

A scintillator can be used to estimate doses in any area of the cross section in a single scan. The distribution of scattered rays can also be grasped by using a high-sensitivity camera.

SDP-PH-31 Normalization Of Temperature Effects For Improved Quantitative Prostate Apparent Diffusion Coefficient (ADC) Imaging Across Multiple Sites

Participants
Ken-Pin Hwang, PHD, Houston, Texas (*Presenter*) Research Grant, General Electric Company;Research Grant, Siemens AG

PURPOSE

While ADC measurements within a protocol may be validated with the use of a standardized phantom, acquisition of these phantom measurements necessitates a phantom temperature of 0oC to eliminate the temperature dependence of ADC. In this study, we investigated the feasibility of using a model for temperature dependence of ADC as a correction factor on measurements acquired at room temperature within a multiparametric prostate protocol on multiple MR scanners.*Methods and Materials The NIST / QIBA diffusion standard phantom was scanned on both 1.5 T and 3T scanners at four separate geographical sites across our institutional network. At each site, the phantom was filled with water that was adjusted to match room temperature. The phantom was acquired with the small FOV DWI sequence employed for our multiparametric prostate MR protocol. 3T non-endorectal and dynamic field correction variants were also acquired.ADC values were measured within each of the vial of the phantom. A model for ADC dependence of PVP on temperature for each vial concentration was used to predict ADC values in our experiments. One set of calculations normalized the measured ADC values to predicted ADC at 20oC, while a second set normalized to predicted ADC using the individual temperatures measured for acquisition. For each set of normalized measurements, percent difference from predicted values was calculated, and the mean and standard deviation of those differences across scanners was compared for each vial.*Results For PVP concentrations from 0% to 40%, the standard deviation of measured ADC across scanners ranged from 2.12% to 5.99% for 1.5T and 5.14% to 7.79% for 3T when measurements were normalized to predicted ADC at 20oC. The standard deviation of the same measurements ranged from 0.21% to 4.87% for 1.5T and 1.12% to 3.13% for 3T when measurements were normalized to predicted ADC at their respective measured temperatures. While normalized ADC at 50% varied widely on a percent basis, measured ADC values generally trended higher than predicted ADC values with increasing PVP concentrations.*Conclusions ADC variance due to temperature can be reduced by applying a model for predicted ADC that takes temperature into account. By reducing or eliminating temperature as a factor, variances of ADC values may more accurately reflect variations in other factors, potentially establishing a simplified QA process for ADC measurements when employing a protocol across multiple scanners at multiple, separate geographic sites.*Clinical Relevance/Application Temperature dependence of ADC can complicate quantitative imaging QA across multiple systems. ADC measurements normalized to values predicted by a model can reduce the variance due to temperature when all other factors are accounted for.

RESULTS

For PVP concentrations from 0% to 40%, the standard deviation of measured ADC across scanners ranged from 2.12% to 5.99% for 1.5T and 5.14% to 7.79% for 3T when measurements were normalized to predicted ADC at 20oC. The standard deviation of the same measurements ranged from 0.21% to 4.87% for 1.5T and 1.12% to 3.13% for 3T when measurements were normalized to predicted ADC at their respective measured temperatures. While normalized ADC at 50% varied widely on a percent basis, measured ADC values generally trended higher than predicted ADC values with increasing PVP concentrations.

CLINICAL RELEVANCE/APPLICATION

Temperature dependence of ADC can complicate quantitative imaging QA across multiple systems. ADC measurements normalized to values predicted by a model can reduce the variance due to temperature when all other factors are accounted for.

SDP-PH-32 Impact Of Deep Learning Reconstructions On Image Quality And Detectability Of Hepatocellular Carcinoma In Multi-energy Spectral Imaging CT: A Phantom Study

Participants
Aurélie Pauthe, Toulouse, France (*Presenter*) Nothing to Disclose

PURPOSE

To quantitatively assess on phantom the impact of a new Deep Learning Image Reconstructions (DLIR) on task-based image quality metrics and the detection of simulated hepatocellular carcinomas (HCC) in Dual-Energy CT (DECT).*Methods and Materials An anthropomorphic phantom with customized liver including mimickers of HCC lesions on a standard patient morphology (BMI 23), was scanned on a DECT (Revolution Apex, GE Healthcare) at 4 dose levels (CTDIvol: 5/8/10/13mGy) each repeated 10 times. Raw data were reconstructed in monochromatic images at 4 energy levels (40/50/60/70 keV) using FBP, ASIRV50, ASIRV100 and DLIR low (DLIR-L), medium (DLIR-M) and high (DLIR-H). The contrast between the lesion and the liver parenchyma, the Noise Power Spectrum (NPS) and the Task-based Transfer Function (TTF) were measured. A detectability index (d') was then computed to model the detection of HCC. Metrics were compared between reconstruction using a Friedman test with follow-up post-hoc multiple comparison (p<.05 considered as statistically significant).*Results The contrast was not impacted by the reconstruction (p=.166). DLIR-M and DLIR-H reduced the noise magnitude compared to ASIRV50 by 13±2 and 31±3% respectively (p<.0001). The noise magnitude was minimized when using ASIRV100 (p<.0001) The average frequency of the NPS (favg), reflecting noise texture, decreased with the energy level and increased with the level of ASIRV and DLIR. While DLIR-M and DLIR-H had texture similar to ASIRV50 (favg= 0.24±0.01, 0.23±0.01 and 0.24±0.01mm-1 respectively), ASIRV100 had the lowest noise frequency component (0.16mm-1 p<.0001). The TTF was degraded when increasing the level of ASIRV and DLIR. Compared to ASIRV50, DLIR-M and DLIR-H increased d' at all energy and dose levels (d'=12.13±1.89, 15.17±2.64 and 18.18±3.37 respectively; p<.0001). There was no significant difference between DLIR-H and ASIRV100 (d'= 19.24±3.40; p=.798).*Conclusions Compared to routinely used level of Iterative Reconstruction, DLIR reduces noise without degrading its texture, and may improve the detectability of HCC, whatever the monochromatic energy level studied.*Clinical Relevance/Application Optimizing reconstruction methods of DECT using DLIR could improve both image texture and detectability of HCC lesions and should be implemented in clinical practice.

RESULTS

The contrast was not impacted by the reconstruction (p=.166). DLIR-M and DLIR-H reduced the noise magnitude compared to ASIRV50 by 13±2 and 31±3% respectively (p<.0001). The noise magnitude was minimized when using ASIRV100 (p<.0001) The average frequency of the NPS (favg), reflecting noise texture, decreased with the energy level and increased with the level of ASIRV and DLIR. While DLIR-M and DLIR-H had texture similar to ASIRV50 (favg= 0.24±0.01, 0.23±0.01 and 0.24±0.01mm-1

respectively), ASIRV100 had the lowest noise frequency component (0.16mm-1 p<.0001). The TTF was degraded when increasing the level of ASIRV and DLIR. Compared to ASIRV50, DLIR-M and DLIR-H increased d' at all energy and dose levels (d'=12.13±1.89, 15.17±2.64 and 18.18±3.37 respectively; p<.0001). There was no significant difference between DLIR-H and ASIRV100 (d'= 19.24±3.40; p=.798).

CLINICAL RELEVANCE/APPLICATION

Optimizing reconstruction methods of DECT using DLIR could improve both image texture and detectability of HCC lesions and should be implemented in clinical practice.

SDP-PH-33 Energy-bin Downsampling Method For Grayscale Image Reconstruction For A Deep Silicon Photon-Counting CT Clinical Prototype

Participants
Taly Gilat Schmidt, PhD, Milwaukee, Wisconsin (*Presenter*) Research Grant, General Electric Company;Research collaboration, Varian Medical Systems, Inc

PURPOSE

An energy-bin downsampling method for grayscale image generation was investigated on a clinical photon-counting CT prototype with deep silicon detector.*Methods and Materials The clinical photon-counting CT prototype uses a deep silicon detector with eight energy bins, with energy thresholds optimized for material decomposition performance. It is desired to form a high-quality grayscale image in a short time after acquisition for initial image review. This work developed an energy-bin downsampling method to reduce the number of energy-bin measurements used to form the grayscale image while maintaining image quality. The proposed method uses a simulated model or calibration transmission measurements to determine the optimal bin combinations. At each iteration, the downsampling optimization method evaluates the combination of all pairs of energy bins and selects the combination that maximizes an image quality metric. Downsampling continues iteratively while the image quality metric is maintained. This work used the CNR between a measurement with and without a contrast element as the image quality metric, but the method generalizes to other metrics. The grayscale image was formed as a virtual monoenergetic image (VMI) after material decomposition. The method was investigated using previously acquired head CT data of a human subject. Grayscale VMI images were reconstructed from the optimally downsampled three energy bins and compared to images reconstructed from the eight acquired energy bins.*Results The downsampling optimization method selected the combination of noncontiguous energy bins, suggesting that the resulting grayscale image may benefit from acquiring eight energy-bins despite subsequent downsampling. The head CT image reconstructed after optimal downsampling to three energy bins provided a bone / soft tissue CNR of 19.9 and soft tissue / adipose CNR of 2.0 compared to CNRs of 21.3 and 2.0, respectively, when reconstructing from eight energy bins.*Conclusions The proposed energy-bin downsampling method maintained grayscale CNR in head CT images from a clinical photon-counting CT prototype. Results suggest that having more native energy bins may benefit the optimal bin combinations.*Clinical Relevance/Application Results suggest that the proposed energy-bin downsampling method provides the image quality advantages of acquiring many energy bins while facilitating the workflow efficiencies of fewer energy bins.

RESULTS

The downsampling optimization method selected the combination of noncontiguous energy bins, suggesting that the resulting grayscale image may benefit from acquiring eight energy-bins despite subsequent downsampling. The head CT image reconstructed after optimal downsampling to three energy bins provided a bone / soft tissue CNR of 19.9 and soft tissue / adipose CNR of 2.0 compared to CNRs of 21.3 and 2.0, respectively, when reconstructing from eight energy bins.

CLINICAL RELEVANCE/APPLICATION

Results suggest that the proposed energy-bin downsampling method provides the image quality advantages of acquiring many energy bins while facilitating the workflow efficiencies of fewer energy bins.

SDP-PH-34 Image Quality Assessment With Deep Learning Based Image Reconstruction Algorithm For Ultra-high-resolution CT: A Phantom Study

Participants
Lingming Zeng, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

To quantify the effects of a deep learning (DL) algorithm on CT values, noise, spatial resolution, and detectability of CT images at different radiation doses compared to FBP and hybrid iterative reconstruction (HIR), and to explore the dose reduction opportunity of the DL algorithm for ultra-high-resolution CT reconstructed with 1024 matrix.*Methods and Materials A phantom was scanned by a 160-slice CT scanner at seven decreasing dose levels. All images were reconstructed using FBP, HIR at strength level 5 and DL algorithm at all strength levels with both 512 × 512 and 1024 × 1024 matrix; CT value, noise power spectrum (NPS), task-based transfer function (TTF), and the detectability index (d') were used to compare image quality.*Results CT values showed excellent consistency among different reconstruction algorithms. The noise reduction performance of DL in 512-matrix images is much better than that of DL in 1024-matrix images. DL algorithm performed very well in image noise reduction when the CTDIvol is 4.71 and 2.36mGy. The loss of spatial resolution increases with the decrease of radiation dose and the increase of DL level. Images reconstructed with a 1024 matrix have an improved spatial resolution compared to 512 matrix reconstructions. At CTDIvol above 7.06mGy, the d' values for DL were similar to those of HIR-5. At low radiation doses, the d' values for DL were significantly higher than those of HIR-5.*Conclusions The DL reconstruction algorithm can reduce radiation dose to 40% of regular dose while maintaining the image quality on 1024-matrix images.*Clinical Relevance/Application Deep learning trained algorithm (DELTA) is a data driven image reconstruction method based on deep learning method, which was aimed at denoising low-dose CT image.The noise reduction performance of DELTA in 512-matrix images is much better than that of DELTA in 1024-matrix images.Our data show that DELTA can reduce radiation dose to 40% of regular dose while maintaining the image quality on 1024-matrix images.

RESULTS

CT values showed excellent consistency among different reconstruction algorithms. The noise reduction performance of DL in 512-matrix images is much better than that of DL in 1024-matrix images. DL algorithm performed very well in image noise reduction when the CTDIvol is 4.71 and 2.36mGy. The loss of spatial resolution increases with the decrease of radiation dose and the increase of DL level. Images reconstructed with a 1024 matrix have an improved spatial resolution compared to 512 matrix reconstructions. At CTDIvol above 7.06mGy, the d' values for DL were similar to those of HIR-5. At low radiation doses, the d' values for DL were significantly higher than those of HIR-5.

SDP-PH-35 Computer-aided Identification Of Clinically Significant Prostate Lesions In Multiparametric MRI For Low-Dose-Rate Prostate Brachytherapy Treatment Planning

Participants
Jeremiah Sanders, Houston, Texas (*Presenter*) Consultant, C4 Imaging LLC

PURPOSE

Deep learning (DL) has the potential to improve MRI based detection and targeting of prostate cancer. Such improvements are critical for the development of image-guided radiotherapy regimens based upon targeted dose escalation instead of whole gland therapy. The purpose of this study was to investigate the feasibility of computer-aided identification of clinically significant prostate lesions on prostate multiparametric MRIs (mpMRIs) in order to facilitate MRI-guided brachytherapy with intraprostatic tumor dose escalation.*Methods and Materials One-hundred-eighteen males with histologically confirmed prostate underwent diagnostic mpMRI of the prostate. mpMRI included axial T2-weighted and diffusion-weighted MRIs; apparent diffusion coefficient (ADC) maps and synthetic high b-value images (b=1400 s/mm2) were computed from the DWIs. Clinically significant lesions were identified by an abdominal radiologist and manually contoured on the T2-weighted MRIs, ADC maps, and high b-value images. Fully convolutional networks (FCNs) were investigated for computer-aided identification of the clinically significant prostate lesions. The FCNs were developed on 100 of the mpMRIs (85%/15% train/validation split) and evaluated on the remaining 18 mpMRIs. Custom extensions to a commercial treatment planning system (TPS) (MIM Symphony, Cleveland, OH) were written to integrate the FCNs into a low-dose-rate prostate brachytherapy (LDRPBT) treatment planning workflow. The lesion identification performance was evaluated in the TPS using a criteria of at least 1 voxel overlap to be considered a true positive.*Results At user defined operating points, 18/19 clinically significant prostate lesions were identified on the mpMRIs with an average of approximately 2 false positives (FPs) per patient. There was a maximum of 7 FPs for one patient.*Conclusions Nearly all clinically significant prostate lesions were automatically identified on the prostate mpMRIs. Integration into the commercial TPS facilitated efficient rejection of false positive findings and additional refinements. Refined predictions may be used for dose escalation to the dominant lesion during treatment planning. Inclusion of additional mpMRIs into the development data set is underway to improve lesion identification performance and potentially facilitate a fullyautomated MRI-based LDRPBT imaging workflow.*Clinical Relevance/Application Computer-aided identification of clinically significant prostate lesions on mpMRI is feasible with DL, and the integration of the DL model into a commercial TPS enables MRI guided brachytherapy with potential for intraprostatic tumor dose escalation.

RESULTS

At user defined operating points, 18/19 clinically significant prostate lesions were identified on the mpMRIs with an average of approximately 2 false positives (FPs) per patient. There was a maximum of 7 FPs for one patient.

CLINICAL RELEVANCE/APPLICATION

Computer-aided identification of clinically significant prostate lesions on mpMRI is feasible with DL, and the integration of the DL model into a commercial TPS enables MRI guided brachytherapy with potential for intraprostatic tumor dose escalation.

SDP-PH-36 Feasibility Of Performing Abdominal Cta In Children With Both Low Radiation Dose And Contrast Medium Dose By Using 70kvp And Deep Learning Image Reconstruction (dlir)

Participants
Jianying Li, Beijing, China (*Presenter*) Employee, General Electric Company

PURPOSE

To assess the feasibility of performing abdominal CTA in children with low radiation dose and contrast medium dose using 70kVp and Deep Learning Image Reconstruction (DLIR) algorithm.*Methods and Materials 37 children (age range 7 month-14 years, average 6.87±3.11 years) underwent low dose abdominal CTA with 70kVp and automatic tube current modulation, the noise index was set at 11-15 based on children's age, contrast medium (CM) dose was 0.8-1.2ml/kg. Images were reconstructed at slice thickness of 0.625 and standard kernel with 50% and 100% Adaptive Statistical Iterative Reconstruction-V (ASIR-V) and DLIR with a high setting (DL-H). Two radiologists in consensus evaluated images for image noise, visualization of large artery and small artery separately on a 5-point scale (5, excellent, 4, good, 3, measurable and acceptable, 2, detectable and 1, not acceptable). CT attenuation number and image noise of Aorta (Ao), liver (LV) and back muscle (Mu) on the same image slice was measured for the objective image quality assessment, the signal-to-noise ratio (SNR) and contrast-to-noise ratio were calculated. The results among the 3 reconstruction groups were statistically compared using Kruskal-Wallis and ANOVA test. Radiation dose and CM dose were recorded.*Results The average CTDIvol and DLP was 1.47±0.26mGy and 37.41±10.98mGy.cm, respectively and the CM dose was 28.19±13.47 ml. The image noises (in HU) of Ao were 30.27±7.88 with 50%ASIR-V, 19.35±6.73 with 100%ASIR-V and 20.48±5.74 with DL-H. The 100%ASIR-V images had over-smoothed vessel margins and only the DL-H images provided acceptable scores on all three aspects (image noise, large artery and small artery) of the qualitative image quality evaluation.*Conclusions It is feasible to provide acceptable sub-mm slice thickness images with both low radiation dose and contrast dose in abdominal CTA in children using 70kVp and DLIR algorithm*Clinical Relevance/Application double-low-dose thin slice thickness abdominal CTA in children can be achieved by combining 70kVp and DL-H algorithm.

RESULTS

The average CTDIvol and DLP was 1.47±0.26mGy and 37.41±10.98mGy.cm, respectively and the CM dose was 28.19±13.47 ml. The image noises (in HU) of Ao were 30.27±7.88 with 50%ASIR-V, 19.35±6.73 with 100%ASIR-V and 20.48±5.74 with DL-H. The 100%ASIR-V images had over-smoothed vessel margins and only the DL-H images provided acceptable scores on all three aspects (image noise, large artery and small artery) of the qualitative image quality evaluation.

CLINICAL RELEVANCE/APPLICATION

double-low-dose thin slice thickness abdominal CTA in children can be achieved by combining 70kVp and DL-H algorithm.

SDP-PH-37 Comparison Of Virtual Unenhanced And True Unenhanced Images Of Upper Abdomen In A Rapid

Kvp-switching Spectral Ct

Participants
Yanhong Zhao, MMed,MMed, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to compare attenuation image quality on virtual unenhanced (VUE) images and true unenhanced (true non-contrast, TNC) images acquired with a rapid kVp-switching spectral CT.*Methods and Materials A total of 21 patients with acute upper abdominal pain underwent multiphase CT examination using a rapid kVp-switching spectral CT scanner (Revolution CT, GE Healthcare). Non-unenhanced, contrast-enhanced hepatic arterial and portal venous phase images were acquired. The following parameters were used in image acquisitions: 80/140 kV, noise index (NI) 8, rotation time 0.5s, pitch 0.992, pre-adaptive statistical iterative reconstruction (ASIR-V) 40%. CT value and image noise of liver, spleen, pancreas, kidney, and aorta were measured on TNC and VUE images (hepatic arterial and portal venous phase). The subjective image quality were independently assessed by two experienced radiologists. A five-point scale system (from 1=poor to 5=excellent) was utilised. Differences between groups were analysed using two-way ANOVA. A p value <0.05 was considered to indicate statistical significance.*Results There was no significant difference in CT values of liver (58.23±7.90 58.38±6.04 61.13±6.10, p=0.297), spleen (51.90±3.53; 52.84±3.33; 52.94±3.64, p=0.577), pancreas (42.79±6.19; 42.41±4.61; 40.14±4.54, p=0.208), kidney (33.21±3.22; 34.18±5.57; 36.12±4.25, p=0.108) and aorta (40.19±6.83; 43.94±8.39; 44.08±6.79, p=0.161) between VUE and TNC images. The image noise of the liver, spleen, pancreas and aorta (p = 0.000, p=0.000, p=0.001, p=0.000) were significantly lower in VUE than in TNC. The subjective image scores of TNC, arterial phase VUE scans, and venous phase VUE scans were 5.00±0.00, 4.81±0.40 and 3.86±0.36, respectively. The subjective image quality scores of arterial phase VUE were higher than that of venous phase (P=0.000).*Conclusions On abdominal examination, arterial phase VUE virtual unenhanced closer to the real plain, has the potential to replace the conventional scan has important clinical value.*Clinical Relevance/Application The VUE arterial phase virtual plain scan image is close to the real plain scan image quality, has the potential to replace the conventional plain scan, and can reduce unnecessary radiation dose in the upper abdominal examination.

RESULTS

There was no significant difference in CT values of liver (58.23±7.90 58.38±6.04 61.13±6.10, p=0.297), spleen (51.90±3.53; 52.84±3.33; 52.94±3.64, p=0.577), pancreas (42.79±6.19; 42.41±4.61; 40.14±4.54, p=0.208), kidney (33.21±3.22; 34.18±5.57; 36.12±4.25, p=0.108) and aorta (40.19±6.83; 43.94±8.39; 44.08±6.79, p=0.161) between VUE and TNC images. The image noise of the liver, spleen, pancreas and aorta (p = 0.000, p=0.000, p=0.001, p=0.000) were significantly lower in VUE than in TNC. The subjective image scores of TNC, arterial phase VUE scans, and venous phase VUE scans were 5.00±0.00, 4.81±0.40 and 3.86±0.36, respectively. The subjective image quality scores of arterial phase VUE were higher than that of venous phase (P=0.000).

CLINICAL RELEVANCE/APPLICATION

The VUE arterial phase virtual plain scan image is close to the real plain scan image quality, has the potential to replace the conventional plain scan, and can reduce unnecessary radiation dose in the upper abdominal examination.

SDP-PH-38 Radiation Dose Dependence Of Noise Level In Reconstructed Images By Advanced CT Noise Reduction Techniques.

Participants
Marcus Hook, MD, Charlottesville, Virginia (*Presenter*) Nothing to Disclose

PURPOSE

In our practice, we are currently using Siemens' iterative algorithm, ADMIRE, for reconstruction of pediatric abdominal CT images. Testing a new post-processing deep learning noise reduction technique, PixelShine, we conducted a comparative study using a phantom, as a first step. ADMIRE requires the user to select a strength of noise reduction when reconstructing images. PixelShine, on the other hand, has Adaptive Processing that automatically determines the strength of post-processing depending on the ideal amount of noise selected. The purpose of this study was to investigate the radiation dose dependence of the noise level in CT images reconstructed using ADMIRE and PixelShine.*Methods and Materials The ACR phantom was scanned with our pediatric abdomen protocol using a technique of 90 kVp with varying effective mAs (22, 44, 88, 131, and 176 mAs) to obtain different radiation dose levels (CTDIvol ranged between 0.5 and 4.0 mGy). Each of the acquired datasets was reconstructed using filter back projection (FBP) and ADMIRE (strength 3, our institutional standard) with a slice thickness of 1.5 mm. The images reconstructed by FBP were processed by PixelShine in Soft Tissue mode (PixelShine S). At each radiation dose level, the noise (standard deviation: SD) was measured at the center of the images reconstructed with FBP, ADMIRE, and processed by PixelShine. The radiation dose and the corresponding SD values were then plotted.*Results For the FBP images, the SD values varied between 16.5 HU (4.0 mGy) and 45.5 HU (0.5 mGy). As expected, the SD values of the ADMIRE images are smaller compared to the SD values of the FBP images, decreasing at a constant rate. The SD values of the ADMIRE images varied from 12.7 HU (4.0 mGy) to 35.0 HU (0.5 mGy). When processed with PixelShine, the noise was reduced to a greater extent than ADMIRE for the lowest does tested (0.5 and 1.0 mGy), and had approximately the same level of noise reduction as ADMIRE for 2.0 mGy. However, at high dose levels (3.0 and 4.0 mGy), little noise reduction was observed with PixelShine compared to FBP. As a result, the SD value of the PixelShine images varied from 16.2 HU (4.0 mGy) to 23.0 HU (0.5 mGy). The results show that compared to FBP and ADMIRE, PixelShine outputs images with smaller swings in the noise level even when the radiation dose changes.*Conclusions The noise in the images processed by PixelShine S was found to be less dose-dependent than that in the images reconstructed by ADMIRE 3. PixelShine S offers greater noise reduction at low-dose and very low-dose techniques than ADMIRE 3.*Clinical Relevance/Application It is clinically useful to understand characteristics of deep learning based noise reduction techniques by comparing with existing iterative reconstruction techniques, which are currently used.

RESULTS

For the FBP images, the SD values varied between 16.5 HU (4.0 mGy) and 45.5 HU (0.5 mGy). As expected, the SD values of the ADMIRE images are smaller compared to the SD values of the FBP images, decreasing at a constant rate. The SD values of the ADMIRE images varied from 12.7 HU (4.0 mGy) to 35.0 HU (0.5 mGy). When processed with PixelShine, the noise was reduced to a greater extent than ADMIRE for the lowest does tested (0.5 and 1.0 mGy), and had approximately the same level of noise reduction as ADMIRE for 2.0 mGy. However, at high dose levels (3.0 and 4.0 mGy), little noise reduction was observed with PixelShine compared to FBP. As a result, the SD value of the PixelShine images varied from 16.2 HU (4.0 mGy) to 23.0 HU (0.5 mGy). The results show that compared to FBP and ADMIRE, PixelShine outputs images with smaller swings in the noise level even when the radiation dose changes.

SDP-PH-39   **Sensitivity Enhanced Fast X-ray-induced Acoustic Computed Tomography (XACT) Imaging System**

Participants
Siqi Wang, Irvine, California (*Presenter*) Nothing to Disclose

PURPOSE

X-ray-induced acoustic computed tomography (XACT) as a novel imaging modality has shown great potential in applications ranging from biomedical imaging to nondestructive testing. A major challenge in XACT imaging is to detect the weak acoustic signal induced by X-ray with high sensitivity. The existing XACT systems require thousands of signal averages to improve the signal to noise ratio (SNR) due to the insufficient signal amplification. We developed a 128-channel data acquisition (DAQ) system with 2-stage amplification for XACT, which drastically reduces the number of averages needed for XACT imaging, and makes 3D imagine from a single X-ray projection realizable.*Methods and Materials The developed system consists of two amplification stages. The first preamplification stage prepares the weak raw acoustic signals into output-ready signals that are noise-tolerant and detectable by the next stage. Next, the conditioned signals travel through another amplification path integrated in the DAQ device. In the end, the 128-channel analog signals are sampled and converted to digital values by the onboard 12-bit ADCs. To demonstrate the performance of the proposed 2-stage amplification and DAQ system in XACT, a T-shaped lead samples fixed inside of a 3% gelatin water-based phantom was used as the imaging target. A 128 channel ring array was used as the ultrasound detector. Reconstruction was done using a universal back projection method.*Results Comparing with similar tests done previously by S. Tang (2017) using the first-generation XACT system configuration, the proposed system achieved comparable reconstruction result by using only 1 pulse of X-ray. In contrast, more than 6000 frames were taken in S. Tang's tests using the first generation SonixDAQ based DAQ system.*Conclusions By utilizing a 128-channel 2 amplification stage design, the developed system can greatly enhance the raw XA signals for further post-processing. With higher SNR, the total X-ray pulses needed for XACT signal averaging can be drastically reduced, which in turn reduces the overall dosage to the target and shortens the scanning time. We expect that the proposed 2-stage DAQ system provides a solid alternative to currently expensive-to-acquire commercially available ultrasound systems.*Clinical Relevance/Application XACT system can achieve 3D volumetric imaging with a single X-ray projection, which reduces the complexity of the operation, the scanning time and radiation dose compared with conventional CT.

RESULTS

Comparing with similar tests done previously by S. Tang (2017) using the first-generation XACT system configuration, the proposed system achieved comparable reconstruction result by using only 1 pulse of X-ray. In contrast, more than 6000 frames were taken in S. Tang's tests using the first generation SonixDAQ based DAQ system.

CLINICAL RELEVANCE/APPLICATION

XACT system can achieve 3D volumetric imaging with a single X-ray projection, which reduces the complexity of the operation, the scanning time and radiation dose compared with conventional CT.

SDP-PH-40   **Sophisticated Characterization Of State-of-the-art Iterative Reconstruction Techniques With A Single Scan Of A Basic Water Phantom**

Participants
Marcel Van Straten, PhD, Rotterdam, Netherlands (*Presenter*) Research collaboration, Siemens AG

PURPOSE

To characterize the performance of iterative reconstruction (IR) techniques in general, and of texture preserving noise removal in particular, without the need for multiple scans and/or complex phantoms.*Methods and Materials A cylindrical, 20 cm diameter, water phantom was scanned with three CT scanners from one manufacturer (Siemens) and reconstructed with and without the iterative reconstruction (IR) technique available at each scanner (SOMATOM Edge with SAFIRE, SOMATOM Force with ADMIRE, and NAEOTOM Alpha with QIR). CTDIvol (1 mGy), pitch (0.8), rotation time (0.5 s), slice thickness (1 mm), and pixel spacing (0.5 mm) were kept constant. Both a kernel with medium spatial resolution and a sharp reconstruction kernel were used. Image noise was determined for all radial distances r from the phantom iso-center by calculating the variance of the CT numbers in the angular direction. Texture preserving noise removal was quantified by the image noise dynamic range (DR), i.e. the ratio of the largest (found at the phantom edge) to the smallest variance (found in water). The noise power spectrum (NPS) was estimated in multiple small regions in water and averaged. The high contrast modulation transfer function (MTF) was estimated via the edge spread function calculated at the radial transition from phantom to air. Inspired by the known relationship between noise variance, NPS, and MTF in case of conventional filtered back projection (FBP), the first moment of the normalized NPS and the second moment of MTF^2 were calculated.*Results At medium resolution, the DR of noise variance varied between approx. 2 (FBP) and 8 (full strength IR) for all scanners. Dependency on IR strength for noise variance in water was virtually the same for all scanners. For the sharp kernel, DR of noise variance for the newest scanner (Alpha) was up to approx. 4 times smaller than for the other scanners. This might be thanks to the smaller detector pixels. Noise levels in water were the lowest for this scanner, but less reduced at maximum IR strength compared to FBP in this case. A shift of the NPS to lower frequencies for higher IR strengths was virtually absent for the newest scanner. MTF was more constant as well while varying IR strength.*Conclusions Based on a single scan, the contribution of texture preserving noise removal was proven to be the dominant factor for the resulting noise level when varying IR strength. Compared to its two predecessors, the latest IR technique leaves the high contrast MTF and normalized NPS more intact when reducing noise by increasing IR strength.*Clinical Relevance/Application A quick assessment of IR techniques with a readily available phantom allows for protocol optimization and standardization, which could be relevant for multi-center clinical trials.

RESULTS

At medium resolution, the DR of noise variance varied between approx. 2 (FBP) and 8 (full strength IR) for all scanners. Dependency on IR strength for noise variance in water was virtually the same for all scanners. For the sharp kernel, DR of noise variance for the newest scanner (Alpha) was up to approx. 4 times smaller than for the other scanners. This might be thanks to the smaller detector pixels. Noise levels in water were the lowest for this scanner, but less reduced at maximum IR strength compared to FBP in this case. A shift of the NPS to lower frequencies for higher IR strengths was virtually absent for the newest scanner. MTF was more constant as well while varying IR strength.

CLINICAL RELEVANCE/APPLICATION

A quick assessment of IR techniques with a readily available phantom allows for protocol optimization and standardization, which could be relevant for multi-center clinical trials.

SDP-PH-41 Feasibility Of Low-tube Voltage For Small-diameter Coronary Stent Imaging Using High-definition 256-detector Row Ct: A Phantom Study

Participants
Yanhong Zhao, MMed,MMed, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the feasibility of low tube voltage, high-definition scan protocol for imaging small-diameter stents.*Methods and Materials Three different types of coronary stent phantoms made of different materials and with different inner diameters were used (3mm Cypher, 3mm Tsunami, and 2.5mm Cypher). The tubes were filled with iodinated contrast medium (10mg/ml), positioned in a plastic container filled with water. The scan was performed using a 256-detector row CT (Revolution CT, GE healthcare) with prospective ECG-triggered axial cardiac mode and ECG simulation at a heart rate of 62 BPM. High definition mode was turned on during data acquisition and different tube voltages (120, 100 and 80 kVp) were applied. Other parameters: noise index of 33.6, auto mA. Subjective image quality was assessed independently by two radiology, image quality was evaluated with five-point Likert scale (1, very poor; 2, suboptimal; 3, acceptable; 4, good; 5, excellent.). CT value, image noise, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR) and visible diameter in percentage (VD%=VD/ID) were compared between all three sets of images.*Results The mean CT values of the sent lumens were significantly different in 120, 100, and 80 kVp images (198.83±25.70 264.30±26.35 343.80±14.11, p=0.001). The SD values in 120, 100, and 80 kVp images were also statistically different (33.43±2.45 38.33±1.22 45.90±1.99, p=0.001). However, there was no significant difference in SNR and CNR between the three groups (6.00±1.22 6.91±0.85 7.49±0.11, p=0.182) (6.66±1.20 7.46±1.19 7.83±0.41, p=0.702). There was no significant difference in the stent internal diameter display rate between the three tube voltages (58.44% ± 5.82% 50.22% ± 6.34% 55.78% ± 10.33%, p = 0.148). The CTDI at 120kv, 100kv, and 80kv tube voltages were (3.87, 3.36, 2.47), respectively. The subjective scores of the three groups of tube voltages were (4.50±0.50 4.33±0.58 4.17±0.29), with no statistical difference (p= 0.405).*Conclusions The low tube voltage, high definition scan protocol using a 256-detector row CT is feasible to evaluate small internal diameter, and it can reduce the radiation dose of patients.*Clinical Relevance/Application The low tube voltage can be used for the imaging of small-diameter stent to reduce the radiation dose while maintaining image quality.

RESULTS

The mean CT values of the sent lumens were significantly different in 120, 100, and 80 kVp images (198.83±25.70 264.30±26.35 343.80±14.11, p=0.001). The SD values in 120, 100, and 80 kVp images were also statistically different (33.43±2.45 38.33±1.22 45.90±1.99, p=0.001). However, there was no significant difference in SNR and CNR between the three groups (6.00±1.22 6.91±0.85 7.49±0.11, p=0.182) (6.66±1.20 7.46±1.19 7.83±0.41, p=0.702). There was no significant difference in the stent internal diameter display rate between the three tube voltages (58.44% ± 5.82% 50.22% ± 6.34% 55.78% ± 10.33%, p = 0.148). The CTDI at 120kv, 100kv, and 80kv tube voltages were (3.87, 3.36, 2.47), respectively. The subjective scores of the three groups of tube voltages were (4.50±0.50 4.33±0.58 4.17±0.29), with no statistical difference (p= 0.405).

CLINICAL RELEVANCE/APPLICATION

The low tube voltage can be used for the imaging of small-diameter stent to reduce the radiation dose while maintaining image quality.

SDP-PH-42 Radioactive Plaque Episcleral Brachytherapy Of Uveal Melanoma: Is Determination Of Eye-ball Curvature At The Tumor Site Through Tomographic Imaging Required For Accurate Treatment Planning?

Participants
Konstantinos Perisinakis, PhD, Heraklion, Greece (*Presenter*) Nothing to Disclose

PURPOSE

To investigate and quantify the effect of episcleral brachytherapy Ru-106 plaque misposition due to differences in curvature between sclera and plaque on dose delivered to uveal melanoma tumors.*Methods and Materials Participants in the study were 15 patients presented with uveal melanoma (UM) and treated with radioactive plaque episcleral brachytherapy (EB). A 24 mm diameter silver Ru-106 plaque was used. Eye-ball curvature at the site of tumor was determined through pre-operation tomographic imaging. A mathematical model was developed to predict the distance of the tumor margin from the plaque when the curvature of the sclera at the tumor region was different than the curvature of the plaque. The standard treatment planning software package was used to determine the dose to apex and the outer margins of the tumor. Doses were determined assuming an eyeball of the same curvature as the radioactive plaque and b) assuming the real curvature at the tumor site. Differences between corresponding doses were recorded for each treated patient.*Results The curvature of patient's eye-ball at the tumor site was found to occasionally differ considerably from the curvature of the radioactive plaque available in our institution. The diameter of the equivalent sphere was found to range 20.5-26.4 mm. Dose difference for the tumor apex was found to be up to 15% while dose differences for the distant tumor margin was found to be up to 35%.*Conclusions The exact eye-ball curvature at the tumor site should be measured through pre-therapy tomographic imaging and taken into account in the treatment planning of radioactive plaque episcleral brachytherapy to avoid uncertainties in dose delivered to the tumor.*Clinical Relevance/Application Radioactive plaque episcleral brachytherapy (EB) is nowadays the dominant vision-preserving alternative treatment against enucleation. The treatment efficiency regarding tumor control is heavily relied on the accuracy of the treatment plan and the correct positioning of the plaque above the tumor during surgery.

RESULTS

The curvature of patient's eye-ball at the tumor site was found to occasionally differ considerably from the curvature of the radioactive plaque available in our institution. The diameter of the equivalent sphere was found to range 20.5-26.4 mm. Dose difference for the tumor apex was found to be up to 15% while dose differences for the distant tumor margin was found to be up to 35%.

CLINICAL RELEVANCE/APPLICATION

Radioactive plaque episcleral brachytherapy (EB) is nowadays the dominant vision-preserving alternative treatment against enucleation. The treatment efficiency regarding tumor control is heavily relied on the accuracy of the treatment plan and the

correct positioning of the plaque above the tumor during surgery.

SDP-PH-43 Phantom Investigation Of Digital Tomosynthesis As An Orbit Screening Modality Prior To MRI

Participants
Christina Brunnquell, PhD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

To investigate and compare digital x-ray tomosynthesis (DT) to 2-view radiography (DR) and CT for detecting tungsten carbide, steel, and aluminum fragments in the orbits for screening prior to MRI.*Methods and Materials A semi-anthropomorphic head phantom was created by placing a human skull model into a water bath. Shaving fragments of aluminum, steel, and tungsten carbide were created. Varying sized fragments of aluminum (N=4, 0.1-2.7mg, 0.04-1.0mm3), steel (N=8, 0.4-5.9mg, 0.05-0.75mm3), and tungsten carbide (N=5, 0.2-8.1mg, 0.01-0.52mm3) were embedded in table grapes, with one fragment in each grape. The grapes were placed into the respective orbits, submerged in a water bath, and imaged with our institution's orbit CT protocol (including thin slices and maximum intensity projections), 2-view facial bone DR protocol, and facial DT protocol. Images were reviewed to qualitatively evaluate comparative detectability on each modality. For each grape with a different fragment embedded, repeatability was investigated by acquiring repeat images after repositioning of the grapes, the skull, and/or no repositioning.*Results Considered as a group, >90% of all fragments were detected on CT, ~65% on DT, and ~55% on DR. All tungsten carbide fragments were detectable on all modalities. All steel fragment sizes were detectable on CT, while 6/8 (=0.7mg) were detectable on DT and 5/8 (=0.8mg) were detectable on DR. Aluminum fragments went undetected on DR, while the largest was just detectable on DT (2.7mg) and 3/4 (=0.7mg) were detectable on CT. Observation of repeat image acquisitions indicated high consistency in metal fragment detectability on CT, while detection of fragments on DR and DT was more position-dependent.*Conclusions With respect to detectability of metal fragments in the orbit, DT performance was found to lie in between that of DR and CT. DT may be an appropriate modality for orbit metal screening, providing a balance between the radiation dose, detection capabilities, and cost of DR and CT. Expansion of this work into a formal detectability study with multiple image readers is warranted, and establishment of optimal DT reconstruction variables (slice thickness and interval) could improve performance.*Clinical Relevance/Application Given the heterogeneity of orbit metal screening practices, the results of this study comparing DT, DR, and CT in an orbit phantom can inform MRI screening decisions to balance conspicuity, resource availability, cost, and radiation dose.

RESULTS

Considered as a group, >90% of all fragments were detected on CT, ~65% on DT, and ~55% on DR. All tungsten carbide fragments were detectable on all modalities. All steel fragment sizes were detectable on CT, while 6/8 (=0.7mg) were detectable on DT and 5/8 (=0.8mg) were detectable on DR. Aluminum fragments went undetected on DR, while the largest was just detectable on DT (2.7mg) and 3/4 (=0.7mg) were detectable on CT. Observation of repeat image acquisitions indicated high consistency in metal fragment detectability on CT, while detection of fragments on DR and DT was more position-dependent.

CLINICAL RELEVANCE/APPLICATION

Given the heterogeneity of orbit metal screening practices, the results of this study comparing DT, DR, and CT in an orbit phantom can inform MRI screening decisions to balance conspicuity, resource availability, cost, and radiation dose.

SDP-PH-44 Survey On The Use Of Artificial Intelligence In The Netherlands

Participants
Paul R. Algra, MD, PhD, Alkmaar, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the use of Artificial Intelligence (AI) applications and the impediments experienced when implementing.*Methods and Materials We conducted a survey among boards of directors from all non-university hospitals in the Netherlands in 2021.*Results We received feedback from 49 institutions (54,4%). Most of the respondents (82,6%) see AI as an opportunity or as opportunity and threat (17,4%) while none sees AI as a threat alone. Larger hospitals (>500 beds) are more likely (57,7%) to implement AI-applications than smaller hospitals (42,2%). AI imaging applications are most frequently implemented (47,7%), followed by other AI applications such as clinical decision support (28,9%) and natural language processing applications (14,0%). Only 11,6% of the hospitals has a long-term policy regarding the implementation of AI. According to the survey, a major impediment of AI implementation, is lack of funding or reimbursement. Hospitals mention low budgets or few investors for implementing AI. Therefore, hospitals often (92,7%) fund the implementation of AI themselves. Sharing data between institutions is also limited. Data for training algorithms is mostly retrieved from own hospital data (69,7%), and 18,2% are using data originating from other hospitals. However, a clear majority of 91,7% is willing to share data with other hospitals for improving the quality of algorithms. A lack of AI knowledge might also be an impediment, since a minority (43,6%) has an AI-team and only 30,3% hospitals have an AI-training for their employees.*Conclusions Dutch non-university hospitals are frequently implementing AI. Lack of funding, sharing data, cooperating with other institutions and knowledge can be named as the most impeding factors when implementing AI.*Clinical Relevance/Application Dutch hospital directors see AI as an opportunity. Lack of reimbursement or funding and not (being able) sharing data are the major obstacles for implementation.

RESULTS

We received feedback from 49 institutions (54,4%). Most of the respondents (82,6%) see AI as an opportunity or as opportunity and threat (17,4%) while none sees AI as a threat alone. Larger hospitals (>500 beds) are more likely (57,7%) to implement AI-applications than smaller hospitals (42,2%). AI imaging applications are most frequently implemented (47,7%), followed by other AI applications such as clinical decision support (28,9%) and natural language processing applications (14,0%). Only 11,6% of the hospitals has a long-term policy regarding the implementation of AI. According to the survey, a major impediment of AI implementation, is lack of funding or reimbursement. Hospitals mention low budgets or few investors for implementing AI. Therefore, hospitals often (92,7%) fund the implementation of AI themselves. Sharing data between institutions is also limited. Data for training algorithms is mostly retrieved from own hospital data (69,7%), and 18,2% are using data originating from other hospitals. However, a clear majority of 91,7% is willing to share data with other hospitals for improving the quality of algorithms. A lack of AI knowledge might also be an impediment, since a minority (43,6%) has an AI-team and only 30,3% hospitals have an AI-training for their employees.

CLINICAL RELEVANCE/APPLICATION

Dutch hospital directors see AI as an opportunity. Lack of reimbursement or funding and not (being able) sharing data are the major

obstacles for implementation.

SDP-PH-45   Crystal Characterization And Differentiation In Spectral Photon Counting CT: Results From The First Clinical Scanner Of Its Generation.

Participants
Florian Huber, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the first clinically approved spectral photon-counting CT (SPCCT) in the differentiation of crystals related with gout (monosodium urate, MSU) vs. pseudogout (calcium pyrophosphate, CPP), and to compare its performance with energy-integrating dual-energy CT (DECT) scanners of the previous generation.*Methods and Materials Agar-based (AG) gels mimicking attenuation of the articular cartilage and synthetic crystal suspensions of MSU and CPP at different concentrations (90-500 and 26-109 mg/mL, respectively) were inserted in a phantom. All samples were scanned with SPCCT (NAEOTOM Alpha, Siemens), dual-source (DS), single-source split-filter (SF) and sequential scan (SS) DECT at comparable dose levels (CTDIvol: 4.4-12.5 for each) and tube potentials (80/140, 120 and 140 kV). Images were post-processed using DE overlay (DEO) values optimized for gout/MSU detection with dual-energy ratios as recommended by the literature (DECT) and vendor (SPCCT). Generated low/high kV HU-values and DEO values were measured for all samples by drawing same-sized ROIs (0.3cm2) on every second axial image for ten consecutive steps. Sample consistency and differences between radiation doses and scanners were investigated for all parameters, separately for concentrations and materials, respectively, using ANOVA, t-testing and analysis of mean differences.*Results Regardless of scanner type, all crystal suspensions showed excellent homogeneity (p=0.23-1).HU-values in SPCCT did not depend on radiation dose overall. Apart from that, all quantitative parameters differed between CT scanner types and dose levels (p<0.01). However, mean differences were comparable between scanners [14.3-28.2]. Both CPP and MSU showed significant concentration-dependent differences in HU and DEO (all p<0.01). Correspondingly, concentrations of at least 195 mg/mL MSU and 47 mg/mL CPP crystals could be reliably differentiated with all techniques (mean DEO in SPCCT: -10.9+/-7.4 vs. -36.7+/-15.4, respectively).*Conclusions Differentiation of gout/MSU from pseudogout/CPP crystals at typical clinical concentrations is feasible with a clinical SPCCT system. Related quantitative measurements are comparable with values from DECT-scanners of the latest generation. First results may indicate better dose-related robustness in SPCCT for material decomposition tasks in the future.*Clinical Relevance/Application This is the first in vitro proof-of-concept for material decomposition in a clinical SPCCT workflow. Further investigations in vivo with ex vivo confirmation are needed to transition current knowledge and DECT-based reference values of material decomposition in musculoskeletal and other settings to a new era of quantitative color CT imaging.

RESULTS

Regardless of scanner type, all crystal suspensions showed excellent homogeneity (p=0.23-1).HU-values in SPCCT did not depend on radiation dose overall. Apart from that, all quantitative parameters differed between CT scanner types and dose levels (p<0.01). However, mean differences were comparable between scanners [14.3-28.2]. Both CPP and MSU showed significant concentration-dependent differences in HU and DEO (all p<0.01). Correspondingly, concentrations of at least 195 mg/mL MSU and 47 mg/mL CPP crystals could be reliably differentiated with all techniques (mean DEO in SPCCT: -10.9+/-7.4 vs. -36.7+/-15.4, respectively).

CLINICAL RELEVANCE/APPLICATION

This is the first in vitro proof-of-concept for material decomposition in a clinical SPCCT workflow. Further investigations in vivo with ex vivo confirmation are needed to transition current knowledge and DECT-based reference values of material decomposition in musculoskeletal and other settings to a new era of quantitative color CT imaging.

SDP-PH-46   Clinical Performance Of Temporal Bone MRI Using 3D Bssfp With High Performance Gradients At 0.5t Is Comparable To Conventional Field Strengths

Participants
Elena Cora, MD, Halifax, Nova Scotia (*Presenter*) Nothing to Disclose

PURPOSE

Magnetic resonance imaging of the temporal bone is difficult, and while a high signal to noise ratio (SNR) sequence such as balanced steady state free precession (bSSFP) is preferred, lower SNR sequences are often used to avoid the banding artifacts that occur due to off-resonance when using bSSFP on conventional clinical systems. The 0.5T EvryTM system (Synaptive Medical) combines low field strength with high-performance components, and we postulate that this combination may produce comparable image quality to higher field clinical systems. Our aim was to demonstrate image quality for 0.5T bSSFP acquisitions that was non-inferior to clinical field strength acquisitions, assessed through radiologist rating.*Methods and Materials We acquired de-identified images from 6 patients that had previously undergone clinical temporal bone exams with bSSFP acquisitions (3 patients at 3T and 3 patients at 1.5T). These patients were then recruited to undergo 0.5T scans during which we acquired axial 3D bSSFP images. All images were then shown to two board-certified neuroradiologists who rated their ability to visualize 5 anatomical structures relevant to clinical temporal bone MRI exams: superior semi-circular canal (SSC), facial nerve, cochlear nerve, vestibule, and cochlea. A Likert scale ranging from 1-5 was used. Rating was recorded separately for each ear, but when analyzing the results of radiologist ratings, the data for the left and right anatomy were concatenated so that one result per anatomical structure was obtained. Many of the patients scanned have existing pathologies that we hope to perform a diagnostic sensitivity analysis upon (as more patients receive scans).*Results The mean Likert score for each of the 5 structures was higher for 0.5T than clinical scans, therefore a one-sided, paired t-test was used to evaluate potential superiority of 0.5T image quality. The results showed that the image quality of the SSC and vestibule at 0.5T both showed statistical advantage (p < 0.01 and p < 0.05, respectively) over clinical field strengths. The overall scores (when all anatomical structures were combined) demonstrated significant improvement at 0.5T, reaching p < 0.01.*Conclusions We have shown that temporal bone bSSFP images acquired at 0.5T with the EvryTM system are rated as having better quality than bSSFP images acquired at clinical field strengths. More specifically, the visualization of the SSC and vestibule at 0.5T show statistically significant advantages.*Clinical Relevance/Application The high resolution temporal bone bSSFP images from EvryTM allow for preferable visualization of the SSC compared to clinical field strengths, while the superior artifact suppression enables confident visualization of any schwannomas, if present.

RESULTS

The mean Likert score for each of the 5 structures was higher for 0.5T than clinical scans, therefore a one-sided, paired t-test was used to evaluate potential superiority of 0.5T image quality. The results showed that the image quality of the SSC and vestibule at 0.5T both showed statistical advantage (p < 0.01 and p < 0.05, respectively) over clinical field strengths. The overall scores

(when all anatomical structures were combined) demonstrated significant improvement at 0.5T, reaching p < 0.01.

CLINICAL RELEVANCE/APPLICATION

The high resolution temporal bone bSSFP images from EvryTM allow for preferable visualization of the SSC compared to clinical field strengths, while the superior artifact suppression enables confident visualization of any schwannomas, if present.

SDP-PH-47 Using Mobile Ct Scanner In A Field Hospital Setting To Manage Patients With Covid-19

Participants
Nikita Kudryavtsev, MD, Moscow, Russian Federation (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the efficacy of the mobile CT scanner in the field hospital setting to manage patients with COVID-19.*Methods and Materials Due to the spread of the COVID-19 pandemic, temporary field hospitals were organized in Moscow. One of such backup hospitals was arranged in the Krylatskoye Ice Palace. Given the obvious technical and time constraints associated with the installation of a stationary CT scanner, one of the suggested options was a mobile CT scanner. The temporary field hospital accepted patients with mild and moderate COVID-19. The patients with suggestive clinical signs were referred to the CT examinations of the chest, brain, abdomen, pelvis, and bones. To assess the CT efficacy the specialists calculated the workload as the ratio between the average number of studies per day and the target value calculated for Moscow clinics (41 studies per three-shift workday).*Results Totally the field hospital personnel performed 6,264 CT studies. ?hest CT - 6,126 studies; brain - 98; abdomen - 31; other - 9 studies. The long-term scans (15-25 sec.) did not let patients with respiratory insufficiency hold their breath for the entire time of the study. The chest CT images had motion artifacts and stair-step artifacts. The brain CT images contained artifacts of different nature, that got more intense near the skull base, which made an evaluation of the subtentorial areas of the brain difficult. The study of the abdominal organs also detected the gas-interface artifacts and the helical artifacts. The achieved average number of studies per three-shift workday amounted to 44 (from 14 at the launch to 110 and more during the busiest days), which corresponded to 106% of the recommended workload.*Conclusions Despite the artifacts, the use of a mobile CT scanner provided sufficient diagnostic capabilities for the imaging of the chest, brain, and abdomen in the field hospital setting amidst the COVID-19 pandemic. The mentioned workload figures confirmed the efficacy of the equipment under study and validated the viability of the mobile CT scanners for field hospitals.*Clinical Relevance/Application Aside from the temporary field hospitals for patients with COVID-19, the mobile CT units may be effective in the medical facilities, where it is not possible to set up a stationary CT scanner. The mobile CT devices may be used in remote settlements and temporary field hospitals during disaster relief operations.The obtained results allowed to build a list of requirements for such mobile CT scanners, justify the need for new kinds of CT equipment that would be tolerant towards the power source parameters, easy to install in the typical field hospital setting, applicable in emergencies, and suitable for remote areas in an unprepared environment.

RESULTS

Totally the field hospital personnel performed 6,264 CT studies. ?hest CT - 6,126 studies; brain - 98; abdomen - 31; other - 9 studies. The long-term scans (15-25 sec.) did not let patients with respiratory insufficiency hold their breath for the entire time of the study. The chest CT images had motion artifacts and stair-step artifacts. The brain CT images contained artifacts of different nature, that got more intense near the skull base, which made an evaluation of the subtentorial areas of the brain difficult. The study of the abdominal organs also detected the gas-interface artifacts and the helical artifacts. The achieved average number of studies per three-shift workday amounted to 44 (from 14 at the launch to 110 and more during the busiest days), which corresponded to 106% of the recommended workload.

CLINICAL RELEVANCE/APPLICATION

Aside from the temporary field hospitals for patients with COVID-19, the mobile CT units may be effective in the medical facilities, where it is not possible to set up a stationary CT scanner. The mobile CT devices may be used in remote settlements and temporary field hospitals during disaster relief operations.The obtained results allowed to build a list of requirements for such mobile CT scanners, justify the need for new kinds of CT equipment that would be tolerant towards the power source parameters, easy to install in the typical field hospital setting, applicable in emergencies, and suitable for remote areas in an unprepared environment.

SDP-PH-48 Developing A Framework For Prospective Evaluation Of MRI Deep Learning Reconstruction: A Case Study Of Higher Resolution And Higher Image Quality In Shorter Scan Time

Participants
Hung Do, PhD, Tustin, California (*Presenter*) Employee, Canon Medical Systems Corporation

PURPOSE

To develop a comprehensive framework for prospective evaluation of Deep Learning Reconstruction (DLR) and apply it to a case study, in which DLR allows MRI acquisition with higher resolution and image quality in shorter scan time.*Methods and Materials IRB-approved written consent was obtained for 20 patients undergoing clinical knee exams on a 3T MRI. Routine protocol was performed (named REF hereafter) followed immediately by a high-resolution shorter scan-time protocol which was reconstructed with DLR and 3 typical conventional reconstruction filters (NL2, GA43, and GA53). The 5 reconstructions (DLR, NL2, GA43, GA53, and REF) per sequence were de-identified, randomized, and shared with 2 MSK experts for blind review using 8 scoring criteria and force-ranking. Readers were asked to review overall image quality and to review and comment on specific anatomical and pathological features. Quantitative SNR, CNR, and full width at half maximum (FWHM) of small features were measured and compared between the 5 reconstructions. Generalized Estimating Equations (GEE) with Bonferroni adjustment was used for comparing reader's scores, SNR, CNR, and FWHM between DLR vs. NL2, GA43, GA53, and REF. Inter-rater agreement was assessed using Gwet's Agreement Coefficient (AC2) with ordinal weighting. Paired Student's T-test was used to compare mean scan time and resolution.*Results Mean scan time was shortened by 10% with DLR from 157 ± 24 to 142 ± 16 s (p = 0.023) per sequence. Readout resolution was increased by 21% from 316 ± 43 to 382 ± 27 (p=0.007). Phase encoding resolution was increased by 55% from 196 ± 11 to 304 ± 51 (p<0.001). DLR's SNR and CNR were statistically higher than those from NL2, GA43, and GA53 (p<0.008) but statistically lower than those from REF (p<0.001). DLR's FWHM was statistically higher than that of REF (p =0.004) and not significantly different from those from NL2, GA43, and GA53 (p>0.03). For reader 1, DLR was rated statistically higher than all 4 other recons in 35/36 comparisons (p<0.002). For reader 2, DLR was rated statistically higher in 19/36 comparisons (p<0.007). The Gwet's agreement coefficients AC2 range from 0.77 to 0.87 (substantial) for 8 scoring criteria and 0.38 (fair) for force-ranking.*Conclusions We propose a framework for prospective evaluation of DLR and use it to demonstrate that DLR allows MR acquisition of 21%-55% higher resolution and higher image quality with 10% shorter scan time.*Clinical Relevance/Application Deep Learning has been applied extensively in medical image reconstruction, however, to our knowledge, there is no comprehensive framework for prospective

evaluation. We aim to develop one and apply it to a case study, in which DLR allows higher resolution and image quality in shorter scan time.

RESULTS

Mean scan time was shortened by 10% with DLR from 157 ± 24 to 142 ± 16 s (p = 0.023) per sequence. Readout resolution was increased by 21% from 316 ± 43 to 382 ± 27 (p=0.007). Phase encoding resolution was increased by 55% from 196 ± 11 to 304 ± 51 (p<0.001). DLR's SNR and CNR were statistically higher than those from NL2, GA43, and GA53 (p<0.008) but statistically lower than those from REF (p<0.001). DLR's FWHM was statistically higher than that of REF (p =0.004) and not significantly different from those from NL2, GA43, and GA53 (p>0.03). For reader 1, DLR was rated statistically higher than all 4 other recons in 35/36 comparisons (p<0.002). For reader 2, DLR was rated statistically higher in 19/36 comparisons (p<0.007). The Gwet's agreement coefficients AC2 range from 0.77 to 0.87 (substantial) for 8 scoring criteria and 0.38 (fair) for force-ranking.

CLINICAL RELEVANCE/APPLICATION

Deep Learning has been applied extensively in medical image reconstruction, however, to our knowledge, there is no comprehensive framework for prospective evaluation. We aim to develop one and apply it to a case study, in which DLR allows higher resolution and image quality in shorter scan time.

SDP-PH-49   **Evaluation Of Apparent Noise And Low Contrast Detectability On Abdominal Phantom CT Images Reconstructed With A New Deep Learning Algorithm**

Participants
Keisuke Fujii, Nagoya, Japan (*Presenter*) Nothing to Disclose

PURPOSE

It is difficult to evaluate image noise such as blocky noise affecting low contrast detectability on non-linear CT images reconstructed with iterative reconstruction (IR) and deep learning reconstruction (DLR) algorithms. The aims of this study is to evaluate apparent image noise and detectability of low contrast modules on an abdominal phantom CT images reconstructed using a new DLR algorithms, and compare them with those using conventional IR and DLR algorithms.*Methods and Materials A standard sized abdominal phantoms having spherical modules with 3-10 mm in diameter and approximately 12 and 22 HU contrast difference were scanned with different milliampere-second (mAs) settings (CTDIvol: 1.3-33.4 mGy) on an Aquilion Precision CT scanner (Canon Medical Systems, Japan) and were reconstructed with adaptive iterative dose reduction three dimensional (AIDR 3D) algorithm, Advanced Intelligent Clear-IQ Engine (AiCE) body as a conventional DLR algorithm, and AiCE body sharp as a new DLR algorithm. To evaluate apparent image noise, we set a square region of interest (ROI) on the CT images, moved average filters in the ROI, and calculated standard deviation (SD) of the mean CT values for each sized filter. The SD values were fitted with a curve inversely proportional to the filter size, and apparent noise index was determined from the slope of curve fitting results. Next, the presence of 10 mm low contrast modules was assessed by four radiological technologists on a four-point likert scale, and low contrast detectability on AiCE body and AiCE body sharp CT images was compared using area under receiver operating characteristics curve (AUC).*Results Apparent noise index of AiCE body sharp images for a lower mAs value was approximately 20% and 18% lower than that of AIDR 3D and AiCE body images, respectively. The mean AUC of 0.99 for AiCE body sharp images was slightly higher than the value of 0.98 for AiCE body images although there was no significant difference between the two AUC.*Conclusions AiCE body sharp algorithm reduced apparent noise on CT images obtained with lower mAs than conventional IR and DLR algorithms while the noise reduction by AiCE body sharp algorithm did not result in the significant improvement of 10 mm low contrast detectability.*Clinical Relevance/Application AiCE body sharp DLR algorithm allows for more significantly reduction of the apparent image noise on abdominal CT images obtained with lower mAs than conventional IR and DLR algorithm.

RESULTS

Apparent noise index of AiCE body sharp images for a lower mAs value was approximately 20% and 18% lower than that of AIDR 3D and AiCE body images, respectively. The mean AUC of 0.99 for AiCE body sharp images was slightly higher than the value of 0.98 for AiCE body images although there was no significant difference between the two AUC.

CLINICAL RELEVANCE/APPLICATION

AiCE body sharp DLR algorithm allows for more significantly reduction of the apparent image noise on abdominal CT images obtained with lower mAs than conventional IR and DLR algorithm.

SDP-PH-5   **Radiation Exposure ; Diagnostic Reference Levels In The Endovascular Therapy Of Subarachnoid Hemorrhage Related Vasospasm**

Participants
Marcel Opitz, MD, Essen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The treatment of cerebral vasospasm (CVS) in patients after spontaneous subarachnoid hemorrhage (sSAH) remains one of the major challenges and endovascular treatment is becoming increasingly important. Nevertheless, diagnostic reference levels (DRLs) of endovascular CVS therapy are lacking in this relatively young treatment field of interventional neuroradiology.*Methods and Materials In a retrospective study design, DRLs & achievable dose (AD) were assessed for all patients undergoing selective intra-arterial vasodilator administration or additional mechanical angioplasty for CVS treatment. All procedures were performed at the flat-panel angiography-systems Allura Xper (Philips Healthcare). Interventional procedures were differentiated according to the type of procedure & the number of probed vessels.*Results Altogether 494 neurointerventional procedures of 121 patients with CVS due to sSAH could be included. The following DRL, AD & mean values could be determined: (I) (ICA bilateral+VA) DRL 80.29Gy*cm², AD 67.77Gy*cm², mean 70.12Gy*cm²; (II) (ICA bilateral) DRL 59.15Gy*cm², AD 49.88Gy*cm², mean 50.25Gy*cm²; (III) (ICA unilateral) DRL 34.70Gy*cm², AD 27.12Gy*cm², mean 33.19Gy*cm²; (IV) (VA unilateral) AD 32.57Gy*cm², mean 34.25Gy*cm², (V) (Nimodipine+TBA) DRL 130.17Gy*cm², AD 108.56Gy*cm², mean 106.09Gy*cm² & (VI) (Nimodipine+stent) DRL 107.60Gy*cm², AD 81.13Gy*cm², mean 86.53Gy*cm². Kruskal-Wallis-test confirmed significant dose difference considering the number of probed vessels (p<0.001). Mann-Whitney-U-test revealed significant differences of DAP and fluoroscopy time between chemical-only & additional mechanical angioplasty (p<0.001).*Conclusions The DRLs of intra-arterial chemical angioplasty are substantially lower compared with DRLs proposed for other therapeutic interventions. However, repeated therapy sessions are often required leading to a cumulatively higher radiation exposure. In the absence of clinical criteria of further CVS-vessel involvement, the total dose may be reduced efficiently by probing selectively the primary target vessels during repeated applications.*Clinical Relevance/Application Cerebral vasospasm (CVS) remains one of the major challenges occurring after spontaneous subarachnoid hemorrhage (sSAH)

resulting in delayed cerebral ischemia, increased morbidity and mortality. Interventional techniques such as selective intra-arterial vasodilator administration & mechanical angioplasty procedures are nowadays considered standard of care for medically refractory vasospasm. Nonetheless, for endovascular treatments of cerebral vasospasm DRLs are still lacking.

RESULTS

Altogether 494 neurointerventional procedures of 121 patients with CVS due to sSAH could be included. The following DRL, AD & mean values could be determined: (I) (ICA bilateral+VA) DRL 80.29Gy*cm², AD 67.77Gy*cm², mean 70.12Gy*cm²; (II) (ICA bilateral) DRL 59.15Gy*cm², AD 49.88Gy*cm², mean 50.25Gy*cm²; (III) (ICA unilateral) DRL 34.70Gy*cm², AD 27.12Gy*cm², mean 33.19Gy*cm²; (IV) (VA unilateral) AD 32.57Gy*cm², mean 34.25Gy*cm², (V) (Nimodipine+TBA) DRL 130.17Gy*cm², AD 108.56Gy*cm², mean 106.09Gy*cm² & (VI) (Nimodipine+stent) DRL 107.60Gy*cm², AD 81.13Gy*cm², mean 86.53Gy*cm². Kruskal-Wallis-test confirmed significant dose difference considering the number of probed vessels (p<0.001). Mann-Whitney-U-test revealed significant differences of DAP and fluoroscopy time between chemical-only & additional mechanical angioplasty (p<0.001).

CLINICAL RELEVANCE/APPLICATION

Cerebral vasospasm (CVS) remains one of the major challenges occurring after spontaneous subarachnoid hemorrhage (sSAH) resulting in delayed cerebral ischemia, increased morbidity and mortality. Interventional techniques such as selective intra-arterial vasodilator administration & mechanical angioplasty procedures are nowadays considered standard of care for medically refractory vasospasm. Nonetheless, for endovascular treatments of cerebral vasospasm DRLs are still lacking.

SDP-PH-50 Impact Of Deep Learning Reconstruction On Low ContrastLiver Lesion Detectability

Participants
Damien Racine, Lausanne, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To compare impact between a deep learning (DL) reconstruction algorithm and an iterative reconstruction on low contrast liver lesion detectability (LCD) at different tube voltages and patient sizes.*Methods and Materials An optimized CT protocol used for liver lesion detection was applied to three anthropomorphic abdomen phantoms that simulated slim (BMI<23), non-overweight (BMI<25) and overweight (BMI>25) patients (QRM, Moehrendorf/Germany) (S: 300 × 200 mm; M: 350 × 250 mm; L: 400 × 300 mm). Phantoms contained two different 5 x 7.5 mm lesions with contrast of +30 HU and -30 HU. These phantoms were imaged at three radiation dose levels (CTDIvol of 4.5, 6.5 and 7.5 mGy, respectively). Tube current was adapted to obtain the same CTDIvol at the four tube voltages (80, 100, 120, 140 kVp). Images were reconstructed using a DL algorithm at high strength (TrueFidelity) and an iterative reconstruction algorithm (ASiR-V at 60%). LCD was assessed using a channelized Hotelling (CHO) model observer. The output of the CHO model observer is the area under the ROC curve (AUC), used as figure of merit. AUC was compared among reconstruction algorithms.*Results For the three phantom sizes, at the same kVp the AUC was always higher with TF as compared to ASiR-V. For the S phantom with TF, the AUC of the four tube voltages was always higher than 0.999 whereas with ASiR-V the AUC reached a peak at 100 kVp (AUC=0.990) and then decreased to 0.983 at 140 kV. For the M phantom with TF, the AUC decreased as tube voltage increased with overall excellent accuracy (range 0.991 - 0.979) whereas with ASiR-V, the highest AUC was obtained at 100 kVp (AUC = 0.921). For the L phantom, the AUC values reached a peak at 120 kVp (AUC = 0.958) whereas it was minimal at 80 kVp (AUC = 0.93).*Conclusions Low contrast liver lesion detectability using TF was improved in comparison to ASIR-V. TF could be interesting for high Z contrast imaging because of its potential to improve detection for low tube voltages in slim and non-overweight patients. However, for overweight patients lowering tube voltage sacrificed low contrast detectability even if TF was used.*Clinical Relevance/Application Tube voltage settings in CT need to be adjusted to patient size and diagnostic task to optimize image quality and patient dose.

RESULTS

For the three phantom sizes, at the same kVp the AUC was always higher with TF as compared to ASiR-V. For the S phantom with TF, the AUC of the four tube voltages was always higher than 0.999 whereas with ASiR-V the AUC reached a peak at 100 kVp (AUC=0.990) and then decreased to 0.983 at 140 kV. For the M phantom with TF, the AUC decreased as tube voltage increased with overall excellent accuracy (range 0.991 - 0.979) whereas with ASiR-V, the highest AUC was obtained at 100 kVp (AUC = 0.921). For the L phantom, the AUC values reached a peak at 120 kVp (AUC = 0.958) whereas it was minimal at 80 kVp (AUC = 0.93).

CLINICAL RELEVANCE/APPLICATION

Tube voltage settings in CT need to be adjusted to patient size and diagnostic task to optimize image quality and patient dose.

SDP-PH-51 Task-based Selection Of Virtual Monoenergetic Images Energy Level In Photon-counting Detector CT Reduces Radiation Dose While Improving Iodine Contrast-to-noise Ratio

Participants
Kishore Rajendran, PhD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

Task-based dose reduction in conventional CT can be achieved using automated kV selection for non-contrast and contrast-enhanced tasks. Due to its energy discrimination capability, photon-counting detector (PCD) CT facilitates single-kV multi-energy acquisition to routinely provide virtual monoenergetic images (VMIs). We evaluated a new task-based automatic VMI (keV) selection feature for dose optimization in PCD-CT.*Methods and Materials Multi-energy CT phantoms (head- 20 cm diameter, body-40 cm width) containing iodine (2, 5, 10, 15 mg/cc) and calcium (100 and 300 mg/cc) were scanned on an investigational PCD-CT system (NAEOTOM Alpha, Siemens Healthineers) using head and body protocols. The head protocol used 120 kV and automatic task-based keV and dose selection (CARE keV) optimized for non-contrast (39 mGy, 70 keV VMI), bone (36.8 mGy, 65 keV VMI), soft tissue with contrast (32.9 mGy, 60 keV VMI) and vascular (24.4 mGy, 55 keV VMI) imaging tasks. The body protocol used 120 kV for non-contrast task (13.8 mGy, 70 keV), bone (13 mGy, 65 keV), soft tissue with contrast (11.7 mGy, 60 keV) and vascular (8.76 mGy, 55 keV) exams. PCD-CT energy thresholds were set to 20 and 65 keV for all scans. Contrast, noise, and contrast-to-noise ratio (CNR) were measured for iodine and calcium for all images. The low energy threshold image (20 to 120 keV) from the non-contrast task was used as the baseline reference since it mimics a conventional 120 kV image. Percent change in CNR was calculated for the auto-selected keV images for bone (65 keV), vascular (55 keV) and soft tissue with contrast (60 keV) tasks.*Results Iodine at 2 mg/cc and 10 mg/cc and calcium at 100 mg/cc were used to evaluate soft tissue with contrast, vascular and bone imaging tasks, respectively. The VMI images determined by the keV selection tool showed increased CNR (11.7%, 15.3% and 8.7% for soft tissue, vascular and bone tasks, respectively) in the head size phantom compared to the low energy threshold

image, despite a 16%, 37% and 6% dose reduction compared to the reference (non-contrast) task. Similarly, the automatically selected keV images using the body size phantom increased the CNR by 39.5%, 28.6% and 12.8% for soft tissue, vascular and bone tasks, respectively, compared to the low energy threshold image, again demonstrating 16%, 37% and 6% lower dose.*Conclusions A new task-based automatic keV selection feature for PCD-CT automatically selected VMI energy levels that improves CNR for different imaging tasks (8.7 - 39.5%) while reducing radiation dose by 6 - 37%.*Clinical Relevance/Application The number of new parameters associated with PCD-CT could make scan parameter selection more complicated. The automated tool to select appropriate kV and keV level will greatly assist operators and simplify workflow.

RESULTS

Iodine at 2 mg/cc and 10 mg/cc and calcium at 100 mg/cc were used to evaluate soft tissue with contrast, vascular and bone imaging tasks, respectively. The VMI images determined by the keV selection tool showed increased CNR (11.7%, 15.3% and 8.7% for soft tissue, vascular and bone tasks, respectively) in the head size phantom compared to the low energy threshold image, despite a 16%, 37% and 6% dose reduction compared to the reference (non-contrast) task. Similarly, the automatically selected keV images using the body size phantom increased the CNR by 39.5%, 28.6% and 12.8% for soft tissue, vascular and bone tasks, respectively, compared to the low energy threshold image, again demonstrating 16%, 37% and 6% lower dose.

CLINICAL RELEVANCE/APPLICATION

The number of new parameters associated with PCD-CT could make scan parameter selection more complicated. The automated tool to select appropriate kV and keV level will greatly assist operators and simplify workflow.

SDP-PH-52   Virtual Monoenergetic Image Reconstruction For Improved Contrast-to-noise Ratio In CT With Iodinated Contrast Agents: Dual Source Photon Counting CT Operating At One Tube Voltage Versus Dual Source Dual Energy CT Operating At Two Tube Voltages

Participants
Ronald Booij, PhD, Rotterdam, Netherlands (*Presenter*) Research Collaboration, Siemens AG

PURPOSE

To evaluate whether the contrast-to-noise ratio (CNR) of iodinated contrast agent in virtual monoenergetic images (VMI) from a clinical dual-source photon-counting detector (PCD) based CT scanner is superior to VMI from a dual-source dual-energy CT scanner with conventional energy-integrating detectors (EID).*Methods and Materials A medium-sized thoracic and a small-sized abdominal anthropomorphic phantom (QRM) with tubes containing water and water with 15 mg iodine/ml were scanned on a dual-source EID CT scanner (Siemens SOMATOM Force; 80 and Sn150 kVp, thorax phantom; 90 and Sn150 kVp, abdomen phantom) and on a clinical dual-source PCD CT scanner (Siemens NAEOTOM Alpha; 120 kVp). Scans were repeated three times. CTDIvol levels were matched between CT systems (3.8 mGy, thorax; 4.0 mGy, abdomen). VMI (range 40 - 100 keV) were reconstructed (MonoEnergetic Plus algorithm). Kernel (Qr40), effective slice thickness (1.0 mm), total beam collimation (57.6 mm), pitch (0.8) and rotation time (0.5 s) were kept constant. The clinically preferred iterative reconstruction (IR) strength of 60% (ADMIRE) was used for the EID scanner and the two closest matching IR strengths of 50% and 75% (Quantum IR) were used for the PCD scanner. CNR was defined as the difference in mean CT numbers of water and water with iodine, divided by the square root of the added variances measured in water and water with iodine.*Results CNR-measurements appeared to be very reproducible (relative standard error <3%). The CNR of the PCD based images with a 75% IR strength, was 9-73% higher than the CNR of the EID based images with a 60% IR-strength (for both phantoms). At a 50% IR-strength, the CNR of PCD CT was 7-50% higher than the corresponding EID images for the lower keV levels only (40-50 keV in the thorax; 40-70 keV in the abdomen). For the PCD based scanner, CNR levels were approximately 14-21% higher in the abdominal phantom than in the thoracic phantom, irrespective of keV-level and IR-strength. This increase was not observed in the EID based scans.*Conclusions Single tube voltage PCD CT outperforms dual-source EID CT operating at two different tube voltages in virtual monoenergetic iodine imaging.*Clinical Relevance/Application Thanks to the improved CNR for iodinated contrast agents, virtual monoenergetic images obtained with PCD CT may facilitate the reduction of contrast agent and radiation dose and improve lesion detection.

RESULTS

CNR-measurements appeared to be very reproducible (relative standard error <3%). The CNR of the PCD based images with a 75% IR strength, was 9-73% higher than the CNR of the EID based images with a 60% IR-strength (for both phantoms). At a 50% IR-strength, the CNR of PCD CT was 7-50% higher than the corresponding EID images for the lower keV levels only (40-50 keV in the thorax; 40-70 keV in the abdomen). For the PCD based scanner, CNR levels were approximately 14-21% higher in the abdominal phantom than in the thoracic phantom, irrespective of keV-level and IR-strength. This increase was not observed in the EID based scans.

CLINICAL RELEVANCE/APPLICATION

Thanks to the improved CNR for iodinated contrast agents, virtual monoenergetic images obtained with PCD CT may facilitate the reduction of contrast agent and radiation dose and improve lesion detection.

SDP-PH-53   A New Monte Carlo Radiation Transport Tool Designed Specifically For Research In Diagnostic Imaging Application.

Participants
Andrew Sampson, PhD, San Antonio, Texas (*Presenter*) Nothing to Disclose

PURPOSE

Monte Carlo radiation transport (MCRT) software tools provide a valuable research component to a wide variety of applications in the radiation sciences. Unfortunately, the most utilized and publicly available MCRT tools can be cumbersome for some diagnostic imaging applications. PHENX is a new MCRT tool designed from scratch for streamlined simulation of diagnostic imaging applications.*Methods and Materials PHENX is written in the updated FORTRAN 2008 programming language due to its efficiency and ease of optimization. PHENX explicitly models photon transport while assuming local energy deposition for secondary electrons. PHENX includes new routines for coherent and incoherent scattering (including Doppler broadening effects), photoionization with associated atomic relaxation, and a new robust parallel-optimized pseudo-random number generator. The EPICS2017 cross-section library, which includes updated atomic form factors and incoherent scattering functions, is utilized due to its availability and accuracy. Furthermore, PHENX includes a geometry package that allows for complex geometries that include both simulated patient-voxel representations obtained by patient CT exams and analytically defined volumes. OpenMP is utilized for fixed-node

parallelization to leverage multi-threaded CPU hardware. Additionally, optional improvements to computational efficiency are available through application of principally based and bias-free variance-reduction strategies for source generation, particle transport, and energy scoring. A simulated abdominal helical-CT exam is used to compute the efficiency gain achieved by using PHENX's acceleration capabilities relative to analog, non-accelerated Monte Carlo.*Results For the patient abdominal CT dose example, 99.75% of all simulated voxels experience an efficiency gain by applying PHENX's acceleration options. The median efficiency gain was 1947 relative to traditional analog MCRT, while 75% of dose voxels experienced a gain of more than 679.*Conclusions PHENX is an efficient MCRT tool for targeted diagnostic imaging research capable of simulating complex geometries three orders of magnitude faster than traditional, analog MCRT. PHENX can be utilized as an accurate, efficient, and convenient tool for radiation transport simulations targeted towards diagnostic imaging applications.*Clinical Relevance/Application New and/or improved clinical processes depend on accurate, efficient, and convenient clinically targeted research, and PHENX meets that need for Monte Carlo radiation transport medical imaging applications.

RESULTS

For the patient abdominal CT dose example, 99.75% of all simulated voxels experience an efficiency gain by applying PHENX's acceleration options. The median efficiency gain was 1947 relative to traditional analog MCRT, while 75% of dose voxels experienced a gain of more than 679.

CLINICAL RELEVANCE/APPLICATION

New and/or improved clinical processes depend on accurate, efficient, and convenient clinically targeted research, and PHENX meets that need for Monte Carlo radiation transport medical imaging applications.

SDP-PH-54 NCIRF: Organ Dose Calculation Program For Patients Undergoing Radiography And Fluoroscopy Imaging

Participants
Choonsik Lee, PhD, Rockville, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Few resources are available to quantify organ absorbed doses, critical data for epidemiological studies, from fluoroscopically-guided interventional procedures. To address this need, we developed a user-friendly cross-platform computer program with a graphical user interface to calculate organ doses for patients undergoing radiography and fluoroscopy imaging procedures.*Methods and Materials We designed a graphical user interface (GUI) for users to enter the parameters related to a patients' habitus (age, gender, and body size), imaging techniques (x ray energy spectrum, source to isocenter distance, field size, imaged anatomy, positioner primary angle, and positioner secondary angle), and Monte Carlo simulations (particle history). The patients' anatomy is modeled using reference sized computational human phantoms ranging from newborn to adult males and females. The Monte Carlo radiation transport calculations are handled by a custom GEANT4 module built into the program. For users who want to run MCNP6 outside the GUI, we added a feature to export the simulation scenario into input files for MCNP6—the "gold standard" radiation transport code.*Results Our program is able to calculate doses to 31 major organs and tissues. We observed reasonable agreement (within 2%) when comparing the results of our own GEANT 4 module with similar calculations using MCNP6. On a standard laptop, it took less than a minute to run a million particle histories reducing the Monte Carlo errors for in-field organs to less than 2%. The program successfully ran on Windows and Mac operating systems.*Conclusions We developed the National Cancer Institute dosimetry system for Radiography and Fluoroscopy (NCIRF), a user-friendly computer program, to readily estimate doses delivered to major radiosensitive organs and tissues of patients undergoing these imaging procedures. The program is available free of charge for researchers.*Clinical Relevance/Application The computer program developed in this study is a convenient tool providing organ doses for fluoroscopy patients based on the reference phantoms and a Monte Carlo radiation transport technique. The program will be useful for epidemiological studies of health effects from medical exposure to radiation.

RESULTS

Our program is able to calculate doses to 31 major organs and tissues. We observed reasonable agreement (within 2%) when comparing the results of our own GEANT 4 module with similar calculations using MCNP6. On a standard laptop, it took less than a minute to run a million particle histories reducing the Monte Carlo errors for in-field organs to less than 2%. The program successfully ran on Windows and Mac operating systems.

CLINICAL RELEVANCE/APPLICATION

The computer program developed in this study is a convenient tool providing organ doses for fluoroscopy patients based on the reference phantoms and a Monte Carlo radiation transport technique. The program will be useful for epidemiological studies of health effects from medical exposure to radiation.

SDP-PH-55 Evaluation Of Gravity Effect On Renal Function Using Multi-posture MRI

Participants
Yuki Oda, Kanazawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Understanding normal regulation of the kidney is important for improving the diagnosis and management of kidney disease. Nevertheless, it is unclear how regional kidney function is altered by postural changes, ie, differences in the effects of gravity. In this study, we evaluated the effect of gravity on regional kidney function in the supine and upright positions using an original magnetic resonance imaging (MRI) system that can obtain functional information in any posture (multiposture MRI).*Methods and Materials Regional kidney functions (the mean renal blood flow, T2, T2', and apparent diffusion coefficient (ADC)) were evaluated in seven healthy volunteers (mean age, 22.9 ± 0.9 years) in the supine and upright positions using multiposture MRI (0.4 T). The mean renal blood flow, T2, T2*, and ADC of the kidney were obtained with the ECG-triggered cine phase-contrast, single-shot diffusion echo-planar imaging, fast multiple spin-echo, and multiple gradient-echo techniques, respectively. T2' was calculated from the T2 and T2*. Then, those functional values in each region of the kidney were compared between postures.*Results The mean renal blood flow in the upright position (right kidney, 0.81 ± 0.65 mL/s; left kidney, 1.36 ± 1.16 mL/s) was significantly lower than that in the supine position (right, 4.14 ± 1.67 mL/s; left, 3.02 ± 0.96 mL/s) (P < 0.05), despite an increase in the heart rate due to the autoregulation to the fluid shift effect as the body was positioned upright (Fig. 2c). The T2 for all regions in the upright position (right, 114 ± 11.3 ms; left, 106 ± 6.22 ms) were significantly lower than that in the supine position (right, 124 ± 11 ms; left, 122 ± 8.86 ms) (P < 0.05), which indicates decrease in blood and urine volume in the kidney during the upright position. These results potentially provide new diagnostic information on the regulatory functions to the gravity as compared with the standard MRI

examination of the kidney. However, no significant difference was observed in the T2' and ADC for all regions between the supine and upright positions.*Conclusions Gravity reduces the blood flow and T2 of the kidney. Multiposture MRI makes it possible to evaluate the effect of gravity on regional kidney function.*Clinical Relevance/Application We assessed the effect of gravity on regional kidney function in the supine and upright positions using an original MRI that can obtain functional information in any posture. Gravity reduced the blood flow and T2 of the kidney, and these differences between postures potentially provide new diagnostic information.

RESULTS

The mean renal blood flow in the upright position (right kidney, 0.81 ± 0.65 mL/s; left kidney, 1.36 ± 1.16 mL/s) was significantly lower than that in the supine position (right, 4.14 ± 1.67 mL/s; left, 3.02 ± 0.96 mL/s) (P < 0.05), despite an increase in the heart rate due to the autoregulation to the fluid shift effect as the body was positioned upright (Fig. 2c). The T2 for all regions in the upright position (right, 114 ± 11.3 ms; left, 106 ± 6.22 ms) were significantly lower than that in the supine position (right, 124 ± 11 ms; left, 122 ± 8.86 ms) (P < 0.05), which indicates decrease in blood and urine volume in the kidney during the upright position. These results potentially provide new diagnostic information on the regulatory functions to the gravity as compared with the standard MRI examination of the kidney. However, no significant difference was observed in the T2' and ADC for all regions between the supine and upright positions.

CLINICAL RELEVANCE/APPLICATION

We assessed the effect of gravity on regional kidney function in the supine and upright positions using an original MRI that can obtain functional information in any posture. Gravity reduced the blood flow and T2 of the kidney, and these differences between postures potentially provide new diagnostic information.

SDP-PH-56 Time-saving Analysis And Clinical Effectiveness Of Computer-aided Triage And Notification (CADt) Devices Based On Queueing Theory

Participants
Elim Thompson, Silver Spring, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

A Computer-Aided Triage and Notification (CADt) device uses artificial intelligence (AI) to prioritize radiological medical images with an intension to speed up reviews of diseased cases in urgent conditions such as stroke, intercranial hemorrhage, and pneumothorax. We investigate an analytical approach based on queueing theory to quantify time-saving ability of CADt devices in various clinical settings.*Methods and Materials Queueing theory is a theoretical model for studying waiting-in-line. It is applied to calculate the mean waiting time per patient image to be read by a radiologist with and without a CADt device. We compute the amount of time savings for diseased patients who are correctly identified by the AI algorithm and time delays for diseased patients missed by the AI. These time savings and delays are used to define the overall time-saving ability of the CADt. The impacts on time performance from various parameters (AI accuracy, disease prevalence, hospital busyness, number of radiologists on-site, interruptions from emergency cases) are studied. Results from the analytical model are verified using Monte Carlo simulation.*Results CADt effectiveness depends on AI accuracy and clinical conditions. In a busy clinic without an emergency room, with an AI sensitivity (95%) and specificity (89%), a 10% disease prevalence, and a basic workflow where a radiologist spends 10 minutes on average per patient image regardless of its disease condition, a diseased patient will be reviewed 35.5 minutes (95% C.I. [22.8, 52.2]) sooner with the CADt than without. The amount of time savings drops significantly to 5.56 minutes [4.26, 7.32] in a quiet clinic and to 10.1 minutes [6.40, 16.3] with three radiologists instead of one. The impacts due to disease prevalence and presence of emergency patients whose images are not triaged by the CADt device are found to be small.*Conclusions We developed a theoretical approach based on queueing theory to quantify the time-saving ability of CADt devices in realistic clinical settings. With a basic workflow, our model suggests CADt devices are most effective in a busy, short-staffed clinic. These results are consistent with clinical intuition and verified by simulation. For evaluation purposes, a summary plot is proposed to characterize both the diagnostic and time-saving abilities of a CADt device.*Clinical Relevance/Application With an effective CADt device, a radiologist can get to review diseased patients quicker, allowing earlier diagnosis and treatment of time-sensitive diseases. This work presents an analytical approach to quantify time-saving ability and to study the impacts on CADt effectiveness from various parameters in a comprehensive manner. Software developed in this work will be made publicly available.

RESULTS

CADt effectiveness depends on AI accuracy and clinical conditions. In a busy clinic without an emergency room, with an AI sensitivity (95%) and specificity (89%), a 10% disease prevalence, and a basic workflow where a radiologist spends 10 minutes on average per patient image regardless of its disease condition, a diseased patient will be reviewed 35.5 minutes (95% C.I. [22.8, 52.2]) sooner with the CADt than without. The amount of time savings drops significantly to 5.56 minutes [4.26, 7.32] in a quiet clinic and to 10.1 minutes [6.40, 16.3] with three radiologists instead of one. The impacts due to disease prevalence and presence of emergency patients whose images are not triaged by the CADt device are found to be small.

CLINICAL RELEVANCE/APPLICATION

With an effective CADt device, a radiologist can get to review diseased patients quicker, allowing earlier diagnosis and treatment of time-sensitive diseases. This work presents an analytical approach to quantify time-saving ability and to study the impacts on CADt effectiveness from various parameters in a comprehensive manner. Software developed in this work will be made publicly available.

SDP-PH-57 Comparison Of The Regression Fits Between Organ Doses Determined By Monte Carlo Simulation And Dose Metrics In Adult Chest-abdomen-pelvis CT Examinations Across CT Scanners

Participants
Keisuke Fujii, Nagoya, Japan (*Presenter*) Nothing to Disclose

PURPOSE

The aims of this study are to determine organ doses determines by Monte Carlo (MC) simulations for individual patients in routine adult chest-abdomen-pelvis (CAP) CT examinations with different CT scanners and to evaluate the correlations between the organ doses and dose metrics.*Methods and Materials The voxelized models of 80 adult patients undergoing CAP CT examinations with three CT scanners of Aquilion ViSION (n=40), Aquilion Precision (n=20) (Canon Medical Systems, Japan), and SOMATOM Definition Flash (n=20) (Siemens Healthcare, Germany) were created by inputting the CT images into the MC simulation software ImpactMC (Advanced Breast CT, GmbH). MC simulations for each voxelized phantom were performed by inputting detailed descriptions of each CT scanner and scanning parameters including our estimated tube current modulation profiles into the simulation software. Next,

region of interests (ROIs) of seven radiosensitive organs (thyroid, lung, esophagus, breast, liver, stomach, and bladder) were created by delineating each organ on each patient CT images. Each ROI was set on the dose distribution images obtained as simulation results and organ doses for each organ were evaluated as average doses within each ROI. For dose metrics, size-specific dose estimates (SSDE) for each patient were calculated using volume CT dose index (CTDIvol) and average water equivalent diameter (WED) calculated from the CT images over the scan range. Organ-specific SSDE were also calculated using the average CTDIvol and WED over each organ position. The correlations between organ doses and dose metrics for CAP CT examinations were evaluated using coefficients of determination.*Results Organ doses exhibited stronger linear relationships with organ-specific SSDE (R2 = 0.82) than CTDIvol and SSDE for the three CT scanners. The coefficients of variation for the slope of the regression fits were approximately 3-9% across organs and 7-10% across CT scanners.*Conclusions The regression fits and organ-specific SSDE can be widely useful for organ dose estimations in CAP CT examinations with various CT scanners because the variation of the regression fits was small across both organs and CT scanners.*Clinical Relevance/Application Regression fits are widely useful for organ dose estimation for adult patients in CAP CT examinations because the regression fits are almost independent of the type of organ and CT scanners.

RESULTS

Organ doses exhibited stronger linear relationships with organ-specific SSDE (R2 = 0.82) than CTDIvol and SSDE for the three CT scanners. The coefficients of variation for the slope of the regression fits were approximately 3-9% across organs and 7-10% across CT scanners.

CLINICAL RELEVANCE/APPLICATION

Regression fits are widely useful for organ dose estimation for adult patients in CAP CT examinations because the regression fits are almost independent of the type of organ and CT scanners.

SDP-PH-58   Analysis Of Venous Blood Flow In The Lower Leg Using MRI During Intermittent Pneumatic Compression

Participants
Yuki Oda, Kanazawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Lower leg intermittent pneumatic compression (IPC) is widely used to improve the venous outflow, reduce the lymphedema, and prevent the deep venous thrombosis in clinical practice. However, the mechanism through which IPC can improve these parameters remains unclear, and the effects of IPC have not been completely verified. Therefore, in this study, we quantitatively assessed dynamic changes in venous blood flow in the lower leg during IPC using phase contrast magnetic resonance imaging (MRI).*Methods and Materials On a 3.0-T MRI, IPC sleeves (DVT-2500, Nitto Kohki, Japan) were positioned around the right and left calves in seven healthy volunteers (mean age = 23.1 ± 2.1 years). Popliteal venous blood flow (PVBF) images were obtained using two-dimensional phase contrast MRI before, during, immediately after, and 90 seconds after IPC for 10 minutes. The blood velocity and cross-sectional area of the popliteal vein were measured and used to calculated PVBF. Calf IPC and foot IPC were performed, and the PVBF values were compared. The purpose and protocol of the investigation were explained to all subjects, and the studies were performed only after informed consent was obtained from each subject. A P value of <0.05 was considered statistically significant.*Results For both calf IPC and foot IPC, PVBF in the compressed phase during IPC was significantly greater than that in the uncompressed phase (P < 0.05). The increase in PVBF during calf-IPC (460%-2300%) was much greater than that during foot IPC (150%-400%) because of differences in the compressed surface area (tangential shear force effect), total blood flow, and physical properties of tissue. There were no significant differences in PVBF between before, immediately after, and 90 seconds after IPC treatment with both calf IPC and foot IPC.*Conclusions IPC temporarily increases venous blood flow in the lower leg. Phase contrast MRI allows for quantitatively assessing dynamic changes in venous blood flow in the lower leg during IPC.*Clinical Relevance/Application Lower leg intermittent pneumatic compression (IPC) is widely used to prevent the deep venous thrombosis in clinical practice. We quantitatively assessed dynamic changes in venous blood flow in the lower leg during IPC using MRI.

RESULTS

For both calf IPC and foot IPC, PVBF in the compressed phase during IPC was significantly greater than that in the uncompressed phase (P < 0.05). The increase in PVBF during calf-IPC (460%-2300%) was much greater than that during foot IPC (150%-400%) because of differences in the compressed surface area (tangential shear force effect), total blood flow, and physical properties of tissue. There were no significant differences in PVBF between before, immediately after, and 90 seconds after IPC treatment with both calf IPC and foot IPC.

CLINICAL RELEVANCE/APPLICATION

Lower leg intermittent pneumatic compression (IPC) is widely used to prevent the deep venous thrombosis in clinical practice. We quantitatively assessed dynamic changes in venous blood flow in the lower leg during IPC using MRI.

SDP-PH-59   Quality Improvement Of Low-dose CT In The Detection Of A Pulmonary Nodule Using Tin-filtered High-kilovoltage Imaging Reducing The Metal Artifacts Due To Artificial Cardiac Pacemaker: A Phantom Study

Participants
Seita Watanabe, Nagoya, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Metal artifacts are commonly seen on computed tomography (CT), deteriorating imaging quality. Among them, those caused by an artificial cardiac pacemaker (PM) can affect the diagnosis of lung nodules. It has been reported that virtual monoenergetic imaging (VMI) using a dual-energy CT reduced metal artifacts. Also, a tin filter may reduce the artifacts by optimizing the effective x-ray energy. The aim of this study was to compare the effect of metal artifacts caused by a PM on the detectability of pulmonary nodules between low-dose CT images acquired by the standard tube potential, high tube potential with a tin filter, and VMI.*Methods and Materials An 8-mm diameter simulated nodule, composed of urethane resin and hydroxyapatite, was placed inside a chest phantom with a PM on its left anterior surface. The CT-attenuation value of the simulated nodule measured -800 Hounsfield units (HU) on the standard tube potential image when placed outside the phantom. We used a third generation dual-source CT system in this experiment. Images were acquired at 120 kVp, 150 kVp with a tin filter (150 kVp-Sn), and 140-keV VMI using a combination of 90 kVp and 150 kVp-Sn. Axial CT images of 1.0 mm slice thickness were reconstructed. The dataset was

reconstructed using the iterative metal artifact reduction (iMAR) algorithm in addition to conventional reconstruction without iMAR. For all acquisitions, variable tube current was applied to adjust the volume CT dose index (CTDIvol) to be 1.0 mGy. A computer-aided detection/diagnosis (CAD) system was utilized to evaluate the detectability, and the artifact index was employed to calculate the extent of the artifacts.*Results The CAD system detected the lung nodule on all the acquisition protocols in the absence of the PM. When accompanied by the PM, the nodule was missed out on the 120-kVp image and 140-keV VMI, regardless of using iMAR. In contrast, the nodule was detected on the 150-kVp-Sn image. The artifact indexes were 96.5, 38.9, and 61.6 for the 120-kVp, 150-kVp-Sn, and 140-keV VMI, respectively.*Conclusions For chest low-dose CT, using 150-kVp tube potential with a tin filter might improve the detectability of pulmonary lesions by reducing metal artifacts due to PMs.*Clinical Relevance/Application For chest low-dose CT, using 150-kVp tube potential with a tin filter might improve the detectability of pulmonary lesions by reducing metal artifacts due to PMs.

RESULTS

The CAD system detected the lung nodule on all the acquisition protocols in the absence of the PM. When accompanied by the PM, the nodule was missed out on the 120-kVp image and 140-keV VMI, regardless of using iMAR. In contrast, the nodule was detected on the 150-kVp-Sn image. The artifact indexes were 96.5, 38.9, and 61.6 for the 120-kVp, 150-kVp-Sn, and 140-keV VMI, respectively.

CLINICAL RELEVANCE/APPLICATION

For chest low-dose CT, using 150-kVp tube potential with a tin filter might improve the detectability of pulmonary lesions by reducing metal artifacts due to PMs.

SDP-PH-6   Evaluation Of Pre-trained Deep Convolutional Neural Network Models For The Classification Of Brain Tumor Magnetic Resonance Images By Transfer Learning

Participants
Kwan Wai Li, Hong Kong, Hong Kong (*Presenter*) Nothing to Disclose

PURPOSE

Diffusion-weighted magnetic resonance imaging, which can perform quantification of tissue cellularity by means of an apparent diffusion coefficient (ADC), has been used extensively in tumor detection and differentiation. Although ADC maps can be generated automatically by built-in software provided by the MRI scanner vendors, placement of region of interest (ROI) inside the lesion is still needed to be done manually to obtain the corresponding ADC. Therefore, the reproducibility of results depends on the size and location of the selected ROI, which might vary significantly between operators. To make the diagnosis operator independent irrespective of radiologists' experience, this study evaluates the performance of three state-of-the-art pre-trained deep convolutional neural network (CNN) models for brain tumor classification using transfer learning.*Methods and Materials A publicly available brain tumor dataset was used, which consists of 3064 T1-weighted contrast-enhanced MR images with three types of brain tumors, namely meningioma, glioma and pituitary tumor. To reduce overfitting, data augmentation was used to expand the dataset. The dataset was split into 80% and 20% for training and testing, respectively. Three pre-trained CNN models trained on ImageNet, (i) VGG16, (ii) VGG19 and (iii) InceptionV3, were selected for comparison in this study. They were used as the base convolutional models and the pre-trained weights were frozen for feature extraction. The top few fully-connected layers were unfrozen and fine-tuned with the modified classifier layer according to the number of classification classes in the MRI dataset. The customization of the three pre-trained models written in Python 3.7.9 were implemented using Keras 2.4.0 library in Tensorflow 2.3 and trained using root mean square propagation (RMSProp) optimizer with a learning rate of 0.00001. The training convergence began at about 30 epochs as observed from the training accuracy and loss curves. The experiment was performed using NVIDIA GeForce RTX 2060 GPU with Intel i7-9750H @ 2.6 GHz and 32 GB RAM.*Results The customized VGG16 model achieved the best results on all the performance metrics among the three customized pre-trained models, with classification accuracy of 96.2%, macro-averaged recall, precision and f1-score of 96.6%, 95.4% and 95.8%, respectively.*Conclusions The customized VGG16 model attained a reasonably high accuracy for the brain tumor MR images classification. Future studies would include in-house data labelled by radiologists.*Clinical Relevance/Application This study demonstrated the feasibility of using pre-trained CNN models as a clinical decision-support tool for radiologists to differentiate between three types of brain tumors automatically.

RESULTS

The customized VGG16 model achieved the best results on all the performance metrics among the three customized pre-trained models, with classification accuracy of 96.2%, macro-averaged recall, precision and f1-score of 96.6%, 95.4% and 95.8%, respectively.

CLINICAL RELEVANCE/APPLICATION

This study demonstrated the feasibility of using pre-trained CNN models as a clinical decision-support tool for radiologists to differentiate between three types of brain tumors automatically.

SDP-PH-60   Photon-Counting Detector CT And Quantum Iterative Reconstruction - A Quantitative Analysis For Portal-Venous Phase Abdominal CT

Participants
Thomas Sartoretti, Zurich, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To quantitatively characterize portal-venous phase CT images acquired on a photon-counting detector CT (PCD-CT) and reconstructed with a novel iterative reconstruction algorithm (Quantum Iterative Reconstruction - QIR).*Methods and Materials A preliminary population of ten patients referred for abdominal CT in portal venous phase and imaged on a first-generation clinical dual-source photon-counting detector CT (PCD-CT; NAEOTOM Alpha, Siemens Healthineers) were included in this ongoing study. Polychromatic images (T3D) and virtual monoenergetic images at 60 keV were reconstructed by means of conventional filtered back projection (FBP) and QIR (4 levels, Q1-Q4). A fully automated computational pipeline for quantitative image characterization was developed in the R programming language. For all image types and reconstructions, noise maps for soft tissues (-300 HU to 100 HU) were generated and the global noise index (GNI) was computed. To quantify differences in attenuation between FBP and QIR images, the standard deviation of the absolute error (AE SD) and the mean absolute error (MAE) were computed. To quantify differences in image structure between FBP and QIR images, the peak signal-to-noise ratio (PSNR) and structural similarity index (SSIM) were computed.*Results For the T3D images, the GNI decreased linearly from FBP (17.4 ± 1.51 HU) to QIR Q4 (10.1 ± 0.63 HU) ($p<0.05$). For the 60 keV images, the GNI decreased linearly from FBP (20.5 ± 2.02 HU) to QIR Q4 (11.7 ± 0.89 HU) ($p<0.05$). For both

T3D and 60 keV images, the differences between FBP and QIR images increased with increasing QIR levels as witnessed by increasing AE SD and MAE values (MAE - T3D: 1.12± 0.26 HU for FBP vs QIR Q1 to 4.49±1 HU for FBP vs QIR Q4 and 60 keV: 1.39±0.32 HU for FBP vs QIR Q1 to 5.6±1.29 HU for FBP vs QIR Q4) ($p<0.05$) and decreasing PSNR and SSIM values (SSIM - T3D: 0.9999991 for FBP vs QIR Q1 to 0.9999862 for FBP vs QIR Q4 and 60 keV: 0.999997 for FBP vs QIR Q1 to 0.9999797 for FBP vs QIR Q4) ($p<0.05$).*Conclusions Global image noise decreased significantly and linearly for each level of QIR compared to FBP in abdominal portal-venous phase CT on a clinical PCD-CT. With increasing levels of QIR, the difference between QIR and FBP images increases both in terms of structural appearance and attenuation.*Clinical Relevance/Application High levels of Quantum Iterative Reconstruction considerably reduce noise on portal-venous phase CT images as acquired with a Photon-counting CT system.

RESULTS

For the T3D images, the GNI decreased linearly from FBP (17.4±1.51 HU) to QIR Q4 (10.1±0.63 HU) ($p<0.05$). For the 60 keV images, the GNI decreased linearly from FBP (20.5±2.02 HU) to QIR Q4 (11.7±0.89 HU) ($p<0.05$). For both T3D and 60 keV images, the differences between FBP and QIR images increased with increasing QIR levels as witnessed by increasing AE SD and MAE values (MAE - T3D: 1.12± 0.26 HU for FBP vs QIR Q1 to 4.49±1 HU for FBP vs QIR Q4 and 60 keV: 1.39±0.32 HU for FBP vs QIR Q1 to 5.6±1.29 HU for FBP vs QIR Q4) ($p<0.05$) and decreasing PSNR and SSIM values (SSIM - T3D: 0.9999991 for FBP vs QIR Q1 to 0.9999862 for FBP vs QIR Q4 and 60 keV: 0.999997 for FBP vs QIR Q1 to 0.9999797 for FBP vs QIR Q4) ($p<0.05$).

CLINICAL RELEVANCE/APPLICATION

High levels of Quantum Iterative Reconstruction considerably reduce noise on portal-venous phase CT images as acquired with a Photon-counting CT system.

SDP-PH-61 Task-specific Spatial Resolution Measurement Using Rod Objects And A Thin Wire Assuming Tasks From Thick And Thin Enhanced Vessels In Computed Tomography

Participants
Yuri Toyohara, Kanazawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

The task transfer functions (TTFs) using the circular edge (CE) method (in-plane) and the plane edge (PE) method (z-directional) are task-specific, and not necessarily universally applicable for objects with different sizes. The present study aimed to evaluate TTFs of deep learning-based image reconstruction (DLIR) and iterative reconstruction (IR) using conventional tasks with rod objects and a task given by a wire of 1 mm in diameter, simulating thick and thin enhanced vessels, respectively.*Methods and Materials Phantoms made of a material equivalent to diluted iodine (12 mg/ml) that exhibits ~250 Hounsfield unit (HU) at 120 kV were placed inside a cylindrical water-bath phantom with a diameter of 300 mm for each measurement. For in-plane TTF, a rod of 30 mm in diameter was used for the CE, and a wire of 1 mm in diameter was used to measure a frequency response from its cross-section (point) image (iodine wire [IW] method). For z-directional TTF, a rod of 50 mm in diameter was used for the PE, and the wire was used for the IW. All acquisitions were performed using a 256-row multi-slice CT system with volume CT dose indices (CTDIvols) of 10 and 5 mGy. CT images with a slice thickness of 0.625 mm were reconstructed with all the reconstruction algorithms.*Results For both the in-plane and z-directional properties, the TTFs for both DLIR and IR using IW were significantly lower not only than those using CE or PE (percentage decrease of 50%TTF: IW vs. CE: 29-35% (DLIR), 27-28% (IR); IW vs. PE: 21-27% (DLIR), 26-29% (IR)) but also than those for filtered back projection (FBP) (22-24% (DLIR), 32-36% (IR)). This means that the spatial resolutions of DLIR and IR were insufficient for the task of a wire of 1 mm in diameter. Reflecting the TTF results, the peak intensities of IW's point images with DLIR and IR were lower than with FBP.*Conclusions For both the DLIR and IR used in this study, the TTFs measured using the IW simulating a 1-mm diameter enhanced vessel were notably lower than those measured using the CE (or PE). TTF measurements for small objects require phantoms that have not only the same contrast but also the same diameter as target objects.*Clinical Relevance/Application The IW method allowed to measure TTFs for a task assuming a thin vessel and thus is useful to assess TTFs for such tasks which have not been properly evaluated using the conventional CE (or PE) method.

RESULTS

For both the in-plane and z-directional properties, the TTFs for both DLIR and IR using IW were significantly lower not only than those using CE or PE (percentage decrease of 50%TTF: IW vs. CE: 29-35% (DLIR), 27-28% (IR); IW vs. PE: 21-27% (DLIR), 26-29% (IR)) but also than those for filtered back projection (FBP) (22-24% (DLIR), 32-36% (IR)). This means that the spatial resolutions of DLIR and IR were insufficient for the task of a wire of 1 mm in diameter. Reflecting the TTF results, the peak intensities of IW's point images with DLIR and IR were lower than with FBP.

CLINICAL RELEVANCE/APPLICATION

The IW method allowed to measure TTFs for a task assuming a thin vessel and thus is useful to assess TTFs for such tasks which have not been properly evaluated using the conventional CE (or PE) method.

SDP-PH-62 Quality Assurance For Deep Learning-based Synthetic CT Generation To Facilitate MRI-only Proton Therapy Planning

Participants
Chuang Wang, Memphis, Tennessee (*Presenter*) Nothing to Disclose

PURPOSE

To develop a quality assurance (QA) method for synthetic CT (sCT) generation with consistent-cycle Generative Adversarial Network (ccGAN) for facilitating safe integration of MRI-only proton therapy planning into clinical practice.*Methods and Materials Planning CT and T1/T2-weighted (T1W/T2W) MR images of 197 brain tumor patients (aged 1-20 y, 105 males) were retrospectively analyzed. MRI was preprocessed with the N4 bias correction and histogram matching intensity standardization methods. The ccGAN models were trained on 148 randomly selected patients and evaluated on the remaining 49 patients. All patients in the training set were deformed to a patient of the median brain size to create a QA reference. The sCT of each test patient was deformed to this reference and compared to generate a flag map (fM), which highlights pixels deviating by >100 HU and outside the mean ± standard deviation window of the reference intensity.Furthermore, the gamma passing rate (10%/3mm) of the sCT against the QA reference on the intensity difference was investigated as a surrogate to the sCT quality, including metrics of peak signal-to-noise ratio (PSNR), structural similarity (SSIM) index, and mean absolute error (MAE) from real CT. The Pearson correlation coefficient between gamma passing rate and MAE was calculated for T1W, T2W and combined sets.*Results The mean ± standard deviation of PSNR, SSIM, and MAE were 32.6±1.89, 0.92±0.02, and 43.4±15.7 HU (23±15 HU in air, and 89±13 HU in bone) for T1W-based sCT,

respectively; 31.6±1.9, 0.91±0.02, and 41.7±13.2 HU (48±26 HU in air, and 79±12 HU in bone) for T2W-based sCT, respectively. Gamma passing rate and MAE were highly correlated (T1W, -0.89; T2W, -0.93; combined T1/T2W, -0.90). The fM was able to identify clusters of inaccurate HUs on sCT, especially around oral cavity, nasal cavity and sinuses.*Conclusions The proposed ccGAN generated highly accurate sCT from brain MRI. When ground truth is not available, the gamma passing rate against the QA reference is a good surrogate of sCT accuracy for catching those with high MAE, and the fM can highlight inaccurate regions within the sCT that are associated with large errors in HUs.*Clinical Relevance/Application Highly accurate sCT generated by the proposed ccGAN with a quality assurance mechanism improves the safety and feasibility of MRI only proton therapy for pediatric brain tumor patients.

RESULTS

The mean ± standard deviation of PSNR, SSIM, and MAE were 32.6±1.89, 0.92±0.02, and 43.4±15.7 HU (23±15 HU in air, and 89±13 HU in bone) for T1W-based sCT, respectively; 31.6±1.9, 0.91±0.02, and 41.7±13.2 HU (48±26 HU in air, and 79±12 HU in bone) for T2W-based sCT, respectively. Gamma passing rate and MAE were highly correlated (T1W, -0.89; T2W, -0.93; combined T1/T2W, -0.90). The fM was able to identify clusters of inaccurate HUs on sCT, especially around oral cavity, nasal cavity and sinuses.

CLINICAL RELEVANCE/APPLICATION

Highly accurate sCT generated by the proposed ccGAN with a quality assurance mechanism improves the safety and feasibility of MRI only proton therapy for pediatric brain tumor patients.

SDP-PH-63 Comparison Of Hydroxyapatite Measurements And Hounsfield Measurementin Dual-energy Spectralctfor The Diagnosis Of Osteoporosisin Female Patients

Participants
Yue Yao, Xi'an, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the accuracy of diagnosing osteoporosis in middle-aged and elder women using hydroxyapatite (HAP) concentration on material decomposition (MD) images and CT value on monochromatic images in dual-energy spectral CT (DEsCT).*Methods and Materials An institutional review board approved this prospective study, and all participants signed the informed consent. A total of 239 consecutive postmenopausal female patients (mean age: 58.45±6.67 years, range 52-82 years) were prospectively enrolled. All patients were examined using both chest DEsCT and Dual energy X-ray absorptiometry (DXA). According to the T-score of the 1st lumbar vertebra on DXA, the patients were divided into the osteoporosis group (T<-2.5, n=112) and non-osteoporosis group (T>-2.5, n=127). The chest DEsCT was performed on a 256-row Revolution CT (GE Healthcare) using the spectral imaging mode: 80-140kVp fast switching, 200mA and 0.5s/r. The HAP values of the 1st lumbar vertebra were measured from the coronal-view, HAP(Fat)-based MD images, and CT values were measured on the 75keV monochromatic image. The HAP and CT cutoff values for differentiating osteoporosis from non-osteoporosis were obtained by drawing a receiver operating characteristic (ROC) curve.*Results Both HAP and CT value of the 1st lumbar vertebra had moderate-high correlation with bone-mineral-density measurement on DXA (HAP, r=0.614;CT value,r=0.625; all P<0.01). The HAP cutoff value of the 1st lumbar vertebra was 142.055mg/cm3 to provide the area-under-the-curve (AUC), sensitivity, specificity, PPV and NPV of 0.754, 0.714, 0.693, 0.68 and 0.752, respectively for diagnosing osteoporosis. The CT cutoff value of the 1st lumbar was vertebra 132HU for AUC, sensitivity, specificity, PPV and NPV of 0.766, 0.741, 0.7, 0.685 and 0.754, respectively.*Conclusions HAP measurements on HAP(Fat)-based MD images in DEsCT showed a similar good performance with the conventional CT measurement on monochromatic images in diagnosing osteoporosis in middle-aged and elder females.*Clinical Relevance/Application DEsCT provides multi-parameters to help the diagnosis of osteoporosis than conventional CT scans.

RESULTS

Both HAP and CT value of the 1st lumbar vertebra had moderate-high correlation with bone-mineral-density measurement on DXA (HAP, r=0.614;CT value,r=0.625; all P<0.01). The HAP cutoff value of the 1st lumbar vertebra was 142.055mg/cm3 to provide the area-under-the-curve (AUC), sensitivity, specificity, PPV and NPV of 0.754, 0.714, 0.693, 0.68 and 0.752, respectively for diagnosing osteoporosis. The CT cutoff value of the 1st lumbar was vertebra 132HU for AUC, sensitivity, specificity, PPV and NPV of 0.766, 0.741, 0.7, 0.685 and 0.754, respectively.

CLINICAL RELEVANCE/APPLICATION

DEsCT provides multi-parameters to help the diagnosis of osteoporosis than conventional CT scans.

SDP-PH-65 Artificial Intelligence Teaching Program For Technicians

Participants
Paul R. Algra, MD, PhD, Alkmaar, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

To establish the need for an Artificial Intelligence (AI) teaching program for technologists in The Netherlands*Methods and Materials We performed a survey among technologists (diagnostic, therapeutic and nuclear) to evaluate the need for AI teaching programs.*Results The survey was carried out among members of Dutch Society Medical Imaging and Radiotherapy in the Netherlands in 2020. 126 (33%) technologists responded: 17 % working in university hospitals and 62 % at non-academic centers. Approximately one third is not using AI and the majority who does, has experience with AI in imaging (30%), dose optimization (28%) and workflow management (17%).More than 71% expects to start working with AI in the next two years and 94 % would like to get involved with AI. From the respondents, most interest is for AI application (83%), basic principles (73%), safety and ethical aspects (69%) programming algorithms (24%).*Conclusions A large majority of the technologists see AI as an important development and welcome education in AI. This is in line with earlier statements by international organizations.*Clinical Relevance/ApplicationSupported by the widely felt need of AI education, the Dutch government funded a nationwide teaching program.

RESULTS

The survey was carried out among members of Dutch Society Medical Imaging and Radiotherapy in the Netherlands in 2020. 126 (33%) technologists responded: 17 % working in university hospitals and 62 % at non-academic centers. Approximately one third is not using AI and the majority who does, has experience with AI in imaging (30%), dose optimization (28%) and workflow

management (17%).More than 71% expects to start working with AI in the next two years and 94 % would like to get involved with AI. From the respondents, most interest is for AI application (83%), basic principles (73%), safety and ethical aspects (69%) programming algorithms (24%).

CLINICAL RELEVANCE/APPLICATION

Supported by the widely felt need of AI education, the Dutch government funded a nationwide teaching program.

SDP-PH-66   Deep Learning Reconstruction Vs. Hybrid-type Iterative Reconstruction Vs. Model-based Iterative Reconstruction: Capability For Image Quality Improvements On Brain Contrast-enhanced CT Angiography For Ultra-high-resolution CT

Participants
Kazuhiro Murayama, MD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation

PURPOSE

To directly compare the capability for image quality improvements on brain contrast-enhanced CT angiography (CE-CTA) for ultra-high-resolution CT (UHR-CT) in intracranial aneurysms patients among deep learning reconstruction (DLR) and hybrid-type iterative reconstruction (IR) and model-based IR.*Methods and Materials 21 consecutive intracranial aneurysms patients underwent brain CE-CTA and reconstructed by DLR, hybrid-type IR and model-based IR using a UHR-CT system with super-high resolution mode (SHR: 0.25mm×160 rows/1792 channels). CT value on each CT dataset at ICA and MCA were assessed by ROI measurements. Image J software were used to generate the profile curves in this study. To assess the capability for improvement of spatial resolution with UHR-CT and DLR, full width at half maximum (FWHM), the width of the edge rise distance (ERD) and the edge rise slope (ERS) were measured at each vessel based on past literatures. For qualitative assessment, overall image quality, artifact, aneurysm and vascular depiction levels were assessed by 5-point scales by two board-certified radiologists. CT values were compared among all data set by Tukey's HSD test. To evaluate the utility of DLR method for accurate visualization of minimal spatial resolution, ERS were compared among all UHR-CT data using Tukey's HSD test. As for qualitatively assessed image quality, inter-observer agreements of each method were evaluated by kappa statistics with ?2 test. All qualitative indexes were compared among all data sets by Wilcoxon signed-rank test.*Results CT values and ERS of model-based IR and DLR were significantly higher than those of hybrid-type IR at MCA (p<0.05). Inter-observer agreement of each index by all methods were determined as moderate, substantial or excellent (0.51=?=0.92, p<0.001). In addition, overall image quality and artifact of DLR were significantly improved as compared with others (p<0.05). Aneurysm and vascular depiction levels had no significant difference among all methods (p>0.05).*Conclusions DLR has a potential for image quality improvements than hybrid-type and model-based IR on brain CE-CTA for UHR-CT.*Clinical Relevance/Application DLR has a potential for image quality improvements than hybrid-type and model-based IR on brain CE-CTA for UHR-CT.

RESULTS

CT values and ERS of model-based IR and DLR were significantly higher than those of hybrid-type IR at MCA (p<0.05). Inter-observer agreement of each index by all methods were determined as moderate, substantial or excellent (0.51=?=0.92, p<0.001). In addition, overall image quality and artifact of DLR were significantly improved as compared with others (p<0.05). Aneurysm and vascular depiction levels had no significant difference among all methods (p>0.05).

CLINICAL RELEVANCE/APPLICATION

DLR has a potential for image quality improvements than hybrid-type and model-based IR on brain CE-CTA for UHR-CT.

SDP-PH-67   Impact Of Reconstruction Kernel On Image Quality Of Coronary Stents With 256-rows Mdct

Participants
Yanhong Zhao, MMed,MMed, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the image quality of coronary stents phantom reconstructed by Detail and HD-detail reconstruction kernel.*Methods and Materials Coronary stents with a range of inner diameters (ID: 4mm, 3mm, and 2.5mm) were implanted in thin plastic tubes to simulate a coronary artery. The tubes were filled with iodinated contrast medium (10mg/ml), positioned in a plastic container filled with water. The phantom was scanned using a 256-row detector CT (Revolution CT, GE Healthcare). Images were acquired with 40% pre-ASiR-V (tube voltage 100kVp, automA, Noise index 26). Detail and HD-detail algorithms were used in image reconstruction. Subjective image quality was assessed independently by two radiologists, image quality was evaluated with five-point Likert scale (1, very poor; 2, suboptimal; 3, acceptable; 4, good; 5, excellent.). Paired-samples t test was applied for the comparison between CT value, visible diameter in percentage (VD%=VD/ID) and subjective image quality.*Results There was a significant difference in CT value of coronary stents between Detail and HD-detail algorithms (433.43 ± 205.58; 310.80 ± 43.72, P=0.330). Significant difference for VD% was observed between the two groups (32.00 ± 11.53%; 64.00 ± 4.00%, p=0.019). The subjective image quality in detail and HD detail was 1.83 ± 0.29 and 4.33 ± 0.58, respectively(p=0.013).*Conclusions The image quality of coronary stents phantom was significantly improved in image with HD-detail kernel, compared to that of HD kernel.*Clinical Relevance/Application HD-detail kernel can be used to generate high quality clinical data in the post-processing of image.

RESULTS

There was a significant difference in CT value of coronary stents between Detail and HD-detail algorithms (433.43 ± 205.58; 310.80 ± 43.72, P=0.330). Significant difference for VD% was observed between the two groups (32.00 ± 11.53%; 64.00 ± 4.00%, p=0.019). The subjective image quality in detail and HD detail was 1.83 ± 0.29 and 4.33 ± 0.58, respectively(p=0.013).

CLINICAL RELEVANCE/APPLICATION

HD-detail kernel can be used to generate high quality clinical data in the post-processing of image.

SDP-PH-68   Optimal Reconstruction Algorithm For Deep Learning Assisted Detection Of Rib Fracture In Emergency Trauma

Participants
Yanhong Zhao, MMed,MMed, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore detection efficiency differences of AI fracture detection system for emergency rib fracture detection under different reconstruction algorithms, and to seek the best reconstruction algorithm in rib fracture detection based on deep learning.*Methods and Materials 43 patients with emergency chest trauma underwent chest CT examination (Revolution CT, GE Healthcare) and images were reconstructed using standard/lung/bone/soft algorithms. AI-assisted diagnostic system (InferRead CT Bone Research,Infervision, Beijing) was used to detect rib fractures under different reconstruction algorithms. The gold standard of rib fracture was made by two radiologists with more than 15 years of experience in chest diagnosis on the review of AI reading results. The total number of rib fractures together with the true and false positive number of rib fractures detected by AI were recorded under four algorithms. Differences in the sensitivity and false positive rate of rib fracture detection under four reconstruction algorithms by AI were compared.*Results There were 202 rib fractures identified and used as the gold standard. Under standard/lung/bone/soft algorithms, AI system detected 170/203/195/161 fractures, of which 158/170/176/152 were true positive and 12/33/19/9 were false positive, respectively. Therefore, sensitivity of standard/lung/bone/soft for fracture detection was 78.22%/84.16%/87.13%/75.25%, respectively, with a significant difference found among groups (P =0.009). The false positive rates of the four algorithms were 1.45%/3.99%/2.29%/1.09%, and there was a statistically significant difference found among groups (P <0.001). Specifically, the sensitivity of AI in detection of rib fracture under bone and lung algorithm was found significantly higher than that under standard or soft algorithm.*Conclusions AI-assisted fracture detection system demonstrated different diagnostic efficacy for emergency traumatic fractures under different reconstruction algorithms. Particularly, bone and lung algorithm were found to be more sensitive in the detection of emergency traumatic fractures in comparison with standard and soft algorithm.*Clinical Relevance/Application AI exhibited improved detection efficiency under lung and bone algorithm for emergency traumatic rib fracture. It is suggested that bone and lung algorithm could be selected in the diagnosis of emergency traumatic rib fracture when artificial intelligence-assisted system was used.

RESULTS

There were 202 rib fractures identified and used as the gold standard. Under standard/lung/bone/soft algorithms, AI system detected 170/203/195/161 fractures, of which 158/170/176/152 were true positive and 12/33/19/9 were false positive, respectively. Therefore, sensitivity of standard/lung/bone/soft for fracture detection was 78.22%/84.16%/87.13%/75.25%, respectively, with a significant difference found among groups (P =0.009). The false positive rates of the four algorithms were 1.45%/3.99%/2.29%/1.09%, and there was a statistically significant difference found among groups (P <0.001). Specifically, the sensitivity of AI in detection of rib fracture under bone and lung algorithm was found significantly higher than that under standard or soft algorithm.

CLINICAL RELEVANCE/APPLICATION

AI exhibited improved detection efficiency under lung and bone algorithm for emergency traumatic rib fracture. It is suggested that bone and lung algorithm could be selected in the diagnosis of emergency traumatic rib fracture when artificial intelligence-assisted system was used.

SDP-PH-69 Quantitative Evaluation Of Metal Artifacts In CT Images Using No-reference Image Quality Assessment: Comparison Of Filtered Back Projection (FBP) And Deep Learning Image Reconstruction (DLIR)

Participants
Wakiko Tani, RT, Kobe, Japan (*Presenter*) Nothing to Disclose

PURPOSE

It is difficult to evaluate quantitatively a metal artifact in clinical images. No-reference image quality assessment (NR-IQA) model called Natural Image Quality Evaluator (NIQE) is one of the objective evaluations of images. We compared the image quality of metal artifact images using NIQE.*Methods and Materials A 26-cm diameter water phantom including a metal rod and two acryl rods were scanned at 3 different CTDIvol (7 mGy, 14 mGy and 28 mGy) with 120-kV. All CT data were reconstructed by FBP and DLIR (medium strength) with and without metal artifacts reduction (MAR). Metal artifact images were evaluated using NIQE and compared with visual evaluation and image noise. NIQE model was trained based on the high radiation dose input images without metal artifacts, NIQE score was calculated. A lower score indicates better image quality. Metal artifacts images were evaluated by using a 4-point score (1 = severe, 2 = strong, 3 = mild, 4 = minimal) by six radiographers blinded to sequence parameters. NIQE score, visual score and image noise were compared between each sequence by one-way ANOVA followed by Tukey test. Relations between NIQE score and visual score or image noise were assessed with the Pearson correlation coefficient.*Results The mean ± SD of NIQE score of FBP 7 mGy, FBP MAR(+) 7 mGy, FBP 14 mGy, FBP MAR(+) 14 mGy, FBP 28 mGy, FBP MAR(+) 28 mGy, DLIR 7 mGy and DLIR MAR(+) 7 mGy were 7.0±0.5, 6.6±0.4, 6.4±0.4, 5.9±0.4, 5.7±0.6, 5.2±0.4, 6.2±0.5 and 5.8±0.5, respectively. NIQE score decreased significantly with radiation dose, while there was no significant difference between FBP 14 mGy and DLIR 7 mGy. The mean ± SD of the visual score of FBP 7 mGy, FBP MAR(+) 7 mGy, FBP 14 mGy, FBP MAR(+) 14 mGy, FBP 28 mGy, FBP MAR(+) 28 mGy, DLIR 7 mGy and DLIR MAR(+) 7 mGy were 1.0±0.0, 2.8±0.4, 1.2±0.4, 3.2±0.4, 1.2±0.4, 4.0±0.0 1.7±0.5 and 3.8±0.4, respectively. Similar to the NIQE score, the visual score was not significantly different between FBP 14 mGy and DLIR 7 mGy. Pearson correlation coefficient of NIQE score and the visual score was -0.609 and NIQE score was associated with the visual score (P < .05). Furthermore, the Pearson correlation coefficient of NIQE score and image noise was 0.636 and NIQE score was associated with the image noise (P < .05).*Conclusions This study suggests that NIQE can quantitatively evaluate metal artifacts.*Clinical Relevance/Application NIQE is useful for evaluating metal artifacts and will be used for clinical images that it is not possible to place a region of interest (ROI) to measure image noise.

RESULTS

The mean ± SD of NIQE score of FBP 7 mGy, FBP MAR(+) 7 mGy, FBP 14 mGy, FBP MAR(+) 14 mGy, FBP 28 mGy, FBP MAR(+) 28 mGy, DLIR 7 mGy and DLIR MAR(+) 7 mGy were 7.0±0.5, 6.6±0.4, 6.4±0.4, 5.9±0.4, 5.7±0.6, 5.2±0.4, 6.2±0.5 and 5.8±0.5, respectively. NIQE score decreased significantly with radiation dose, while there was no significant difference between FBP 14 mGy and DLIR 7 mGy. The mean ± SD of the visual score of FBP 7 mGy, FBP MAR(+) 7 mGy, FBP 14 mGy, FBP MAR(+) 14 mGy, FBP 28 mGy, FBP MAR(+) 28 mGy, DLIR 7 mGy and DLIR MAR(+) 7 mGy were 1.0±0.0, 2.8±0.4, 1.2±0.4, 3.2±0.4, 1.2±0.4, 4.0±0.0 1.7±0.5 and 3.8±0.4, respectively. Similar to the NIQE score, the visual score was not significantly different between FBP 14 mGy and DLIR 7 mGy. Pearson correlation coefficient of NIQE score and the visual score was -0.609 and NIQE score was associated with the visual score (P < .05). Furthermore, the Pearson correlation coefficient of NIQE score and image noise was 0.636 and NIQE score was associated with the image noise (P < .05).

CLINICAL RELEVANCE/APPLICATION

NIQE is useful for evaluating metal artifacts and will be used for clinical images that it is not possible to place a region of interest

NIQL is useful for evaluating metal artifacts and will be used for clinical images that it is not possible to place a region of interest (ROI) to measure image noise.

SDP-PH-7 A New Quantification Method Of Hand Rheumatoid Arthritis Progression In X-ray Radiographs Using Deep Learning

Participants
Kohei Nakatsu, Himeji, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To propose a novel method to automatically quantify the progress of hand rheumatoid arthritis (RA) using X-ray radiograph.*Methods and Materials This study was approved by the Ethics Committee of Hyogo Prefectural Kakogawa Medical Center. A total of 90 X-ray radiograph images of both hands were used. For training and evaluation purpose, experts annotated the finger joint, the fingertip, and the modified Total Shape Score (mTSS). The mTSS is the standard diagnosis method of RA progression using X-ray radiograph, and is defined as a sum of "erosion" and "joint space narrowing (JSN)" score of hand joints. The proposed method first automatically detects finger joints using support vector machine (SVM) and statistical shape model (SSM). SVM estimates the degree of finger joints and the degree of fingertip for each pixel. Hand joint SSM can represent the spatial relationship among 14 finger joints and 5 fingertips by 6 shape parameters. The hand joint model can be reconstructed from the shape parameters, and the likelihood is estimated by using the finger joint and fingertip degrees. Thus, the proposed method can detect all finger joints by optimizing the 6 shape parameters.Next, the method estimates the erosion and JSN scores from the small image patch at the detected joint. This study compares the performance of some estimation models, ridge regression (RR) and deep learning (DL) with several network architectures. RR model first calculates HOG features, and then estimates the scores. DL model evaluates the image patches directly without feature extraction process. The evaluated network architectures are VGG16, DenseNet201 and Xception. The finger joint detection method was validated using leave-one-out cross validation. The erosion and JSN score estimation method were validated using 10-fold CV. The estimation results were evaluated by the root mean squared error(RMSE) of the estimated and actual scores.*Results The accuracy of finger joint detection with the proposed method was 94.8%. The RMSE of erosion estimation was 0.827 with RR, 0.854 with VGG16, 0.948 with DenseNet201, and 1.03 with Xception. And, the RMSE of JSN estimation was 0.697 with RR, 0.708 with VGG16, 0.821 with DenseNet201, and 0.877 with Xception.*Conclusions The SVM and SSM method detected the finger joint positions in X-ray radiograph with an accuracy of 94.8%. and estimation the mTSS with an accuracy of about 0.8 RMSE.*Clinical Relevance/Application For effective treatment of rheumatoid arthritis, the mTSS should be measured several times a year, but because there are many points to evaluate, manual evaluation requires a great deal of time. If automatic estimation of the mTSS becomes possible through this research, it will reduce the burden on physicians and improve the accuracy of diagnosis.

RESULTS

The accuracy of finger joint detection with the proposed method was 94.8%. The RMSE of erosion estimation was 0.827 with RR, 0.854 with VGG16, 0.948 with DenseNet201, and 1.03 with Xception. And, the RMSE of JSN estimation was 0.697 with RR, 0.708 with VGG16, 0.821 with DenseNet201, and 0.877 with Xception.

CLINICAL RELEVANCE/APPLICATION

For effective treatment of rheumatoid arthritis, the mTSS should be measured several times a year, but because there are many points to evaluate, manual evaluation requires a great deal of time. If automatic estimation of the mTSS becomes possible through this research, it will reduce the burden on physicians and improve the accuracy of diagnosis.

SDP-PH-70 Iterative Reconstruction Vs. Deep Learning Image Reconstruction: Comparison Of Image Quality In Low-dose Lower Extremity CT Angiography

Participants
Tingting Qu, Xi'an, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare image quality in low-dose CT angiography (CTA) of lower extremity between"adaptive statistical iterative reconstruction-V" (ASIR-V) and deep learning reconstruction (DLIR).*Methods and Materials Forty-six patients with lower extremity artery CTA were prospectively collected. Patients were scanned with low dose scheme (80kVp and automatic mA modulation for noise index (NI) of 20), front ASIR-V was 0%. The contrast medium was injected at the flow rates of 4.5ml/s (50ml) and 2.5ml/s (40ml). Images were reconstructed with three ASIR-V (blending factor of 0%, 50% and 100% (AV-100)) and two DLIR (medium-, and high-strength-level (DL-H) settings). CT number and SD values were measured at the upper edge of abdominal aortic bifurcation and left popliteal artery. Conventional indicators (CT number, SD values, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR)) of selected regions of interest were determined. For qualitative analyses, the degrees of quantum mottle and blurring were assessed by 5-grade method.*Results The higher the blending factor in ASIR-V or the strength in DLIR, the lower the noise, and the higher the SNR and CNR values. The SNR and CNR values of DLIR images were significantly higher than those of AV-0 and AV-50 images and lower than those of AV-100 images (all p<0.001). Through the evaluation of image blur and quantum mottle, the image quality of DLIR is better than that of ASIR-V (p<0.001), the overall qualitative image quality was best in DL-H images, the image blur of AV-100 was much higher than that of other reconstruction, and the mottle of AV-0 was much higher than that of other reconstruction.*Conclusions Compared with DL-M and ASIR-V, DL-H was the most balanced image in terms of image noise and sharpness in low-dose lower extremity CTA scanning.*Clinical Relevance/Application DL-H can balance the task of reducing image noise and maintaining spatial resolution to provide the best overall image quality in CTA of lower extremities.

RESULTS

The higher the blending factor in ASIR-V or the strength in DLIR, the lower the noise, and the higher the SNR and CNR values. The SNR and CNR values of DLIR images were significantly higher than those of AV-0 and AV-50 images and lower than those of AV-100 images (all p<0.001). Through the evaluation of image blur and quantum mottle, the image quality of DLIR is better than that of ASIR-V (p<0.001), the overall qualitative image quality was best in DL-H images, the image blur of AV-100 was much higher than that of other reconstruction, and the mottle of AV-0 was much higher than that of other reconstruction.

CLINICAL RELEVANCE/APPLICATION

DL-H can balance the task of reducing image noise and maintaining spatial resolution to provide the best overall image quality in CTA of lower extremities.

SDP-PH-71 Towards Big Data And Visualization Analytics: Dose Management 3.0 In A Multi-center European Settings

Participants
Federica Zanca, PhD, Leuven, Belgium (*Presenter*) Nothing to Disclose

PURPOSE

To comply with the 2013/59/Euratom Basic Safety Standards Directive continuous monitoring of dose data is mandatory. The aim of this study was to assess the impact on patient safety improvement and protocol optimization of a Business Intelligence (BI) tools for real-time dose management, in a multinational healthcare organization.*Methods and Materials Two countries were installed with a centralized dose monitoring solution (DoseWatch, GE Healthcare), collecting data from 31 CT scanner installed in diagnostic centers of the same healthcare provider. All protocols were standardized in terms of clinical indications and number of irradiations and mapped through a unique RadLex identifier. An Extract Transform and Load (ETL) framework for the two dose data repositories was used to feed, in real-time, a BI platform. Monitoring goals were defined for: dose metrics, dose alerts, justification of high doses, protocol standardization and optimization, equipment technical performance. To develop tracking dashboards, Key Performance Indicators (KPIs) were defined, and improvement processes put in place.*Results Preliminary metadata of 27687 exams were collected between January 2021 and April 2021. 81% of performed exams was covered by oncology follow up thorax-abdomen-pelvis (29%), head and C-spine trauma (17%), general chest (14%), head trauma (8%), general abdomen-pelvis (7%), general head (6%). Dose alerts for the above clinical indications varied between 2.5% (oncology thorax-abdomen-pelvis) to 0.5% (head and C- spine trauma) and the most recurrent justification were overweight patient, additional phase, or protocol, or over length acquisition. The % of protocols performed with a standard number of irradiations varied between 77% (head and C- spine trauma) and 55% (oncology abdomen-pelvis). Analyses of the median dose distribution per clinical indication showed optimized protocols with dose below institution and European Dose Reference Levels (DRLs), well harmonized across centers. Analysis of the impact of technology is undergoing.*Conclusions BI tools are very helpful software tools for monitoring patient exposure, optimisation, compliance with DRLs and quality assurance in a multinational healthcare organization.*Clinical Relevance/Application Real-time visualization of dose statistical data from CTs in a multinational organization allows to continuously benchmark data while strengthening patient safety and clinical excellence.

RESULTS

Preliminary metadata of 27687 exams were collected between January 2021 and April 2021. 81% of performed exams was covered by oncology follow up thorax-abdomen-pelvis (29%), head and C-spine trauma (17%), general chest (14%), head trauma (8%), general abdomen-pelvis (7%), general head (6%). Dose alerts for the above clinical indications varied between 2.5% (oncology thorax-abdomen-pelvis) to 0.5% (head and C- spine trauma) and the most recurrent justification were overweight patient, additional phase, or protocol, or over length acquisition. The % of protocols performed with a standard number of irradiations varied between 77% (head and C- spine trauma) and 55% (oncology abdomen-pelvis). Analyses of the median dose distribution per clinical indication showed optimized protocols with dose below institution and European Dose Reference Levels (DRLs), well harmonized across centers. Analysis of the impact of technology is undergoing.

CLINICAL RELEVANCE/APPLICATION

Real-time visualization of dose statistical data from CTs in a multinational organization allows to continuously benchmark data while strengthening patient safety and clinical excellence.

SDP-PH-72 Deep Learning Reconstruction Vs. Hybrid-type Iterative Reconstruction Vs. Model-based Iterative Reconstruction: Capability For Image Quality And Disease Depiction Improvements On Unenhanced Brain CT In Acute Ischemic Stroke Patients

Participants
Kazuhiro Murayama, MD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation

PURPOSE

To directly compare the capability for image quality and disease depiction improvements on unenhanced brain CT in acute ischemic stroke patients among deep learning reconstruction (DLR), hybrid-type iterative reconstruction (IR) and model-based IR.*Methods and Materials 15 consecutive acute ischemic stroke patients underwent unenhanced CT by DLR, conventional hybrid-type IR and model-based IR using a CT system. For quantitative image quality assessment in each patient, SNRs of normal gray- and white matters and CNRs between normal gray- and white matters and between normal gray- and ischemic gray matters were determined by ROI measurements. For qualitative assessment, two board-certified radiologists assessed overall image quality, artifacts and disease depiction level by a 5-point scoring system. To compare quantitative indexes among three methods, SNRs and CNRs were compared among DLR and hybrid-type IR and model-based IR by Wilcoxon signed-rank test. For evaluating inter-observer agreement of each index, weighted kappa statistics and ?2 test was performed. To compare each qualitative index among three methods, each index was also compared among three methods by Wilcoxon signed-rank test.*Results SNRs of DLR were significantly higher than those of hybrid-type IR (p<0.001). CNR of DLR between normal gray- and white matters was significantly higher than that of others (p<0.05). Moreover, CNR of DLR between normal gray- and ischemic gray matters was significantly higher than that of hybrid IR (p<0.001). Inter-observer agreements for diagnostic confidence on all methods were assessed as excellent (0.86=?=0.90, p<0.001), although inter-observer agreements for overall image quality and artifact on all methods were assessed as substantial (0.63=?=0.66, p<0.05). Overall image quality and artifact scores of DLR were significantly higher than that of others (p<0.05). Disease depiction level of DLR were significantly higher than that of hybrid-type IR (p<0.001).*Conclusions DLR has a superior capability for image quality and disease depiction improvements on unenhanced brain CT in acute ischemic stroke patients as compared with conventional hybrid-type and model-based IRs.*Clinical Relevance/Application DLR has a higher capability than conventional hybrid IR and model-based IR for image quality and disease depiction improvements on unenhanced brain CT in acute ischemic stroke patients.

RESULTS

SNRs of DLR were significantly higher than those of hybrid-type IR (p<0.001). CNR of DLR between normal gray- and white matters was significantly higher than that of others (p<0.05). Moreover, CNR of DLR between normal gray- and ischemic gray matters was significantly higher than that of hybrid IR (p<0.001). Inter-observer agreements for diagnostic confidence on all methods were assessed as excellent (0.86=?=0.90, p<0.001), although inter-observer agreements for overall image quality and artifact on all methods were assessed as substantial (0.63=?=0.66, p<0.05). Overall image quality and artifact scores of DLR were significantly higher than that of others (p<0.05). Disease depiction level of DLR were significantly higher than that of hybrid-type IR (p<0.001).

SDP-PH-73 Identification Of The Optimal Asir-v Blending Level For CT Portal Venography

Participants
Yanhong Zhao, MMed,MMed, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To assess the image quality of CT portal venography with different blending levels of adaptive statistical iterative reconstruction V (ASiR-V) algorithm, and investigate the optimal blending level of ASiR-V algorithm in the proportion of CT portal venography.*Methods and Materials Thirty patients suspected abdominal disease were enrolled. All the patients underwent upper abdominal enhancement CT scan with a 256 row wide-coverage volumetric CT (Revolution CT, GE healthcare, Milwaukee, WI). The Tube voltage was 120kV, the automatic tube current modulation technique was used with noise index of 10. For each patient, 11 image sets were reconstructed with ASiR-V blending level of 0 to 100% with 10% increasement. Two radiologists independently evaluated the image quality score with 5-point scale for the image artifacts, the capacity of the tiny structures of three level portal vein branches and the capacity of the tiny structures of lesion. The image noise of portal vein and liver parenchyma was measured. Image noise among different image sets was compared with two-way ANOVA, the image score among different image sets was compared with friedman test.*Results With the increase of ASiR-V blending level, the image noise of portal vein and liver parenchyma decreased gradually (both p<0.05). At 50% ,60% and 70% blending levels of ASiR-V, the image quality scores of image artifacts and the capacity of the tiny structures of lesion were the highest, and images scores of these three image sets had no statistical difference (P>0.05). At 50% and 60% blending levels of ASiR-V, the image quality scores of the showing the tiny structures of three level portal vein branches were the highest (4.83±0.36 and 4.78±0.39), and images scores of these two image sets had no statistical difference(P=0.673). At 30% to 80%, the image score of artifacts was above than 3.5 points. At 30% to 80%, the image score of the showing the tiny structures of three level portal vein branches was above than 3.5 points. At 30% to 90%, the image score of the capacity of the tiny structures of lesion was above than 3.5 points.*Conclusions ASiR-V algorithm reduce image noise of CT portal venography. 50% ,60% and 70% blending levels have the highest image quality. High blending level of ASiR-V may cause "fuzzy" effects of the images.*Clinical Relevance/Application ASiR-V algorithm reduce image noise of CT portal venography. 50% ,60% and 70% blending levels have the highest image quality. High blending level of ASiR-V may cause "fuzzy" effects of the images.

RESULTS

With the increase of ASiR-V blending level, the image noise of portal vein and liver parenchyma decreased gradually (both p<0.05). At 50% ,60% and 70% blending levels of ASiR-V, the image quality scores of image artifacts and the capacity of the tiny structures of lesion were the highest, and images scores of these three image sets had no statistical difference (P>0.05). At 50% and 60% blending levels of ASiR-V, the image quality scores of the showing the tiny structures of three level portal vein branches were the highest (4.83±0.36 and 4.78±0.39), and images scores of these two image sets had no statistical difference(P=0.673). At 30% to 80%, the image score of artifacts was above than 3.5 points. At 30% to 80%, the image score of the showing the tiny structures of three level portal vein branches was above than 3.5 points. At 30% to 90%, the image score of the capacity of the tiny structures of lesion was above than 3.5 points.

CLINICAL RELEVANCE/APPLICATION

ASiR-V algorithm reduce image noise of CT portal venography. 50% ,60% and 70% blending levels have the highest image quality. High blending level of ASiR-V may cause "fuzzy" effects of the images.

SDP-PH-74 Evaluation Of Skin Doses For Cone-beam Computed Tomography In Dentomaxillofacial Imaging

Participants
Carolin Reidelbach, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Evaluation of skin organ doses in six different cone-beam computed tomography scanners (CBCT) dedicated to dentomaxillofacial imaging. Our hypothesis is that the dose varies between different devices, protocols and skin areas.*Methods and Materials An anthropomorphic adult head and neck phantom was used to which a dosimeter (Waterproof Farmer® Chamber, PTW, Freiburg, Germany) was attached to anatomic landmarks of both parotid glands, both ocular lenses, the thyroid gland and the neurocranium. CBCT examinations were performed on six different CBCT devices dedicated to dentomaxillofacial imaging with standard settings and if available also in high dose settings. Measurements were repeated five times each.*Results The measured mean organ skin doses ranged from 0.48 to 2.21 mGy. The comparison of the region based dose evaluation showed a high correlation between the single measurements. Furthermore, the distribution of dosesbetween regions was similar in all devices, except that four devices showed side differences for the dose of the parotid region and one device showed side differences for the lens region. The directly exposed regions, such as the parotid glands, showed significant higher values than the more distant regions like the neurocranium.When comparing examination protocols, a significant difference between the standard dose and the high dose acquisitions could be detected. But also a significant dose difference between the different CBCTs could be shown. 3D Accuitomo 170 (Morita, Osaka, Japan) showed the highest absorbed mean dose value for standard settings with 2.21 mGy, especially at the directly exposed regions and their adjacent organs. The lowest mean value for standard settings was achieved with VGi evo (NewTom, Verona, Italy) with 0.48 mGy.*Conclusions Repeated measurements of skin organ doses in six different CBCT scanners using a surface dosimeter showed side differences in distribution of dose in five devices for the parotid and lens region. Additionally, significant dose differences between the devices could be detected. Further studies should be performed to confirm these results.*Clinical Relevance/Application The possibility of asymmetric dose distribution should be considered in the assessment of and in future studies on radiation dose in dentomaxillofacial CBCT. Furthermore, significant dose differences between the individual devices must be expected.

RESULTS

The measured mean organ skin doses ranged from 0.48 to 2.21 mGy. The comparison of the region based dose evaluation showed a high correlation between the single measurements. Furthermore, the distribution of dosesbetween regions was similar in all devices, except that four devices showed side differences for the dose of the parotid region and one device showed side differences for the lens region. The directly exposed regions, such as the parotid glands, showed significant higher values than the more distant

regions like the neurocranium.When comparing examination protocols, a significant difference between the standard dose and the high dose acquisitions could be detected. But also a significant dose difference between the different CBCTs could be shown. 3D Accuitomo 170 (Morita, Osaka, Japan) showed the highest absorbed mean dose value for standard settings with 2.21 mGy, especially at the directly exposed regions and their adjacent organs. The lowest mean value for standard settings was achieved with VGi evo (NewTom, Verona, Italy) with 0.48 mGy.

CLINICAL RELEVANCE/APPLICATION

The possibility of asymmetric dose distribution should be considered in the assessment of and in future studies on radiation dose in dentomaxillofacial CBCT. Furthermore, significant dose differences between the individual devices must be expected.

SDP-PH-75   Does Detector Pixel Size Have An Effect On Perceived Clinical Image Quality?

Participants
Lesley Cockmartin, Leuven, Belgium (*Presenter*) Nothing to Disclose

PURPOSE

To assess the influence of detector pixel size and dose level on clinical image quality of orthopedic and chest radiography applications.*Methods and Materials Seven x-ray detectors from different vendors, with pixel sizes (ps) ranging from 76µm to 175µm, were assessed at 5 detector air kerma (DAK) levels, from 1.3µGy to 7.4µGy. Four anatomical regions were imaged: human cadaver hand, human cadaver foot, rabbit cadaver pelvis and living rabbit chest. Agfa Musica3 image processing (Agfa Musica3) was applied to the raw images. A visual grading study was set up using, as reference, the detector with an intermediate ps (124µm) at median DAK (2.7µGy to 3.8µGy, depending on application). Four radiologists read the images, scoring sharpness of specific anatomical features on a scale from -2 to +2, from worse to better than the reference. Noise was similarly scored, from -5 to +5. Ordinal logistic regression was applied to evaluate the effect of detector type (i.e. ps) and DAK on perceived sharpness and noise. Reader agreement was assessed using intra-class correlation coefficient (ICC).*Results ICC values ranged from 0.62 to 0.83. Logistic regression showed that dose significantly influenced perceived sharpness and noise (p<0.0001 for all 4 anatomies) with odds ratios (OR) from 4.5 to 27 indicating higher ratings for increasing dose. Pixel size did not significantly influence perceived sharpness, except for the following cases: (1) the detectors with ps of 76µm and 100µm were better (p=0.036,OR=28 and p=0.029,OR=31) than the reference for sharpness in the chest, (2) detectors with ps of 148µm and 175µm had lower sharpness ratings in the foot (p=0.04,OR=0.057, and p=0.001,OR=0.0035), (3) sharpness in the pelvic bones and the hand scored worse for the 175µm pixel detector (p=0.01,OR=0.027 and p=0.04,OR=0.032).*Conclusions A significant reduction in perceived sharpness was only found for the 175µm pixel detector compared to the reference 124µm pixel detector at the same dose, whereas using pixel sizes as small as 76µm did not significantly improve sharpness scores. Dose was the dominant factor in perceived clinical image quality.*Clinical Relevance/Application For routine, plain radiological applications, the benefit of small pixel size detectors may be limited; choice of dose level remains important.

RESULTS

ICC values ranged from 0.62 to 0.83. Logistic regression showed that dose significantly influenced perceived sharpness and noise (p<0.0001 for all 4 anatomies) with odds ratios (OR) from 4.5 to 27 indicating higher ratings for increasing dose. Pixel size did not significantly influence perceived sharpness, except for the following cases: (1) the detectors with ps of 76µm and 100µm were better (p=0.036,OR=28 and p=0.029,OR=31) than the reference for sharpness in the chest, (2) detectors with ps of 148µm and 175µm had lower sharpness ratings in the foot (p=0.04,OR=0.057, and p=0.001,OR=0.0035), (3) sharpness in the pelvic bones and the hand scored worse for the 175µm pixel detector (p=0.01,OR=0.027 and p=0.04,OR=0.032).

CLINICAL RELEVANCE/APPLICATION

For routine, plain radiological applications, the benefit of small pixel size detectors may be limited; choice of dose level remains important.

SDP-PH-76   Comparison Of Performance Of Material Suppression Iodine (msi) Images And Virtual Unenhanced (vue) Images In Liver Ct

Participants
Yanhong Zhao, MMed,MMed, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare between images of true non-contrast scan (TNC) and images produced by two different iodine removal techniques - virtual unenhanced (VUE) and material suppressed iodine (MSI) - in liver CT examination.*Methods and Materials A total of 18 patients with suspected upper abdominal disease underwent multiphase CT examination using a rapid kVp-switching spectral CT scanner (Revolution CT, GE Healthcare). Conventional non-contrast scan was followed by two-phase (hepatic arterial and portal venous phase) contrast-enhanced spectral scan using fast kV switching 80/140 kV, noise index (NI) of 8, rotation time of 0.5s, pitch 0.992, and 40% ASIR-V. TNC images were reconstructed from the conventional plain scan, and VUE and MSI images were reconstructed from the spectral data of contrast-enhanced hepatic arterial and portal venous phases. CT value and image noise of liver were measured on TNC, VUE and MSI images. The subjective image quality was independently assessed by two experienced radiologists using a five-point scale system (from 1=poor to 5=excellent). Differences between groups were analysed using two-way ANOVA.*Results There was no significant difference in CT values of five groups (P=0.310). The image noise of TNC, arterial phase VUE, venous phase VUE, arterial phase MSI, venous phase MSI images were 12.70±2.39, 12.27±1.36, 10.72±1.41, 11.44±1.79, and 8.11±1.73, respectively. There was no significant difference between the TNC and the arterial phase VUE (p=0.472), while the image noise of TNC was significantly higher than the venous phase VUE, the arterial phase MSI and the venous phase MSI (p =0.000). The subjective image scores of TNC, arterial phase VUE scans, venous phase VUE scans, arterial phase MSI scans, venous phase MSI scans were (5.00±0.00 4.83±0.38 3.83±0.38 4.33±0.59 3.17±0.51)respectively. The subjective image quality scores of arterial phase VUE and MSI images were better than those of venous phase VUE and MSI (P1=0.000, P2=0.000). Subjective scores of the arterial phase VUE were better than those of the arterial phase MSI (P=0.001)*Conclusions In liver CT examination,the arterial phase VUE was better than the arterial phase MSI, and was closer to conventional plain scan.*Clinical Relevance/Application In the liver energy spectrum CT examination, the VUE image quality is superior to the MSI image,and it has the potential to replace TNC.

RESULTS

There was no significant difference in CT values of five groups (P=0.310). The image noise of TNC, arterial phase VUE, venous phase VUE, arterial phase MSI, venous phase MSI images were 12.70±2.39, 12.27±1.36, 10.72±1.41, 11.44±1.79, and 8.11±1.73,

respectively. There was no significant difference between the TNC and the arterial phase VUE (p=0.472), while the image noise of TNC was significantly higher than the venous phase VUE, the arterial phase MSI and the venous phase MSI (p =0.000). The subjective image scores of TNC, arterial phase VUE scans, venous phase VUE scans, arterial phase MSI scans, venous phase MSI scans were (5.00±0.00 4.83±0.38 3.83±0.38 4.33±0.59 3.17±0.51)respectively. The subjective image quality scores of arterial phase VUE and MSI images were better than those of venous phase VUE and MSI (P1=0.000, P2=0.000). Subjective scores of the arterial phase VUE were better than those of the arterial phase MSI (P=0.001)

CLINICAL RELEVANCE/APPLICATION

In the liver energy spectrum CT examination, the VUE image quality is superior to the MSI image,and it has the potential to replace TNC.

SDP-PH-77   Reduction Of Beam Hardening Artefact With Anew Generation Spectralct: Comparison Of Spectral CT Mode And Conventional CT Modeobjective

Participants
Yanhong Zhao, MMed,MMed, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

The aim of study was to compare the reduction of beam hardening artefact (BHA) with conventional CT mode versus spectral CT imaging mode.*Methods and Materials A cylindrical phantom with nine tubes containing iodine with different concentration (0, 1.25, 2.5, 5, 10, 15, 20, 40, 40mgI/ml) was scanned using a MDCT (Revolution CT, GE Healthcare). The phantom was examined with both conventional CT imaging (tube voltage 120kVp, automA, Noise index 6.2,rotation time 0.5s, pitch 0.992) and spectral CT imaging (80/140 kV,automA, Noise index 6.2,rotation time 0.5s, pitch 0.992) mode. Images were reconstructed at a blend of monochromatic energy levels (40 to 140 keV with 10keV interval). A circular region of interest was placed on the region with highest amount of beam hardening. Noise was recorded within the region of interest (A-region between 20 mgI/ml tube and 40 mgI/ml tube, B-region between 40mgI/ml and 10mgI/ml, C-region within 40 mgI/ml tube). BHA was calculated through square root of the squared noise difference between the region of interest (Nr) and background (Nb). The differences between groups were assessed with T test.*Results The SD was 14.2±0.6, 10.5±0.7, 9.0±0.8 in conventional scanning mode and 8.3±0.4, 7.8±0.4, 7.7±0.4 in spectral CT mode. The AI is (12.8±0.6, 8.8 ± 0.9, 7.0 ± 1.0) in conventional scanning mode and (5.2 ± 0.3, 4.3 ± 0.8, 4.1 ± 1.2) in spectral CT modeThe SD and AI values of the GSI mode was lower than those of the conventional CT mode, and the differences were statistically significant (P<0.0.5 for all).*Conclusions The use of spectral CT can reduce the beam hardening artefacts created by high concentration iodine contrast.*Clinical Relevance/Application The use of spectral CT can reduce the beam hardening artefacts created by high concentration iodine contrast.

RESULTS

The SD was 14.2±0.6, 10.5±0.7, 9.0±0.8 in conventional scanning mode and 8.3±0.4, 7.8±0.4, 7.7±0.4 in spectral CT mode. The AI is (12.8±0.6, 8.8 ± 0.9, 7.0 ± 1.0) in conventional scanning mode and (5.2 ± 0.3, 4.3 ± 0.8, 4.1 ± 1.2) in spectral CT modeThe SD and AI values of the GSI mode was lower than those of the conventional CT mode, and the differences were statistically significant (P<0.0.5 for all).

CLINICAL RELEVANCE/APPLICATION

The use of spectral CT can reduce the beam hardening artefacts created by high concentration iodine contrast.

SDP-PH-78   Comparison of Volume High-resolution CT and Conventional High-resolution CT In Interstitial Lung Disease

Participants
