Breast Monday Poster Discussions

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Ellen Mendelson, MD, Chicago, IL (*Moderator*) Medical Advisory Board, Seno Medical Instruments, Inc;Medical Advisory Board, Delphinus Medical Technologies, Inc

Sub-Events

M2-SPBR-1 Post-market Real-world Data Demonstrates that an AI System Can Detect Cancers Missed by Human Readers in Breast Cancer Screening Without Unnecessary Recalls: A Stepping Stone Towards Implementation

Participants
Jonathan Nash, San Francisco, CA (*Presenter*) Medical Director, Kheiron Medical Technologies Ltd;Stockholder, Kheiron Medical Technologies Ltd

PURPOSE

To demonstrate real-world post-market benefit of artificial intelligence (AI) as an extra reader in breast cancer screening (BCS).

METHODS AND MATERIALS

A commercially available AI system was employed as an extra reader (XR) in addition to standard human double reading (HDR) at a breast cancer screening center from Apr-Sept 2021. The XR workflow involved flagging cases the AI suggested to recall which HDR did not recall, i.e. positive discordant cases, for arbitration by an experienced radiologist. The deep learning model and the thresholds for the operating points of the AI were predefined and validated in previous studies. Primary outcome was cancer detection rate. All detected cancers were pathology-confirmed.

RESULTS

Standard HDR for 3746 patients had an arbitration rate of 3.0% (114 patients), a recall rate of 6.7% (250 patients), and a cancer detection rate (CDR) of 12.5/1000 (47 cancer cases). Of the cases that were not recalled by HDR, the AI flagged 396 cases to recommend recall (positive discordance rate 10.6%). Extra arbitration resulted in recalling 6 patients, all of whom were diagnosed with breast cancer. This equated to a total arbitration rate of 13.6% and 1.6/1000 increase in CDR (sum 14.1/1000). An exact simulation with a less sensitive AI operating point yielded a total arbitration rate of 5.3%, while still detecting 5 of 6 extra cancer cases.

CONCLUSION

s This real-world deployment of AI increased cancer detection rates without recalling extra false positives, indicating the effectiveness of AI as an extra reader. Combining the XR workflow with workflows focused on workload savings will mitigate the increased arbitration rate and optimise clinical and operational benefits. The results provide important, real-world evidence showing the benefit of using an AI reader in breast cancer screening, paving the way for innovative workflows where synergy of humans and AI achieve optimal performance for patients.

CLINICAL RELEVANCE/APPLICATION

One of the first prospectively collected data sets where AI is actually being employed in real-world breast cancer screening shows increased cancer detection rate for AI an as extra reader.

M2-SPBR-2 Artificial-Intelligence-Driven Volumetric Breast Density Estimation as a Predictor of Individualized Breast Cancer Risk

Participants
Vinayak Ahluwalia, BS, Philadelphia, PA (*Presenter*) Nothing to Disclose

PURPOSE

Breast density is a well-established risk factor for breast cancer. We present an artificial intelligence (AI) algorithm to estimate volumetric breast density (VBD) solely from 3D-reconstructed digital breast tomosynthesis (DBT) images, rather than raw images rarely kept by clinical centers, and analyze its ability to perform individualized breast cancer risk assessment.

METHODS AND MATERIALS

We retrospectively analyzed 1,080 negative DBT screening exams obtained between 2011 and 2016 from the Hospital of the University of Pennsylvania (41.2% White, 54.2% Black, 4.6% Other; mean age ± SD, 57 ± 11 years; mean BMI ± SD, 28.7 ± 7.1 kg/m2), for which both 2D raw and 3D reconstructed DBT images (Selenia Dimensions, Hologic Inc) were available. Corresponding 3D reference-standard tissue segmentations were generated from previously validated software that uses both 3D reconstructed slices and raw 2D DBT data. We based our deep learning algorithm on the U-Net architecture within the open-source Generally

Nuanced Deep Learning Framework (GaNDLF) and created a 3-label image segmentation task (background, dense tissue, and fatty tissue). Our dataset was randomly split into training (70%), validation (15%) and test (15%) sets. Our evaluation measure was the weighted Dice score (DSC), with 0 signifying no overlap and 1 signifying perfect overlap, overall and separately for each label. Subsequently, we created a conditional logistic regression model using an independent case-control set of 907 subjects from the same hospital system to evaluate if the VBD estimated from the AI algorithm and BMI is associated with breast cancer risk.

RESULTS

On an independent testing set, our AI algorithm achieved unweighted and weighted DSC of 0.78 (STD=0.09) and 0.56 (STD=0.19), respectively. It accurately segmented the three labels of background, fatty tissue, and dense tissue, with Dice scores of 0.94, 0.89, and 0.49, respectively. In conditional logistic regression, VBD (Odds ratio 1.27, 95% confidence interval [1.03, 1.55], p=0.022) and BMI (Odds ratio 1.37, 95% confidence interval [1.12, 1.68], p=0.002) were shown to be statistically significant factors in individualized breast cancer prediction.

CONCLUSION

s This AI method demonstrates promise in the estimation of VBD from 3D-reconstructed DBT images. Moreover, this estimation, along with BMI, has been shown to be associated with breast cancer risk. Such a tool can enable large retrospective epidemiological and personalized risk assessments of breast density with DBT.

CLINICAL RELEVANCE/APPLICATION

We have created an AI algorithm for estimating VBD from 3D-reconstructed DBT images that does not require the use of raw image data and could aid in predicting an individual's risk of breast cancer.

M2-SPBR-3 Clinical Implications of Changes in Artificial Intelligence Software Case Scores from Prior to Current Digital Breast Tomosynthesis Screening Exam

Participants
Emily F. Conant, MD, Philadelphia, PA (*Presenter*) Research Grant, Hologic, Inc;Advisory Panel, Hologic, Inc;Research Grant, OM1, Inc;Research Grant, iCad, Inc;Advisory Panel, iCad, Inc;Speaker, WebMD LLC

PURPOSE

To evaluate the degree of change in digital breast tomosynthesis (DBT) artificial intelligence software (AI-CAD) case scores over sequential screens relative to outcomes.

METHODS AND MATERIALS

In an IRB-approved, HIPAA-compliant observational study at a single site from 2/3/20-3/16/22, a total of 25220 DBT screens were performed on 18251 women of which 22927 were scored at the exam-level with a DBT-derived, AI algorithm (Profound AI v2, iCAD, Inc.). Study outcome groups were compared using EMR/tumor registry data. For true negatives (TN) and false positives (FP) screens, 1 year follow-up was required. Biopsy-proven, cancer cases were deemed either true positive (TP) or false negative (FN) based on mode of detection. The differences in AI-derived case score between second screen (time2 = t2, "current screen") and first screen (time1 = t1, "prior screen") were compared across outcome groups based on outcome of the current screen. For each outcome group, the mean and median change in case scores was calculated.

RESULTS

Of 22927 screens with case scores, outcomes were: 159 TP and 18 FN cancer cases and 20777 negative or 1973 benign. For non-cancer cases with 1 year follow-up, there were 9527 TN and 765 FP. Average age was TP: 62.6, FP: 55.5, TN: 58.5, FN: 58.5; 5467 of the women were Black, 4299 White, 325 Asian, 378 "Other". The average (range) of case scores was: TP-75 (7-100), FP-42 (0-100), TN-34 (0-100), FN-37 (0-88). The 10469 screens were in 10219 women with TP, FP, TN or FN; 9969 had a single screen and 250 had 2 screens. Of women with only one screen, there were: TP=132, FP=743, TN=9079, FN=15. Of 250 women with 2 screens (and 1 year follow-up for TN and FPs), there were: TP=27, FP=13, TN=207, FN=3 on current screens and FP=9, TN=241 on prior screens. DBT AI-CAD case score change from prior to current screen in the 250 women based on outcomes demonstrated median and mean differences in case score for t2 - t1 were: TP: 15 and 22.8; FP: 3 and 2.4; TN: 0 and -1.6; FN: -10 and -6.

CONCLUSION

s DBT AI-CAD case scores from sequential screens allow assessment of score changes, with larger increases in mean score difference from prior to current for women with screen-detected cancers compared to other outcomes

CLINICAL RELEVANCE/APPLICATION

Changes in DBT AI-derived case scores over sequential screens should be considered; the degree of AI-derived score change may be indicative of increased likelihood of screen-detected cancer.

M2-SPBR-4 Assessment of Breast Positioning in Digital Mammography: Performance of Artificial Intelligent Quality Control System and Agreement Between AI and Radiographers

Participants
Huizhi Cao, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the performance of breast positioning in digital mammography using an artificial intelligent quality control system(AIQCS) and determine the agreement between AI system and radiographers.

METHODS AND MATERIALS

Assessment of breast positioning was performed by AI system (Edison, GE Healthcare)and by four radiographers on 1223 examinations of women. Nine image quality criteria were used for craniocaudal and mediolateral-oblique views. The criteria evaluated the appearance of the nipple, breast rotation, pectoral muscle, inframammary fold, pectoral nipple line, shoulder overlap shadow, abdominal skin, contralateral breast and foreign body. The area under the receiver operating characteristic curve (AUC) of poor imaging quality prediction by AI system according to incomplete gland, incomplete pectoralis muscle, over or insufficient exposure were calculated and overall accuracy were evaluated. Intraclass correlation and Cohen's kappa coefficient (?) were used

to investigate the correlation and agreement between the radiographer's assessments and AI.

RESULTS

The AUC of poor imaging quality prediction by AI system according to incomplete gland, incomplete pectoralis muscle, over or insufficient exposure was (0.903 vs 0.937 vs 982). Overall accuracy of AI system were 0.958. The intraclass correlation for the pectoral nipple line between the radiographers and AI was >0.80. A substantial to almost perfect agreement (? > 0.85) was observed between the radiographers and AI on the nipple in profile criterion. We observed a slight to moderate agreement for the other criteria (? = 0.40-0.65) and generally a higher agreement between the two pairs of radiographers (mean ? = 0.70) than between the radiographers and AI (mean ? = 0.61).

CONCLUSION

s AI has great potential in evaluating breast position criteria in mammography by reducing subjectivity. However, varying agreement between radiographers and AI was observed.

CLINICAL RELEVANCE/APPLICATION

Breast position with AI system has great importance for quality control of mammography and are great value to reach optimal image quality in mammography.

M2-SPBR-5 Initial Experience with Contrast-Enhanced Mammography Guided Biopsy: A Single Institution Case Series

Participants
Abeer Mousa, MD, Phoenix, AZ (*Presenter*) Nothing to Disclose

PURPOSE

CEM (contrast-enhanced mammography) utilizes iodinated contrast to highlight areas of neovascularity in the breast tissues with sensitivity comparable to that of breast MR imaging. Review of our data has shown that 4% of our CEM cases have suspicious areas of CEM enhancement, which are mammographically and sonographically-occult. In these instances, we have previously performed MRI-guided biopsies given the lack of CEM-guided biopsy capability. In 2020, the FDA cleared a device to support CEM biopsy. As a pilot site testing the Hologic Affirm contrast biopsy device, we present a preliminary overview of our experience with this new technology.

METHODS AND MATERIALS

IRB approved, HIPAA compliant post-market, prospective case review of 28 patients who underwent a CEM-guided biopsy for suspicious CEM only findings. Six biopsies were canceled due to lack of lesion enhancement at the time of biopsy (n=5) or benign skin lesion (n=1). Hologic Selenia Dimensions mammography system with updated I-View software for CEM localization and biopsy was used. After intravenous injection of iodinated contrast, enhancing lesions were localized using 2D stereotactic image acquisition followed by stereotactic biopsy.

RESULTS

28 patients underwent CEM guided biopsy, mean patient age 57.2 years (34-78y). Mean size of biopsied lesion was 12 mm (5-29 mm). Pathology demonstrated malignancy in 5/28 (18%) (3 invasive lobular carcinoma, 2 ductal carcinoma in situ), high risk lesions in 6/28 (21%), and benign findings in 17/28 (61%). When available, average length of procedure was 11 min (5-20 min). One patient with a benign biopsy was categorized as clinically discordant and had subsequent MRI-guided biopsy, which demonstrated invasive ductal carcinoma, resulting in one false negative.

CONCLUSION

s Our study demonstrates that CEM-guided biopsies are technically feasible, with average length of time relatively shorter than that of MR biopsy. Pathology concordance remains of utmost importance using a newer biopsy technique.

CLINICAL RELEVANCE/APPLICATION

As future work evolves, CEM and CEM-guided biopsies could provide for a more cost-effective and relatively quick breast tissue biopsy mechanism. Future work will need to be performed to compare costs, patient wait times, procedure times and patient experience of CEM to MRI biopsy.

M2-SPBR-6 Explorative Multicenter Study to Assess Patient Comfort: Radiographers Usability and Image Quality of Spiral Breast CT

Participants
Matthias Wetzl, MD, Erlangen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Dedicated spiral breast CT is a promising method in breast imaging and is increasingly used in radiology departments. This explorative, multicenter study aimed to assess image quality of dedicated spiral breast CT and its acceptability among patients and radiographers in different radiology sites.

METHODS AND MATERIALS

The prospective study was approved by the local ethics committee and conducted in three centers from August 2021 to March 2022. On a 5-point Likert Scale, patient comfort (1 = very good comfort; 5 = severe injury) and usability by radiographers (1 = very good usability; 5 = examination not possible) were assessed. Radiologists rated overall image quality (1 = very good; 5 = diagnosis not possible), depiction of calcifications (1 = very good; 5 = diagnosis not possible), and coverage of breast tissue (1 = glandular tissue complete and parts of pectoralis muscle; 2 = almost complete glandular tissue and part of pectoralis muscle; 3 = major parts of glandular tissue and no pectoralis muscle; 4 = major parts of glandular tissue missing).

RESULTS

393 women (age: 59 years old, range 35 - 89) participated in the study. Both breasts were examined in 92 % and intravenous

contrast media was applied in 39 % of patients. Patient comfort (n = 313) was very good in 71 % (CI 67 - 76 %) and good in 28 % (CI 22 - 32 %), while 1 % had minor problems. One woman needed physiotherapy due to pain in cervical spine, which exaggerated after the procedure. Usability by radiographers (n = 298) was very good in 61 % (CI 55 - 66 %) and good in 26 % (CI 22 - 31 %), while examination was not possible in one women, since the breasts were too large for the scanner. Image quality (n = 224) was rated very good in 57 % (CI 51 - 64 %) and good in 34 % (CI 29 - 40 %). Detectability of calcifications (n = 116) was very good in 75 % (CI 67 - 83 %), while 8 % (CI 3 - 13 %) of calcifications presented insufficiently (Likert Scale 3 - 5). Breast coverage (n = 224) was complete in 38 % (CI 32 - 45 %), almost complete in 29 % (CI 23 - 34 %), major parts of glandular tissue were covered in 30 % (CI 23 - 35 %), and coverage was insufficient in 3 % (CI 1 - 6 %).

CONCLUSION

s Dedicated spiral breast CT has a high acceptance among patients and radiographers. Image quality is high in dedicated breast CT and breast coverage adequate.

CLINICAL RELEVANCE/APPLICATION

Dedicated spiral breast CT delivers a high image quality and is well accepted by radiographers and patients in a prospective multicenter study.

M2-SPBR-7 Preoperative MRI Characteristics of Invasive Breast Cancer: Association with Lympho Vascular Invasion and Disease-free Survival

Participants
Zeyan Xu, (*Presenter*) Nothing to Disclose

PURPOSE

As an adverse prognostic factor in patients with invasive breast cancer, lymphovascular invasion (LVI) is closely associated with axillary lymph node (ALN) involvement, disease recurrence, and distant metastasis. This study aims to investigate the relationship of preoperative MRI characteristics with LVI and disease-free survival (DFS).

METHODS AND MATERIALS

This retrospective study included patients with available LVI status who underwent preoperative MRI examination at two hospitals from January 2013 to August 2020. Univariable and multivariable logistic regression analyses were performed to evaluate the independent predictors of LVI. A prediction model was established and a scoring system was carried out according to the odds ratio of multivariable analysis in the primary set, and the results were further verified in the validation set. The Kaplan-Meier method and log-rank test were applied to analyze the association of the risk score with DFS.

RESULTS

A total of 575 women (median age, 50 years; range, 24-79 years) were included. LVI-positive status was confirmed in 26.9% (104 of 386) and 27.5% (52 of 189) of the primary and validation set. At the primary set, Ki-67 index, MRI-ALN status, breast edema score, multicentricity or multifocality showed significantly independent values in predicting LVI status (P lt; 0.05). The area under the receiver operating characteristic curve of the model using these predictors in the primary and validation set was 0.75 (95% confidence interval [CI]: 0.69, 0.81) and 0.75 (95% CI: 0.67, 0.83), respectively. Across the entire study population, higher grades of simplified scores tended to have a higher proportion of positive LVI status. Furthermore, patients with high-score were significantly associated with a worse DFS (HR for high vs. low, 3.08; 95% CI: 1.32-7.18, P = 0.006).

CONCLUSION

s The prediction model incorporating Ki-67 index, MRI-ALN status, breast edema score, multicentricity or multifocality shows good predictive performance for LVI status and is associated with DFS in patients with invasive breast cancer.

CLINICAL RELEVANCE/APPLICATION

A feasible predictive model combining preoperative breast MRI characteristics and clinicopathological factors can help identify the presence of lymphovascular invasion in patients with invasive breast cancer. Furthermore, the variables used in our model are readily available in routine clinical practice and could help optimize clinical workflows.

Post-market Real-world Data Demonstrates that an AI System Can Detect Cancers Missed by Human Readers in Breast Cancer Screening Without Unnecessary Recalls: A Stepping Stone Towards Implementation

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Jonathan Nash, San Francisco, CA (*Presenter*) Medical Director, Kheiron Medical Technologies Ltd;Stockholder, Kheiron Medical Technologies Ltd

PURPOSE

To demonstrate real-world post-market benefit of artificial intelligence (AI) as an extra reader in breast cancer screening (BCS).

METHODS AND MATERIALS

A commercially available AI system was employed as an extra reader (XR) in addition to standard human double reading (HDR) at a breast cancer screening center from Apr-Sept 2021. The XR workflow involved flagging cases the AI suggested to recall which HDR did not recall, i.e. positive discordant cases, for arbitration by an experienced radiologist. The deep learning model and the thresholds for the operating points of the AI were predefined and validated in previous studies. Primary outcome was cancer detection rate. All detected cancers were pathology-confirmed.

RESULTS

Standard HDR for 3746 patients had an arbitration rate of 3.0% (114 patients), a recall rate of 6.7% (250 patients), and a cancer detection rate (CDR) of 12.5/1000 (47 cancer cases). Of the cases that were not recalled by HDR, the AI flagged 396 cases to recommend recall (positive discordance rate 10.6%). Extra arbitration resulted in recalling 6 patients, all of whom were diagnosed with breast cancer. This equated to a total arbitration rate of 13.6% and 1.6/1000 increase in CDR (sum 14.1/1000). An exact simulation with a less sensitive AI operating point yielded a total arbitration rate of 5.3%, while still detecting 5 of 6 extra cancer cases.

CONCLUSION

s This real-world deployment of AI increased cancer detection rates without recalling extra false positives, indicating the effectiveness of AI as an extra reader. Combining the XR workflow with workflows focused on workload savings will mitigate the increased arbitration rate and optimise clinical and operational benefits. The results provide important, real-world evidence showing the benefit of using an AI reader in breast cancer screening, paving the way for innovative workflows where synergy of humans and AI achieve optimal performance for patients.

CLINICAL RELEVANCE/APPLICATION

One of the first prospectively collected data sets where AI is actually being employed in real-world breast cancer screening shows increased cancer detection rate for AI an as extra reader.

M2-SPBR-2

Artificial-Intelligence-Driven Volumetric Breast Density Estimation as a Predictor of Individualized Breast Cancer Risk

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Vinayak Ahluwalia, BS, Philadelphia, PA (*Presenter*) Nothing to Disclose

PURPOSE

Breast density is a well-established risk factor for breast cancer. We present an artificial intelligence (AI) algorithm to estimate volumetric breast density (VBD) solely from 3D-reconstructed digital breast tomosynthesis (DBT) images, rather than raw images rarely kept by clinical centers, and analyze its ability to perform individualized breast cancer risk assessment.

METHODS AND MATERIALS

We retrospectively analyzed 1,080 negative DBT screening exams obtained between 2011 and 2016 from the Hospital of the University of Pennsylvania (41.2% White, 54.2% Black, 4.6% Other; mean age ± SD, 57 ± 11 years; mean BMI ± SD, 28.7 ± 7.1 kg/m2), for which both 2D raw and 3D reconstructed DBT images (Selenia Dimensions, Hologic Inc) were available. Corresponding 3D reference-standard tissue segmentations were generated from previously validated software that uses both 3D reconstructed slices and raw 2D DBT data. We based our deep learning algorithm on the U-Net architecture within the open-source Generally Nuanced Deep Learning Framework (GaNDLF) and created a 3-label image segmentation task (background, dense tissue, and fatty tissue). Our dataset was randomly split into training (70%), validation (15%) and test (15%) sets. Our evaluation measure was the weighted Dice score (DSC), with 0 signifying no overlap and 1 signifying perfect overlap, overall and separately for each label. Subsequently, we created a conditional logistic regression model using an independent case-control set of 907 subjects from the same hospital system to evaluate if the VBD estimated from the AI algorithm and BMI is associated with breast cancer risk.

RESULTS

On an independent testing set, our AI algorithm achieved unweighted and weighted DSC of 0.78 (STD=0.09) and 0.56 (STD=0.19), respectively. It accurately segmented the three labels of background, fatty tissue, and dense tissue, with Dice scores of 0.94, 0.89, and 0.49, respectively. In conditional logistic regression, VBD (Odds ratio 1.27, 95% confidence interval [1.03, 1.55], p=0.022) and BMI (Odds ratio 1.37, 95% confidence interval [1.12, 1.68], p=0.002) were shown to be statistically significant factors in individualized breast cancer prediction.

CONCLUSION

s This AI method demonstrates promise in the estimation of VBD from 3D-reconstructed DBT images. Moreover, this estimation, along with BMI, has been shown to be associated with breast cancer risk. Such a tool can enable large retrospective epidemiological and personalized risk assessments of breast density with DBT.

CLINICAL RELEVANCE/APPLICATION

We have created an AI algorithm for estimating VBD from 3D-reconstructed DBT images that does not require the use of raw image data and could aid in predicting an individual’s risk of breast cancer.

M2-SPBR-3

Clinical Implications of Changes in Artificial Intelligence Software Case Scores from Prior to Current Digital Breast Tomosynthesis Screening Exam

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Emily F. Conant, MD, Philadelphia, PA (*Presenter*) Research Grant, Hologic, Inc;Advisory Panel, Hologic, Inc;Research Grant, OM1, Inc;Research Grant, iCad, Inc;Advisory Panel, iCad, Inc;Speaker, WebMD LLC

PURPOSE

To evaluate the degree of change in digital breast tomosynthesis (DBT) artificial intelligence software (AI-CAD) case scores over sequential screens relative to outcomes.

METHODS AND MATERIALS

In an IRB-approved, HIPAA-compliant observational study at a single site from 2/3/20-3/16/22, a total of 25220 DBT screens were performed on 18251 women of which 22927 were scored at the exam-level with a DBT-derived, AI algorithm (Profound AI v2, iCAD, Inc.). Study outcome groups were compared using EMR/tumor registry data. For true negatives (TN) and false positives (FP) screens, 1 year follow-up was required. Biopsy-proven, cancer cases were deemed either true positive (TP) or false negative (FN) based on mode of detection. The differences in AI-derived case score between second screen (time2 = t2, "current screen") and first screen (time1 = t1, "prior screen") were compared across outcome groups based on outcome of the current screen. For each outcome group, the mean and median change in case scores was calculated.

RESULTS

Of 22927 screens with case scores, outcomes were: 159 TP and 18 FN cancer cases and 20777 negative or 1973 benign. For non-cancer cases with 1 year follow-up, there were 9527 TN and 765 FP. Average age was TP: 62.6, FP: 55.5, TN: 58.5, FN: 58.5; 5467 of the women were Black, 4299 White, 325 Asian, 378 "Other". The average (range) of case scores was: TP-75 (7-100), FP-42 (0-100), TN-34 (0-100), FN-37 (0-88). The 10469 screens were in 10219 women with TP, FP, TN or FN; 9969 had a single screen and 250 had 2 screens. Of women with only one screen, there were: TP=132, FP=743, TN=9079, FN=15. Of 250 women with 2 screens (and 1 year follow-up for TN and FPs), there were: TP=27, FP=13, TN=207, FN=3 on current screens and FP=9, TN=241 on prior screens. DBT AI-CAD case score change from prior to current screen in the 250 women based on outcomes demonstrated median and mean differences in case score for t2 - t1 were: TP: 15 and 22.8; FP: 3 and 2.4; TN: 0 and -1.6; FN: -10 and -6.

CONCLUSION

s DBT AI-CAD case scores from sequential screens allow assessment of score changes, with larger increases in mean score difference from prior to current for women with screen-detected cancers compared to other outcomes

CLINICAL RELEVANCE/APPLICATION

Changes in DBT AI-derived case scores over sequential screens should be considered; the degree of AI-derived score change may be indicative of increased likelihood of screen-detected cancer.

Assessment of Breast Positioning in Digital Mammography: Performance of Artificial Intelligent Quality Control System and Agreement Between AI and Radiographers

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Huizhi Cao, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the performance of breast positioning in digital mammography using an artificial intelligent quality control system(AIQCS) and determine the agreement between AI system and radiographers.

METHODS AND MATERIALS

Assessment of breast positioning was performed by AI system (Edison, GE Healthcare)and by four radiographers on 1223 examinations of women. Nine image quality criteria were used for craniocaudal and mediolateral-oblique views. The criteria evaluated the appearance of the nipple, breast rotation, pectoral muscle, inframammary fold, pectoral nipple line, shoulder overlap shadow, abdominal skin, contralateral breast and foreign body. The area under the receiver operating characteristic curve (AUC) of poor imaging quality prediction by AI system according to incomplete gland, incomplete pectoralis muscle, over or insufficient exposure were calculated and overall accuracy were evaluated. Intraclass correlation and Cohen's kappa coefficient (?) were used to investigate the correlation and agreement between the radiographer's assessments and AI.

RESULTS

The AUC of poor imaging quality prediction by AI system according to incomplete gland, incomplete pectoralis muscle, over or insufficient exposure was (0.903 vs 0.937 vs 982). Overall accuracy of AI system were 0.958. The intraclass correlation for the pectoral nipple line between the radiographers and AI was >0.80. A substantial to almost perfect agreement (? > 0.85) was observed between the radiographers and AI on the nipple in profile criterion. We observed a slight to moderate agreement for the other criteria (? = 0.40-0.65) and generally a higher agreement between the two pairs of radiographers (mean ? = 0.70) than between the radiographers and AI (mean ? = 0.61).

CONCLUSION

s AI has great potential in evaluating breast position criteria in mammography by reducing subjectivity. However, varying agreement between radiographers and AI was observed.

CLINICAL RELEVANCE/APPLICATION

Breast position with AI system has great importance for quality control of mammography and are great value to reach optimal image quality in mammography.

Initial Experience with Contrast-Enhanced Mammography Guided Biopsy: A Single Institution Case Series

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Abeer Mousa, MD, Phoenix, AZ (*Presenter*) Nothing to Disclose

PURPOSE

CEM (contrast-enhanced mammography) utilizes iodinated contrast to highlight areas of neovascularity in the breast tissues with sensitivity comparable to that of breast MR imaging. Review of our data has shown that 4% of our CEM cases have suspicious areas of CEM enhancement, which are mammographically and sonographically-occult. In these instances, we have previously performed MRI-guided biopsies given the lack of CEM-guided biopsy capability. In 2020, the FDA cleared a device to support CEM biopsy. As a pilot site testing the Hologic Affirm contrast biopsy device, we present a preliminary overview of our experience with this new technology.

METHODS AND MATERIALS

IRB approved, HIPAA compliant post-market, prospective case review of 28 patients who underwent a CEM-guided biopsy for suspicious CEM only findings. Six biopsies were canceled due to lack of lesion enhancement at the time of biopsy (n=5) or benign skin lesion (n=1). Hologic Selenia Dimensions mammography system with updated I-View software for CEM localization and biopsy was used. After intravenous injection of iodinated contrast, enhancing lesions were localized using 2D stereotactic image acquisition followed by stereotactic biopsy.

RESULTS

28 patients underwent CEM guided biopsy, mean patient age 57.2 years (34-78y). Mean size of biopsied lesion was 12 mm (5-29 mm). Pathology demonstrated malignancy in 5/28 (18%) (3 invasive lobular carcinoma, 2 ductal carcinoma in situ), high risk lesions in 6/28 (21%), and benign findings in 17/28 (61%). When available, average length of procedure was 11 min (5-20 min). One patient with a benign biopsy was categorized as clinically discordant and had subsequent MRI-guided biopsy, which demonstrated invasive ductal carcinoma, resulting in one false negative.

CONCLUSION

s Our study demonstrates that CEM-guided biopsies are technically feasible, with average length of time relatively shorter than that of MR biopsy. Pathology concordance remains of utmost importance using a newer biopsy technique.

CLINICAL RELEVANCE/APPLICATION

As future work evolves, CEM and CEM-guided biopsies could provide for a more cost-effective and relatively quick breast tissue biopsy mechanism. Future work will need to be performed to compare costs, patient wait times, procedure times and patient experience of CEM to MRI biopsy.

Explorative Multicenter Study to Assess Patient Comfort: Radiographers Usability and Image Quality of Spiral Breast CT

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Matthias Wetzl, MD, Erlangen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Dedicated spiral breast CT is a promising method in breast imaging and is increasingly used in radiology departments. This explorative, multicenter study aimed to assess image quality of dedicated spiral breast CT and its acceptability among patients and radiographers in different radiology sites.

METHODS AND MATERIALS

The prospective study was approved by the local ethics committee and conducted in three centers from August 2021 to March 2022. On a 5-point Likert Scale, patient comfort (1 = very good comfort; 5 = severe injury) and usability by radiographers (1 = very good usability; 5 = examination not possible) were assessed. Radiologists rated overall image quality (1 = very good; 5 = diagnosis not possible), depiction of calcifications (1 = very good; 5 = diagnosis not possible), and coverage of breast tissue (1 = glandular tissue complete and parts of pectoralis muscle; 2 = almost complete glandular tissue and part of pectoralis muscle; 3 = major parts of glandular tissue and no pectoralis muscle; 4 = major parts of glandular tissue missing).

RESULTS

393 women (age: 59 years old, range 35 - 89) participated in the study. Both breasts were examined in 92 % and intravenous contrast media was applied in 39 % of patients. Patient comfort (n = 313) was very good in 71 % (CI 67 - 76 %) and good in 28 % (CI 22 - 32 %), while 1 % had minor problems. One woman needed physiotherapy due to pain in cervical spine, which exaggerated after the procedure. Usability by radiographers (n = 298) was very good in 61 % (CI 55 - 66 %) and good in 26 % (CI 22 - 31 %), while examination was not possible in one women, since the breasts were too large for the scanner. Image quality (n = 224) was rated very good in 57 % (CI 51 - 64 %) and good in 34 % (CI 29 - 40 %). Detectability of calcifications (n = 116) was very good in 75 % (CI 67 - 83 %), while 8 % (CI 3 - 13 %) of calcifications presented insufficiently (Likert Scale 3 - 5). Breast coverage (n = 224) was complete in 38 % (CI 32 - 45 %), almost complete in 29 % (CI 23 - 34 %), major parts of glandular tissue were covered in 30 % (CI 23 - 35 %), and coverage was insufficient in 3 % (CI 1 - 6 %).

CONCLUSION

s Dedicated spiral breast CT has a high acceptance among patients and radiographers. Image quality is high in dedicated breast CT and breast coverage adequate.

CLINICAL RELEVANCE/APPLICATION

Dedicated spiral breast CT delivers a high image quality and is well accepted by radiographers and patients in a prospective multicenter study.

Preoperative MRI Characteristics of Invasive Breast Cancer: Association with Lympho Vascular Invasion and Disease-free Survival

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Zeyan Xu, (*Presenter*) Nothing to Disclose

PURPOSE

As an adverse prognostic factor in patients with invasive breast cancer, lymphovascular invasion (LVI) is closely associated with axillary lymph node (ALN) involvement, disease recurrence, and distant metastasis. This study aims to investigate the relationship of preoperative MRI characteristics with LVI and disease-free survival (DFS).

METHODS AND MATERIALS

This retrospective study included patients with available LVI status who underwent preoperative MRI examination at two hospitals from January 2013 to August 2020. Univariable and multivariable logistic regression analyses were performed to evaluate the independent predictors of LVI. A prediction model was established and a scoring system was carried out according to the odds ratio of multivariable analysis in the primary set, and the results were further verified in the validation set. The Kaplan-Meier method and log-rank test were applied to analyze the association of the risk score with DFS.

RESULTS

A total of 575 women (median age, 50 years; range, 24-79 years) were included. LVI-positive status was confirmed in 26.9% (104 of 386) and 27.5% (52 of 189) of the primary and validation set. At the primary set, Ki-67 index, MRI-ALN status, breast edema score, multicentricity or multifocality showed significantly independent values in predicting LVI status (P lt; 0.05). The area under the receiver operating characteristic curve of the model using these predictors in the primary and validation set was 0.75 (95% confidence interval [CI]: 0.69, 0.81) and 0.75 (95% CI: 0.67, 0.83), respectively. Across the entire study population, higher grades of simplified scores tended to have a higher proportion of positive LVI status. Furthermore, patients with high-score were significantly associated with a worse DFS (HR for high vs. low, 3.08; 95% CI: 1.32-7.18, P = 0.006).

CONCLUSION

s The prediction model incorporating Ki-67 index, MRI-ALN status, breast edema score, multicentricity or multifocality shows good predictive performance for LVI status and is associated with DFS in patients with invasive breast cancer.

CLINICAL RELEVANCE/APPLICATION

A feasible predictive model combining preoperative breast MRI characteristics and clinicopathological factors can help identify the presence of lymphovascular invasion in patients with invasive breast cancer. Furthermore, the variables used in our model are readily available in routine clinical practice and could help optimize clinical workflows.

M2-SPCA-1 Photon-Counting CT Coronary Stent Imaging with Dedicated Ultra-Sharp Convolution Kernels: A Phantom Study

Participants
Bernhard Petritsch, MD, Wuerzburg, Germany (*Presenter*) Research Consultant, Siemens AG

PURPOSE

To assess the impact of different dedicated (ultra-) sharp vascular convolution kernels on quantitative and subjective image characteristics using a clinical photon-counting detector (PCD) CT system in comparison to a conventional energy-integrating detector (EID) CT system.

METHODS AND MATERIALS

In this phantom study, 10 different coronary stents (3.0 mm diameter) were expanded into plastic vessel phantoms filled with contrast agent. Stent-containing vessel phantoms were positioned in an anthropomorphic phantom (QRM) simulating a medium-sized patient. CT scans were acquired parallel to the scanners z-axis using a 1st generation PCD CT system (NAEOTOM Alpha, Siemens). Examinations were performed with two different scan-modes (standard-resolution [SR mode - 2x2 binning] and ultra-high-resolution [UHR mode- subpixels readout separately]). A state of the art EID CT system from the same vendor served as reference standard (SOMATOM Force, Siemens). CTDIvol matched images were reconstructed with identical reconstruction parameters using different convolution kernels (Bv59 [EID]; Bv60 [SR-PCD], Bv68 [SR + UHR-PCD], Bv84 [UHR-PCD]). In-stent lumen visibility (%), image noise (HU), and subjective image quality (IQ) (Likert sale 1-4) were assessed.

RESULTS

PCD-UHR mode in Bv84 achieved highest in-stent lumen visibility and best subjective IQ [=1] while PCD-SR mode in Bv60 provided lowest noise levels and comparable IQ [=3] to the EID CT. In-stent lumen visibility was significantly higher ($p<0.001$) with PCD UHR in Bv68 (73.3%) [IQ=2], and PCD UHR in Bv84 (83.3%) when compared to conventional EID (60.0%). Image noise of PCD CT was significantly lower ($p<0.001$) for Bv60 SR (24 HU), and Bv68 UHR (27 HU) mode compared to conventional EID images (66 HU). The ultra sharp Bv84 kernel provided similar ($p=1.000$) noise levels (68 HU) as conventional Bv59 EID images.

CONCLUSION

s In an in vitro setting, the combination of PCD CT and ultra-sharp convolution kernels provides superior in-stent lumen visibility and subkective image quality at identical (Bv84) or even lower (Bv68) noise levels when compared to conventional EID CT technology.

CLINICAL RELEVANCE/APPLICATION

PCD CT allows for improved assessment of coronary artery stents and potentially in-stent restenosis in particular, respectively.

M2-SPCA-2 Dual Energy versus Single Energy Coronary CT Angiography for The Evaluation of Coronary Artery Disease

Participants
Carlos Capunay, MD, Vicente Lopez, Argentina (*Presenter*) Nothing to Disclose

PURPOSE

To explore the diagnostic performance of dual energy CT coronary angiography (DE-CTCA) in comparison with single energy CTCA (SE-CTCA) in patients with intermediate to high likelihood of coronary artery disease (CAD) referred to invasive coronary angiography (ICA).

METHODS AND MATERIALS

Study protocol include consecutive symptomatic patients with suspected CAD referred for ICA who underwent DE-CTCA and a coronary artery calcium scoring (CACS) whithin the month before the ICA. DE-CTCA was analyzed in a polychromatic fashion to resemble a SE-CTCA and using monochromatic images at 85 keV to reduce blooming artifact. Two blinded experienced observers (O) analyzed the images. O1 analyzed DE-CTCA and O2 analyzed the equivalent SE-CTCA group of images. Stenosis over 50% were considered a positive finding. The 95% confidence interval for the proportions were calculated by the exact binomial method. ROC curve analyses were performed using specific software for ROC analysis. Pairwise comparison of ROC curves were performed using the method of DeLong et al. for detection of differences between two AUC, and calculated the binomial exact confidence interval for the AUC. A two-sided p value of less than 0.05 indicated statistical significance.

RESULTS

Fifty patients were included, mean age 63 years-old; 70% male. The mean effective radiation dose of DE-CTCA was 4 mSv. The

Fifty patients were included, mean age 65 years-old, 76% male. The mean effective radiation dose of DE-CTCA was 4 mSv. The median CAC scoring of the patients was 589 (interquartile range 183-1085). The sensitivity, specificity, PPV, NPV, LR +, LR - and AUC for the detection of stenosis = 50% (per segment analysis; 711 segments) for SE-CTA were 93.8%, 90.7%, 71.7%, 98.3%, 10.1, 0.07 and 0.92; for DE-CTA 94.4%, 96,2%, 84.3%, 98.7%, 24.7, 0.05 and 0.95. Improvement of PPV, LR+ and in diagnostic performance was observed between techniques, p=0.006.

CONCLUSION

s In symptomatic patients with intermediate to high likelihood of CAD, DE-CTCA showed a good diagnostic performance to identify obstructive disease with better diagnostic performance than SE-CTCA.

CLINICAL RELEVANCE/APPLICATION

Dual Energy computed tomography coronary angiography emerged as a novel promising CT technology to attenuate some of the limitations related to the polychromatic nature of the x-rays (such as blooming artifact).

M2-SPCA-3 Coronary Stent Image Quality with A Spectral Photon Counting CT: Initial Results in Humans

Participants
Sara Boccalini, MD, PhD, Lyon, France (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study is to compare the image quality (IQ) of in-vivo coronary stents between a dual-energy dual-source CT (DECT) and a clinical prototype of Spectral Photon Counting CT (SPCCT).

METHODS AND MATERIALS

In January-April 2021 patients with coronary stents were prospectively enrolled to undergo a coronary CT with a DECT (IQon, Philips) and a SPCCT (Philips). The study was approved by the local ethical committee and patients signed an informed consent. An acquisition with retrospective ECG gating was performed with optimized matching parameters on the two scanners (DECT: collimation=64x0.625, kV=120, mAs=255, dose modulation, rotation time=0.27; SPCCT: collimation=64x0.275, kV=120, mAs=255, rotation time=0.33). The injection protocol was the same on the two scanners: 65-75mL of Iomeron (Bracco) at 5mL/sec. Images were reconstructed with slice thickness of 0.67mm, 512 matrix, XCD kernel, iDose 3 for DECT and 0.25mm slice thickness, 1024 matrix and sharp kernel, iDose 6 for SPCCT. ROIs were drawn in the lumen of the stent and of the upstream coronary artery and the difference (?HU) between the respective values was calculated. Measures of the proximal and distal outer and inner diameter of the stents were used to quantify blooming artefacts. For subjective IQ, 2 experienced observers graded with a 4-point scale the image quality of different parameters: coronary wall before the stent, stent lumen, stent structure, calcifications surrounding the stent, beam hardening artefacts.

RESULTS

7 patients (age: 69±5; all males; BMI: 25.9±2.1) with 14 stents were scanned. Two stents were not evaluable due to motion artifacts. Of the remaining, 7 were active stents of Platinum-Chromium (5 Synergy; 1 Promus) and Cobalt-Chromium (Ultimaster); for the others no information could be retrieved. Whereas HU values within the coronary arteries on the two scanners were similar (p=0.56), the ?HU was higher for the DECT (median(IQ)=201(278) vs 112(59); p<0.01). The mean external diameter of the stents was 4.5 vs 4mm and the internal 1.5 vs 2.2mm (without the 1 stent the internal diameter of which was not assessable on the DECT). Blooming artefacts were more pronounced on the DECT (69%(16) vs 48%(10); p<0.001). SPCCT IQ had higher subjective scores for stent lumen, stent structure, surrounding calcifications and beam hardening (all p=0.001). The IQ of the coronary wall scored higher as well, but not significantly (3 vs 2; p=0.19).

CONCLUSION

s SPCCT demonstrated improved objective and subjective image quality as compared to DECT for the evaluation of coronary stents.

CLINICAL RELEVANCE/APPLICATION

Stent assessment remains a challenge of coronary CT. With its proven higher spatial resolution and artefacts reduction capabilities, SPCCT might overcome these limitations.

Photon-Counting CT Coronary Stent Imaging with Dedicated Ultra-Sharp Convolution Kernels: A Phantom Study

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - CA DPS

Participants
Bernhard Petritsch, MD, Wuerzburg, Germany (*Presenter*) Research Consultant, Siemens AG

PURPOSE

To assess the impact of different dedicated (ultra-) sharp vascular convolution kernels on quantitative and subjective image characteristics using a clinical photon-counting detector (PCD) CT system in comparison to a conventional energy-integrating detector (EID) CT system.

METHODS AND MATERIALS

In this phantom study, 10 different coronary stents (3.0 mm diameter) were expanded into plastic vessel phantoms filled with contrast agent. Stent-containing vessel phantoms were positioned in an anthropomorphic phantom (QRM) simulating a medium-sized patient. CT scans were acquired parallel to the scanners z-axis using a 1st generation PCD CT system (NAEOTOM Alpha, Siemens). Examinations were performed with two different scan-modes (standard-resolution [SR mode - 2x2 binning] and ultra-high-resolution [UHR mode- subpixels readout separately]). A state of the art EID CT system from the same vendor served as reference standard (SOMATOM Force, Siemens). CTDIvol matched images were reconstructed with identical reconstruction parameters using different convolution kernels (Bv59 [EID]; Bv60 [SR-PCD], Bv68 [SR + UHR-PCD], Bv84 [UHR-PCD]). In-stent lumen visibility (%), image noise (HU), and subjective image quality (IQ) (Likert sale 1-4) were assessed.

RESULTS

PCD-UHR mode in Bv84 achieved highest in-stent lumen visibility and best subjective IQ [=1] while PCD-SR mode in Bv60 provided lowest noise levels and comparable IQ [=3] to the EID CT. In-stent lumen visibility was significantly higher ($p<0.001$) with PCD UHR in Bv68 (73.3%) [IQ=2], and PCD UHR in Bv84 (83.3%) when compared to conventional EID (60.0%). Image noise of PCD CT was significantly lower ($p<0.001$) for Bv60 SR (24 HU), and Bv68 UHR (27 HU) mode compared to conventional EID images (66 HU). The ultra sharp Bv84 kernel provided similar ($p=1.000$) noise levels (68 HU) as conventional Bv59 EID images.

CONCLUSION

s In an in vitro setting, the combination of PCD CT and ultra-sharp convolution kernels provides superior in-stent lumen visibility and subkective image quality at identical (Bv84) or even lower (Bv68) noise levels when compared to conventional EID CT technology.

CLINICAL RELEVANCE/APPLICATION

PCD CT allows for improved assessment of coronary artery stents and potentially in-stent restenosis in particular, respectively.

M2-SPCH-1 CT Findings of Systemic Sclerosis: Precise Radiologic-pathologic Correlation in 29 Patients

Participants
Taiki Fukuda, MD, PhD, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

There has been no report of a precise radiologic-pathologic correlation of systemic sclerosis-related interstitial lung disease (SSc-ILD). Moreover, despite the early therapeutic intervention is desirable, early CT findings of SSc-ILD has been still unclear. The purposes of this study were two-fold; (1) To decide pathological backgrounds of CT findings of SSc-ILD and (2) To clarify the early CT findings and their pathological features.

METHODS AND MATERIALS

Twenty-nine patients with SSc-ILD diagnosed by surgical lung biopsy (SLB) were enrolled. A total of 82 specimens were obtained. The histological findings of each specimen were correlated with the corresponding CT side by side by two radiologists and two pathologists. Whole lung CT was evaluated by the other two radiologists, independently. Early CT findings were extracted from the whole lung CT according to the rationale that diseases with lower lobe predominance show their early findings in more upper zones. Their pathological findings were examined from the area of SLB which corresponded to early CT findings.

RESULTS

Pathologically, non-specific interstitial pneumonia was diagnosed in 18 cases, while usual interstitial pneumonia and fibrosing organizing pneumonia were diagnosed in 9 and 2 cases respectively. Emphysematous change was pathologically observed in 19 cases and identified on CT in 11 cases. Four of those were non-smokers. Pathologically, vascular wall thickening was observed in 14 cases. Small faint nodules superimposed on amorphous ground-glass opacity within 1 cm from the pleura, which we term faint amorphous opacity (FAC), were present in 18 cases, particularly in the anterolateral upper lobes. FAC pathologically corresponded to either peribronchial metaplasia, centriacinar mucostasis or periacinar alveolar septal fibrosis.

CONCLUSION

s Pathological detectability of the emphysematous changes was superior to CT. Vasculopathy might be another cause of emphysema other than smoking. FAC could be an early CT finding of SSc-ILD, representing either peribronchial metaplasia, centriacinar mucostasis, or periacinar alveolar septal fibrosis pathologically.

CLINICAL RELEVANCE/APPLICATION

Understanding the pathological features of SSc-ILD will help to analyze the pathogenesis and determine the disease progression on CT. The aforementioned early CT finding may allow a more accurate diagnosis of SSc-ILD and prompt therapeutic intervention.

M2-SPCH-2 Radiologic Predictors of Pulmonary Hypertension in Patients with Fibrosing Interstitial Lung Disease

Participants
Lubna Siddiqi, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The development of pulmonary hypertension (PH) in fibrosing ILD is associated with significantly shorter survival. Currently, risk stratification for PH is exclusively based on clinical and echocardiographic findings. We sought to use objective values from CT imaging to predict the presence of associated pulmonary hypertension in patients with fibrosing interstitial lung disease (ILD).

METHODS AND MATERIALS

An initial 128 patients with fibrosing ILD followed at the London Health Sciences Centre underwent right heart catheterization (RHC). Of these, 94 patients (66 male, 28 female, with average age of 66.2) with CT thorax within 6 months of RHC were assessed for main pulmonary artery to aorta ratio (MPA:Ao), right to left ventricular ratio (RV:LV), caliber of the right and left pulmonary arteries, interventricular septal thickness, and right ventricular wall thickness, as well as the presence of pulmonary thromboembolic disease and degree of mosaic attenuation. PH was defined as a mean pulmonary arterial pressure (mPAP) =25 mmHg on RHC. Radiologic data were then analyzed using stepwise regression analysis to determine the best predictors of associated PH. Results were adjusted for sex, BMI, and age.

RESULTS

Thirty-eight patients (40%) underwent RHC electively and 56 (60%) as part of a lung transplant (LTx) assessment. Average mPAP was 25±6 mmHg, wedge pressure 9±4 mmHg, cardiac output 5.0±1.0 L/min and pulmonary vascular resistance 3.3±1.4 Wood units.

Sixty-six patients (70%) had PH. Among patients with PH, average mPAP was 38±11 mmHg and PVR was 5.7±2.6 Wood Units. On stepwise multiple regression analysis, MPA and RV diameter were independent and significant predictors of PVR (F ratio 6.64 and 6.32, p-values 0.0137 and 0.0159 respectively). Importantly, the correlation between MPA and RV was weak (Spearman's rank 0.17, not significant), with no collinearity observed. MPA was also a significant predictor of mPAP (F ratio 11.5, p-value 0.0015).

CONCLUSION

s The presence of associated PH has a significant impact on the appearance of CT thorax in fibrosing ILD. Both MPA and RV diameter are predictors of PH. A combination of radiologic parameters obtained from CT thorax may be used to reliably risk stratify patients with fibrosing ILD for the presence and severity of associated PH. We will seek validation of these data in a separate cohort of patients.

CLINICAL RELEVANCE/APPLICATION

In patients with fibrosing ILD, a combination of radiologic parameters may be used to predict the presence and severity of PH and to guide clinical decisions on RHC, LTx assessment and prognosis. These parameters could be especially helpful in populations for whom RHC is not readily available, or is a contraindication.

M2-SPCH-3 Deep Learning-based Fibrosis Quantification on Chest CT as a Prognostic Predictor in Patient with Idiopathic Pulmonary Fibrosis

Participants
Ju Gang Nam, MD, Seoul, Korea, Republic Of (*Presenter*) Research Grant, VUNO Inc

PURPOSE

Radiology plays a crucial role in the diagnosis and management of patients with idiopathic pulmonary fibrosis (IPF), however, degree of fibrosis on CT is not easy to be quantified and thus seldom used as an objective prognostic factor. We aimed to explore prognostic value of the CT-quantified degree of lung fibrosis using a commercial deep learning software.

METHODS AND MATERIALS

Patients diagnosed with IPF and underwent nonenhanced chest CT and spirometry within 3 months in between 2005-2009 were retrospectively collected from a single institution, and their overall survival information were documented. Proportions of normal lung volume (CT-Norm%) and fibrotic lung volume (CT-Fib%), including reticular opacities and honeycombing, were calculated on chest CT using a commercial deep learning software. Correlation of CT-Norm% and CT-fib% with spirometry results including forced vital capacity (FVC) and diffusion capacity of carbon monoxide (DLCO) were calculated. The multivariable-adjusted hazard ratios (aHRs) of CT-Norm% and CT-Fib% were evaluated with clinical prognostic factors using the Cox regression. Survival prediction performances of modified GAP indices utilizing CT-norm% (CTNorm%-GAP) or CT-fib% (CTFib%-GAP) instead of DLCO were evaluated using Harrell C index at 5-year and compared with that of original GAP index.

RESULTS

A total of 170 patients (median age [interquartile range], 68 years [62-73]; 104 men) were evaluated. CT-Norm% and CT-Fib% showed significant correlation with FVC (Pearson coefficient, 0.40 [95% CI; 0.25, 0.52; P<.001] for CT-Norm% and -0.37 [-0.47, -0.24; P<.001] for CT-Fib%) and DLCO (0.52 [0.43, 0.60; P<.001] for CT-Norm% and -0.46 [-0.56, -0.33; P<.001] for CT-Fib%). On multivariable Cox regression, both CT-Norm% and CT-Fib% worked as independent survival predictors when adjusted to age, sex, smoking status, comorbidities of chronic diseases, FVC, and DLCO (aHRs per 1% increment, 0.98 [0.97, 0.99; P=.002] for CT-Norm% and 1.03 [1.01, 1.05; P=.01] for CT-Fib%). Modified GAP indices showed comparable C indices compared with the original GAP index without information of DLCO (CTNorm%-GAP vs. GAP, 0.76 vs. 0.75; P=.89 and CTFib%-GAP vs. GAP, 0.77 vs. 0.75; P=.27).

CONCLUSION

s Normal lung and fibrotic lung proportions calculated from chest CT-based deep learning algorithm worked as independent predictors of the patients' overall survival. Modified GAP indices showed comparable survival prediction performance to the original GAP index.

CLINICAL RELEVANCE/APPLICATION

Predicting prognosis is important in determining treatment options and follow-up intervals in patients with IPF. Automatic CT quantification using deep learning may provide additional prognostic information in routine practice.

M2-SPCH-4 Generalized Lymphatic Anomaly of The Chest: Pathological Subtypes and Imaging Manifestations

Participants
Qi Hao, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Generalized lymphatic Abnormal(GLA) is a complex type of lymphatic malformation or lymphangiomatosis characterized by diffuse or multiple organ involvement. This study is to annlysis retrospectively the imaging manifestations of three subtypes of GLA in the chest.

METHODS AND MATERIALS

From June 2006 to March 2020, 86 patients with GLA in our hospital were collected, including 37 males and 49 females, aged from 1 month to 58 years (median age 15.8). All patients underwent X-ray film, CT scan and ultrasound examination, 76 MRI or MRL in 76, 62 direct lymphangiography and MSCT lymphangiography in 62, and Nuclide lymphoscintigraphy in 57. Follow up for two years, 5 cases died 32 cases (37.2%) died and 54 cases (62.8%) had poor prognosis.

RESULTS

According to the clinical and imaging features, 86 GLAs were divided into three subtypes: kaposiform lymphangiomatosis(KIA, n=32), multifocal Lymphangiomas (ML,n=36), giant complex Lymphangiomas (GCL, n=18). The imaging features included: (1) 80 cases (93%) with abnormal mediastinum, including thickening and turbidity of mediastinum (n=39, 32/KIA,5/ML,2/GCL); thin-walled cystic cavity (n=24, 24/ML) and huge mixed cystic lesions(n=17, 16/GCL, 1/ML); (2) pulmonary lesions (n=49, 32/KIA, 9/ML, 8/GCL),

including thickening of bronchovascular bundle and interlobular septum (n=46, 32/KIA, 11/ML, 3/GCL, P<0.05), GGO (n=42, 32/KIA, 7/ML, 3/GCL, P<0.05), consolidation shadow(n=17, 13/KIA, 1/ML, 3/GCL, P<0.05), and cystic nodules or masses(n=12, 5/KIA, 7/ML); (3) pleural or extrapleural and chest wall lesions(n=72, 30/KIA, 31/ML, 11/GCL); (4)osteo-lesions(n=31, 9/KIA, 18/ML, 4/GCL, P<0.05).

CONCLUSION

s The three subtypes of GLA have different clinical manifestations, imaging types and histopathological features. Multimodality image are important methods for accurate diagnosis, staging and grading evaluation of lymphatic diseases.

CLINICAL RELEVANCE/APPLICATION

Multimodality image are important methods for accurate diagnosis of the three subtypes of GLA.

M2-SPCH-5 What Happens when Artificial Intelligence (AI) Feedback Is Wrong? A Multi-reader Pilot Study Examining the Human Factors of AI Implementation

Participants
Grayson Baird, PhD, Providence, RI (*Presenter*) Nothing to Disclose

PURPOSE

To examine whether incorrect AI feedback impacts radiologist performance, and if so, whether human factors can be optimized to reduce error.

METHODS AND MATERIALS

A prospective multi-reader design was used, where 6 radiologists interpreted 90 identical chest radiographs (follow-up CT needed: yes/no) on four occasions from 09/20 to 01/22. Sessions were separated by a minimum of 1 month, and the order of chest radiographs was identical in each session. In session 1, the radiologist interpreted images without AI. Sham AI feedback was provided for sessions 2-4, and 12 cases were manipulated to be incorrect (8 False Positives [FP], 4 False Negatives [FN]) (.87 ROCAUC). Radiologists anticipated a performance evaluation. In the Delete AI (No Box) condition, radiologists were told AI results would not be saved for the evaluation. In Keep AI (No Box) and Keep AI (Box), radiologists were told results would be saved. Radiologists were told these instructions were analogous to keeping or deleting AI feedback in the patient's record. In Keep AI (Box), the ostensible AI program visually outlined the region of suspicion. AI feedback was constant between conditions. FP and FN rates for the 12 erroneous cases were examined between conditions using generalized linear mixed modeling (GLMM) assuming a binary distribution.

RESULTS

Relative to the No AI condition (FN=2.7%, FP=51.4%), FN and FP rates were higher in the Keep AI (No Box) (FN=33.0%, FP=86.0%), Delete AI (No Box) (FN=26.7%, FP=80.5%), and Keep AI (Box) conditions (FN= to 20.7%, FP=80.5%), all ps<.05. FN rates were higher in the Keep AI (No Box) condition (33.0%) than the Keep AI (Box) condition (20.7%), p=.04. FP rates were higher in the Keep AI (No Box) (86.0%) condition than the Delete AI (No Box) condition (80.5%), p=.03.

CONCLUSION

s Incorrect AI causes radiologists to make incorrect follow-up decisions when they were correct without AI. This effect is mitigated when a box is provided around the region of interest and when AI feedback is deleted from the patient's record. Human factors for AI implementation are important.

CLINICAL RELEVANCE/APPLICATION

AI is often right but sometimes wrong. To maximize patient outcomes, we must consider how to prevent radiologists from being influenced by incorrect feedback.

M2-SPCH-6 Prevalence and Long-term Outcome of Interstitial Lung Abnormality in the Asian Health-screening Population: A Multicenter Study

Participants
Seolbin Park, MD, Gwangju, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate interstitial lung abnormality (ILA) prevalence in the Asian health-screening population and determine rates and risks for disease progression, lung cancer development, and 10-year mortality.

METHODS AND MATERIALS

This observational, retrospective, multicenter study included subjects = 50 years old who underwent chest computed tomography (CT) at three health screening centers over a 4-year period (2007 - 2010). ILA status was classified as none, equivocal ILA, and ILA, and ILA was further subcategorized into non-fibrotic or fibrotic ILA. Progression was evaluated between baseline and last follow-up CT. Kaplan-Meier analysis with the log-rank test was performed to estimate mortality according to ILA status. Cox proportional hazards models were used to assess factors associated with ILA progression, lung cancer development, and mortality.

RESULTS

In total, 2,765 subjects who underwent health screening chest CT were identified (mean age, 59±7 years; 2,068 men). Of the 2,765 subjects, 94 (3%) had a finding of ILA (35 non-fibrotic and 59 fibrotic ILA), and 119 (4%) had a finding of equivocal ILA. The mean follow-up period was approximately 12 years, and ILA progression was observed in 85% (34/40) of fibrotic ILA patients and 70% (14/20) of non-fibrotic ILA patients. Kaplan-Meier analysis showed subjects with ILA had a significantly higher mortality rate than those without ILA (P<.05). Multivariate Cox proportional hazards analysis revealed that fibrotic ILA was significantly associated with ILA progression (hazard ratio [HR], 10.3; 95% confidence interval [CI], 6.4-16.4; P<.001) and lung cancer development (HR, 4.4, 95% CI, 2.1-9.1; P<.001). Furthermore, subjects with fibrotic ILA had a significantly higher risk of disease-specific mortality (HR, 6.7; 95% CI, 3.6-12.2; P<.001) and all-cause mortality (HR, 2.5; 95% CI, 1.6 - 3.8; P<.001) than those without ILA.

CONCLUSION

s The prevalence of ILA in the Asian health-screening population was approximately 3%, and fibrotic ILA was an independent risk factor for disease progression, lung cancer development, and mortality over a 10-year follow-up period.

CLINICAL RELEVANCE/APPLICATION

Our study reveals ILA prevalence in the Asian health-screening population and demonstrates the association between ILAs and long-term outcomes.

M2-SPCH-7 Survival Impact of Incidental Abnormalities on Screening Thoracic Computed Tomography: Long-term Follow-up Analysis

Participants
Jaehyun Park, MD, Gwangju, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The present study aimed to assess the association between long-term mortality and incidental abnormalities on thoracic computed tomography (CT) among the general screening population.

METHODS AND MATERIALS

We retrospectively collected the medical records and CT images of subjects who visited a single health promotion center between 2007 and 2010. Two thoracic radiologists independently reviewed all CT images and evaluated incidental abnormalities by visual assessment, which is interstitial lung abnormality (ILA), emphysema, and coronary artery calcification (CAC). Kaplan-Meier analysis was performed using a log-rank test to evaluate the association between incidental CT abnormalities and mortality. A Cox proportional hazards model was used to analyze the association factors between incidental CT abnormalities and mortality.

RESULTS

A total of 859 subjects were identified (59 ± 6.7 years of age, 582 men). The median follow-up time was approximately 10.9 years. Of the 859 subjects, 57 (6.6%), 318 (37%), and 178 (21%) had findings of ILA, CAC, and emphysema, respectively. Subjects with fibrotic ILA, CAC of any degree, and emphysema of any degree exhibited significantly higher mortality during Kaplan-Meier analysis with the log-rank test ($p < 0.05$). A multivariate Cox proportional hazards model revealed that fibrotic ILAs were independently associated with higher mortality (hazard ratio, 2.59, [95% confidence interval, 1.07-6.27], $p = 0.035$) among the incidental CT abnormalities and clinically relevant factors.

CONCLUSION

s Incidental abnormalities on screening thoracic CT were associated with an increased hazard of mortality in the general screening population. Fibrotic ILAs in particular were independently associated with increased hazard of mortality compared to other incidental CT abnormalities.

CLINICAL RELEVANCE/APPLICATION

Our study reveals the relationship between incidental abnormalites found in screening thoracic CT and long-term morality.

M2-SPCH-8 Post-COVID-19 Interstitial Lung Disease (PC-ILD): The Role of Lung Imaging Andpulmonary Function Testing in The Long-term Follow-up of Patients with COVID-19 Pneumonia

Participants
Emanuele Messina, MD, Roma, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Post COVID-19 Interstitial Lung Disease (PC-ILD) is characterized by fibrotic-like signs at High Resolution Computed Tomography (HRCT) and Pulmonary Function Tests (PFTs) abnormalities after SARS-CoV-2 infection. It is still not clear how frequent these tests should be performed to rule out long-term consequences of COVID-19 pneumonia. The aims of our study are to evaluate the incidence and risk factors of PC-ILD and possibly to propose a long-term follow-up program.

METHODS AND MATERIALS

In this prospective single-center study, 100 patients, hospitalized in our ward for moderate to critical COVID-19, underwent two follow-up visits at 3 and 15 months, performing HRCT and PFTs.

RESULTS

At 3-month follow up, HRCTs showed that lung parenchymal abnormalities were still present in 22% of patients, mainly consisting in ground glass opacities (GGO) and fibrotic-like alterations (63% and 78%, respectively); 37% showed PFTs abnormalities consistent with PC-ILD. 48 patients underwent the 15-month follow up: at HRCT, residual fibrotic-like abnormalities were found in 40% of patients with almost complete reduction of GGO and consolidation; at PFTs, 33.3% showed residual respiratory functional impairment (PC-ILD); 8% of patients showed residual radiological and functional signs consistent with PC-ILD. All but one of these patients had already demonstrated PFTs and HRCT alterations at first follow-up visit, the last one patient showed worsening of lung function during follow up.

CONCLUSION

s These findings highlight the negative predictive value of HRCT and PFTs at three months follow-up for the development of PC-ILD. Ageing, severity of COVID-19 and degree of pulmonary involvement during acute infection proved to be significant risk factors for developing PC-ILD. Our study highlights the importance of PFTs in the long-term follow-up of patients affected by moderate to critical COVID-19 pneumonia. HRCT should be obtained in those patients still presenting PFTs abnormalities at 15 months.

CLINICAL RELEVANCE/APPLICATION

This is the first study investigating such a long-term follow up with HRCT and PFTs, at fifteen months.

M2-SPCH-1

CT Findings of Systemic Sclerosis: Precise Radiologic-pathologic Correlation in 29 Patients

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Taiki Fukuda, MD, PhD, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

There has been no report of a precise radiologic-pathologic correlation of systemic sclerosis-related interstitial lung disease (SSc-ILD). Moreover, despite the early therapeutic intervention is desirable, early CT findings of SSc-ILD has been still unclear. The purposes of this study were two-fold; (1) To decide pathological backgrounds of CT findings of SSc-ILD and (2) To clarify the early CT findings and their pathological features.

METHODS AND MATERIALS

Twenty-nine patients with SSc-ILD diagnosed by surgical lung biopsy (SLB) were enrolled. A total of 82 specimens were obtained. The histological findings of each specimen were correlated with the corresponding CT side by side by two radiologists and two pathologists. Whole lung CT was evaluated by the other two radiologists, independently. Early CT findings were extracted from the whole lung CT according to the rationale that diseases with lower lobe predominance show their early findings in more upper zones. Their pathological findings were examined from the area of SLB which corresponded to early CT findings.

RESULTS

Pathologically, non-specific interstitial pneumonia was diagnosed in 18 cases, while usual interstitial pneumonia and fibrosing organizing pneumonia were diagnosed in 9 and 2 cases respectively. Emphysematous change was pathologically observed in 19 cases and identified on CT in 11 cases. Four of those were non-smokers. Pathologically, vascular wall thickening was observed in 14 cases. Small faint nodules superimposed on amorphous ground-glass opacity within 1 cm from the pleura, which we term faint amorphous opacity (FAC), were present in 18 cases, particularly in the anterolateral upper lobes. FAC pathologically corresponded to either peribronchial metaplasia, centriacinar mucostasis or periacinar alveolar septal fibrosis.

CONCLUSION

s Pathological detectability of the emphysematous changes was superior to CT. Vasculopathy might be another cause of emphysema other than smoking. FAC could be an early CT finding of SSc-ILD, representing either peribronchial metaplasia, centriacinar mucostasis, or periacinar alveolar septal fibrosis pathologically.

CLINICAL RELEVANCE/APPLICATION

Understanding the pathological features of SSc-ILD will help to analyze the pathogenesis and determine the disease progression on CT. The aforementioned early CT finding may allow a more accurate diagnosis of SSc-ILD and prompt therapeutic intervention.

M2-SPCH-2

Radiologic Predictors of Pulmonary Hypertension in Patients with Fibrosing Interstitial Lung Disease

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Lubna Siddiqi, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The development of pulmonary hypertension (PH) in fibrosing ILD is associated with significantly shorter survival. Currently, risk stratification for PH is exclusively based on clinical and echocardiographic findings. We sought to use objective values from CT imaging to predict the presence of associated pulmonary hypertension in patients with fibrosing interstitial lung disease (ILD).

METHODS AND MATERIALS

An initial 128 patients with fibrosing ILD followed at the London Health Sciences Centre underwent right heart catheterization (RHC). Of these, 94 patients (66 male, 28 female, with average age of 66.2) with CT thorax within 6 months of RHC were assessed for main pulmonary artery to aorta ratio (MPA:Ao), right to left ventricular ratio (RV:LV), caliber of the right and left pulmonary arteries, interventricular septal thickness, and right ventricular wall thickness, as well as the presence of pulmonary thromboembolic disease and degree of mosaic attenuation. PH was defined as a mean pulmonary arterial pressure (mPAP) =25 mmHg on RHC. Radiologic data were then analyzed using stepwise regression analysis to determine the best predictors of associated PH. Results were adjusted for sex, BMI, and age.

RESULTS

Thirty-eight patients (40%) underwent RHC electively and 56 (60%) as part of a lung transplant (LTx) assessment. Average mPAP was 25±6 mmHg, wedge pressure 9±4 mmHg, cardiac output 5.0±1.0 L/min and pulmonary vascular resistance 3.3±1.4 Wood units. Sixty-six patients (70%) had PH. Among patients with PH, average mPAP was 38±11 mmHg and PVR was 5.7±2.6 Wood Units. On stepwise multiple regression analysis, MPA and RV diameter were independent and significant predictors of PVR (F ratio 6.64 and 6.32, p-values 0.0137 and 0.0159 respectively). Importantly, the correlation between MPA and RV was weak (Spearman's rank 0.17, not significant), with no collinearity observed. MPA was also a significant predictor of mPAP (F ratio 11.5, p-value 0.0015).

CONCLUSION

s The presence of associated PH has a significant impact on the appearance of CT thorax in fibrosing ILD. Both MPA and RV diameter are predictors of PH. A combination of radiologic parameters obtained from CT thorax may be used to reliably risk stratify patients with fibrosing ILD for the presence and severity of associated PH. We will seek validation of these data in a separate cohort of patients.

CLINICAL RELEVANCE/APPLICATION

In patients with fibrosing ILD, a combination of radiologic parameters may be used to predict the presence and severity of PH and to guide clinical decisions on RHC, LTx assessment and prognosis. These parameters could be especially helpful in populations for whom RHC is not readily available, or is a contraindication.

Deep Learning-based Fibrosis Quantification on Chest CT as a Prognostic Predictor in Patient with Idiopathic Pulmonary Fibrosis

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Ju Gang Nam, MD, Seoul, Korea, Republic Of (*Presenter*) Research Grant, VUNO Inc

PURPOSE

Radiology plays a crucial role in the diagnosis and management of patients with idiopathic pulmonary fibrosis (IPF), however, degree of fibrosis on CT is not easy to be quantified and thus seldom used as an objective prognostic factor. We aimed to explore prognostic value of the CT-quantified degree of lung fibrosis using a commercial deep learning software.

METHODS AND MATERIALS

Patients diagnosed with IPF and underwent nonenhanced chest CT and spirometry within 3 months in between 2005-2009 were retrospectively collected from a single institution, and their overall survival information were documented. Proportions of normal lung volume (CT-Norm%) and fibrotic lung volume (CT-Fib%), including reticular opacities and honeycombing, were calculated on chest CT using a commercial deep learning software. Correlation of CT-Norm% and CT-fib% with spirometry results including forced vital capacity (FVC) and diffusion capacity of carbon monoxide (DLCO) were calculated. The multivariable-adjusted hazard ratios (aHRs) of CT-Norm% and CT-Fib% were evaluated with clinical prognostic factors using the Cox regression. Survival prediction performances of modified GAP indices utilizing CT-norm% (CTNorm%-GAP) or CT-fib% (CTFib%-GAP) instead of DLCO were evaluated using Harrell C index at 5-year and compared with that of original GAP index.

RESULTS

A total of 170 patients (median age [interquartile range], 68 years [62-73]; 104 men) were evaluated. CT-Norm% and CT-Fib% showed significant correlation with FVC (Pearson coefficient, 0.40 [95% CI; 0.25, 0.52; P<.001] for CT-Norm% and -0.37 [-0.47, -0.24; P<.001] for CT-Fib%) and DLCO (0.52 [0.43, 0.60; P<.001] for CT-Norm% and -0.46 [-0.56, -0.33; P<.001] for CT-Fib%). On multivariable Cox regression, both CT-Norm% and CT-Fib% worked as independent survival predictors when adjusted to age, sex, smoking status, comorbidities of chronic diseases, FVC, and DLCO (aHRs per 1% increment, 0.98 [0.97, 0.99; P=.002] for CT-Norm% and 1.03 [1.01, 1.05; P=.01] for CT-Fib%). Modified GAP indices showed comparable C indices compared with the original GAP index without information of DLCO (CTNorm%-GAP vs. GAP, 0.76 vs. 0.75; P=.89 and CTFib%-GAP vs. GAP, 0.77 vs. 0.75; P=.27).

CONCLUSION

s Normal lung and fibrotic lung proportions calculated from chest CT-based deep learning algorithm worked as independent predictors of the patients' overall survival. Modified GAP indices showed comparable survival prediction performance to the original GAP index.

CLINICAL RELEVANCE/APPLICATION

Predicting prognosis is important in determining treatment options and follow-up intervals in patients with IPF. Automatic CT quantification using deep learning may provide additional prognostic information in routine practice.

Generalized Lymphatic Anomaly of The Chest: Pathological Subtypes and Imaging Manifestations

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Qi Hao, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Generalized lymphatic Abnormal(GLA) is a complex type of lymphatic malformation or lymphangiomatosis characterized by diffuse or multiple organ involvement. This study is to annlysis retrospectively the imaging manifestations of three subtypes of GLA in the chest.

METHODS AND MATERIALS

From June 2006 to March 2020, 86 patients with GLA in our hospital were collected, including 37 males and 49 females, aged from 1 month to 58 years (median age 15.8). All patients underwent X-ray film, CT scan and ultrasound examination, 76 MRI or MRL in 76, 62 direct lymphangiography and MSCT lymphangiography in 62, and Nuclide lymphoscintigraphy in 57. Follow up for two years, 5 cases died 32 cases (37.2%) died and 54 cases (62.8%) had poor prognosis.

RESULTS

According to the clinical and imaging features, 86 GLAs were divided into three subtypes: kaposiform lymphangiomatosis(KIA, n=32), multifocal Lymphangiomas (ML,n=36), giant complex Lymphangiomas (GCL, n=18). The imaging features included: (1) 80 cases (93%) with abnormal mediastinum, including thickening and turbidity of mediastinum (n=39, 32/KIA,5/ML,2/GCL); thin-walled cystic cavity (n=24, 24/ML) and huge mixed cystic lesions(n=17, 16/GCL, 1/ML); (2) pulmonary lesions (n=49, 32/KIA, 9/ML, 8/GCL), including thickening of bronchovascular bundle and interlobular septum (n=46, 32/KIA, 11/ML, 3/GCL, $P<0.05$), GGO (n=42, 32/KIA, 7/ML, 3/GCL, $P<0.05$), consolidation shadow(n=17, 13/KIA, 1/ML, 3/GCL, $P<0.05$), and cystic nodules or masses(n=12, 5/KIA, 7/ML); (3) pleural or extrapleural and chest wall lesions(n=72, 30/KIA, 31/ML, 11/GCL); (4)osteo-lesions(n=31, 9/KIA, 18/ML, 4/GCL, $P<0.05$).

CONCLUSION

s The three subtypes of GLA have different clinical manifestations, imaging types and histopathological features. Multimodality image are important methods for accurate diagnosis, staging and grading evaluation of lymphatic diseases.

CLINICAL RELEVANCE/APPLICATION

Multimodality image are important methods for accurate diagnosis of the three subtypes of GLA.

What Happens when Artificial Intelligence (AI) Feedback Is Wrong? A Multi-reader Pilot Study Examining the Human Factors of AI Implementation

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Grayson Baird, PhD, Providence, RI (*Presenter*) Nothing to Disclose

PURPOSE

To examine whether incorrect AI feedback impacts radiologist performance, and if so, whether human factors can be optimized to reduce error.

METHODS AND MATERIALS

A prospective multi-reader design was used, where 6 radiologists interpreted 90 identical chest radiographs (follow-up CT needed: yes/no) on four occasions from 09/20 to 01/22. Sessions were separated by a minimum of 1 month, and the order of chest radiographs was identical in each session. In session 1, the radiologist interpreted images without AI. Sham AI feedback was provided for sessions 2-4, and 12 cases were manipulated to be incorrect (8 False Positives [FP], 4 False Negatives [FN]) (.87 ROCAUC). Radiologists anticipated a performance evaluation. In the Delete AI (No Box) condition, radiologists were told AI results would not be saved for the evaluation. In Keep AI (No Box) and Keep AI (Box), radiologists were told results would be saved. Radiologists were told these instructions were analogous to keeping or deleting AI feedback in the patient's record. In Keep AI (Box), the ostensible AI program visually outlined the region of suspicion. AI feedback was constant between conditions. FP and FN rates for the 12 erroneous cases were examined between conditions using generalized linear mixed modeling (GLMM) assuming a binary distribution.

RESULTS

Relative to the No AI condition (FN=2.7%, FP=51.4%), FN and FP rates were higher in the Keep AI (No Box) (FN=33.0%, FP=86.0%), Delete AI (No Box) (FN=26.7%, FP=80.5%), and Keep AI (Box) conditions (FN= to 20.7%, FP=80.5%), all ps<.05. FN rates were higher in the Keep AI (No Box) condition (33.0%) than the Keep AI (Box) condition (20.7%), p=.04. FP rates were higher in the Keep AI (No Box) (86.0%) condition than the Delete AI (No Box) condition (80.5%), p=.03.

CONCLUSION

s Incorrect AI causes radiologists to make incorrect follow-up decisions when they were correct without AI. This effect is mitigated when a box is provided around the region of interest and when AI feedback is deleted from the patient's record. Human factors for AI implementation are important.

CLINICAL RELEVANCE/APPLICATION

AI is often right but sometimes wrong. To maximize patient outcomes, we must consider how to prevent radiologists from being influenced by incorrect feedback.

Prevalence and Long-term Outcome of Interstitial Lung Abnormality in the Asian Health-screening Population: A Multicenter Study

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Seolbin Park, MD, Gwangju, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate interstitial lung abnormality (ILA) prevalence in the Asian health-screening population and determine rates and risks for disease progression, lung cancer development, and 10-year mortality.

METHODS AND MATERIALS

This observational, retrospective, multicenter study included subjects = 50 years old who underwent chest computed tomography (CT) at three health screening centers over a 4-year period (2007 - 2010). ILA status was classified as none, equivocal ILA, and ILA, and ILA was further subcategorized into non-fibrotic or fibrotic ILA. Progression was evaluated between baseline and last follow-up CT. Kaplan-Meier analysis with the log-rank test was performed to estimate mortality according to ILA status. Cox proportional hazards models were used to assess factors associated with ILA progression, lung cancer development, and mortality.

RESULTS

In total, 2,765 subjects who underwent health screening chest CT were identified (mean age, 59±7 years; 2,068 men). Of the 2,765 subjects, 94 (3%) had a finding of ILA (35 non-fibrotic and 59 fibrotic ILA), and 119 (4%) had a finding of equivocal ILA. The mean follow-up period was approximately 12 years, and ILA progression was observed in 85% (34/40) of fibrotic ILA patients and 70% (14/20) of non-fibrotic ILA patients. Kaplan-Meier analysis showed subjects with ILA had a significantly higher mortality rate than those without ILA (P<.05). Multivariate Cox proportional hazards analysis revealed that fibrotic ILA was significantly associated with ILA progression (hazard ratio [HR], 10.3; 95% confidence interval [CI], 6.4-16.4; P<.001) and lung cancer development (HR, 4.4, 95% CI, 2.1-9.1; P<.001). Furthermore, subjects with fibrotic ILA had a significantly higher risk of disease-specific mortality (HR, 6.7; 95% CI, 3.6-12.2; P<.001) and all-cause mortality (HR, 2.5; 95% CI, 1.6 - 3.8; P<.001) than those without ILA.

CONCLUSION

s The prevalence of ILA in the Asian health-screening population was approximately 3%, and fibrotic ILA was an independent risk factor for disease progression, lung cancer development, and mortality over a 10-year follow-up period.

CLINICAL RELEVANCE/APPLICATION

Our study reveals ILA prevalence in the Asian health-screening population and demonstrates the association between ILAs and long-term outcomes.

Survival Impact of Incidental Abnormalities on Screening Thoracic Computed Tomography: Long-term Follow-up Analysis

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Jaehyun Park, MD, Gwangju, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The present study aimed to assess the association between long-term mortality and incidental abnormalities on thoracic computed tomography (CT) among the general screening population.

METHODS AND MATERIALS

We retrospectively collected the medical records and CT images of subjects who visited a single health promotion center between 2007 and 2010. Two thoracic radiologists independently reviewed all CT images and evaluated incidental abnormalities by visual assessment, which is interstitial lung abnormality (ILA), emphysema, and coronary artery calcification (CAC). Kaplan-Meier analysis was performed using a log-rank test to evaluate the association between incidental CT abnormalities and mortality. A Cox proportional hazards model was used to analyze the association factors between incidental CT abnormalities and mortality.

RESULTS

A total of 859 subjects were identified (59 ± 6.7 years of age, 582 men). The median follow-up time was approximately 10.9 years. Of the 859 subjects, 57 (6.6%), 318 (37%), and 178 (21%) had findings of ILA, CAC, and emphysema, respectively. Subjects with fibrotic ILA, CAC of any degree, and emphysema of any degree exhibited significantly higher mortality during Kaplan-Meier analysis with the log-rank test ($p < 0.05$). A multivariate Cox proportional hazards model revealed that fibrotic ILAs were independently associated with higher mortality (hazard ratio, 2.59, [95% confidence interval, 1.07-6.27], $p = 0.035$) among the incidental CT abnormalities and clinically relevant factors.

CONCLUSION

s Incidental abnormalities on screening thoracic CT were associated with an increased hazard of mortality in the general screening population. Fibrotic ILAs in particular were independently associated with increased hazard of mortality compared to other incidental CT abnormalities.

CLINICAL RELEVANCE/APPLICATION

Our study reveals the relationship between incidental abnormalites found in screening thoracic CT and long-term morality.

Post-COVID-19 Interstitial Lung Disease (PC-ILD): The Role of Lung Imaging Andpulmonary Function Testing in The Long-term Follow-up of Patients with COVID-19 Pneumonia

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Emanuele Messina, MD, Roma, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Post COVID-19 Interstitial Lung Disease (PC-ILD) is characterized by fibrotic-like signs at High Resolution Computed Tomography (HRCT) and Pulmonary Function Tests (PFTs) abnormalities after SARS-CoV-2 infection. It is still not clear how frequent these tests should be performed to rule out long-term consequences of COVID-19 pneumonia. The aims of our study are to evaluate the incidence and risk factors of PC-ILD and possibly to propose a long-term follow-up program.

METHODS AND MATERIALS

In this prospective single-center study, 100 patients, hospitalized in our ward for moderate to critical COVID-19, underwent two follow-up visits at 3 and 15 months, performing HRCT and PFTs.

RESULTS

At 3-month follow up, HRCTs showed that lung parenchymal abnormalities were still present in 22% of patients, mainly consisting in ground glass opacities (GGO) and fibrotic-like alterations (63% and 78%, respectively); 37% showed PFTs abnormalities consistent with PC-ILD. 48 patients underwent the 15-month follow up: at HRCT, residual fibrotic-like abnormalities were found in 40% of patients with almost complete reduction of GGO and consolidation; at PFTs, 33.3% showed residual respiratory functional impairment (PC-ILD); 8% of patients showed residual radiological and functional signs consistent with PC-ILD. All but one of these patients had already demonstrated PFTs and HRCT alterations at first follow-up visit, the last one patient showed worsening of lung function during follow up.

CONCLUSION

s These findings highlight the negative predictive value of HRCT and PFTs at three months follow-up for the development of PC-ILD. Ageing, severity of COVID-19 and degree of pulmonary involvement during acute infection proved to be significant risk factors for developing PC-ILD. Our study highlights the importance of PFTs in the long-term follow-up of patients affected by moderate to critical COVID-19 pneumonia. HRCT should be obtained in those patients still presenting PFTs abnormalities at 15 months.

CLINICAL RELEVANCE/APPLICATION

This is the first study investigating such a long-term follow up with HRCT and PFTs, at fifteen months.

M2-SPGI-1 Automated multi-organ segmentation tool for both non-contrast and post-contrast abdominal CT: a deep learning algorithm developed using dual-energy CT images

Participants
Sun Kyung Jeon, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a deep learning-based fully-automated abdominal multi-organ segmentation algorithm, robust to both non-contrast and post-contrast CT images, using dual-energy CT (DECT) images.

METHODS AND MATERIALS

For development, 75 abdominal DECT scans (portal venous phase (PVP) images and the spatiotemporally matched virtual non-contrast (VNC) images; 18174 slices in each) were used as the input. A single three-dimensional (3D) nnU-Net-based algorithm for multi-organ segmentation (liver, spleen, right kidney, left kidney, and pancreas, respectively) was trained. On an external validation set of 30 single-energy CT scans with both PVP and true non-contrast (TNC) images, the performance of the developed algorithm for each organ was evaluated using the dice similarity score (DSS) for segmentation; and linear regression analysis and Bland-Altman analysis for measurement of the volumetric indices, in comparison to the ground truth manual segmentation.

RESULTS

For 3D segmentation of the liver, spleen, right kidney, left kidney, and pancreas, the fully-automated segmentation algorithm achieved a mean DSS of 0.982, 0.972, 0.972, 0.970, 0.847 in PVP image; and 0.968, 0.956, 0.940, 0.955, and 0.807 in TNC images, respectively. For the measurement of volumetric indices of those organs, manual and automated organ segmentation strongly correlated both in PVP and TNC (R2 = 0.99, 0.99, 0.99, 0.98, and 0.80 in PVP; and 0.98, 0.99, 0.95, 0.98, 0.72 in TNC, all Ps <0.001), and the mean differences (95 % limits of agreement) were -1.0% (-3.2, 1.1), 0.3% (-5.2, 5.8), -0.9% (-5.5, 3.8), -2.3% (-7.2, 2.5), 5.8% (-20.1, 31.8) in PVP images; and -1.9% (-3.7, 7.5), -3.1% (-10.9, 4.6), 2.2% (-7.0, 11.3), 3.4% (-1.0, 7.9), -0.3% (-25.8, 25.2) in TNC images, respectively.

CONCLUSION

s The deep learning-based fully-automated segmentation algorithm developed using virtual non-contrast and post-contrast CT images from DECT provided accurate segmentation of abdominal solid organs at both CT scans with and without contrast.

CLINICAL RELEVANCE/APPLICATION

By using paired DECT images, a fully-automated multi-organ segmentation algorithm that is robust to both non-contrast and post-contrast CT can be developed with a relatively small number of datasets, which can be applied to volumetric analysis of abdominal organs of large cohort studies.

M2-SPGI-10 A review of the use of Computed Tomography (CT) Colonography in acute diverticulitis follow up

Participants
Amy Verrinder, MBBS, (*Presenter*) Nothing to Disclose

PURPOSE

Direct visualisation of the bowel lumen is recommended as follow up for all acute diverticulitis cases. This includes CT Colonography (CTC). In Newcastle Upon Tyne Hospitals (NUTH), surgical practice is that all patients admitted with diverticulitis have a follow up CTC approximately 3 months from discharge.

METHODS AND MATERIALS

A Radiology Information system (RIS) search of CTCs performed in NUTH trust between 1/1/2019-31/12/2019. Reports were excluded if the indication was not acute diverticulitis follow-up. Remaining reports were assessed for compliance with standards.Joint guidance from the BSGAR and RCR: Standards of practice for CTC (2021); and Royal College of Surgeons commissioning guide into Colonic Diverticular disease (2014).Percentage of CTC reports following acute diverticulitis accordant with standards of practice.1. CTC should be completed within 3 months of acute episode 2. Local target of 100% sensitivity for colonic malignancy. 3. Polyp identification rate of >13% of patients 4. Indeterminate CTC report (leading to further investigation) in <25%References: Royal College of Radiologists. (2021). Joint guidance from the BSGAR and RCR: Standards of practice for CTC.Royal College of Surgeons. (2014). Colonic Diverticular disease - Commissioning Guide.

RESULTS

Of the 1282 CTC reports identified, 1207 (94%) were excluded. Of the remaining 75 reports, no cases had a colonic malignancy later identified which was not reported at the time of CTC (100% sensitivity). There was a wide range in the time interval to CTC, from 3 to 69 weeks. 15 cases (20%) had polyps identified. 6 reports (8%) were indeterminate (C score of 3c) and required further investigation.

CONCLUSION

s CTC in acute diverticulitis follow-up achieved targets in malignancy and polyp sensitivity, and indeterminate rates. However, the time interval was very variable and could be standardised to produce a more robust pathway for patients requiring acute diverticulitis follow-up. Results have been presents regionally.

CLINICAL RELEVANCE/APPLICATION

CTC in acute diverticulitis follow up has superseded the Colonoscopy at NUTH. This has been a success story for the Radiology teams with increased trust in CTC reports from the General Surgical teams. This audit shows this trust is well placed with national standards met using this less invasive, more accessible and better tolerated test. Going forward this pathway could be standardised to set up a routine follow up time interval for CTC following acute diverticulitis which would stream line patient management and improve efficiency.

M2-SPGI-2 Phenotypic and Biomarker Associations with Lean Steatosis using Image-derived Phenotypes from Abdominal CT Scans

Participants
Hersh Sagreiya, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose

PURPOSE

Although non-alcoholic fatty liver disease (NAFLD) is associated with obesity, a significant subgroup of NAFLD patients have normal body mass index (BMI) or "lean steatosis." We investigated characteristics associated with lean steatosis using biobank data by aggregating ICD codes and CT scans to perform a phenome-wide association study (PheWAS) and biomarker analysis.

METHODS AND MATERIALS

We collected chest and abdominal CTs, blood biomarkers, and ICD-9 codes from 11,559 biobank participants, excluding patients with alcohol use disorder, alcohol-related liver disease, and end-stage liver disease (ESLD). CT scans were segmented using deep learning. Hepatic fat (HF) was estimated by computing liver attenuation - spleen attenuation (in Hounsfield units); a lower value indicated more HF. Lean patients were defined as those with BMI 18.5- 25. PheWAS was conducted for HF, and logistic regression determined the interaction between the variables 'lean' and 'HF,' controlling for age, gender, and race. Livers were categorized as steatotic or non-steatotic according to an attenuation threshold determined by receiver operating characteristic analysis of biopsy-obtained HF measurement. Biomarkers included AST, ALT, ALP, HDL, LDL, triglycerides, total cholesterol, and hemoglobin A1c.

RESULTS

4650 NAFLD and 879 lean steatotic patients were identified. PheWAS yielded 35 significant associations, with links to several renal pathologies. Lean steatosis patients had higher ALP and HDL and lower ALT, triglycerides, and hemoglobin A1c compared to overweight steatosis patients. AST, LDL, and total cholesterol were not significantly different.

CONCLUSION

s Our study is the first to link CKD and other renal pathologies to lean steatosis using a high-throughput imaging-guided pipeline. We report several metabolic biomarker differences between lean and overweight steatotic patients. These associations remained significant when removing ESLD patients and controlling for age, race, and gender. We plan further study to characterize the risk factors and pathophysiologic mechanisms contributing to the metabolic and renal associations with lean steatosis.

CLINICAL RELEVANCE/APPLICATION

Applying deep learning, PheWAS, and biomarker analysis to CT scans can provide new clinical insights, differentiating overweight steatosis from the less well-understood lean steatosis phenotype.

M2-SPGI-4 EvaluationofRespiratory-Related Predictors for Image Quality of Respiratory-gating and Breath-hold 3D Magnetic Resonance Cholangiopancreatography (MRCP): A Single-Center Prospective Study

Participants
Ke Wang, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The study aimed to compare the image quality of single breath-hold 3D GRASE MRCP (BH-MRCP) and respiratory-gating 3D FSE MRCP (RG-MRCP), and to explore the respiratory factors based on the breathing curve that may affect the image quality of BH- and RG- MRCP sequences.

METHODS AND MATERIALS

A total of 126 study participants were enrolled from May to December 2021 and underwent RG-MRCP and BH-MRCP at a 3-T MR scanner (uMR790, United Imaging Healthcare, Shanghai, China). The imaging was evaluated by three radiologists based on a 5-point Likert scale. Respiratory parameters were extracted from the breathing curve (Fig.1). Wilcoxon test was used to compare the image quality between two MRCPs. Multivariable linear regression and logistic regression analyses were performed to identify breathing predictor variables of a higher image quality score and better image quality.

RESULTS

The overall image quality scores were 4.45±0.73 for RG-MRCP and 4.69±0.6 for BH-MRCP (p?<?0.05). Multivariable predictors of a higher RG-MRCP image quality score (ß=-0.455 to -0.307) included lower Standard deviation of respiratory amplitude on minimum-peak (SDAmp-minimum-peak) (p<0.001) and lower standard deviation of time interval between the two trigger points (SDbreath-time) (p<0.001) (Fig. 2). A higher BH-MRCP image quality score was predicted by lower standard deviation of respiratory amplitude

(SDamp) (ß=-0.630, p<0.001) (Fig. 3). The results of multivariable logistic regression showed that lower SDAmp-minimum-peak (OR=0.147, 95% CI=0.058-0.370, p<0.001) was the only predictor of relatively good RG-MRCP image quality. For BH-MRCP, the factor predicting relatively good image quality was SDamp (OR=0.665, 95% CI= 0.572-0.773, p<0.001) (Table 1).

CONCLUSION

s In conclusion, both RG-MRCP and BH-MRCP demonstrated satisfied image quality. The overall image quality of BH-GRASE-MRCP was significantly better than RG-MRCP on group level, but not for every individual. Respiratory conditions exerted significant impact on the image quality of MRCP, and parameters derived from respiratory curve could help predict image quality of both sequences.

CLINICAL RELEVANCE/APPLICATION

?The evaluation of the breathing curve could benefit for the individualized scanning plan. ?In addition, during breathing training, patients could be guided in a more targeted manner. ?The evaluation of the breathing curve was not limited to the application of MRCP, and could also be applied in the whole process of MRI scanning of the upper abdomen.

M2-SPGI-5 Preoperative CT Staging of Intrahepatic Cholangiocarcinoma: Impact of Up-staging of Tumor Multiplicity on Survival Outcomes

Participants
June Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop a preoperative CT staging system for intrahepatic cholangiocarcinoma (iCCA) using American Joint Committee on Cancer (AJCC) staging parameters and focusing on tumor multiplicity.

METHODS AND MATERIALS

Patients who underwent preoperative multiphasic CT and curative-intent resection for mass-forming iCCA were retrospectively recruited from multiple institutions from January 2009 to December 2015. Based on Cox proportional hazards regression analysis of the AJCC staging parameters, preoperative CT staging system was modified from the AJCC system with subdivision of tumor multiplicity (satellitosis vs. intrahepatic metastasis). Kaplan-Meier method was used to estimate overall survival (OS). Harrell's concordance indices (C-indices) of AJCC and modified systems were compared with bootstrap methods.

RESULTS

This study included 319 patients (median age, 64 years; 208 men). In the modified staging system, multiple tumors (adjusted hazard ratio [HR]; satellitosis, 3.03, P <0.001; intrahepatic metastasis, 3.92, P <0.001) were up-staged from T2 to T3 (T3a, satellitosis; T3b, intrahepatic metastasis); solitary tumor with intrahepatic vascular invasion (adjusted HR, 1.98, P = 0.003) or solitary tumor perforating the visceral peritoneum (adjusted HR, 2.00, P = 0.001) were designated as T2. Preoperative T2 and T3 stages according to the AJCC system failed to discriminate the survival curves (log-rank P value for T2 vs. T3 = 0.812; 5-year OS, 23.4% vs. 26.8%), but modified T2 stage showed better OS outcomes than modified T3 stage (log-rank P value for T2 vs. T3a vs. T3b = 0.003; 5-year OS, 33.8% vs. 8.4% vs. 4.8%). The C-indices of modified staging system were higher than those of AJCC staging system for predicting OS, marginally approaching the statistical significance (T staging, 0.647 vs. 0.626, P = 0.061; tumor-node-metastasis staging, 0.636 vs. 0.614, P = 0.069).

CONCLUSION

s The modified staging system which upstages tumor multiplicity provides better prognostic stratification for OS than AJCC staging system when applied to preoperative CT in patients with iCCA.

CLINICAL RELEVANCE/APPLICATION

The presence of tumor multiplicity on preoperative CT indicates worse prognosis than current AJCC T2 or T3 staging parameters, and may need subdivision into satellitosis and intrahepatic metastasis.

M2-SPGI-7 A Diagnostic Value of MR Radiomics for Predicting Lateral Pelvic Lymph Node Metastasis in Patients with Locally Advanced Rectal Cancer: A Multicenter Retrospective Study

Participants
Jeongin Yoo, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop a MRI radiomics-based prediction model for lateral pelvic lymph node (LPLN) metastasis in rectal cancer patients who underwent LPLN dissection as well as to validate model performance using an external validation dataset.

METHODS AND MATERIALS

A total of 344 patients (198 in the development cohort and 146 in the validation cohort) who underwent rectal cancer surgery and LPLN dissection were enrolled. Patients' clinical and laboratory features were recorded. Radiomics features of LPLN were extracted from pre- post-chemoradiation therapy high-resolution T2-weighted axial or coronal MR images. The least absolute shrinkage and selection operator regression analysis was conducted to select predictive radiomics features in the development cohort, and a radiomics score for predicting LPLN metastasis was calculated based on the selected features. Model performance was assessed by receiver operating characteristics curve, calibration curves, and decision curve analysis (DCA). The prediction model was externally validated in the validation cohort.

RESULTS

In the development cohort, 70 (35.4%) of 198 patients had metastatic LPLN. Of clinical features, neoadjuvant radiotherapy is the sole significant feature. Of 116 radiomics features, histogram-based energy and histogram-based total energy were selected as significant features. Radiomics score can be calculated as a following formula: radiomics score = -0.58618 + 1.7252902E-9 x histogram-based energy + 1.1056922E-9 x histogram-based total energy. A combined model using clinical features and radiomics score showed better prediction performance compared to the clinical feature only (area under the curve [AUC] value: 0.73 vs 0.61) in the development cohort (P<0.0001). DCA demonstrated that the combined model has the highest net benefit in threshold probability of 25% - 75%. In the validation cohort, a combined model using clinical features and radiomics score showed better

prediction performance compared to the clinical feature only (AUC value: 0.61 vs 0.51) (P=0.0318) and had the highest net benefit in threshold probability of 30%-75%.

CONCLUSION

s An application of radiomics on rectal MRI showed the best prediction performance of a combined model using clinical features and radiomics score to predict LPLN metastasis.

CLINICAL RELEVANCE/APPLICATION

An application of radiomics on rectal MRI can be useful for accurately predicting LPLN metastasis in patients with rectal cancer

M2-SPGI-8 Diagnostic performance of Apparent Diffusion Coefficient to assess the therapeutic response to biological therapy in Crohn's disease

Participants
Jordi Rimola, MD, PhD, (*Presenter*) Consultant, Alimentiv Health Trust;Speaker, Takeda Pharmaceutical Company Limited;Consultant, Johnson & Johnson;Consultant, Boehringer Ingelheim GmbH;Research Grant, AbbVie Inc

PURPOSE

to determine prospectively the performance of the Apparent Diffusion Coefficient (ADC) to assess response to biological therapy in Crohn’s disease (CD) using MR enterography (MRE) and ileocolonoscopy as reference standards.

METHODS AND MATERIALS

Seventy four CD &9;patients underwent MRE with ADC calculation before and at 46-week after treatment with biological therapy. MRE images were analyzed including measurement of ADC. Segmental MaRIA was considered the reference standard to identify presence and severity of inflammation. Similar analysis was done in the 41 subjects who underwent ileocolonoscopy at both time points.

RESULTS

MRE identified 125 intestinal segments with severe inflammation (MaRIA > or = 11) at baseline. Of them, 54% achieved healing of severe inflammation (MaRIA <11) at week 46.&9;Using a receiver operating characteristic (ROC) curve, we determined at baseline an ADC threshold of 1.301×10-3mm2/s to predict severity, yielding a sensitivity of 0.78 and specificity of 0.94 to identify segments with MaRIA > or = 11 (AUROC=0.92). Using the same threshold, ADC has a sensitivity and specificity of 0.90 and 0.75 respectively to identify healing of severe inflammation (MaRIA<11) at week 46. Using ileocolonoscopy as reference, the ADC threshold to predict endoscopic severity (ulcers) was very similar (1.382x10-3mm2/s) yielding a sensitivity and specificity of 0.76 and 0.89, and 0.95 and 0.71 to identify endoscopic ulcer healing. The MaRIA score was superior to ADC to predict endoscopic ulcer healing (AUROC 0.94 vs. 0.83 p=0.01).

CONCLUSION

s ADC showed robust thresholds to predict severe inflammation in CD using either MaRIA or ileocolonoscopy, and could be used as an alternative to the MaRIA index to assess therapeutic response in CD.

CLINICAL RELEVANCE/APPLICATION

ADC is a potential imaging biomarker alternative to MaRIA score or ileocolonoscopy to assess the treatment response to biological therapy in Crohn’s disease

M2-SPGI-9 MRI Defecography: A Useful Tool to Guide Surgical Management in Patients With Pelvic Floor Dysfunction

Participants
John Gao, MD, Kansas City, KS (*Presenter*) Nothing to Disclose

PURPOSE

To retrospectively evaluate magnetic resonance (MR) defecography findings in patients with pelvic floor dysfunction to assess which findings on MR defecography influence decisions to perform subsequent pelvic floor surgery.

METHODS AND MATERIALS

This retrospective cohort study included women 18 and older who had an MRI defecography exam from 1/1/2017 - 6/30/2021. Patients were excluded if they were male, under 18, unable to comply with the exam, or had insufficient imaging. Demographic, clinical, and imaging information were obtained from the electronic medical record and Picture Archiving and Communications Systems (PACS). Imaging reports were retrospectively reviewed using the original interpretations.

RESULTS

One hundred sixty-eight patients with 171 MR defecography exams were included. Twenty out of 168 total patients (11.9%) patients had subsequent pelvic floor surgery in the year following their exam. Multiple measurements on MRI demonstrated a statistically significant odds ratio for subsequent pelvic floor surgery, including M line at maximal strain (OR=1.5, p=0.070) and the presence of sigmoidocele (OR=27.7, p=0.011) and enterocele (OR=6.8, p=0.015). Patients in the surgical group had higher M-lines at maximal strain (5.7 cm) than in the non-surgical group (4.7 cm).

CONCLUSION

s MRI defecography is an important tool to evaluate anatomical and functional abnormalities in patients with pelvic floor dysfunction. Certain measurements and findings may help guide decisions to pursue surgical treatment. The presence of sigmoidoceles and enteroceles is a significant finding that may direct patients and clinicians to pursue surgical management, which should be highlighted in the radiology report.

CLINICAL RELEVANCE/APPLICATION

Radiologists should highlight key measurements and findings on MRI defecography exams as well as recommend surgical consultation

in certain patients.

M2-SPGI-1

Automated multi-organ segmentation tool for both non-contrast and post-contrast abdominal CT: a deep learning algorithm developed using dual-energy CT images

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Sun Kyung Jeon, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a deep learning-based fully-automated abdominal multi-organ segmentation algorithm, robust to both non-contrast and post-contrast CT images, using dual-energy CT (DECT) images.

METHODS AND MATERIALS

For development, 75 abdominal DECT scans (portal venous phase (PVP) images and the spatiotemporally matched virtual non-contrast (VNC) images; 18174 slices in each) were used as the input. A single three-dimensional (3D) nnU-Net-based algorithm for multi-organ segmentation (liver, spleen, right kidney, left kidney, and pancreas, respectively) was trained. On an external validation set of 30 single-energy CT scans with both PVP and true non-contrast (TNC) images, the performance of the developed algorithm for each organ was evaluated using the dice similarity score (DSS) for segmentation; and linear regression analysis and Bland-Altman analysis for measurement of the volumetric indices, in comparison to the ground truth manual segmentation.

RESULTS

For 3D segmentation of the liver, spleen, right kidney, left kidney, and pancreas, the fully-automated segmentation algorithm achieved a mean DSS of 0.982, 0.972, 0.972, 0.970, 0.847 in PVP image; and 0.968, 0.956, 0.940, 0.955, and 0.807 in TNC images, respectively. For the measurement of volumetric indices of those organs, manual and automated organ segmentation strongly correlated both in PVP and TNC ($R2 = 0.99, 0.99, 0.99, 0.98$, and 0.80 in PVP; and 0.98, 0.99, 0.95, 0.98, 0.72 in TNC, all Ps <0.001), and the mean differences (95 % limits of agreement) were -1.0% (-3.2, 1.1), 0.3% (-5.2, 5.8), -0.9% (-5.5, 3.8), -2.3% (-7.2, 2.5), 5.8% (-20.1, 31.8) in PVP images; and -1.9% (-3.7, 7.5), -3.1% (-10.9, 4.6), 2.2% (-7.0, 11.3), 3.4% (-1.0, 7.9), -0.3% (-25.8, 25.2) in TNC images, respectively.

CONCLUSION

s The deep learning-based fully-automated segmentation algorithm developed using virtual non-contrast and post-contrast CT images from DECT provided accurate segmentation of abdominal solid organs at both CT scans with and without contrast.

CLINICAL RELEVANCE/APPLICATION

By using paired DECT images, a fully-automated multi-organ segmentation algorithm that is robust to both non-contrast and post-contrast CT can be developed with a relatively small number of datasets, which can be applied to volumetric analysis of abdominal organs of large cohort studies.

M2-SPGI-10

A review of the use of Computed Tomography (CT) Colonography in acute diverticulitis follow up

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Amy Verrinder, MBBS, (*Presenter*) Nothing to Disclose

PURPOSE

Direct visualisation of the bowel lumen is recommended as follow up for all acute diverticulitis cases. This includes CT Colonography (CTC). In Newcastle Upon Tyne Hospitals (NUTH), surgical practice is that all patients admitted with diverticulitis have a follow up CTC approximately 3 months from discharge.

METHODS AND MATERIALS

A Radiology Information system (RIS) search of CTCs performed in NUTH trust between 1/1/2019-31/12/2019. Reports were excluded if the indication was not acute diverticulitis follow-up. Remaining reports were assessed for compliance with standards.Joint guidance from the BSGAR and RCR: Standards of practice for CTC (2021); and Royal College of Surgeons commissioning guide into Colonic Diverticular disease (2014).Percentage of CTC reports following acute diverticulitis accordant with standards of practice.1. CTC should be completed within 3 months of acute episode 2. Local target of 100% sensitivity for colonic malignancy. 3. Polyp identification rate of >13% of patients 4. Indeterminate CTC report (leading to further investigation) in <25%References: Royal College of Radiologists. (2021). Joint guidance from the BSGAR and RCR: Standards of practice for CTC.Royal College of Surgeons. (2014). Colonic Diverticular disease - Commissioning Guide.

RESULTS

Of the 1282 CTC reports identified, 1207 (94%) were excluded. Of the remaining 75 reports, no cases had a colonic malignancy later identified which was not reported at the time of CTC (100% sensitivity). There was a wide range in the time interval to CTC, from 3 to 69 weeks. 15 cases (20%) had polyps identified. 6 reports (8%) were indeterminate (C score of 3c) and required further investigation.

CONCLUSION

s CTC in acute diverticulitis follow-up achieved targets in malignancy and polyp sensitivity, and indeterminate rates. However, the time interval was very variable and could be standardised to produce a more robust pathway for patients requiring acute diverticulitis follow-up. Results have been presents regionally.

CLINICAL RELEVANCE/APPLICATION

CTC in acute diverticulitis follow up has superseded the Colonoscopy at NUTH. This has been a success story for the Radiology teams with increased trust in CTC reports from the General Surgical teams. This audit shows this trust is well placed with national standards met using this less invasive, more accessible and better tolerated test. Going forward this pathway could be standardised to set up a routine follow up time interval for CTC following acute diverticulitis which would stream line patient management and improve efficiency.

Phenotypic and Biomarker Associations with Lean Steatosis using Image-derived Phenotypes from Abdominal CT Scans

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Hersh Sagreiya, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose

PURPOSE

Although non-alcoholic fatty liver disease (NAFLD) is associated with obesity, a significant subgroup of NAFLD patients have normal body mass index (BMI) or "lean steatosis." We investigated characteristics associated with lean steatosis using biobank data by aggregating ICD codes and CT scans to perform a phenome-wide association study (PheWAS) and biomarker analysis.

METHODS AND MATERIALS

We collected chest and abdominal CTs, blood biomarkers, and ICD-9 codes from 11,559 biobank participants, excluding patients with alcohol use disorder, alcohol-related liver disease, and end-stage liver disease (ESLD). CT scans were segmented using deep learning. Hepatic fat (HF) was estimated by computing liver attenuation - spleen attenuation (in Hounsfield units); a lower value indicated more HF. Lean patients were defined as those with BMI 18.5- 25. PheWAS was conducted for HF, and logistic regression determined the interaction between the variables 'lean' and 'HF,' controlling for age, gender, and race. Livers were categorized as steatotic or non-steatotic according to an attenuation threshold determined by receiver operating characteristic analysis of biopsy-obtained HF measurement. Biomarkers included AST, ALT, ALP, HDL, LDL, triglycerides, total cholesterol, and hemoglobin A1c.

RESULTS

4650 NAFLD and 879 lean steatotic patients were identified. PheWAS yielded 35 significant associations, with links to several renal pathologies. Lean steatosis patients had higher ALP and HDL and lower ALT, triglycerides, and hemoglobin A1c compared to overweight steatosis patients. AST, LDL, and total cholesterol were not significantly different.

CONCLUSION

s Our study is the first to link CKD and other renal pathologies to lean steatosis using a high-throughput imaging-guided pipeline. We report several metabolic biomarker differences between lean and overweight steatotic patients. These associations remained significant when removing ESLD patients and controlling for age, race, and gender. We plan further study to characterize the risk factors and pathophysiologic mechanisms contributing to the metabolic and renal associations with lean steatosis.

CLINICAL RELEVANCE/APPLICATION

Applying deep learning, PheWAS, and biomarker analysis to CT scans can provide new clinical insights, differentiating overweight steatosis from the less well-understood lean steatosis phenotype.

M2-SPGI-4

EvaluationofRespiratory-Related Predictors for Image Quality of Respiratory-gating and Breath-hold 3D Magnetic Resonance Cholangiopancreatography (MRCP): A Single-Center Prospective Study

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Ke Wang, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The study aimed to compare the image quality of single breath-hold 3D GRASE MRCP (BH-MRCP) and respiratory-gating 3D FSE MRCP (RG-MRCP), and to explore the respiratory factors based on the breathing curve that may affect the image quality of BH- and RG- MRCP sequences.

METHODS AND MATERIALS

A total of 126 study participants were enrolled from May to December 2021 and underwent RG-MRCP and BH-MRCP at a 3-T MR scanner (uMR790, United Imaging Healthcare, Shanghai, China). The imaging was evaluated by three radiologists based on a 5-point Likert scale. Respiratory parameters were extracted from the breathing curve (Fig.1). Wilcoxon test was used to compare the image quality between two MRCPs. Multivariable linear regression and logistic regression analyses were performed to identify breathing predictor variables of a higher image quality score and better image quality.

RESULTS

The overall image quality scores were 4.45±0.73 for RG-MRCP and 4.69±0.6 for BH-MRCP (p?<?0.05). Multivariable predictors of a higher RG-MRCP image quality score (ß=-0.455 to -0.307) included lower Standard deviation of respiratory amplitude on minimum-peak (SDAmp-minimum-peak) (p<0.001) and lower standard deviation of time interval between the two trigger points (SDbreath-time) (p<0.001) (Fig. 2). A higher BH-MRCP image quality score was predicted by lower standard deviation of respiratory amplitude (SDamp) (ß=-0.630, p<0.001) (Fig. 3). The results of multivariable logistic regression showed that lower SDAmp-minimum-peak (OR=0.147, 95% CI=0.058-0.370, p<0.001) was the only predictor of relatively good RG-MRCP image quality. For BH-MRCP, the factor predicting relatively good image quality was SDamp (OR=0.665, 95% CI= 0.572-0.773, p<0.001) (Table 1).

CONCLUSION

s In conclusion, both RG-MRCP and BH-MRCP demonstrated satisfied image quality. The overall image quality of BH-GRASE-MRCP was significantly better than RG-MRCP on group level, but not for every individual. Respiratory conditions exerted significant impact on the image quality of MRCP, and parameters derived from respiratory curve could help predict image quality of both sequences.

CLINICAL RELEVANCE/APPLICATION

?The evaluation of the breathing curve could benefit for the individualized scanning plan. ?In addition, during breathing training, patients could be guided in a more targeted manner. ?The evaluation of the breathing curve was not limited to the application of MRCP, and could also be applied in the whole process of MRI scanning of the upper abdomen.

M2-SPGI-5

Preoperative CT Staging of Intrahepatic Cholangiocarcinoma: Impact of Up-staging of Tumor Multiplicity on Survival Outcomes

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
June Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop a preoperative CT staging system for intrahepatic cholangiocarcinoma (iCCA) using American Joint Committee on Cancer (AJCC) staging parameters and focusing on tumor multiplicity.

METHODS AND MATERIALS

Patients who underwent preoperative multiphasic CT and curative-intent resection for mass-forming iCCA were retrospectively recruited from multiple institutions from January 2009 to December 2015. Based on Cox proportional hazards regression analysis of the AJCC staging parameters, preoperative CT staging system was modified from the AJCC system with subdivision of tumor multiplicity (satellitosis vs. intrahepatic metastasis). Kaplan-Meier method was used to estimate overall survival (OS). Harrell's concordance indices (C-indices) of AJCC and modified systems were compared with bootstrap methods.

RESULTS

This study included 319 patients (median age, 64 years; 208 men). In the modified staging system, multiple tumors (adjusted hazard ratio [HR]; satellitosis, 3.03, P <0.001; intrahepatic metastasis, 3.92, P <0.001) were up-staged from T2 to T3 (T3a, satellitosis; T3b, intrahepatic metastasis); solitary tumor with intrahepatic vascular invasion (adjusted HR, 1.98, P = 0.003) or solitary tumor perforating the visceral peritoneum (adjusted HR, 2.00, P = 0.001) were designated as T2. Preoperative T2 and T3 stages according to the AJCC system failed to discriminate the survival curves (log-rank P value for T2 vs. T3 = 0.812; 5-year OS, 23.4% vs. 26.8%), but modified T2 stage showed better OS outcomes than modified T3 stage (log-rank P value for T2 vs. T3a vs. T3b = 0.003; 5-year OS, 33.8% vs. 8.4% vs. 4.8%). The C-indices of modified staging system were higher than those of AJCC staging system for predicting OS, marginally approaching the statistical significance (T staging, 0.647 vs. 0.626, P = 0.061; tumor-node-metastasis staging, 0.636 vs. 0.614, P = 0.069).

CONCLUSION

s The modified staging system which upstages tumor multiplicity provides better prognostic stratification for OS than AJCC staging system when applied to preoperative CT in patients with iCCA.

CLINICAL RELEVANCE/APPLICATION

The presence of tumor multiplicity on preoperative CT indicates worse prognosis than current AJCC T2 or T3 staging parameters, and may need subdivision into satellitosis and intrahepatic metastasis.

M2-SPGI-7

A Diagnostic Value of MR Radiomics for Predicting Lateral Pelvic Lymph Node Metastasis in Patients with Locally Advanced Rectal Cancer: A Multicenter Retrospective Study

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Jeongin Yoo, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop a MRI radiomics-based prediction model for lateral pelvic lymph node (LPLN) metastasis in rectal cancer patients who underwent LPLN dissection as well as to validate model performance using an external validation dataset.

METHODS AND MATERIALS

A total of 344 patients (198 in the development cohort and 146 in the validation cohort) who underwent rectal cancer surgery and LPLN dissection were enrolled. Patients' clinical and laboratory features were recorded. Radiomics features of LPLN were extracted from pre- post-chemoradiation therapy high-resolution T2-weighted axial or coronal MR images. The least absolute shrinkage and selection operator regression analysis was conducted to select predictive radiomics features in the development cohort, and a radiomics score for predicting LPLN metastasis was calculated based on the selected features. Model performance was assessed by receiver operating characteristics curve, calibration curves, and decision curve analysis (DCA). The prediction model was externally validated in the validation cohort.

RESULTS

In the development cohort, 70 (35.4%) of 198 patients had metastatic LPLN. Of clinical features, neoadjuvant radiotherapy is the sole significant feature. Of 116 radiomics features, histogram-based energy and histogram-based total energy were selected as significant features. Radiomics score can be calculated as a following formula: radiomics score = -0.58618 + 1.7252902E-9 x histogram-based energy + 1.1056922E-9 x histogram-based total energy. A combined model using clinical features and radiomics score showed better prediction performance compared to the clinical feature only (area under the curve [AUC] value: 0.73 vs 0.61) in the development cohort (P<0.0001). DCA demonstrated that the combined model has the highest net benefit in threshold probability of 25% - 75%. In the validation cohort, a combined model using clinical features and radiomics score showed better prediction performance compared to the clinical feature only (AUC value: 0.61 vs 0.51) (P=0.0318) and had the highest net benefit in threshold probability of 30%-75%.

CONCLUSION

s An application of radiomics on rectal MRI showed the best prediction performance of a combined model using clinical features and radiomics score to predict LPLN metastasis.

CLINICAL RELEVANCE/APPLICATION

An application of radiomics on rectal MRI can be useful for accurately predicting LPLN metastasis in patients with rectal cancer

M2-SPGI-8

Diagnostic performance of Apparent Diffusion Coefficient to assess the therapeutic response to biological therapy in Crohn's disease

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Jordi Rimola, MD, PhD, (*Presenter*) Consultant, Alimentiv Health Trust;Speaker, Takeda Pharmaceutical Company Limited;Consultant, Johnson & Johnson;Consultant, Boehringer Ingelheim GmbH;Research Grant, AbbVie Inc

PURPOSE

to determine prospectively the performance of the Apparent Diffusion Coefficient (ADC) to assess response to biological therapy in Crohn’s disease (CD) using MR enterography (MRE) and ileocolonoscopy as reference standards.

METHODS AND MATERIALS

Seventy four CD &9;patients underwent MRE with ADC calculation before and at 46-week after treatment with biological therapy. MRE images were analyzed including measurement of ADC. Segmental MaRIA was considered the reference standard to identify presence and severity of inflammation. Similar analysis was done in the 41 subjects who underwent ileocolonoscopy at both time points.

RESULTS

MRE identified 125 intestinal segments with severe inflammation (MaRIA > or = 11) at baseline. Of them, 54% achieved healing of severe inflammation (MaRIA <11) at week 46.&9;Using a receiver operating characteristic (ROC) curve, we determined at baseline an ADC threshold of 1.301×10-3mm2/s to predict severity, yielding a sensitivity of 0.78 and specificity of 0.94 to identify segments with MaRIA > or = 11 (AUROC=0.92). Using the same threshold, ADC has a sensitivity and specificity of 0.90 and 0.75 respectively to identify healing of severe inflammation (MaRIA<11) at week 46. Using ileocolonoscopy as reference, the ADC threshold to predict endoscopic severity (ulcers) was very similar (1.382x10-3mm2/s) yielding a sensitivity and specificity of 0.76 and 0.89, and 0.95 and 0.71 to identify endoscopic ulcer healing. The MaRIA score was superior to ADC to predict endoscopic ulcer healing (AUROC 0.94 vs. 0.83 p=0.01).

CONCLUSION

s ADC showed robust thresholds to predict severe inflammation in CD using either MaRIA or ileocolonoscopy, and could be used as an alternative to the MaRIA index to assess therapeutic response in CD.

CLINICAL RELEVANCE/APPLICATION

ADC is a potential imaging biomarker alternative to MaRIA score or ileocolonoscopy to assess the treatment response to biological therapy in Crohn’s disease

M2-SPGI-9

MRI Defecography: A Useful Tool to Guide Surgical Management in Patients With Pelvic Floor Dysfunction

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
John Gao, MD, Kansas City, KS (*Presenter*) Nothing to Disclose

PURPOSE

To retrospectively evaluate magnetic resonance (MR) defecography findings in patients with pelvic floor dysfunction to assess which findings on MR defecography influence decisions to perform subsequent pelvic floor surgery.

METHODS AND MATERIALS

This retrospective cohort study included women 18 and older who had an MRI defecography exam from 1/1/2017 - 6/30/2021. Patients were excluded if they were male, under 18, unable to comply with the exam, or had insufficient imaging. Demographic, clinical, and imaging information were obtained from the electronic medical record and Picture Archiving and Communications Systems (PACS). Imaging reports were retrospectively reviewed using the original interpretations.

RESULTS

One hundred sixty-eight patients with 171 MR defecography exams were included. Twenty out of 168 total patients (11.9%) patients had subsequent pelvic floor surgery in the year following their exam. Multiple measurements on MRI demonstrated a statistically significant odds ratio for subsequent pelvic floor surgery, including M line at maximal strain (OR=1.5, p=0.070) and the presence of sigmoidocele (OR=27.7, p=0.011) and enterocele (OR=6.8, p=0.015). Patients in the surgical group had higher M-lines at maximal strain (5.7 cm) than in the non-surgical group (4.7 cm).

CONCLUSION

s MRI defecography is an important tool to evaluate anatomical and functional abnormalities in patients with pelvic floor dysfunction. Certain measurements and findings may help guide decisions to pursue surgical treatment. The presence of sigmoidoceles and enteroceles is a significant finding that may direct patients and clinicians to pursue surgical management, which should be highlighted in the radiology report.

CLINICAL RELEVANCE/APPLICATION

Radiologists should highlight key measurements and findings on MRI defecography exams as well as recommend surgical consultation in certain patients.

Genitourinary Monday Poster Discussions

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - GU DPS

Sub-Events

M2-SPGU-1 Comparison of diagnostic accuracy between an artificial-intelligence-based prostate MRI protocol, mpMRI and bpMRI in dependence on the radiologist experience

Participants
Daniel Nissler, MD, (*Presenter*) Grant, Zentrales Innovations;Speaker, Bayer AG;Travel support, Bayer AG

PURPOSE

Evaluation of the diagnostic accuracy of three rating radiologists with different degree of experience in prostate MRI assessment for an artificial intelligence supported biparametric MRI protocol (ai) in comparison to a multiparametric MRI (mp) as well as a biparametric MRI (bp) protocol.

METHODS AND MATERIALS

In this retrospective study, the diagnostic accuracy of prostate cancer detection between ai, mp and bp was compared. The software used T2-weighted und diffusion sequences from a 3.0 T MRI system to run an automatic segmentation of suspicious prostate lesions using an Aniso-3D-U-Net and a VGG-Net for lesion classification. Three radiologist with different degree of experience in prostate MRI (1- high, 2- intermedium, 3- low) evaluated the PI-RADS score for the patients in three different branches of the study: ai, mp, bp. Ground truth was the histology from the combined systematic and targeted transrectal US fusion biopsy.

RESULTS

PI-RADS scores from 105 men (median age, 66 years; range, 46-85 years/ median PSA, 9.4 [ng/ml]; range, 1-56 [ng/ml]) were matched with the Gleason score (GS) to determine the AUC for each branch (ai, mp, bp) and reader (1-3). The AUC to detect prostate cancer (GS = 3 + 3) for reader 1 was 0.850 for ai, 0.849 for mp, and 0.829 for bp. The corresponding values for reader 2 were 0.847 (ai), 0.781 (mp), 0.762 (bp) and for reader 3 0.819 (ai), 0.775 (mp), 0.712 (bp). There were no statically significant differences for reader 1 between ai, mp and bp. The difference between ai and bp for reader 2 (p = 0,006) and 3 (p = 0.008) was statically significant. For all readers the diagnostic accuracy for bp was lower than mp, but not statically significant.

CONCLUSION

s Radiologist with low or intermedium degree of experience in prostate MRI assessment benefit from ai and reach higher accuracy then mp and bp, whereas radiologist with high experience reached equal AUC for ai and mp. For all readers ai can compensate the decreased accuracy in bp.

CLINICAL RELEVANCE/APPLICATION

The results reveal first signs, that the ai protocol shows similarly good values as the mp protocol, so that an ai supported bp protocol could possibly detach a contrast agent assisted protocol.

M2-SPGU-2 Image quality of virtual monochromatic imaging of half-iodine-load contrast-enhanced abdomen-pelvis CT by Gemstone Spectral Imaging with deep learning reconstruction

Participants
Shingo Harashima, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Image quality (IQ) of Gemstone Spectral Imaging (GSI) has been improving with recent introduction of deep learning reconstruction (DLR). We prospectively assessed IQ of virtual monochromatic imaging (VMI) of half-iodine-load contrast-enhanced abdomen-pelvis CT (CE-APCT) with the minimal slice thickness by GSI with DLR.

METHODS AND MATERIALS

In 28 patients with moderate-severe renal impairment who underwent half-iodine-load (300 mgI/kg) CE-APCT during the nephrographic phase using a 256-detector GSI scanner (Revolution CT, GE), we reconstructed VMI at 40-140 keV (1-keV interval) of the minimal slice thickness of 0.625 mm with filtered back projection (FBP), iterative reconstruction (IR), and DLR (TrueFidelity, GE); placed regions of interest in the liver, spleen, aorta, portal vein, paraspinal muscle, and subcutaneous fat in the abdomen and in the prostate/uterus, gluteal muscle, and subcutaneous fat in the pelvis to measure each organ's CT value and contrast-noise ratio (CNR) as (CT value of each organ - that of the muscle)/standard deviation of CT value of the fat in the abdomen and pelvis; determined the optimal keV to achieve the maximal CNR. Two independent radiologists subjectively assessed image noise, contrast, and sharpness, delineation of small structures, and overall IQ using a 4-pont scale (1, poor; 4, excellent; 2-4, acceptable). We used Kruskal-Wallis test with Bonferroni correction to compare each organ's CT value and CNR and subjective IQ scores among FBP, IR, and DLR and weighted ? test to quantify inter-reader agreement.

RESULTS

Each organ's CT value and CNR continuously increased from 140 to 40 keV with FBP, IR, and DLR. At the optimal keV (i.e., 40 keV), CNR of the prostate/uterus was significantly greater with DLR than with FBP ($P < 0.05$) but comparable between FBP and IR and between IR and DLR ($P > 0.05$) and CNR of any other organs significantly increased from FBP to IR to DLR ($P < 0.05$), whereas each organ's CT value was comparable among the 3 reconstructions ($P > 0.05$). All the IQ scores significantly improved from FBP to IR to DLR ($P < 0.05$) and were acceptable in all the patients only with DLR. Inter-reader agreement was substantial (? = 0.65).

CONCLUSION

s Combined use of 40 keV and DLR offers the maximal CNR and subjectively acceptable IQ in VMI of half-iodine-load CE-APCT with the minimal slice thickness.

CLINICAL RELEVANCE/APPLICATION

VMI at 40 keV by GSI can preserve image contrast and improve delineation of fine anatomies and lesions in half-iodine-load CE-APCT with the minimal slice thickness by achieving acceptable IQ by DLR.

Image quality of virtual monochromatic imaging of half-iodine-load contrast-enhanced abdomen-pelvis CT by Gemstone Spectral Imaging with deep learning reconstruction

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - GU DPS

Participants
Shingo Harashima, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Image quality (IQ) of Gemstone Spectral Imaging (GSI) has been improving with recent introduction of deep learning reconstruction (DLR). We prospectively assessed IQ of virtual monochromatic imaging (VMI) of half-iodine-load contrast-enhanced abdomen-pelvis CT (CE-APCT) with the minimal slice thickness by GSI with DLR.

METHODS AND MATERIALS

In 28 patients with moderate-severe renal impairment who underwent half-iodine-load (300 mgI/kg) CE-APCT during the nephrographic phase using a 256-detector GSI scanner (Revolution CT, GE), we reconstructed VMI at 40-140 keV (1-keV interval) of the minimal slice thickness of 0.625 mm with filtered back projection (FBP), iterative reconstruction (IR), and DLR (TrueFidelity, GE); placed regions of interest in the liver, spleen, aorta, portal vein, paraspinal muscle, and subcutaneous fat in the abdomen and in the prostate/uterus, gluteal muscle, and subcutaneous fat in the pelvis to measure each organ's CT value and contrast-noise ratio (CNR) as (CT value of each organ - that of the muscle)/standard deviation of CT value of the fat in the abdomen and pelvis; determined the optimal keV to achieve the maximal CNR. Two independent radiologists subjectively assessed image noise, contrast, and sharpness, delineation of small structures, and overall IQ using a 4-pont scale (1, poor; 4, excellent; 2-4, acceptable). We used Kruskal-Wallis test with Bonferroni correction to compare each organ's CT value and CNR and subjective IQ scores among FBP, IR, and DLR and weighted ? test to quantify inter-reader agreement.

RESULTS

Each organ's CT value and CNR continuously increased from 140 to 40 keV with FBP, IR, and DLR. At the optimal keV (i.e., 40 keV), CNR of the prostate/uterus was significantly greater with DLR than with FBP ($P < 0.05$) but comparable between FBP and IR and between IR and DLR ($P > 0.05$) and CNR of any other organs significantly increased from FBP to IR to DLR ($P < 0.05$), whereas each organ's CT value was comparable among the 3 reconstructions ($P > 0.05$). All the IQ scores significantly improved from FBP to IR to DLR ($P < 0.05$) and were acceptable in all the patients only with DLR. Inter-reader agreement was substantial (? = 0.65).

CONCLUSION

s Combined use of 40 keV and DLR offers the maximal CNR and subjectively acceptable IQ in VMI of half-iodine-load CE-APCT with the minimal slice thickness.

CLINICAL RELEVANCE/APPLICATION

VMI at 40 keV by GSI can preserve image contrast and improve delineation of fine anatomies and lesions in half-iodine-load CE-APCT with the minimal slice thickness by achieving acceptable IQ by DLR.

Head and Neck Monday Poster Discussions

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - HN DPS

Sub-Events

M2-SPHN-1 How Reliably can MRI Visualize the Endolymphatic Duct in Patients With and Without Vestibular Aqueduct Enlargement?

Awards
Trainee Research Prize - Fellow

Participants
Olutayo Olubiyi, MBChB, MPH, (*Presenter*) Nothing to Disclose

PURPOSE

To determine 1) whether normal-sized endolymphatic ducts (ELD) are routinely visible on high-resolution temporal bone MRI and 2) how reliably MRI detects vestibular aqueduct (VA) enlargement.

METHODS AND MATERIALS

The study was approved by our center's IRB. 100 pediatric patients who underwent temporal bone CT and MRI between January 2017 and December 2020 were included for this study. VA width was measured at the midpoint and operculum on axial CT and at the midpoint on Poschl reconstructions. Enlargement of the VA (eVA) was determined using the Cincinnati criteria. Corresponding heavily T2-weighted high-resolution MRI images were reviewed, with visibility of each ELD categorized as: type 1=not visible; type 2=indistinct; or type 3=easily visible (Figure).Mixed-effect logistic regression analyses were used to evaluate 1) whether MRI visibility was associated with eVA and 2) whether mean vestibular aqueduct diameters differ based on MRI visibility. A p-value<0.05 was used as the level of statistical significance in all analyses.

RESULTS

eVA was identified in 21% of the analyzed ears. There was a significant association between the presence of eVA on CT and ELD visibility on MRI (p=0.0001). In eVA- ears, ELD visibility on MRI was type 1 in 87%, type 2 in 13%, and type 3 in 0%. In eVA+ ears, the ELDs were type 1 in 21%, type 2 in 21%, and type 3 in 57%.There were significant differences in predicted mean VA widths based on MRI visibility (p<0.0001) regardless of the method of VA measurement. E.g., the mean predicted axial mid-VA widths were: 0.63 mm for type 1, 0.97 mm for type 2, and 2.1 mm for type 3 ELDs (Tukey-adjusted p-value <0.0001 for all comparisons).

CONCLUSION

s ELDs were never easily visible and were usually invisible on high-resolution MRI in eVA- ears on CT. Easy visibility of the ELD was only noted in eVA+ ears, in whom, the majority of cases were type 3; however, in 21% of eVA+ ears, the ELD was not visible on MRI, suggesting that MRI should not be used as a substitute for CT in ruling out eVA.

CLINICAL RELEVANCE/APPLICATION

Our data suggested that MRI cannot be substituted for temporal bone CT to rule out eVA in pediatric patients. Furthermore, in the vast majority of ears without eVA, the ELD is not visible on MRI.

M2-SPHN-3 CT-guided Core Needle Biopsy in Head and Neck Masses: Evaluation of Accuracy and Safety

Participants
Thomas J. Vogl, MD, PhD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the procedure of CT-guided core needle biopsy of head and neck masses focusing on accuracy and safety.

METHODS AND MATERIALS

In this retrospective single-center study the accuracy and safety of CT-guided core needle biopsies in head and neck masses was evaluated from April 2007 to December 2021. A total of 154 patients (mean: 55.9y; 61% males, 39% females) with biopsies were evaluated. 57.1% of all patients had a history of malignoma, 56.7% of the lesions were located cranial to the os hyoideum. The most common needle approach of suprahyoid lesions (33%) was the subzygomatic approach. The average diameters of all lesions were 36x23mm. The location of the lesions was divided in cranial and caudal to the os hyoideum. To ensure the diagnostic accuracy, the initial histological results were compared with the final medical diagnosis and an additional follow-up of at least six months.

RESULTS

10 of 154 biopsies showed insufficient and inconclusive samples and were excluded from the evalulation. The remaining 144 biopsies

showed a sensitivity of 94.1%, a specificity of 100% and an accuracy of 97.3%. There were four false negative and no false positive biopsies, resulting in a positive predictive value of 100% and a negative predictive value of 95.1%. Eight cases presented minor complications such as postpunctate hematomas, without requiring any intervention. The average dosis-length-product was 276,4 mGy x cm.

CONCLUSION

s CT-guided core needle biopsy of head and neck masses is a safe and effective procedure, which shows a low rate of complications with a high diagnostic accuracy.

CLINICAL RELEVANCE/APPLICATION

CT-guided biopsy of head and neck masses is of high clinical relevance

How Reliably can MRI Visualize the Endolymphatic Duct in Patients With and Without Vestibular Aqueduct Enlargement?

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - HN DPS

Awards
Trainee Research Prize - Fellow

Participants
Olutayo Olubiyi, MBChB, MPH, (*Presenter*) Nothing to Disclose

PURPOSE

To determine 1) whether normal-sized endolymphatic ducts (ELD) are routinely visible on high-resolution temporal bone MRI and 2) how reliably MRI detects vestibular aqueduct (VA) enlargement.

METHODS AND MATERIALS

The study was approved by our center's IRB. 100 pediatric patients who underwent temporal bone CT and MRI between January 2017 and December 2020 were included for this study. VA width was measured at the midpoint and operculum on axial CT and at the midpoint on Poschl reconstructions. Enlargement of the VA (eVA) was determined using the Cincinnati criteria. Corresponding heavily T2-weighted high-resolution MRI images were reviewed, with visibility of each ELD categorized as: type 1=not visible; type 2=indistinct; or type 3=easily visible (Figure).Mixed-effect logistic regression analyses were used to evaluate 1) whether MRI visibility was associated with eVA and 2) whether mean vestibular aqueduct diameters differ based on MRI visibility. A p-value<0.05 was used as the level of statistical significance in all analyses.

RESULTS

eVA was identified in 21% of the analyzed ears. There was a significant association between the presence of eVA on CT and ELD visibility on MRI (p=0.0001). In eVA- ears, ELD visibility on MRI was type 1 in 87%, type 2 in 13%, and type 3 in 0%. In eVA+ ears, the ELDs were type 1 in 21%, type 2 in 21%, and type 3 in 57%.There were significant differences in predicted mean VA widths based on MRI visibility (p<0.0001) regardless of the method of VA measurement. E.g., the mean predicted axial mid-VA widths were: 0.63 mm for type 1, 0.97 mm for type 2, and 2.1 mm for type 3 ELDs (Tukey-adjusted p-value <0.0001 for all comparisons).

CONCLUSION

s ELDs were never easily visible and were usually invisible on high-resolution MRI in eVA- ears on CT. Easy visibility of the ELD was only noted in eVA+ ears, in whom, the majority of cases were type 3; however, in 21% of eVA+ ears, the ELD was not visible on MRI, suggesting that MRI should not be used as a substitute for CT in ruling out eVA.

CLINICAL RELEVANCE/APPLICATION

Our data suggested that MRI cannot be substituted for temporal bone CT to rule out eVA in pediatric patients. Furthermore, in the vast majority of ears without eVA, the ELD is not visible on MRI.

M2-SPIN-1 Mask Interpolation, Autocorrection, and Fast Annotation for Medical Imaging Labels

Participants
Kuan Zhang, PhD, , MN (*Presenter*) Nothing to Disclose

PURPOSE

Training a segmentation model requires human annotations, which are tedious. Since the annotation is performed among slices, the out-of-plane signals can be noisy with heterogeneous artifacts. There is a growing demand for efficient mask interpolation to alleviate annotation efforts and help with data preprocessing and augmentation. Here, we developed new interpolation and autocorrection algorithms for mask data. Based on them, a simple fast-annotation scheme was proposed.

METHODS AND MATERIALS

Tri-cubic interpolation (TCI) is often used to normalize imaging data as it provides more smooth transitions than nearest-neighbor interpolation (NNI). However, both methods fail for mask data due to the piecewise distribution. In addition to the zig-zag artifacts in the lateral planes, TCI can result in in-plane discontinuity artifacts. We created a distance field (dist-field) evaluating the nearest distance to the label boundary before TCI. It helps convert the piecewise mask data into continuous functions and corrects artifacts. Given the noisy signals in the lateral planes, we developed a label autocorrection (LAC) algorithm by optimizing the signals with a total-variation (TV) regularization term. We applied the TV on the dist-field rather than the original mask. Besides, the regularization rate is tuned pixel-wisely given the size and smoothness of the object obtained from the connected component analysis. We evaluated methods applied on our annotations of LiTZ data and compared with the official mask data as the ground truth. Besides, we trained and evaluated 3D U-Net models on the original body-decomposition labels and the labels with LAC.

RESULTS

Full annotation achieves a Dice Score (DS) as 0.966 (0.964 - 0.967) for liver and 0.862 (0.802 - 0.895) for tumor. Applying LAC on the full annotation, the DS increased to 0.974 (0.972 - 0.976) for liver and 0.890 (0.834 - 0.918) for tumor. Performing the fast-annotation scheme can achieve DS 0.970 (0.965 - 0.974) for liver and 0.873 (0.806 - 0.920) for tumor. Besides, if we label every five slices and do TCI, the DS decreased to 0.963 (0.959 - 0.966) for liver and 0.857 (0.793 - 0.898) for tumor. The time spent on fast annotation is one-fifth of the full annotation. Trained on body-decomposition datasets, the validation DS increased among 23 organs and decreased among five. The medium difference with and without LAC is +0.018.

CONCLUSION

s We developed new algorithms to interpolate, autocorrect and fast annotate imaging labels.

CLINICAL RELEVANCE/APPLICATION

DL segmentation is widely performed in clinical practice and research. Human annotations limit its development in terms of efficiency and accuracy. The proposed methods can be smoothly embedded into the routine pipeline and improve performance.

M2-SPIN-2 Transformation of Multiphasic Intraprocedural Angiograms into Physiologic Models for Identification of Tumor Bed Saturation in Y-90 Radioembolization Planning

Participants
John Mayfield, MD, MS, Lithia, FL (*Presenter*) Nothing to Disclose

PURPOSE

Since the first appearance of CT angiography in Radiology in 1992, this technology has found a growing use in Interventional Radiology. A large volume of literature has evolved describing how to best provide intraprocedural and as well as predictive surrogates of pathophysiological processes. Past attempts of translating images into realistic models ranged from two-dimensional flow diagrams to three-dimensional rigid wall synthetic structures. We propose a unique method of using multiphase intra-arterial CT angiogram in a population of patients with Neuroendocrine tumor liver metastases (NETLMs).

METHODS AND MATERIALS

We retrospectively reviewed three patients with NETLMs who were candidates for Y-90 radioembolization. Pre-embolization mapping was carried out in the angiography suite of two target hepatic arteries with injection of Isovue-250® (iopamidol, Bracco diagnostics Inc, Monroe Township, NJ) during intra-arterial CT angiography (CTA) on a Canon 4D Scanner (Canon Medical Systems, Tustin, CA) captured at 6 and 14 seconds to provide multiphasic images. Subsequent CTAs were deidentified and exported as DICOM images to Mimics and 3Matic software packages (Materialise, Plymouth, MI) where the artery distal to the tip of microcatheter placement was segmented and exported to COMSOL Multiphysics (COMSOL, Stockholm, Sweden). From the intraprocedural nursing records, the patient's specific vital signs and physiologic parameters were parameterized in the model with

Monte Carlo simulation until a solution converged.

RESULTS

In all three patients, late-phase (14s) intraprocedural angiograms demonstrated significantly improved visualization of the tumor vascular beds in comparison to the early arterial phase (6s). The tumor vascular bed and feeding arteries were effectively segmented and represented in the resultant geometry in the modeling software. Variant flow patterns were mapped in the distal feeding vessels as well as tumor vascular beds. Four maximum velocity thresholds helped identify potential areas of low perfusion or "blind spots" where the Y-90 radioembolization microspheres would not deposit adequately based upon blood flow distribution.

CONCLUSION

s We demonstrate that utilization of multiphase intra-arterial CT angiography provides high-quality images that include tumor vascular beds, which in turn allow effective, patient-specific computational modeling of these systems from an off-the-shelf software suite that can be utilized in mapping hepatic tumors.

CLINICAL RELEVANCE/APPLICATION

Visualization of the three-dimensional blood flow behavior can help to identify potential regions of decreased radioembolization based upon bead distribution and alter treatment delivery mechanisms and dose.

M2-SPIN-4 FDA's list of Artificial Intelligence and Machine Learning Enabled Medical Devices- Radiology Leads the Way

Participants
Larisa Gorenstein, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The US food and drug administration (FDA) ensures the safety and efficacy of healthcare-related products and promotes public health through innovation. Artificial intelligence (AI) has become an area of extreme interest in healthcare in the past decade. Understanding FDA-approved application trends in different medical fields can direct future industry and research resource allocations and regulatory efforts.Our objective was to assess the role of radiology in the FDA's list of AI-enabled medical devices.

METHODS AND MATERIALS

We accessed the list of Artificial Intelligence and Machine Learning Enabled Medical Devices-publicly available on the FDA website ("https://www.fda.gov/medical-devices/software-medical-device-samd/artificial-intelligence-and-machine-learning-aiml-enabled-medical-devices). The site was Accessed on 1/4/2022, and the data is current to 09/22/2021. Entries' medical field and registration dates were analyzed.

RESULTS

A total of 343 entries were listed. 241 (70%) of the entries are from Radiology. 41 (12%) cardiovascular devices. 13 (4%) hematological entries, and 12 (3.5%) from the field of Neurology. Gastroenterology-Urology, General and Plastic Surgery, Anesthesiology, Microbiology, Pathology, Orthopedics, Obstetrics and gynecology and Dental had less than ten entries each. 38 (11%) were listed in 2021, only partially included. 29 (76%) of those were from Radiology. In 2020 out of 100 entries 54 were in Radiology. The largest number of entries by a single conglomerate was 22 (6%), all from the field of Radiology. All devices except one were submitted via 510(k) clearance or De Novo request.

CONCLUSION

s Radiology led the FDA's list by a wide margin with a rise in recent years. AI in medical imaging is in the front line of the entire healthcare innovation. In light of our findings, prioritization of the regulatory resources for radiological medical devices should be considered. The substantial number of devices approved in radiology and the nuances of this field require specialists in radiology to be an integral part of the regulatory process.

CLINICAL RELEVANCE/APPLICATION

The allocation of regulatory resources towards radiology should be considered.

M2-SPIN-5 Long-Tailed Classification of Thorax Diseases on Chest X-Ray

Participants
Yifan Peng, New York, NY (*Presenter*) Nothing to Disclose

PURPOSE

Medical imaging exams, such as CXR, will yield a small set of common findings and a much larger set of uncommon findings. While a trained radiologist can learn uncommon findings by studying a few representative examples, it is more difficult to train a machine learning model from such a "long-tailed" distribution. In this work, we present a comprehensive benchmark study of the long-tailed learning problem in the specific domain of thorax diseases on CXR.

METHODS AND MATERIALS

We introduced a new challenging CXR benchmark to facilitate research on developing long-tailed learning methods. The benchmark consists of two datasets, NIH-CXR-LT and MIMIC-CXR-LT, for 19- and 20-way thorax disease classification, respectively (Figure 1). We compared 15 different long-tail learning methods (Figure 2), which could be grouped into three categories: re-balancing, augmentation, and others. We present results on both the balanced test set and the imbalanced test set for each model and dataset.

RESULTS

For the NIH-CXR-LT, the baseline of softmax cross-entropy loss achieves a group-wise average accuracy of 0.168, but improves to 0.260 and 0.264 when using class-balanced and sklearn weights, respectively (Figure 2). Furthermore, re-weighting constantly improves performance, and class-balanced methods achieve the highest group-wise average accuracy on the balanced test set. On the MIMIC-CXR-LT, re-weighting is always beneficial; for example, class-balanced re-weighting and sklearn re-weighting improve

focal loss performance from 0.181 to 0.278 and 0.299, respectively. However, unlike the NIH-CXR-LT results, DRW brings more gains to a re-weighted LDAM loss, improving group-wise accuracy by an absolute margin of at least 0.05. Interestingly, classifier re-training achieves both the highest group-wise average accuracy on the balanced test set and the highest balanced accuracy on the test set by a considerable margin.

CONCLUSION

s We conducted the first comprehensive study of long-tailed learning methods for disease classification on CXR. We will publicly release all code, models, and data to encourage the development of long-tailed learning methods for medical image classification.

CLINICAL RELEVANCE/APPLICATION

Medical imaging exams often yield a small set of common but a much larger set of uncommon findings. We present a benchmark study of long-tailed learning on chest X-rays to facilitate future research.

M2-SPIN-6 Development and Validation of A Deep Learning Model for Prediction of The 30-day Mortality of Patients With Community-acquired pneumonia from Chest X-ray

Participants
Changi Kim, BS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a deep learning (DL) model to predict the 30-day mortality of patients with community-acquired pneumonia (CAP) using the chest X-ray (CXR) of patients.

METHODS AND MATERIALS

For model development, initial CXRs of patients diagnosed with CAP at a single institution (Institution A) between 2013 and 2019 were included (Developmental dataset). A convolutional neural network-based DL model was trained to predict the hazard of death within 30 days from the diagnosis of CAP. [B1] For validation of model performance, patients who visited the emergency departments of three institutions (Institutions A [temporally separated with developmental dataset], B, and C) due to CAP were included (External validation datasets). The predictive performance for the 30-day mortality was evaluated using the area under the receiver operating characteristic curves (AUCs). The AUC of the DL model was compared with that of CURB-65 score, a widely used tool for risk evaluation in CAP. Finally, the results from the DL model were categorized into three risk groups, and simply added to the CURB-65 scores (combined scores), and the AUC of the combined score was compared with that of the CURB-65 score.

RESULTS

Developmental dataset comprised 7,105 patients (62% men; mean age, 68 years; 30-day mortality rate, 11.4%), while external validation datasets from institution A, B, and C comprised 947 (63% men; mean age, 71 years; 30-day mortality rate, 17.6%), 467 (63% men; mean age, 73 years; 30-day mortality rate, 8.4%), and 381 (63.8% men; mean age, 71 years; 30-day mortality rate, 10.8%) patients, respectively. The DL model exhibited significantly higher AUC than CURB-65 score in external validation dataset from institution A (0.77 vs. 0.67, P<.001); while the difference did not reach statistical significance in datasets from institutions B (0.80 vs. 0.73, P=.194) and C (0.80 vs. 0.72, P=.081). Finally, combined scores exhibited significantly higher AUCs than CURB-65 scores in all three external validation datasets (Institution A, 0.74, P<.001; Institution B, 0.80, P=.002; Institution C, 0.79, P<.001).

CONCLUSION

s A DL model could predict the 30-day mortality of patients with CAP using CXRs, with higher performance than the CURB-65 score. Adding risk scores from the DL model to the CURB-65 score could improve the prediction performance.

CLINICAL RELEVANCE/APPLICATION

Evaluation of CXRs of patients with CAP using the DL model for mortality prediction may help improve risk stratification and clinical decision-making for hospitalization or intensive care.

Mask Interpolation, Autocorrection, and Fast Annotation for Medical Imaging Labels

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IN DPS

Participants
Kuan Zhang, PhD, , MN (*Presenter*) Nothing to Disclose

PURPOSE

Training a segmentation model requires human annotations, which are tedious. Since the annotation is performed among slices, the out-of-plane signals can be noisy with heterogeneous artifacts. There is a growing demand for efficient mask interpolation to alleviate annotation efforts and help with data preprocessing and augmentation. Here, we developed new interpolation and autocorrection algorithms for mask data. Based on them, a simple fast-annotation scheme was proposed.

METHODS AND MATERIALS

Tri-cubic interpolation (TCI) is often used to normalize imaging data as it provides more smooth transitions than nearest-neighbor interpolation (NNI). However, both methods fail for mask data due to the piecewise distribution. In addition to the zig-zag artifacts in the lateral planes, TCI can result in in-plane discontinuity artifacts. We created a distance field (dist-field) evaluating the nearest distance to the label boundary before TCI. It helps convert the piecewise mask data into continuous functions and corrects artifacts. Given the noisy signals in the lateral planes, we developed a label autocorrection (LAC) algorithm by optimizing the signals with a total-variation (TV) regularization term. We applied the TV on the dist-field rather than the original mask. Besides, the regularization rate is tuned pixel-wisely given the size and smoothness of the object obtained from the connected component analysis. We evaluated methods applied on our annotations of LiTZ data and compared with the official mask data as the ground truth. Besides, we trained and evaluated 3D U-Net models on the original body-decomposition labels and the labels with LAC.

RESULTS

Full annotation achieves a Dice Score (DS) as 0.966 (0.964 - 0.967) for liver and 0.862 (0.802 - 0.895) for tumor. Applying LAC on the full annotation, the DS increased to 0.974 (0.972 - 0.976) for liver and 0.890 (0.834 - 0.918) for tumor. Performing the fast-annotation scheme can achieve DS 0.970 (0.965 - 0.974) for liver and 0.873 (0.806 - 0.920) for tumor. Besides, if we label every five slices and do TCI, the DS decreased to 0.963 (0.959 - 0.966) for liver and 0.857 (0.793 - 0.898) for tumor. The time spent on fast annotation is one-fifth of the full annotation. Trained on body-decomposition datasets, the validation DS increased among 23 organs and decreased among five. The medium difference with and without LAC is +0.018.

CONCLUSION

s We developed new algorithms to interpolate, autocorrect and fast annotate imaging labels.

CLINICAL RELEVANCE/APPLICATION

DL segmentation is widely performed in clinical practice and research. Human annotations limit its development in terms of efficiency and accuracy. The proposed methods can be smoothly embedded into the routine pipeline and improve performance.

PURPOSE

Medical imaging exams, such as CXR, will yield a small set of common findings and a much larger set of uncommon findings. While a trained radiologist can learn uncommon findings by studying a few representative examples, it is more difficult to train a machine learning model from such a "long-tailed" distribution. In this work, we present a comprehensive benchmark study of the long-tailed learning problem in the specific domain of thorax diseases on CXR.

METHODS AND MATERIALS

We introduced a new challenging CXR benchmark to facilitate research on developing long-tailed learning methods. The benchmark consists of two datasets, NIH-CXR-LT and MIMIC-CXR-LT, for 19- and 20-way thorax disease classification, respectively (Figure 1). We compared 15 different long-tail learning methods (Figure 2), which could be grouped into three categories: re-balancing, augmentation, and others. We present results on both the balanced test set and the imbalanced test set for each model and dataset.

RESULTS

For the NIH-CXR-LT, the baseline of softmax cross-entropy loss achieves a group-wise average accuracy of 0.168, but improves to 0.260 and 0.264 when using class-balanced and sklearn weights, respectively (Figure 2). Furthermore, re-weighting constantly improves performance, and class-balanced methods achieve the highest group-wise average accuracy on the balanced test set. On the MIMIC-CXR-LT, re-weighting is always beneficial; for example, class-balanced re-weighting and sklearn re-weighting improve focal loss performance from 0.181 to 0.278 and 0.299, respectively. However, unlike the NIH-CXR-LT results, DRW brings more gains to a re-weighted LDAM loss, improving group-wise accuracy by an absolute margin of at least 0.05. Interestingly, classifier re-training achieves both the highest group-wise average accuracy on the balanced test set and the highest balanced accuracy on the test set by a considerable margin.

CONCLUSION

s We conducted the first comprehensive study of long-tailed learning methods for disease classification on CXR. We will publicly release all code, models, and data to encourage the development of long-tailed learning methods for medical image classification.

CLINICAL RELEVANCE/APPLICATION

Medical imaging exams often yield a small set of common but a much larger set of uncommon findings. We present a benchmark study of long-tailed learning on chest X-rays to facilitate future research.

M2-SPIN-6

Development and Validation of A Deep Learning Model for Prediction of The 30-day Mortality of Patients With Community-acquired pneumonia from Chest X-ray

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IN DPS

Participants
Changi Kim, BS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a deep learning (DL) model to predict the 30-day mortality of patients with community-acquired pneumonia (CAP) using the chest X-ray (CXR) of patients.

METHODS AND MATERIALS

For model development, initial CXRs of patients diagnosed with CAP at a single institution (Institution A) between 2013 and 2019 were included (Developmental dataset). A convolutional neural network-based DL model was trained to predict the hazard of death within 30 days from the diagnosis of CAP. [B1] For validation of model performance, patients who visited the emergency departments of three institutions (Institutions A [temporally separated with developmental dataset], B, and C) due to CAP were included (External validation datasets). The predictive performance for the 30-day mortality was evaluated using the area under the receiver operating characteristic curves (AUCs). The AUC of the DL model was compared with that of CURB-65 score, a widely used tool for risk evaluation in CAP. Finally, the results from the DL model were categorized into three risk groups, and simply added to the CURB-65 scores (combined scores), and the AUC of the combined score was compared with that of the CURB-65 score.

RESULTS

Developmental dataset comprised 7,105 patients (62% men; mean age, 68 years; 30-day mortality rate, 11.4%), while external validation datasets from institution A, B, and C comprised 947 (63% men; mean age, 71 years; 30-day mortality rate, 17.6%), 467 (63% men; mean age, 73 years; 30-day mortality rate, 8.4%), and 381 (63.8% men; mean age, 71 years; 30-day mortality rate, 10.8%) patients, respectively. The DL model exhibited significantly higher AUC than CURB-65 score in external validation dataset from institution A (0.77 vs. 0.67, P<.001); while the difference did not reach statistical significance in datasets from institutions B (0.80 vs. 0.73, P=.194) and C (0.80 vs. 0.72, P=.081). Finally, combined scores exhibited significantly higher AUCs than CURB-65 scores in all three external validation datasets (Institution A, 0.74, P<.001; Institution B, 0.80, P=.002; Institution C, 0.79, P<.001).

CONCLUSION

s A DL model could predict the 30-day mortality of patients with CAP using CXRs, with higher performance than the CURB-65 score. Adding risk scores from the DL model to the CURB-65 score could improve the prediction performance.

CLINICAL RELEVANCE/APPLICATION

Evaluation of CXRs of patients with CAP using the DL model for mortality prediction may help improve risk stratification and clinical decision-making for hospitalization or intensive care.

M2-SPIR

Interventional Monday Poster Discussions

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IR DPS

Sub-Events

M2-SPIR-1 Strategy of Target Biopsy and Number of Target Cores for a PI-RADS 3-5 Index Lesion to Reduce Gleason Score Underestimation: A Propensity Score Matching Analysis

Participants
Byung Kwan Park, MD, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

To determine the number of target cores and targeting strategy to reduce GS underestimation.

METHODS AND MATERIALS

Between May 2017 and April 2020, a total of 385 patients undergoing target cognitive or image fusion biopsy of PI-RADS 3-5 index lesions and radical prostatectomies (RP) were 2:1 matched with propensity score using multiple variables and divided into the 1-4 core (n = 242) and 5-6 core (n = 143) groups, which were obtained with multiple logistic regression with restricted cubic spline curve. Target cores of 1-3 and 4-6 were sampled from central and peripheral areas, respectively. Pathologic outcomes and target cores were retrospectively assessed to analyze the GS difference or changes between biopsy and RP with Wilcoxon signed-rank test.

RESULTS

The median of target cores was 3 and 6 in the 1-4 core and 5-6 core groups, respectively ($p < 0.001$). Restricted cubic spline curve showed that GS upgrade was significantly reduced from the 5th core and there was no difference between 5th and 6th cores. Among the matched patients, 35.4% (136/385; 95% confidence interval, 0.305-0.403) had a GS upgrade after RP. The GS upgrades in the 1-4 core and 5-6 core groups were observed in 40.6% (98/242, 0.343-0.470) and 26.6% (38/143, 0.195-0.346), respectively ($p = 0.023$). Although there was no statistical difference between the matched groups in terms of RP GS ($p = 0.092$), the 5-6 core group had significantly higher biopsy GS ($p = 0.006$) and lower GS change from biopsy to RP ($p = 0.027$).

CONCLUSION

s Five or more target cores sampling from both periphery and center of an index tumor contribute to reduce GS upgrade.

CLINICAL RELEVANCE/APPLICATION

1. Five or more cores reduces underestimation of Gleason score compared to four or less in targeting an index lesion of PI-RADS 3-5. [D1] 2. Sampling the periphery as well as the center of an index lesion may reduce underestimation of Gleason grade.[D2]

M2-SPIR-2 Renal Mass Biopsy: Evaluating Post-Biopsy Complications to Determine Optimal Observation Time

Participants
Sebastien Robert, MD, (*Presenter*) Nothing to Disclose

PURPOSE

This study evaluates post renal mass biopsy (RMB) complications to determine the minimum recovery time for safe discharge.

METHODS AND MATERIALS

An approved multi-site retrospective study of 571 patients who underwent percutaneous US or CT guided RMB between January 1, 2008 and June 1, 2020 was performed. Post-RMB clinical course was evaluated for all patients to identify the frequency and timing of all bleeding and non-bleeding related acute (<24 hours) or delayed (<30 days) complications. The timing of bleeding complications was established by first clinical deviation from standard recovery, defined as unplanned imaging, bloodwork, or analgesia. Complications were graded using the SIR Adverse Event Classification system.

RESULTS

613 RMB procedures were performed by 22 different radiologists (mean tumor diameter 4.3±3.2 cm, RENAL nephrometry 7.6±2.0). Diagnostic yield was 88% (65% renal cell carcinoma). Acute post-RMB complications occurred in 3.4% (21/613) of cases of which 76% (16/21) were bleeding related. Delayed bleeding complications were reported in 0.5% (3/613) of cases. Of all reported complications, two (0.3%) were deemed severe or life-threatening. Post-RMB interventions included: 3 embolization, 2 patients receiving blood transfusion, and 11 admissions to hospital (median 1 night). No patient deaths were reported. The mean time to clinical deviation from the expected post-RMB course was 59 minutes (range 13-135 minutes) in the acute bleeding complication cohort. Initial deviation occurred within 3 hours in all acute bleeding cases. The remaining delayed post-RMB bleeding cases all presented multiple days following discharge. Pre-RMB platelet counts and endophytic tumor location were independent predictors of bleeding complication (p=<0.05). No recorded patient characteristics including age, gender, or prior anticoagulation use were

associated with a significant increase in post-RMB bleeding complications. Kidney characteristics, tumor morphology, and radiologist experience also did not show any association.

CONCLUSION

s Post-RMB complications are uncommon and usually present acutely. All acute bleeding complications occurred within a 3-hour post-procedure window, suggesting that this time frame may be sufficient for safe patient discharge.

CLINICAL RELEVANCE/APPLICATION

Short recovery times (2-3 hours) following renal mass biopsy (RMB) might allow for procedural cost efficiency by using a single recovery bed for two sequential RMB procedures.

M2-SPIR-3 American Society of Anesthesiologists Physical Status Classification as a Predictor of Random Native Kidney Biopsy Complications in Hospitalized Patients

Participants
Anisha Mittal, BA, (*Presenter*) Nothing to Disclose

PURPOSE

The American Society of Anesthesiology (ASA) physical status classification system is designed to assess a patient's pre-anesthesia physiological status which can be helpful in predicting perioperative risk. We compared the complication rates and types of complications of random native renal biopsies among hospitalized patients with a low ASA classification (best physiological status) vs. a high ASA classification (worse physiological status) to predict perioperative risk of a radiological procedure for which the ASA classification is not commonly used.

METHODS AND MATERIALS

We conducted a retrospective chart review of 105 consecutive inpatient random native kidney biopsies performed by radiologists between 2006 and 2020 at an academic medical center. Variables included the number and types of perioperative complications per patient. Patients' ASA physical status classification levels were calculated according to the guidelines provided by the ASA based on clinical factors and comorbidities. Hospitalized patients with a low ASA classification (class 1-2) were compared to those with a high ASA classification (class 3-4) for complication rate and types of complications using the Society of Interventional Radiology's Adverse Event Classification system.

RESULTS

105 hospitalized adult patients (58 females and 47 males; average age 53 years) underwent random native kidney biopsy during the study period. 53 (50.5%) were in ASA class 1-2 and 52 (49.5%) in ASA class 3-4. No patients in our study were in ASA class 5 or 6. Overall complication rates between ASA class 1-2 patients and ASA class 3-4 patients were 10/53 (19%) vs. 23/52 (44%), respectively (p = .006). ASA class 1-2 patients had 4 major and 6 minor complications, and ASA class 3-4 patients had 17 major and 6 minor complications.

CONCLUSION

s High ASA physical status classifications were associated with a higher overall complication rate for random native kidney biopsies as compared to low ASA classifications. While the ASA classification is not commonly used for radiological procedures such as a random native kidney biopsy, this study provides evidence that the ASA classification may be used in conjunction with other clinical factors to help predict the perioperative complication risk of random native kidney biopsy in hospitalized patients.

CLINICAL RELEVANCE/APPLICATION

A greater utilization of the ASA classification by radiologists may help reduce the perioperative risk of random native kidney biopsy in hospitalized patients.

M2-SPIR-4 Catheter Tract Seeding in Indwelling Pleural Catheter Placement for the Drainage of Malignant Pleural Effusions: Incidence and Related Clinical and Imaging Factors

Participants
Yoojin Nam, MD, Changwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the incidence of IPC-related cancer tract seeding and seek for related demographic, clinical or imaging factors to the tract seeding.

METHODS AND MATERIALS

This was a retrospective study regarding 124 consecutive patients seen between January 2011 and December 2021 who underwent IPC placement for the drainage of malignant pleural effusion. Chest radiographs before IPC placement and serial chest CT studies were obtained in all patients. The incidence of IPC-related cancer tract seeding, and related factors were assessed by reviewing medical records.

RESULTS

The incidence of IPC tract seeding was 21.7% (27 of 124 malignant effusions). Of 27 patients with seeding, 15 had primary lung cancer and remaining 12 had extra-thoracic malignancy. Adenocarcinoma (19 of 27, 70.3%) either from the lung (n = 12) or extra-thoracic malignancy (n = 7) was the most common cell type. Mean time elapsed until tract seeding occurrence after IPC placement was 94 days (ranges; 26-300 days). The survival in seeding group after IPC placement was 123 days (ranges, 16-457 days). On odd ratio analysis, the presence of mediastinal pleural thickening (OR [95% CI]; 9.79 (2.67-35.84), P = 0.001) was significantly related to the presence of tract seeding. Neither, tumor volume in pleural space (P = 0.168), duration of IPC indwelling (P = 0.142), days of survival after IPC placement (P = 0.699), nor pleural effusion amount (P = 0.481) was related to the cancer tract seeding.

CONCLUSION

s IPC tract seeding is seen in 27 (21.7%) of 124 malignant pleural effusion patients, particularly with adenocarcinoma cytology. CT

features of mediastinal pleural thickening prior to IPC insertion are related to the occurrence of tract seeding.

CLINICAL RELEVANCE/APPLICATION

Detailed analysis of CT findings of malignant pleural effusion may help predict oncoming tract seeding after IPC placement for malignant pleural effusion evacuation. When tract seeding is expected with the analyses of CT findings, prophylactic radiation therapy immediately after the placement of the catheter or thoracentesis (reducing intrapleural pressure) before IPC placement may be considered as the way of reducing tract seeding occurrence.

M2-SPIR-5 Multiparametric Bone MRI Targeting Improves CT-guided Sclerotic Bone Biopsy Success in Metastatic Castrate Resistant Prostate Cancer: A Prospective Evaluation

Participants
Ricardo Donners, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to prospectively validate a multiparametric bone MRI (mpBMRI) target lesion selection algorithm to improve CT-guided sclerotic bone biopsy success in metastatic castrate-resistant prostate cancer (mCRPC) patients with sclerotic bone disease mCRPC.

METHODS AND MATERIALS

20 CT-guided bone biopsies were performed by interventional radiologists in 17 mCRPC patients with only sclerotic bone disease. Biopsy targets were selected based on mpBMRI, including diffusion-weighted (DWI) and diagnostic, T1-weighted gradient-echo Dixon images, allowing for calculation of apparent diffusion coefficient (ADC) and relative fat-fraction percentages (rFF%), respectively. Bone marrow with high DWI signal, ADC <1100 µm2/s and rFF <20% was the preferred biopsy target. Biopsy tumour content and next-generation genomic sequencing (NGS)-feasibility was assessed by a pathologist. Prognostic values of routine laboratory blood parameters, tumour marker levels, target lesion size, biopsy tract length, visual CT density (mild or dense sclerosis), means of HU, ADC and rFF% to distinguish between successful and unsuccessful biopsies were tested for statistical significance ($p < 0.05$ = significant).

RESULTS

17/20 (85%) biopsies were tumour-positive and NGS was feasible in 13/18 (72%). Neither laboratory parameters, target diameter, tract length nor visual CT density grading showed significant differences between a positive versus negative or NGS feasible versus non-feasible biopsy result (each $p > 0.137$). Lesion mean HU was 387±187 HU in NGS feasible and 493±218 HU in non-feasible biopsies ($p = 0.521$). 13/14 (93%) biopsies in targets fulfilling mpBMRI selection algorithm criteria were tumour-positive and 10/12 (83%) provided sufficient material for NGS. In six biopsies mean rFF% was >20% (range 21 - 25%). 4/6 (60%) biopsies were tumour-positive and NGS was feasible in 3/6 (50%).

CONCLUSION

s MpBMRI can facilitate CT-guided bone biopsy target selection in mCPRC patients with sclerotic metastases and improves diagnostic yield and NGS feasibility.

CLINICAL RELEVANCE/APPLICATION

Obtaining high quality tumour tissue samples for NGS can be challenging in mCRPC patients with sclerotic bone disease. Improving bone biopsy success rates by using multiparametric bone MRI to identify active bone metastases allows this patient cohort to benefit from personalised oncology therapy based on individual tumor genomics.

M2-SPIR-6 Risk Reduction Protocol for Mitigating Bleeding Complications after an Image—Guided Kidney Biopsy

Participants
Ali Kord, MD, MPH, Cincinnati, OH (*Presenter*) Nothing to Disclose

PURPOSE

There are Society of Interventional Radiology (SIR) guidelines to correct peri-procedural variables that can affect bleeding complications after kidney biopsy, yet bleedings are seen after kidney biopsies. This study is designed to assess the variables affecting bleeding complications in patients who underwent an image-guided kidney biopsy with controlled peri-procedural clinical variables.

METHODS AND MATERIALS

A total of 200 consecutive patients (100 native, 100 transplant, Mean age: 52 ± 17 years) underwent an image-guided kidney biopsy. All biopsies were performed using a 17-gauge coaxial access needle and an 18-gauge biopsy needle. Hemoglobin (HGB), Platelet (PLT), international normalized ratio (INR), and systolic and diastolic blood pressure (SBP, DBP) were checked and corrected based on the SIR guidelines, if needed (Table.1). Gelfoam was used in some cases to embolize the biopsy path. Post-procedure bleeding complications were categorized using SIR adverse event classification. The peri-procedural variables were compared between patients without and with bleeding after kidney biopsy using univariate and multivariate analysis. Statistical significance was considered at 0.05.

RESULTS

Technical success was 99%. Minor and major bleedings were observed in 4.5% and 3.0% of the patients, respectively. As expected, bleeding complications were seen more often after native kidney biopsies compared to the transplant kidneys ($p < 0.001$). Patients with bleeding were more likely to need CT for kidney biopsy ($p = 0.02$). Gelfoam embolization of the biopsy path was not associated with reduced bleeding after kidney biopsy ($p = 0.8$). The mean SBPs and DBPs were higher in patients with bleeding than in patients without bleeding ($p < 0.05$, Table.1). In multi-variate analysis, pre- and post-biopsy SBP and DBP remained significantly different between native kidneys with and without bleeding (Fig.1, $p < 0.04$).

CONCLUSION

s Higher peri-procedural blood pressures are associated with increased bleeding after an image-guided kidney biopsy. A stricter blood pressure control should be considered both before and after kidney biopsy as part of the procedural protocol.

CLINICAL RELEVANCE/APPLICATION

A stricter blood pressure control should be part of the procedural protocol for native kidney biopsy.

M2-SPIR-7 Air Embolism in CT-Guided Transthoracic Needle Biopsy and Localization: Emphasis on Pulmonary Vein Injury

Participants
Yura Ahn, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To assess whether pulmonary vein injury is detectable on CT and associated with air embolism after percutaneous transthoracic needle biopsy (PTNB) and wire localization in a tertiary referral hospital.

METHODS AND MATERIALS

Between January 2012 and November 2021, 11905 consecutive CT-guided PTNBs and 1553 wire localizations in 12042 patients were retrospectively evaluated. Air embolism was identified by reviewing radiologic reports. Pulmonary vein injury was defined as the presence of the pulmonary vein in the needle pathway or shooting range of the cutting needle with presence of parenchymal hemorrhage. The association between pulmonary vein injury and air embolism was assessed using logistic regression analysis in matched patients with and without air embolism with a ratio of 1:4.

RESULTS

A total of 30 cases of air embolism (median age, 67 years; range, 48-80 years; 25 men) was found with an incidence of 0.22% (30/13458). Pulmonary vein injury during the procedures was identifiable on CT in 26 of 30 patients (86.7%) whereas it was 1.7% (2/120) for matched patients without air embolism The veins beyond the target lesion (65.3% [17/26]) were injured more frequently than the veins in the needle pathway before the target lesion (34.6% [9/26]). In univariable and multivariable analyses, pulmonary vein injury was associated with air embolism (odds ratio, 86.92; 95% confidence interval, 21.71->999.99, p <.001).

CONCLUSION

s Pulmonary vein injury was actually detected on CT and was associated with air embolism.

CLINICAL RELEVANCE/APPLICATION

Avoiding pulmonary vein injury with careful planning of the needle pathway on CT may reduce air embolism risk.

M2-SPIR-8 The Effect of Music on Patients Anxiety in CT-guided Percutaneous Interventions: A Prospective Randomized Controlled Trial

Participants
Florian Fleckenstein, MS, (*Presenter*) Nothing to Disclose

PURPOSE

CT-guided percutaneous interventions oftentimes cause patients to experience a high level of stress and anxiety before the operation. As a proven medium to lessen anxiety and pain in the peri-operational setting, music could potentially serve as relief. The aim of this study is to contribute to further understanding the effect of music on anxiety and pain compared to basic operational procedures.

METHODS AND MATERIALS

A total of 178 patients were included in this randomized controlled trial. The participants were randomized in a music group (MG) and a control group (CG). Items of anxiety were analysed by using the STAI-6 pre- and post-intervention, while a numeric rating scale with faces served to rate the level of pain after the procedure. Post-interventional state anxiety levels and the reduction of anxiety were set as primary outcomes, whereas the level of pain experienced during the procedure was chosen as a secondary outcome.

RESULTS

176 patients were eligible for statistical analysis. N=91 patients underwent the procedure in the MG, compared to n=85 participants in the CG. Median post-interventional item values in the MG ranked more towards lower levels of anxiety than the same item values of the CG ($p<0.001$). The reduction of anxiety between pre- and post-procedural states was stronger in the MG, but also detectable in the CG ($p<0.001$). Of note, the level of experienced post-procedural pain was significantly lower in the MG ($p<0.001$).

CONCLUSION

s This study could show, that exposure to music during CT-guided percutaneous procedures can aid in lowering peri-interventional anxiety and pain thus improves patient care without any negative side-effects.

CLINICAL RELEVANCE/APPLICATION

Music can act as a safe, easily applicable, free of charge and non-invasive aid to reduce anxiety in the peri-interventional setting to improve quality of care. Apart from statistical significances, we believe our findings are of high clinical relevance beyond the field of IR.

M2-SPIR-9 Safety of Image-guided Splenic Biopsy: Retrospective Outcomes Analysis From Eight Academic Institutions

Participants
Hadiseh Kavandi, MD, Boston, MA (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the safety of image-guided targeted and non-targeted splenic biopsy as performed in eight US academic institutions.

METHODS AND MATERIALS

This retrospective IRB-approved, HIPAA-compliant, multi-institutional study included consecutive patients that underwent ultrasound or CT-guided splenic biopsy between 3/1/2001 and 3/31/2022. Significant bleeding after the procedure was defined by the presence of bleeding on CT performed within 30 days or angiography and/or surgery performed to manage the bleeding.

RESULTS

384 splenic biopsies, ultrasound (97/384, 25%) and CT-guided (287, 75%), on 372 patients from 8 academic institutions were included (age 59±17 years, 183 (48%) female, 337 (88%) targeted, 184 (48%) co-axial, 312 (81%) core biopsy, median of 3 samples). Bleeding occurred following 31/384 (8%) biopsies, treated angiographically in 4/384 (1%) cases and surgically in 3/384 (1%) cases; one of the surgical cases had IR intervention before surgery. 8/384 (2%) patients received RBC transfusion. 4/384 (1%) patients readmitted (3 (1%) for bleeding, 1 (0.5%) for sepsis) and 8/384 (2%) had ED visits for pain management. There were no deaths related to the biopsy. Bleeding risk was inversely associated with lesion size, with a median size of 2.1 cm in patients who bled vs. 3.6 cm in patients who did not, p=0.03. In patients with a history of lymphoma or leukemia, there was a lower incidence of bleeding 3/92 (3%) vs. 28/292 (10%), p=0.05. There was no association of bleeding with patient's gender, age, history of anticoagulation, modality of guidance, targeted vs. non-targeted, coaxial vs non-coaxial technique, number of samples, the gauge of core biopsy, or core vs. FNA; lesion location, CT attenuation, US echogenicity, vascularity, all p>0.05. Incidence of bleeding was higher in patients with tract embolization (10/59, 17% vs. 18/301, 6%), as tract embolization was likely performed to treat the bleeding.

CONCLUSION

s Bleeding after splenic biopsy occurred after 8% of procedures, with 2% requiring medical, 1% angiographic, and 1% surgical management. Smaller lesions and patients with no hematological history had a higher incidence of bleeding.

CLINICAL RELEVANCE/APPLICATION

The image-guided splenic biopsy is safe with a small number of patients requiring treatment for clinically significant post-procedure bleeding.

Strategy of Target Biopsy and Number of Target Cores for a PI-RADS 3-5 Index Lesion to Reduce Gleason Score Underestimation: A Propensity Score Matching Analysis

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Byung Kwan Park, MD, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

To determine the number of target cores and targeting strategy to reduce GS underestimation.

METHODS AND MATERIALS

Between May 2017 and April 2020, a total of 385 patients undergoing target cognitive or image fusion biopsy of PI-RADS 3-5 index lesions and radical prostatectomies (RP) were 2:1 matched with propensity score using multiple variables and divided into the 1-4 core (n = 242) and 5-6 core (n = 143) groups, which were obtained with multiple logistic regression with restricted cubic spline curve. Target cores of 1-3 and 4-6 were sampled from central and peripheral areas, respectively. Pathologic outcomes and target cores were retrospectively assessed to analyze the GS difference or changes between biopsy and RP with Wilcoxon signed-rank test.

RESULTS

The median of target cores was 3 and 6 in the 1-4 core and 5-6 core groups, respectively ($p < 0.001$). Restricted cubic spline curve showed that GS upgrade was significantly reduced from the 5th core and there was no difference between 5th and 6th cores. Among the matched patients, 35.4% (136/385; 95% confidence interval, 0.305-0.403) had a GS upgrade after RP. The GS upgrades in the 1-4 core and 5-6 core groups were observed in 40.6% (98/242, 0.343-0.470) and 26.6% (38/143, 0.195-0.346), respectively ($p = 0.023$). Although there was no statistical difference between the matched groups in terms of RP GS ($p = 0.092$), the 5-6 core group had significantly higher biopsy GS ($p = 0.006$) and lower GS change from biopsy to RP ($p = 0.027$).

CONCLUSION

s Five or more target cores sampling from both periphery and center of an index tumor contribute to reduce GS upgrade.

CLINICAL RELEVANCE/APPLICATION

1. Five or more cores reduces underestimation of Gleason score compared to four or less in targeting an index lesion of PI-RADS 3-5. [D1] 2. Sampling the periphery as well as the center of an index lesion may reduce underestimation of Gleason grade.[D2]

Renal Mass Biopsy: Evaluating Post-Biopsy Complications to Determine Optimal Observation Time

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Sebastien Robert, MD, (*Presenter*) Nothing to Disclose

PURPOSE

This study evaluates post renal mass biopsy (RMB) complications to determine the minimum recovery time for safe discharge.

METHODS AND MATERIALS

An approved multi-site retrospective study of 571 patients who underwent percutaneous US or CT guided RMB between January 1, 2008 and June 1, 2020 was performed. Post-RMB clinical course was evaluated for all patients to identify the frequency and timing of all bleeding and non-bleeding related acute (<24 hours) or delayed (<30 days) complications. The timing of bleeding complications was established by first clinical deviation from standard recovery, defined as unplanned imaging, bloodwork, or analgesia. Complications were graded using the SIR Adverse Event Classification system.

RESULTS

613 RMB procedures were performed by 22 different radiologists (mean tumor diameter 4.3±3.2 cm, RENAL nephrometry 7.6±2.0). Diagnostic yield was 88% (65% renal cell carcinoma). Acute post-RMB complications occurred in 3.4% (21/613) of cases of which 76% (16/21) were bleeding related. Delayed bleeding complications were reported in 0.5% (3/613) of cases. Of all reported complications, two (0.3%) were deemed severe or life-threatening. Post-RMB interventions included: 3 embolization, 2 patients receiving blood transfusion, and 11 admissions to hospital (median 1 night). No patient deaths were reported. The mean time to clinical deviation from the expected post-RMB course was 59 minutes (range 13-135 minutes) in the acute bleeding complication cohort. Initial deviation occurred within 3 hours in all acute bleeding cases. The remaining delayed post-RMB bleeding cases all presented multiple days following discharge. Pre-RMB platelet counts and endophytic tumor location were independent predictors of bleeding complication (p=<0.05). No recorded patient characteristics including age, gender, or prior anticoagulation use were associated with a significant increase in post-RMB bleeding complications. Kidney characteristics, tumor morphology, and radiologist experience also did not show any association.

CONCLUSION

s Post-RMB complications are uncommon and usually present acutely. All acute bleeding complications occurred within a 3-hour post-procedure window, suggesting that this time frame may be sufficient for safe patient discharge.

CLINICAL RELEVANCE/APPLICATION

Short recovery times (2-3 hours) following renal mass biopsy (RMB) might allow for procedural cost efficiency by using a single recovery bed for two sequential RMB procedures.

American Society of Anesthesiologists Physical Status Classification as a Predictor of Random Native Kidney Biopsy Complications in Hospitalized Patients

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Anisha Mittal, BA, (*Presenter*) Nothing to Disclose

PURPOSE

The American Society of Anesthesiology (ASA) physical status classification system is designed to assess a patient's pre-anesthesia physiological status which can be helpful in predicting perioperative risk. We compared the complication rates and types of complications of random native renal biopsies among hospitalized patients with a low ASA classification (best physiological status) vs. a high ASA classification (worse physiological status) to predict perioperative risk of a radiological procedure for which the ASA classification is not commonly used.

METHODS AND MATERIALS

We conducted a retrospective chart review of 105 consecutive inpatient random native kidney biopsies performed by radiologists between 2006 and 2020 at an academic medical center. Variables included the number and types of perioperative complications per patient. Patients' ASA physical status classification levels were calculated according to the guidelines provided by the ASA based on clinical factors and comorbidities. Hospitalized patients with a low ASA classification (class 1-2) were compared to those with a high ASA classification (class 3-4) for complication rate and types of complications using the Society of Interventional Radiology's Adverse Event Classification system.

RESULTS

105 hospitalized adult patients (58 females and 47 males; average age 53 years) underwent random native kidney biopsy during the study period. 53 (50.5%) were in ASA class 1-2 and 52 (49.5%) in ASA class 3-4. No patients in our study were in ASA class 5 or 6. Overall complication rates between ASA class 1-2 patients and ASA class 3-4 patients were 10/53 (19%) vs. 23/52 (44%), respectively (p = .006). ASA class 1-2 patients had 4 major and 6 minor complications, and ASA class 3-4 patients had 17 major and 6 minor complications.

CONCLUSION

s High ASA physical status classifications were associated with a higher overall complication rate for random native kidney biopsies as compared to low ASA classifications. While the ASA classification is not commonly used for radiological procedures such as a random native kidney biopsy, this study provides evidence that the ASA classification may be used in conjunction with other clinical factors to help predict the perioperative complication risk of random native kidney biopsy in hospitalized patients.

CLINICAL RELEVANCE/APPLICATION

A greater utilization of the ASA classification by radiologists may help reduce the perioperative risk of random native kidney biopsy in hospitalized patients.

Catheter Tract Seeding in Indwelling Pleural Catheter Placement for the Drainage of Malignant Pleural Effusions: Incidence and Related Clinical and Imaging Factors

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Yoojin Nam, MD, Changwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the incidence of IPC-related cancer tract seeding and seek for related demographic, clinical or imaging factors to the tract seeding.

METHODS AND MATERIALS

This was a retrospective study regarding 124 consecutive patients seen between January 2011 and December 2021 who underwent IPC placement for the drainage of malignant pleural effusion. Chest radiographs before IPC placement and serial chest CT studies were obtained in all patients. The incidence of IPC-related cancer tract seeding, and related factors were assessed by reviewing medical records.

RESULTS

The incidence of IPC tract seeding was 21.7% (27 of 124 malignant effusions). Of 27 patients with seeding, 15 had primary lung cancer and remaining 12 had extra-thoracic malignancy. Adenocarcinoma (19 of 27, 70.3%) either from the lung (n = 12) or extra-thoracic malignancy (n = 7) was the most common cell type. Mean time elapsed until tract seeding occurrence after IPC placement was 94 days (ranges; 26-300 days). The survival in seeding group after IPC placement was 123 days (ranges, 16-457 days). On odd ratio analysis, the presence of mediastinal pleural thickening (OR [95% CI]; 9.79 (2.67-35.84), P = 0.001) was significantly related to the presence of tract seeding. Neither, tumor volume in pleural space (P = 0.168), duration of IPC indwelling (P = 0.142), days of survival after IPC placement (P = 0.699), nor pleural effusion amount (P = 0.481) was related to the cancer tract seeding.

CONCLUSION

s IPC tract seeding is seen in 27 (21.7%) of 124 malignant pleural effusion patients, particularly with adenocarcinoma cytology. CT features of mediastinal pleural thickening prior to IPC insertion are related to the occurrence of tract seeding.

CLINICAL RELEVANCE/APPLICATION

Detailed analysis of CT findings of malignant pleural effusion may help predict oncoming tract seeding after IPC placement for malignant pleural effusion evacuation. When tract seeding is expected with the analyses of CT findings, prophylactic radiation therapy immediately after the placement of the catheter or thoracentesis (reducing intrapleural pressure) before IPC placement may be considered as the way of reducing tract seeding occurrence.

Multiparametric Bone MRI Targeting Improves CT-guided Sclerotic Bone Biopsy Success in Metastatic Castrate Resistant Prostate Cancer: A Prospective Evaluation

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Ricardo Donners, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to prospectively validate a multiparametric bone MRI (mpBMRI) target lesion selection algorithm to improve CT-guided sclerotic bone biopsy success in metastatic castrate-resistant prostate cancer (mCRPC) patients with sclerotic bone disease mCRPC.

METHODS AND MATERIALS

20 CT-guided bone biopsies were performed by interventional radiologists in 17 mCRPC patients with only sclerotic bone disease. Biopsy targets were selected based on mpBMRI, including diffusion-weighted (DWI) and diagnostic, T1-weighted gradient-echo Dixon images, allowing for calculation of apparent diffusion coefficient (ADC) and relative fat-fraction percentages (rFF%), respectively. Bone marrow with high DWI signal, ADC <1100 µm2/s and rFF <20% was the preferred biopsy target. Biopsy tumour content and next-generation genomic sequencing (NGS)-feasibility was assessed by a pathologist. Prognostic values of routine laboratory blood parameters, tumour marker levels, target lesion size, biopsy tract length, visual CT density (mild or dense sclerosis), means of HU, ADC and rFF% to distinguish between successful and unsuccessful biopsies were tested for statistical significance ($p < 0.05$ = significant).

RESULTS

17/20 (85%) biopsies were tumour-positive and NGS was feasible in 13/18 (72%). Neither laboratory parameters, target diameter, tract length nor visual CT density grading showed significant differences between a positive versus negative or NGS feasible versus non-feasible biopsy result (each $p > 0.137$). Lesion mean HU was 387±187 HU in NGS feasible and 493±218 HU in non-feasible biopsies ($p = 0.521$). 13/14 (93%) biopsies in targets fulfilling mpBMRI selection algorithm criteria were tumour-positive and 10/12 (83%) provided sufficient material for NGS. In six biopsies mean rFF% was >20% (range 21 - 25%). 4/6 (60%) biopsies were tumour-positive and NGS was feasible in 3/6 (50%).

CONCLUSION

s MpBMRI can facilitate CT-guided bone biopsy target selection in mCPRC patients with sclerotic metastases and improves diagnostic yield and NGS feasibility.

CLINICAL RELEVANCE/APPLICATION

Obtaining high quality tumour tissue samples for NGS can be challenging in mCRPC patients with sclerotic bone disease. Improving bone biopsy success rates by using multiparametric bone MRI to identify active bone metastases allows this patient cohort to benefit from personalised oncology therapy based on individual tumor genomics.

Risk Reduction Protocol for Mitigating Bleeding Complications after an Image—Guided Kidney Biopsy

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Ali Kord, MD, MPH, Cincinnati, OH (*Presenter*) Nothing to Disclose

PURPOSE

There are Society of Interventional Radiology (SIR) guidelines to correct peri-procedural variables that can affect bleeding complications after kidney biopsy, yet bleedings are seen after kidney biopsies. This study is designed to assess the variables affecting bleeding complications in patients who underwent an image-guided kidney biopsy with controlled peri-procedural clinical variables.

METHODS AND MATERIALS

A total of 200 consecutive patients (100 native, 100 transplant, Mean age: 52 ± 17 years) underwent an image-guided kidney biopsy. All biopsies were performed using a 17-gauge coaxial access needle and an 18-gauge biopsy needle. Hemoglobin (HGB), Platelet (PLT), international normalized ratio (INR), and systolic and diastolic blood pressure (SBP, DBP) were checked and corrected based on the SIR guidelines, if needed (Table.1). Gelfoam was used in some cases to embolize the biopsy path. Post-procedure bleeding complications were categorized using SIR adverse event classification. The peri-procedural variables were compared between patients without and with bleeding after kidney biopsy using univariate and multivariate analysis. Statistical significance was considered at 0.05.

RESULTS

Technical success was 99%. Minor and major bleedings were observed in 4.5% and 3.0% of the patients, respectively. As expected, bleeding complications were seen more often after native kidney biopsies compared to the transplant kidneys ($p < 0.001$). Patients with bleeding were more likely to need CT for kidney biopsy ($p = 0.02$). Gelfoam embolization of the biopsy path was not associated with reduced bleeding after kidney biopsy ($p = 0.8$). The mean SBPs and DBPs were higher in patients with bleeding than in patients without bleeding ($p < 0.05$, Table.1). In multi-variate analysis, pre- and post-biopsy SBP and DBP remained significantly different between native kidneys with and without bleeding (Fig.1, $p < 0.04$).

CONCLUSION

s Higher peri-procedural blood pressures are associated with increased bleeding after an image-guided kidney biopsy. A stricter blood pressure control should be considered both before and after kidney biopsy as part of the procedural protocol.

CLINICAL RELEVANCE/APPLICATION

A stricter blood pressure control should be part of the procedural protocol for native kidney biopsy.

Air Embolism in CT-Guided Transthoracic Needle Biopsy and Localization: Emphasis on Pulmonary Vein Injury

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Yura Ahn, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To assess whether pulmonary vein injury is detectable on CT and associated with air embolism after percutaneous transthoracic needle biopsy (PTNB) and wire localization in a tertiary referral hospital.

METHODS AND MATERIALS

Between January 2012 and November 2021, 11905 consecutive CT-guided PTNBs and 1553 wire localizations in 12042 patients were retrospectively evaluated. Air embolism was identified by reviewing radiologic reports. Pulmonary vein injury was defined as the presence of the pulmonary vein in the needle pathway or shooting range of the cutting needle with presence of parenchymal hemorrhage. The association between pulmonary vein injury and air embolism was assessed using logistic regression analysis in matched patients with and without air embolism with a ratio of 1:4.

RESULTS

A total of 30 cases of air embolism (median age, 67 years; range, 48-80 years; 25 men) was found with an incidence of 0.22% (30/13458). Pulmonary vein injury during the procedures was identifiable on CT in 26 of 30 patients (86.7%) whereas it was 1.7% (2/120) for matched patients without air embolism The veins beyond the target lesion (65.3% [17/26]) were injured more frequently than the veins in the needle pathway before the target lesion (34.6% [9/26]). In univariable and multivariable analyses, pulmonary vein injury was associated with air embolism (odds ratio, 86.92; 95% confidence interval, 21.71->999.99, p <.001).

CONCLUSION

s Pulmonary vein injury was actually detected on CT and was associated with air embolism.

CLINICAL RELEVANCE/APPLICATION

Avoiding pulmonary vein injury with careful planning of the needle pathway on CT may reduce air embolism risk.

The Effect of Music on Patients Anxiety in CT-guided Percutaneous Interventions: A Prospective Randomized Controlled Trial

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Florian Fleckenstein, MS, (*Presenter*) Nothing to Disclose

PURPOSE

CT-guided percutaneous interventions oftentimes cause patients to experience a high level of stress and anxiety before the operation. As a proven medium to lessen anxiety and pain in the peri-operational setting, music could potentially serve as relief. The aim of this study is to contribute to further understanding the effect of music on anxiety and pain compared to basic operational procedures.

METHODS AND MATERIALS

A total of 178 patients were included in this randomized controlled trial. The participants were randomized in a music group (MG) and a control group (CG). Items of anxiety were analysed by using the STAI-6 pre- and post-intervention, while a numeric rating scale with faces served to rate the level of pain after the procedure. Post-interventional state anxiety levels and the reduction of anxiety were set as primary outcomes, whereas the level of pain experienced during the procedure was chosen as a secondary outcome.

RESULTS

176 patients were eligible for statistical analysis. N=91 patients underwent the procedure in the MG, compared to n=85 participants in the CG. Median post-interventional item values in the MG ranked more towards lower levels of anxiety than the same item values of the CG ($p<0.001$). The reduction of anxiety between pre- and post-procedural states was stronger in the MG, but also detectable in the CG ($p<0.001$). Of note, the level of experienced post-procedural pain was significantly lower in the MG ($p<0.001$).

CONCLUSION

s This study could show, that exposure to music during CT-guided percutaneous procedures can aid in lowering peri-interventional anxiety and pain thus improves patient care without any negative side-effects.

CLINICAL RELEVANCE/APPLICATION

Music can act as a safe, easily applicable, free of charge and non-invasive aid to reduce anxiety in the peri-interventional setting to improve quality of care. Apart from statistical significances, we believe our findings are of high clinical relevance beyond the field of IR.

Safety of Image-guided Splenic Biopsy: Retrospective Outcomes Analysis From Eight Academic Institutions

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Hadiseh Kavandi, MD, Boston, MA (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the safety of image-guided targeted and non-targeted splenic biopsy as performed in eight US academic institutions.

METHODS AND MATERIALS

This retrospective IRB-approved, HIPAA-compliant, multi-institutional study included consecutive patients that underwent ultrasound or CT-guided splenic biopsy between 3/1/2001 and 3/31/2022. Significant bleeding after the procedure was defined by the presence of bleeding on CT performed within 30 days or angiography and/or surgery performed to manage the bleeding.

RESULTS

384 splenic biopsies, ultrasound (97/384, 25%) and CT-guided (287, 75%), on 372 patients from 8 academic institutions were included (age 59±17 years, 183 (48%) female, 337 (88%) targeted, 184 (48%) co-axial, 312 (81%) core biopsy, median of 3 samples). Bleeding occurred following 31/384 (8%) biopsies, treated angiographically in 4/384 (1%) cases and surgically in 3/384 (1%) cases; one of the surgical cases had IR intervention before surgery. 8/384 (2%) patients received RBC transfusion. 4/384 (1%) patients readmitted (3 (1%) for bleeding, 1 (0.5%) for sepsis) and 8/384 (2%) had ED visits for pain management. There were no deaths related to the biopsy. Bleeding risk was inversely associated with lesion size, with a median size of 2.1 cm in patients who bled vs. 3.6 cm in patients who did not, p=0.03. In patients with a history of lymphoma or leukemia, there was a lower incidence of bleeding 3/92 (3%) vs. 28/292 (10%), p=0.05. There was no association of bleeding with patient's gender, age, history of anticoagulation, modality of guidance, targeted vs. non-targeted, coaxial vs non-coaxial technique, number of samples, the gauge of core biopsy, or core vs. FNA; lesion location, CT attenuation, US echogenicity, vascularity, all p>0.05. Incidence of bleeding was higher in patients with tract embolization (10/59, 17% vs. 18/301, 6%), as tract embolization was likely performed to treat the bleeding.

CONCLUSION

s Bleeding after splenic biopsy occurred after 8% of procedures, with 2% requiring medical, 1% angiographic, and 1% surgical management. Smaller lesions and patients with no hematological history had a higher incidence of bleeding.

CLINICAL RELEVANCE/APPLICATION

The image-guided splenic biopsy is safe with a small number of patients requiring treatment for clinically significant post-procedure bleeding.

M2-SPMK-1 Diagnosis of Foot and Ankle Injuries with Multiple-view Radiographic Studies by HAMIL-Net

Participants
Amilcare Gentili, MD, MBA, San Diego, CA (*Presenter*) Institutional Grant, VoxelCloud

PURPOSE

Automated diagnosis of orthopedic injuries can save time by providing a preliminary interpretation on the presence of orthopaedic trauma. AI deep learning has been shown to be promising but many challenges need to be overcome. For orthopaedic injuries, one of the key challenges is that a radiographic study usually consists of multiple image views of different angles of different body parts, but the available data might not pinpoint specific views where abnormalities are observable. For example, MURA, a widely used dataset in the public domain, provides a single label of normal or abnormal for each study. While providing view-level labels is expensive.

METHODS AND MATERIALS

We considered "HAMIL-Net," a deep neural net architecture with hierarchical attention (HA) mechanism and multiple instance learning (MIL) to discriminate body parts and selectively attend to different views and regions. Previously, 0.91 AUC for MURA was reported. The study team used a dataset of 580K musculoskeletal imaging studies for 138K patients with 17 body parts. 148K were foot and ankle. We designed an ontology that consists of 26 orthopedic pathologies with 8 levels of classification of positive/negative, high/low certainty, and acute/chronic and leveraged PyContextNLP, a rule-based natural language processing (NLP) tool to semi-automatically label each study based on the ontology. To compare with MURA, we focused on 8 pathologies (i.e., fracture, hardware, arthritis, subluxations etc.) with high certainty. 24K abnormal and 47K normal studies were included. Image views per study were 3.16 (2.72 in MURA). Data were randomly split at 8:2 for training/test.

RESULTS

HAMIL-Net achieved 0.84 AUC (95% CI 0.8475, 0.8325), compared to 0.82(95% CI 0.8244, 0.8155) by ResNet34 and 0.83(95% CI 0.8343, 0.8257) by DenseNet169 as baselines. The baselines, however, classified each view instead of the whole study. When considering fracture only, HAMIL-Net achieved 0.86 AUC (95% CI 0.8687, 0.8513). Pretraining HAMIL-Net with MURA did not improve or degrade the performance.

CONCLUSION

s Foot and ankle studies contain more views per study than upper extremity studies in MURA and may be more challenging. HAMIL-Net outperformed baselines by considering multiple views and performed even better when considering fracture only. Our HAMIL-Net implementation considered four views for all studies. Our future work is to relax this limitation.

CLINICAL RELEVANCE/APPLICATION

Automated initial interpretation of orthopaedic injury studies by shortening the communication gap between the point of injury and patient care, which could lead to earlier treatment and better outcomes.

M2-SPMK-2 Will Novel Deep Learning Architectures 'Transform' MSK Radiograph Diagnosis? A Comparison of Vision Transformers and Convolutional Neural Networks for Abnormality Detection in Extremity Radiographs

Participants
Paul Yi, MD, Baltimore, MD (*Presenter*) Consultant, FH Orthopedics SAS;Consultant, BunkerHill Health

PURPOSE

Visual transformers (VTs) are a new type of deep learning algorithm that has shown advantage in classification tasks for general imaging datasets compared to traditional convolutional neural networks (CNNs). However, it is unclear if these advantages translate to radiology-specific tasks. We compared performance, sample efficiency, and hidden stratification of multiple ViT and CNN architectures for diagnosis of abnormalities on extremity radiographs using transfer learning.

METHODS AND MATERIALS

We used Stanford's MURA dataset of 40,005 upper extremity radiographs from five anatomic regions labeled as normal or abnormal; these images were divided into 70/20/10% train/validation/testing splits. We finetuned Data-efficient Image Transformer (DeiT) ViT and CNN classification models pretrained on ImageNet using these images to identify abnormal images. Performance was assessed

using weighted AUROC across anatomical regions (wAUC). Our primary comparison was DeiT-B ViT vs. DenseNet121 CNN with secondary comparisons including DeiT-Ti, ResNet152, and EfficientNetB7. We evaluated sample efficiency by training models on varying dataset sizes ranging from 1% to 100% of total data. We evaluated hidden stratification by comparing prevalence of arthritis, fracture, and hardware in false positive (FP) and false negative (FN) predictions. Finally, we visually compared the localization ability of ViT attention and CNN grad-CAM heatmaps.

RESULTS

DeiT-B wAUC was significantly lower than DenseNet121 (0.887 vs. 0.893, p<0.001). DeiT-B and DeiT-Ti both performed worse than all CNNs evaluated (p<0.001, all comparisons). ViTs and CNNs showed similar sample efficiency. There was no significant difference in hidden stratification between ViTs and CNNs with arthritis being more prevalent in FP and FN predictions than fracture or hardware. ViT attention heatmaps qualitatively were more accurate and tightly bounded to radiographic abnormalities compared to CNN heatmaps.

CONCLUSION

s Although DeiT ViT models had lower wAUCs than CNNs for extremity abnormality diagnosis, the absolute differences were small. Additionally, ViT models had similar sample efficiency with more reassuring heatmaps that may prove more useful for disease localization than CNN heatmaps. As ViT architectures are in their infancy, there will almost assuredly continue to be improvements in performance and we optimistically recommend continued evaluation of ViTs for MSK imaging as they mature in the coming years.

CLINICAL RELEVANCE/APPLICATION

Even in their early stages, visual transformers provide similar performance to convolutional neural networks while outputting more reassuring heatmaps, which may prove useful for disease localization in MSK radiograph diagnosis.

M2-SPMK-3 Patient-Specific Hip Arthroplasty Dislocation Risk Calculator: An Explainable Multimodal Machine Learning Based Approach

Participants
Bardia Khosravi, MD, MPH, Rochester, MN (*Presenter*) Nothing to Disclose

PURPOSE

Total hip arthroplasty (THA) is among the most common elective surgeries in the United States. While typically THA is quite successful, complications can occur. Implant dislocation is the most common complication of THA that might require revision surgery. However, there are also well-described intraoperative choices within a surgeon's control that can be used to mitigate the risk of dislocation. This study develops a multimodal machine learning-based pipeline to predict the patient-specific risk of dislocation following primary THA that can help surgeons with preoperative planning.

METHODS AND MATERIALS

This study retrospectively evaluates 17,073 patients who underwent primary THA between 1998-2018. A test set of 1,733 patients was held out. A hybrid network of EfficientNet-B4 and Swin-B vision transformer was developed to classify patients based on 5-year dislocation outcomes from preoperative anteroposterior (AP) pelvis radiographs and clinical (demographics, comorbidities, and surgical) characteristics. The most informative imaging features, that the mentioned model extracted were selected and concatenated with clinical features. A collection of these features was then used to train a multimodal survival XGBoost model to predict the individualized risk of dislocation. A clinical-only survival XGBoost was trained as a benchmark to compare addition of imaging features. C-index was used to evaluate the multimodal survival model on the test set and compare it with the clinical-only model. Integrated gradient maps and Shapley additive explanation (SHAP) values were used for the classifier and survival model explanation, respectively.

RESULTS

On the holdout test set, the clinical-only model achieved a C-index of 63.8% (95% CI: 59.5%-68.1%); adding imaging features boosted multimodal model performance to a C-index of 73.6% (95% CI: 69.2%-78.0%). Imaging features represented 4 of the top 5 and 10 of the top 13 most influential variables in the multimodal model. The imaging feature showed focus of the model on the area of maximum load in the hip joint articulation, the lesser trochanter, and the acetabular teardrop.

CONCLUSION

s A multimodal calculator for predicting dislocation was introduced by combining preoperative characteristics and radiographic features of patients undergoing primary THA. This study highlights the superiority of imaging features compared to clinical variables and the synergy between these modes of patient evaluation.

CLINICAL RELEVANCE/APPLICATION

The developed tool enables patient-specific dislocation risk prediction with an acceptable C-index, and more importantly, shows the degree to which this risk is modified by decisions within a surgeon's control.

M2-SPMK-4 Deep-Learning-Based Evaluation and Quantification of Real-Time MRI for the Assessment of Active Wrist Motion in Health and Disease

Participants
Lena Wilms, Dusseldorf, Germany (*Presenter*) Nothing to Disclose

PURPOSE

For wrist imaging, clinical MRI sequences focus on the morphologic appearance of a structure to assess its condition. Yet, such MRI sequences are acquired in a static condition, thereby potentially missing complex dynamic instability patterns. Based on real-time MRI during active wrist motion and deep-learning based image post-processing using convolutional neural networks (CNN), this study aimed to develop and validate an automated wrist motion quantification method.

METHODS AND MATERIALS

After systematic Fast Low Angle Shot (FLASH) sequence variation, 56 bilateral wrists (28 healthy volunteers) were imaged during continuous active radioulnar abduction at a temporal resolution of 95 ms/image. After CNN based segmentations of carpal bone

contours, scapholunate (SL) and lunotriquetral (LT) gap widths were determined as a function of wrist position across the entire range-of-motion. Manual segmentations and quantification of gap widths served as reference standard. Clinical applicability of the framework was assessed in two ligament-injured patients (partial and complete SL injuries). Mean SL and LT gap widths were evaluated using a linear mixed model based on multivariable statistics. Bland-Altman plots were used comparatively evaluate automatically and manually determined SL and LT gap widths and wrist angles.

RESULTS

Automatic segmentations agreed excellently with manual reference segmentations, performed independently by two radiologists, as shown by the Dice similarity coefficients of 0.96±0.02 and the consistent and unskewed Bland-Altman plots. Clinical applicability of the framework was demonstrated in two patients with diagnosed SL injuries indicating significantly greater SL gap widths over the entire range-of-motion in patients than in controls (SL gap widths: 3.4±1.2mm [patients], 1.6±0.4mm [controls], $p<0.001$), particularly at maximum radial abduction, and displaying distinctly different motion patterns and trajectories.

CONCLUSION

s The combination of advanced image acquisition and post-processing techniques permits dynamic wrist assessment over the entire range of active radioulnar motion, both in healthy volunteers and ligament-injured patients. Merging real-time wrist MRT and the introduced technical framework, thus, provides a powerful diagnostic tool for dynamic quantification of wrist function and, if confirmed in clinical trials, dynamic carpal instability that may elude static assessment using clinical-standard morphologic MRI.

CLINICAL RELEVANCE/APPLICATION

If confirmed in clinical trials, the combination of advanced image acquisition using real-time wrist MRI and post-processing techniques may serve as a contrast agent-free surrogate of carpus integrity and dynamic wrist function.

Diagnosis of Foot and Ankle Injuries with Multiple-view Radiographic Studies by HAMIL-Net

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - MK DPS

Participants
Amilcare Gentili, MD, MBA, San Diego, CA (*Presenter*) Institutional Grant, VoxelCloud

PURPOSE

Automated diagnosis of orthopedic injuries can save time by providing a preliminary interpretation on the presence of orthopaedic trauma. AI deep learning has been shown to be promising but many challenges need to be overcome. For orthopaedic injuries, one of the key challenges is that a radiographic study usually consists of multiple image views of different angles of different body parts, but the available data might not pinpoint specific views where abnormalities are observable. For example, MURA, a widely used dataset in the public domain, provides a single label of normal or abnormal for each study. While providing view-level labels is expensive.

METHODS AND MATERIALS

We considered "HAMIL-Net," a deep neural net architecture with hierarchical attention (HA) mechanism and multiple instance learning (MIL) to discriminate body parts and selectively attend to different views and regions. Previously, 0.91 AUC for MURA was reported. The study team used a dataset of 580K musculoskeletal imaging studies for 138K patients with 17 body parts. 148K were foot and ankle. We designed an ontology that consists of 26 orthopedic pathologies with 8 levels of classification of positive/negative, high/low certainty, and acute/chronic and leveraged PyContextNLP, a rule-based natural language processing (NLP) tool to semi-automatically label each study based on the ontology. To compare with MURA, we focused on 8 pathologies (i.e., fracture, hardware, arthritis, subluxations etc.) with high certainty. 24K abnormal and 47K normal studies were included. Image views per study were 3.16 (2.72 in MURA). Data were randomly split at 8:2 for training/test.

RESULTS

HAMIL-Net achieved 0.84 AUC (95% CI 0.8475, 0.8325), compared to 0.82(95% CI 0.8244, 0.8155) by ResNet34 and 0.83(95% CI 0.8343, 0.8257) by DenseNet169 as baselines. The baselines, however, classified each view instead of the whole study. When considering fracture only, HAMIL-Net achieved 0.86 AUC (95% CI 0.8687, 0.8513). Pretraining HAMIL-Net with MURA did not improve or degrade the performance.

CONCLUSION

s Foot and ankle studies contain more views per study than upper extremity studies in MURA and may be more challenging. HAMIL-Net outperformed baselines by considering multiple views and performed even better when considering fracture only. Our HAMIL-Net implementation considered four views for all studies. Our future work is to relax this limitation.

CLINICAL RELEVANCE/APPLICATION

Automated initial interpretation of orthopaedic injury studies by shortening the communication gap between the point of injury and patient care, which could lead to earlier treatment and better outcomes.

Will Novel Deep Learning Architectures 'Transform' MSK Radiograph Diagnosis? A Comparison of Vision Transformers and Convolutional Neural Networks for Abnormality Detection in Extremity Radiographs

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - MK DPS

Participants
Paul Yi, MD, Baltimore, MD (*Presenter*) Consultant, FH Orthopedics SAS;Consultant, BunkerHill Health

PURPOSE

Visual transformers (VTs) are a new type of deep learning algorithm that has shown advantage in classification tasks for general imaging datasets compared to traditional convolutional neural networks (CNNs). However, it is unclear if these advantages translate to radiology-specific tasks. We compared performance, sample efficiency, and hidden stratification of multiple ViT and CNN architectures for diagnosis of abnormalities on extremity radiographs using transfer learning.

METHODS AND MATERIALS

We used Stanford's MURA dataset of 40,005 upper extremity radiographs from five anatomic regions labeled as normal or abnormal; these images were divided into 70/20/10% train/validation/testing splits. We finetuned Data-efficient Image Transformer (DeiT) ViT and CNN classification models pretrained on ImageNet using these images to identify abnormal images. Performance was assessed using weighted AUROC across anatomical regions (wAUC). Our primary comparison was DeiT-B ViT vs. DenseNet121 CNN with secondary comparisons including DeiT-Ti, ResNet152, and EfficientNetB7. We evaluated sample efficiency by training models on varying dataset sizes ranging from 1% to 100% of total data. We evaluated hidden stratification by comparing prevalence of arthritis, fracture, and hardware in false positive (FP) and false negative (FN) predictions. Finally, we visually compared the localization ability of ViT attention and CNN grad-CAM heatmaps.

RESULTS

DeiT-B wAUC was significantly lower than DenseNet121 (0.887 vs. 0.893, $p<0.001$). DeiT-B and DeiT-Ti both performed worse than all CNNs evaluated ($p<0.001$, all comparisons). ViTs and CNNs showed similar sample efficiency. There was no significant difference in hidden stratification between ViTs and CNNs with arthritis being more prevalent in FP and FN predictions than fracture or hardware. ViT attention heatmaps qualitatively were more accurate and tightly bounded to radiographic abnormalities compared to CNN heatmaps.

CONCLUSION

s Although DeiT ViT models had lower wAUCs than CNNs for extremity abnormality diagnosis, the absolute differences were small. Additionally, ViT models had similar sample efficiency with more reassuring heatmaps that may prove more useful for disease localization than CNN heatmaps. As ViT architectures are in their infancy, there will almost assuredly continue to be improvements in performance and we optimistically recommend continued evaluation of ViTs for MSK imaging as they mature in the coming years.

CLINICAL RELEVANCE/APPLICATION

Even in their early stages, visual transformers provide similar performance to convolutional neural networks while outputting more reassuring heatmaps, which may prove useful for disease localization in MSK radiograph diagnosis.

Patient-Specific Hip Arthroplasty Dislocation Risk Calculator: An Explainable Multimodal Machine Learning Based Approach

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - MK DPS

Participants
Bardia Khosravi, MD, MPH, Rochester, MN (*Presenter*) Nothing to Disclose

PURPOSE

Total hip arthroplasty (THA) is among the most common elective surgeries in the United States. While typically THA is quite successful, complications can occur. Implant dislocation is the most common complication of THA that might require revision surgery. However, there are also well-described intraoperative choices within a surgeon's control that can be used to mitigate the risk of dislocation. This study develops a multimodal machine learning-based pipeline to predict the patient-specific risk of dislocation following primary THA that can help surgeons with preoperative planning.

METHODS AND MATERIALS

This study retrospectively evaluates 17,073 patients who underwent primary THA between 1998-2018. A test set of 1,733 patients was held out. A hybrid network of EfficientNet-B4 and Swin-B vision transformer was developed to classify patients based on 5-year dislocation outcomes from preoperative anteroposterior (AP) pelvis radiographs and clinical (demographics, comorbidities, and surgical) characteristics. The most informative imaging features, that the mentioned model extracted were selected and concatenated with clinical features. A collection of these features was then used to train a multimodal survival XGBoost model to predict the individualized risk of dislocation. A clinical-only survival XGBoost was trained as a benchmark to compare addition of imaging features. C-index was used to evaluate the multimodal survival model on the test set and compare it with the clinical-only model. Integrated gradient maps and Shapley additive explanation (SHAP) values were used for the classifier and survival model explanation, respectively.

RESULTS

On the holdout test set, the clinical-only model achieved a C-index of 63.8% (95% CI: 59.5%-68.1%); adding imaging features boosted multimodal model performance to a C-index of 73.6% (95% CI: 69.2%-78.0%). Imaging features represented 4 of the top 5 and 10 of the top 13 most influential variables in the multimodal model. The imaging feature showed focus of the model on the area of maximum load in the hip joint articulation, the lesser trochanter, and the acetabular teardrop.

CONCLUSION

s A multimodal calculator for predicting dislocation was introduced by combining preoperative characteristics and radiographic features of patients undergoing primary THA. This study highlights the superiority of imaging features compared to clinical variables and the synergy between these modes of patient evaluation.

CLINICAL RELEVANCE/APPLICATION

The developed tool enables patient-specific dislocation risk prediction with an acceptable C-index, and more importantly, shows the degree to which this risk is modified by decisions within a surgeon's control.

Deep-Learning-Based Evaluation and Quantification of Real-Time MRI for the Assessment of Active Wrist Motion in Health and Disease

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - MK DPS

Participants
Lena Wilms, Dusseldorf, Germany (*Presenter*) Nothing to Disclose

PURPOSE

For wrist imaging, clinical MRI sequences focus on the morphologic appearance of a structure to assess its condition. Yet, such MRI sequences are acquired in a static condition, thereby potentially missing complex dynamic instability patterns. Based on real-time MRI during active wrist motion and deep-learning based image post-processing using convolutional neural networks (CNN), this study aimed to develop and validate an automated wrist motion quantification method.

METHODS AND MATERIALS

After systematic Fast Low Angle Shot (FLASH) sequence variation, 56 bilateral wrists (28 healthy volunteers) were imaged during continuous active radioulnar abduction at a temporal resolution of 95 ms/image. After CNN based segmentations of carpal bone contours, scapholunate (SL) and lunotriquetral (LT) gap widths were determined as a function of wrist position across the entire range-of-motion. Manual segmentations and quantification of gap widths served as reference standard. Clinical applicability of the framework was assessed in two ligament-injured patients (partial and complete SL injuries). Mean SL and LT gap widths were evaluated using a linear mixed model based on multivariable statistics. Bland-Altman plots were used comparatively evaluate automatically and manually determined SL and LT gap widths and wrist angles.

RESULTS

Automatic segmentations agreed excellently with manual reference segmentations, performed independently by two radiologists, as shown by the Dice similarity coefficients of 0.96±0.02 and the consistent and unskewed Bland-Altman plots. Clinical applicability of the framework was demonstrated in two patients with diagnosed SL injuries indicating significantly greater SL gap widths over the entire range-of-motion in patients than in controls (SL gap widths: 3.4±1.2mm [patients], 1.6±0.4mm [controls], $p<0.001$), particularly at maximum radial abduction, and displaying distinctly different motion patterns and trajectories.

CONCLUSION

s The combination of advanced image acquisition and post-processing techniques permits dynamic wrist assessment over the entire range of active radioulnar motion, both in healthy volunteers and ligament-injured patients. Merging real-time wrist MRT and the introduced technical framework, thus, provides a powerful diagnostic tool for dynamic quantification of wrist function and, if confirmed in clinical trials, dynamic carpal instability that may elude static assessment using clinical-standard morphologic MRI.

CLINICAL RELEVANCE/APPLICATION

If confirmed in clinical trials, the combination of advanced image acquisition using real-time wrist MRI and post-processing techniques may serve as a contrast agent-free surrogate of carpus integrity and dynamic wrist function.

Multisystem Monday Poster Discussions

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - MS DPS

Sub-Events

M2-SPMS-1 Functional Imaging with Dual-energy Computed Tomography for Supplementary Non-invasive Assessment of Mast Cell Burden in Systemic Mastocytosis

Participants
Julia Riffel, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Systemic mastocytosis (SM) is characterized by multifocal accumulation of neoplastic mast cells (MCs), predominately affecting the bone marrow (BM). Imaging with computed tomography (CT) is routinely used for assessment of bone mineral density and bone structure. However, the value of functional imaging with dual-energy CT (DECT) and the assessment of virtual-non-calcium attenuation values (VNCa-AV) for visualization of BM disease burden in SM has not yet been assessed.

METHODS AND MATERIALS

DECT of the axial skeleton was performed in 18 patients with SM (indolent SM [ISM], n=6; smoldering SM [SSM]/advanced SM [AdvSM], n=12) and 18 control subjects. VNCa-AV were obtained in 5 representative vertebraes per patient and correlated with laboratory, morphologic and molecular parameters. Visual evaluation of osteosclerosis was performed on morphologic CT images.

RESULTS

VNCa-AV strongly correlated with quantitative bone marrow mast infiltration (r=0.7, R2=0.49, P=0.001) and serum tryptase levels (r=0.7, R2=0.54, P<0.001). Mean VNCa-AV were significantly higher in patients with SSM/AdvSM as compared to ISM (-9HU vs. -54HU, P<0.005) and controls (38HU, P<0.005). Nine of 10 (90%) patients with a VNCa-AV > -30HU and 7/7 (100%) patients with a VNCa-AV > -10HU had SSM or AdVSM.

CONCLUSION

s Bone marrow VNCa-AV provide information about the mast cell burden of SM patients and correlate with SM subtypes. Since conventional CT is used to assess for organomegaly, pathological bone mineral density, osteolyses and fractures, functional imaging with DECT may serve as supplementary tool for diagnosis, subclassification and monitoring of SM disease in a one-stop-shop session.

CLINICAL RELEVANCE/APPLICATION

Dual-energy CT allows non-invasive assessment of the mast cell burden in systemic mastocytosis and may serve as supplementary tool for diagnosis, subclassification and monitoring of systemic mastocytosis in a one-stop-shop session.

M2-SPNMMI-1 PET Respiratory Motion Correction Improves Metabolic Tumor Volume Accuracy for Lung Base Lesions on Oncologic PET/CT

Participants
Genevieve Munoz, (*Presenter*) Nothing to Disclose

PURPOSE

Respiratory motion can distort lung base tumors on PET imaging, potentially altering metabolic tumor volume (MTV) and impacting radiotherapy planning. This study assessed the impact of several respiratory motion mitigation strategies on lung base tumor MTVs, utilizing CT-based segmentation volumes as the reference standard.

METHODS AND MATERIALS

To date, this IRB-approved, HIPAA-compliant prospective study has enrolled 10 patients with tracer-avid lung base tumors. All subjects provided written informed consent. Imaging occurred on a Biograph Vision PET/CT (Siemens Healthineers). A weight-based radiotracer dose was given ~60 min before imaging. Four PET reconstructions were performed: 1) without motion correction (uncorrected); 2) using end-expiratory counts (EE-gate); 3) using elastic motion correction with deblurring (EMCD) to correct counts to a reference gate, as informed by the Anzai system (Anz-EMCD); and 4) using EMCD to correct counts to a reference gate via a purely data-driven approach (OncoFreeze AI). For each reconstruction, metabolic tumor volume (MTV) was calculated in MIM software using an adaptive segmentation strategy. Each lesion was manually segmented on CT. Differences between MTVs and reference CT volumes (MTV-CT) were compared across reconstructions. Statistical comparisons were based on the Wilcoxon signed-rank test (a = 0.05).

RESULTS

All data reported are median MTV-CTs [interquartile ranges] for the 10 subjects. The MTV-CT was significantly higher for uncorrected (0.96 ml [3.57]) images than for EE-gate (0.55 ml [0.72]; $p < 0.05$), Anz-EMCD (0.35 ml [0.38]; $p = 0.005$), or OncoFreeze AI (0.37 ml [0.39]; $p = 0.012$) images. MTV-CT was not significantly different for EE-gate versus Anz-EMCD ($p = 0.646$) or Anz-EMCD versus OncoFreeze AI ($p > 0.05$) images. Visually, image noise was lower and overall image quality was higher for Anz-EMCD and OncoFreeze AI images relative to EE-gate images.

CONCLUSION

s For lung base tumors, PET reconstructions without motion correction exhibit greater bias toward higher MTVs than EE-gate, Anz-EMCD, or OncoFreeze AI reconstructions. Anz-EMCD and OncoFreeze AI reconstructions, which utilize all counts, result in better image quality than end-expiratory gated reconstructions.

CLINICAL RELEVANCE/APPLICATION

EMCD using the Anzai system or OncoFreeze AI improves PET volume quantification without sacrificing image quality, potentially resulting in more accurate tumor response assessments and more precise radiotherapy plans.

M2-SPNMMI-3 Does the Finding of Two Areas of TC-99M Sestamibi Retention on Parathyroid Scintigraphy Always Indicate Double Parathyroid Adenomas? Results of a 10-Year Analysis

Participants
Charles M. Intenzo, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose

PURPOSE

Tc-99m sestamibi (MIBI) scintigraphy is commonly utilized for the preoperative localization of parathyroid adenomas. A focal area of tracer retention that persists on delayed images is fairly specific for a parathyroid adenoma. Occasionally, there are 2 foci of MIBI retention on delayed imaging, which theoretically suggests a double parathyroid adenoma. However, on follow-up review of pathology reports, many of these were signed out as "asymmetric parathyroid hyperplasia" by the cytopathologist Our aim was to determine just how often this finding was shown to represent a double parathyroid adenoma.

METHODS AND MATERIALS

Over a 10-yea interval, both retrospectively and prospectively, all parathyroid scans with the finding of 2 areas of MIBI concentration in initial images of the neck, that retained the tracer on 3-hour delayed images were collected and corresponding histopathological results were reviewed.

RESULTS

A total of 49 patients demonstrated the above finding. Of these, 41 underwent neck exploration; 33 were diagnosed as having asymmetric parathyroid gland hyperplasia, while only 8 were diagnosed with double parathyroid adenoma.

CONCLUSION

s Of the group of 41 patients whose parathyroid scintigraphy showed 2 areas of MIBI retention on 3-hour delayed images of neck, 33 (80.5%) had asymmetric parathyroid gland hyperplasia, whereas only 8 patients with this finding had true double adenoma. In parathyroid scintigraphy, 2 foci of tracer retention more than likely indicate parathyroid gland hyperplasia, as opposed to double parathyroid adenoma.

CLINICAL RELEVANCE/APPLICATION

For the finding of 2 focal areas of sestamibi retention on sestamibi scintigraphy, both parathyroid gland hyperplasia and double parathyroid adenoma should be given as a differential diagnosis in the scan report summary.

M2-SPNPM-1 Reliability of 3D Image Analysis and Comparison of Diagnostic Accuracy of 2D and 3D Measurements to Determine Opportunistic Screening of Osteoporosis Using the Proximal Femur on Abdomen-Pelvic CT

Participants
Minsu Park, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the reliability of 3D image analysis and compare the osteoporosis-predicting ability of computed tomography (CT) indexes in abdomen-pelvic CT (APCT) using the proximal femur and the reliability of measurements in two and three-dimensional analyses.

METHODS AND MATERIALS

430 female patients who underwent dual-energy X-ray absorptiometry (DXA) and APCT within 1 month were retrospectively selected. The volumes of interest (VOIs) from the femoral head to the lesser trochanter and the femoral neck were expressed as 3DFemur. Total volume, mean-HU, and HU histogram analysis (HUHA) values of the extracted femur were calculated. Also, round regions of interest (ROIs) of image plane drawn over the femoral neck touching the outer cortex were determined as 2Dcoronal. In HUHA, the percentages of HU histogram ranges related to the ROI or VOI were classified as HUHAfat (<0HU) and HUHAbone (126HU=). Reliability of 3D image analysis was assessed by calculating intra- and interobserver correlation coefficients (ICCs). In addition, diagnostic performance, correlation analysis and measurement reliability were analyzed by receiver operating characteristic curves, correlation coefficient and ICC, respectively. Furthurmore, the effect of contrast medium administration was evaluated by the paired t-test.

RESULTS

All ICCs of 3D volume measurements showed excellent reproducibility (all ICCs>0.90). AUCs of each HUHA and mean-HU measurement on 2D-ROI and 3D-VOI were 0.94 or higher (P<0.001). Both 3DFemur-mean-HU and 3DFemur-HUHAbone showed the highest AUC (0.96). The cut-off value of 3DFemur-mean-HU was 231HU or less (P<0.001) for diagnosis of osteoporosis. There was no superiority between AUCs in 2D-ROI and 3D-VOI measurements (P>0.05). Reliability of the 3D-VOI measurement showed perfect agreement (ICC=0.94), and 2D-ROI showed moderate to good agreement (ICC range: 0.63~0.84). The mean difference in HU after contrast agent administration (-2.2HU) was not significant (P=0.27).

CONCLUSION

s Image analysis based on 3D volume measurement of the proximal femur showed excellent reliability with the contrast agent administration showing negligible influence on the mean-HU, and CT indexes on 3D-VOI for predicting femoral osteoporosis showed similar diagnostic accuracy with better reproducibility of measurement, compared with 2D-ROI.

CLINICAL RELEVANCE/APPLICATION

Since DXA is a 2D technique, clinically relevant diagnostic errors can be made. Using APCT, BMD can be assessed in femur by measuring HU without additional imaging, radiation exposure, or patient time. Also, measurements performed with a VOI in the 3D image plane may not be substantially affected by structural complexity of femur and cross-section selection as well as the ROI location.

M2-SPNPM-2 Observer Recall Bias in Diagnostic Test Accuracy Comparative Studies: Much Room for Improvement

Participants
Bharadwaj Pindiprolu, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Diagnostic test accuracy (DTA) studies often compare two or more imaging modalities, yet little is known on the impact of reading-order effects. Observer recall bias occurs when a subsequently performed test seems more accurate than an earlier test due to retention of information from the earlier test, rather than a true difference in test performance. The purpose of this study was to perform a methodological review of DTA comparative studies to assess strategies employed to limit observer recall bias.

METHODS AND MATERIALS

MEDLINE was used to identify DTA systematic reviews published in imaging journals from 2000 to 2021. Two reviewers

independently conducted title, abstract and full-text review to identify all systematic reviews comparing two or more index tests including at least one diagnostic imaging modality. Each reviewer extracted data from the primary studies within each systematic review. Disagreements were resolved by consensus or using a third reviewer where needed.

RESULTS

87 radiologic comparative DTA studies were included, of which 38 (44%) had the same radiologist interpret both modalities, 24 (28%) used separate radiologists, and 25 (29%) provided no details. A minimum time delay between interpretations was only reported in 25 studies. Most studies (24%) required a minimum of 1 week between reads, followed by 2 weeks (16%) and 3 weeks (12%). Two readers were most frequently used (44/87; 50.6%) to interpret index tests and most commonly, reading sessions were conducted independently (40/87; 46.0%) rather than by consensus (14/87; 16.1%). Reader order was randomized in 20/87 (23%) studies. 54/87 (62.1%) studies utilized some form of blinding to minimize clinical review bias.

CONCLUSION

s Strategies for addressing observer recall bias vary considerably in DTA comparative studies and are often suboptimal. Increased awareness of this potential source of bias is needed.

CLINICAL RELEVANCE/APPLICATION

Reading-order effects are a potential source of bias in many diagnostic test accuracy comparative studies; increased recognition of this pitfall could improve study quality and reporting consistency.

Reliability of 3D Image Analysis and Comparison of Diagnostic Accuracy of 2D and 3D Measurements to Determine Opportunistic Screening of Osteoporosis Using the Proximal Femur on Abdomen-Pelvic CT

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NPM DPS

Participants
Minsu Park, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the reliability of 3D image analysis and compare the osteoporosis-predicting ability of computed tomography (CT) indexes in abdomen-pelvic CT (APCT) using the proximal femur and the reliability of measurements in two and three-dimensional analyses.

METHODS AND MATERIALS

430 female patients who underwent dual-energy X-ray absorptiometry (DXA) and APCT within 1 month were retrospectively selected. The volumes of interest (VOIs) from the femoral head to the lesser trochanter and the femoral neck were expressed as 3DFemur. Total volume, mean-HU, and HU histogram analysis (HUHA) values of the extracted femur were calculated. Also, round regions of interest (ROIs) of image plane drawn over the femoral neck touching the outer cortex were determined as 2Dcoronal. In HUHA, the percentages of HU histogram ranges related to the ROI or VOI were classified as HUHAfat (<0HU) and HUHAbone (126HU=). Reliability of 3D image analysis was assessed by calculating intra- and interobserver correlation coefficients (ICCs). In addition, diagnostic performance, correlation analysis and measurement reliability were analyzed by receiver operating characteristic curves, correlation coefficient and ICC, respectively. Furthurmore, the effect of contrast medium administration was evaluated by the paired t-test.

RESULTS

All ICCs of 3D volume measurements showed excellent reproducibility (all ICCs>0.90). AUCs of each HUHA and mean-HU measurement on 2D-ROI and 3D-VOI were 0.94 or higher (P<0.001). Both 3DFemur-mean-HU and 3DFemur-HUHAbone showed the highest AUC (0.96). The cut-off value of 3DFemur-mean-HU was 231HU or less (P<0.001) for diagnosis of osteoporosis. There was no superiority between AUCs in 2D-ROI and 3D-VOI measurements (P>0.05). Reliability of the 3D-VOI measurement showed perfect agreement (ICC=0.94), and 2D-ROI showed moderate to good agreement (ICC range: 0.63~0.84). The mean difference in HU after contrast agent administration (-2.2HU) was not significant (P=0.27).

CONCLUSION

s Image analysis based on 3D volume measurement of the proximal femur showed excellent reliability with the contrast agent administration showing negligible influence on the mean-HU, and CT indexes on 3D-VOI for predicting femoral osteoporosis showed similar diagnostic accuracy with better reproducibility of measurement, compared with 2D-ROI.

CLINICAL RELEVANCE/APPLICATION

Since DXA is a 2D technique, clinically relevant diagnostic errors can be made. Using APCT, BMD can be assessed in femur by measuring HU without additional imaging, radiation exposure, or patient time. Also, measurements performed with a VOI in the 3D image plane may not be substantially affected by structural complexity of femur and cross-section selection as well as the ROI location.

Observer Recall Bias in Diagnostic Test Accuracy Comparative Studies: Much Room for Improvement

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NPM DPS

Participants
Bharadwaj Pindiprolu, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Diagnostic test accuracy (DTA) studies often compare two or more imaging modalities, yet little is known on the impact of reading-order effects. Observer recall bias occurs when a subsequently performed test seems more accurate than an earlier test due to retention of information from the earlier test, rather than a true difference in test performance. The purpose of this study was to perform a methodological review of DTA comparative studies to assess strategies employed to limit observer recall bias.

METHODS AND MATERIALS

MEDLINE was used to identify DTA systematic reviews published in imaging journals from 2000 to 2021. Two reviewers independently conducted title, abstract and full-text review to identify all systematic reviews comparing two or more index tests including at least one diagnostic imaging modality. Each reviewer extracted data from the primary studies within each systematic review. Disagreements were resolved by consensus or using a third reviewer where needed.

RESULTS

87 radiologic comparative DTA studies were included, of which 38 (44%) had the same radiologist interpret both modalities, 24 (28%) used separate radiologists, and 25 (29%) provided no details. A minimum time delay between interpretations was only reported in 25 studies. Most studies (24%) required a minimum of 1 week between reads, followed by 2 weeks (16%) and 3 weeks (12%). Two readers were most frequently used (44/87; 50.6%) to interpret index tests and most commonly, reading sessions were conducted independently (40/87; 46.0%) rather than by consensus (14/87; 16.1%). Reader order was randomized in 20/87 (23%) studies. 54/87 (62.1%) studies utilized some form of blinding to minimize clinical review bias.

CONCLUSION

s Strategies for addressing observer recall bias vary considerably in DTA comparative studies and are often suboptimal. Increased awareness of this potential source of bias is needed.

CLINICAL RELEVANCE/APPLICATION

Reading-order effects are a potential source of bias in many diagnostic test accuracy comparative studies; increased recognition of this pitfall could improve study quality and reporting consistency.

M2-SPNR-1 How Are We Handling All Those Fluoroscopic Guided Lumbar Puncture Requests? A Nationwide Survey of Practice Trends

Participants
Tyler Richards, MD, Salt Lake City, UT (*Presenter*) Nothing to Disclose

PURPOSE

Our study's purpose was to determine how radiologists in different practice settings manage fluoroscopy guided lumbar puncture (FGLP) referrals.

METHODS AND MATERIALS

An online questionnaire was sent to radiologists and trainees to survey their methodology of handling FGLP requests, pre-procedural work-up including lab value and head imaging requirements, utilization of physician extenders (PEs)/trainees to perform FGLPs, among others. Odds ratio (OR) was used to compare the categories.

RESULTS

Of 131 responses, 93.9% were from the U.S. and 81.7% were from an academic practice (AP) and 18.3% from a private practice (PP). Regarding FGLP referrals, 27.5% of respondents stated it was not standard practice in their department that a bedside lumbar puncture is attempted by a clinician prior to FGLP referral, a practice 4 x more common among PP respondents (OR 4.19 (95% CI: 1.86,9.65)). Morbid obesity (80.2%), congenitally altered anatomy (71.0%), and prior lumbar surgery with hardware (61.1%) were some of the most frequent reasons respondents did not require a bedside LP attempt prior to referral for FGLP. 95.8% of PP and 84.1% of AP respondents were asked often to perform an FGLP by clinicians because the clinician does not feel competent performing LPs. Of those, 74.3% stated they will always or sometimes agree to the request; a 4.7 higher likelihood that a PP radiologist would oblige and always agree to perform the FGLP compared to an academic radiologist (OR 4.7 (95% CI: 1.3-20.5). 42.0% of respondents stated that they would always comply if a patient specifically requests an FGLP without a bedside LP attempt, 2.5 x higher likelihood for PP respondents (OR 2.5 (95%CI: 1.15-5.56)). Regarding FGLP operators, AP respondents were less likely to have PEs perform FGLPs compared to PP respondents (31.8% vs. 45.8%; (OR 0.65 (95% CI: 0.3,1.42)). In academic practices, 72.9% reported trainees perform >50% of their FGLPs. Regarding pre-procedural work up, 42.0% of respondents stated that they check coagulation labs on all patients prior to FGLP and 84.0% of respondents stated that patients should get a head CT prior to an FLGP only if there is high suspicion for increased intracranial pressure, similar between PP and AP respondents.

CONCLUSION

s This survey demonstrates that many academic and private practice radiology practitioners are relatively lenient in obliging to perform FGLPs in patients. There were many differences and some similarities in management of FGLP referrals and pre-procedural workup between academic and private practice groups.

CLINICAL RELEVANCE/APPLICATION

Our findings demonstrate the current methods of how private practice and academic radiologists handle FGLPs referrals and can be potentially used to develop guidelines of best FGLP practices.

M2-SPNR-11 Leptomeningeal Metastases in Glioma Revisited: High Incidence and Their Molecular Predictors based on Recent Imaging and Molecular Diagnostics

Participants
Sung Soo Ahn, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Leptomeningeal metastases (LM) in glioma has been underestimated due to low incidence and lack of reliable imaging. This study

Leptomeningeal metastases (LM) in glioma has been underestimated due to low incidence and lack of reliable imaging. This study aimed to investigate a real-world incidence of LM using a CSF-sensitive MR imaging technique and analyze molecular predictors for LM in the molecular era.

METHODS AND MATERIALS

Total 1,405 adult glioma patients underwent post-contrast fluid attenuated inversion recovery (FLAIR) imaging at initial diagnosis and during treatment monitoring between March 2001 and October 2021. Molecular data included isocitrate dehydrogenase (IDH) mutation, 1p/19q co-deletion, H3 K27M alteration, and O6-methylguanine-methyltransferase (MGMT) promoter methylation status. Multivariable logistic regression analysis for LM development was performed in molecular data, clinical data, and imaging characteristics. Median overall survival (OS) was compared between patients with and without LM using Kaplan-Meier survival curves and log-rank test.

RESULTS

LM was identified in 16.2% of glioma (228 of 1405), with 7.8% (110 of 1405) at initial diagnosis, and 8.4% (118 of 1405) at recurrence. Among molecular diagnostics, IDH-wildtype (odds ratio [OR] 3.14, P = .001) and MGMT promoter unmethylation (OR 1.43, P = .034) were independent predictors of LM. WHO grade 4 (OR 10.52, P <.001) and nonlobar location (OR 1.54, P=.048) were associated with LM at initial diagnosis, whereas IDH-wildtype (OR 5.04, P <.001) and H3 K27M alteration (OR 3.39, P =.003) were significantly associated with LM at recurrence. Patients with LM had a worse median OS than those without LM (16.7 vs. 32.0 months, log-rank test; P <.001). N

CONCLUSION

s CSF-sensitive MR imaging diagnostics aid diagnosis of LM and reduced an underdiagnosed condition in adult gliomas. Molecular markers affect LM at initial diagnosis and at recurrence, and patients with aggressive molecular markers warrant imaging surveillance of LM.

CLINICAL RELEVANCE/APPLICATION

The incidence of LM in glioma is underestimated due to lack of sensitive imaging protocol. Here, we utilized CSF-sensitive MRI with post-contrast FLAIR and discovered a high frequency of 228 (16.2%) patients diagnosed with LM in 1,405 diffuse glioma patients. Our findings emphasize the role of molecular markers in the development of LM in glioma patients. Patients with aggressive molecular markers such as IDH-wildtype and H3 K27M alteration warrant imaging surveillance of LM.

M2-SPNR-12 Use of VASARI Features for The Systematic Identification of Typical and Atypical Primary Central Nervous System Lymphomas

Participants
Irene Dixe de Oliveira Santo, MD, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

The imaging appearance of PCNSL is highly variable with a significant proportion of cases demonstrating atypical features, frequently leading to a significant delay in diagnosis. Standardized classification of features has the potential to improve recognition of atypical variants, which is especially important given the drastically different treatment approach from the similar-appearing gliomas.

METHODS AND MATERIALS

Presurgical MR images of 71 patients with histologically-proven PCNSL were scored independently according to the VASARI (Visually Accessible Rembrandt Images) features by two different neuroradiologists. Classification into typical versus atypical PCNSL was based on enhancement pattern, presence or absence of necrosis, hemorrhage, and calcification. Age at diagnosis, gender, presenting symptoms, immune status, biochemical and molecular profile of the neoplasms, treatment, and overall survival were also recorded. The influence of visual appearance (atypical versus typical) on overall survival was analyzed using the Kaplan-Meier method and tested for significance using log-rank test (alpha=0.05).

RESULTS

Appearance of PCNSL was highly variable ranging from multiple infiltrative solid masses to ring-enhancing lesions. Periventricular and ependymal involvement were among the most common locations. Systematic scoring classified 44 (62%) patients into typical and 27 (38%) patients into atypical PCNSL. Presence of hemorrhage on SWI was often responsible for classification into atypical. Regarding survival, median OS was significantly lower for atypical (203 days) compared to typical (767 days) PCNSL (p = 0.012).

CONCLUSION

s Up to a third of our PCNSL patients demonstrated atypical MRI features, which may complicate diagnosis.

CLINICAL RELEVANCE/APPLICATION

Awareness of varying imaging presentations of PCNSL may alert the interpreting radiologist to consider lymphoma early and expedite diagnosis and treatment.

M2-SPNR-13 Usefulness of the Wave-CAIPI for the Post-contrast 3D T1-SPACE in The Evaluation of Brain Metastases

Participants
Youngjin Heo, MD, (*Presenter*) Nothing to Disclose

PURPOSE

High-resolution post-contrast 3D T1WI is a widely used sequence for evaluating brain metastasis, despite the long scan time. This study aimed to compare highly accelerated post-contrast 3D T1-weighted sampling perfection with application-optimized contrasts by using different flip angle evolution using Wave-controlled aliasing in parallel imaging (Wave-T1-SPACE) with the commonly used standard high-resolution post-contrast 3D T1-SPACE for the evaluation of brain metastases.

METHODS AND MATERIALS

Among the 387 patients who underwent post-contrast wave-T1-SPACE and standard SPACE, 56 patients with suspected brain metastases were retrospectively included. Two neuroradiologists assessed the number of enhancing lesions according to lesion size, contrast-to-noise ratio (CNR) lesion/parenchyma, CNR white matter/gray matter, contrast ratio (CR) lesion/parenchyma, and overall image quality for the two different sequences.

RESULTS

Although there was no significant difference in the evaluation of larger enhancing lesions (>5 mm) between the two different sequences (P=0.66 for observer 1, P=0.26 for observer 2), wave-T1-SPACE showed significantly lower number of smaller enhancing lesions (<5 mm) than standard SPACE (1.61±0.29 vs 2.84±0.47 for observer 1, 1.41±0.19 vs 2.68±0.43 for observer 2). Furthermore, mean CNRlesion/parenchyma and overall image quality of wave-T1-SPACE were significantly lower than standard SPACE.

CONCLUSION

s Post-contrast wave-T1-SPACE showed comparable diagnostic performance for larger enhancing lesions (>5 mm) and marked scan time reduction as compared with standard SPACE. However, post-contrast wave-T1-SPACE showed underestimation of smaller enhancing lesions (<5 mm) and lower image quality than standard SPACE. Therefore, post-contrast wave-T1-SPACE should be interpreted carefully in the evaluation of brain metastasis.

CLINICAL RELEVANCE/APPLICATION

Recently, accelerated 3D acquisition techniques have been developed to reduce the scan time of high-resolution 3D T1WI sequences while preserving image quality. Wave-controlled aliasing in parallel imaging (Wave-CAIPI; Siemens Healthineers) is advanced parallel imaging technique that combines a corkscrew gradient trajectory with CAIPI shifts in the ky and kz directions to efficiently encode k-space and evenly spread the voxel aliasing in all dimensions. This allow to take better advantage of the 3D coil sensitivity information to provide highly accelerated parallel imaging with negligible artifacts and signal-to-noise ratio penalties. Therefore, we evaluated the diagnostic performance according to the lesion size and overall image quality of post-contrast wave-T1-SPACE for the evaluation of brain metastases.

M2-SPNR-14 White Matter Hyperintensities in Younger Mild Traumatic Brain Injured Patients

Participants
Priya Santhanam, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

This study aims to identify associations between white matter hyperintensities (WMH) and the presentation and progression of post-concussive symptoms in patients 40 years and younger with mild traumatic brain injury (mTBI).

METHODS AND MATERIALS

MTBI patients (n=152; mean age=30 yrs) without preexisting head pathology were included in this study. Axial T2-weighted and T2-FLAIR sequences were performed on a 3.0 Tesla MR Signa HDxt system. Hyperintensities were regionally classified by lobe (frontal, parietal, temporal, or occipital) or cerebellum. Clinical data, including presence of several post-concussive symptoms, was obtained via retrospective chart review. Patient groups were compared by the presence or absence of WMH on imaging as well as by whether the patient had loss-of-consciousness (LOC) during injury. Interval-censored data analyses were performed to test the time to recovery between the comparison groups as recovery is only known to be between two examinations.

RESULTS

At least one WMH was present in 44% of male and 52% of female patients. Single WMH were predominantly located in the frontal lobe (84%) and more commonly in the left hemisphere (65%). LOC was more prevalent (p=0.018) in those with WMH as compared to those without WMH. While symptoms improved or resolved in both groups, a larger percentage of patients without WMH showed improvement as compared to patients with WMH. Patients with WMH also took significantly longer to recover from cognitive deficits than those without WMH (p=0.0177). Patients with LOC had a higher incidence of balance deficits as compared to patients without LOC (p=0.0391), while a larger percentage of those without LOC showed improvement or resolution of symptoms, specifically headache (p=0.0406), balance deficits (p=0.0173), and cognitive deficit (p=0.0341).

CONCLUSION

s This study revealed several significant associations between quantitative WMH findings, loss of consciousness, and clinical outcomes following mTBI. Taken together, findings suggest the presence of WMH in younger TBI patients may influence patient symptomology, while co-morbid LOC may lead to poor outcomes and recovery for affected individuals.

CLINICAL RELEVANCE/APPLICATION

The presence of white matter hyperintensities in younger patients with mild traumatic brain injury and loss of consciousness could be related to symptom prevalence, long-term outcomes, and recovery.

M2-SPNR-15 IDH and 1p19q Diagnosis in Diffuse Glioma from Preoperative MRI Using Artificial Intelligence

Participants
Hugh McHugh, BMBCh, Auckland, New Zealand (*Presenter*) Clinical AI Registrar, Harrison AI Research Grant, RANZCR

PURPOSE

Isocitrate dehydrogenase (IDH) mutation and 1p19q codeletion are key molecular markers in glioma which both confer a more favorable prognosis. In the 2021 WHO classification of CNS tumours IDH and 1p19q status determine the glioma sub-categories of glioblastoma, astrocytoma and oligodendroglioma. IDH and 1p19q status is unknown until after surgery unless there is a biopsy which is uncommon. Reliable preoperative molecular characterization may facilitate tailored treatment approaches, for example if molecular status affects the optimal extent of tumor resection.Emerging research supports the potential of MRI-based IDH and 1p19q diagnosis. A limitation is the relative lack of generalization and external validation outside the widely used The Cancer Imaging Archive (TCIA) dataset. We present a combined IDH and 1p19q classification algorithm and assess performance on a local retrospective cohort and a fully independent cohort from the Erasmus Glioma Database (EGD).

METHODS AND MATERIALS

2D convolutional neural networks were trained to provide IDH and 1p19q classification. Inputs are T1 post-contrast, T2, and FLAIR sequences. Training data consists of preoperative imaging from the TCIA dataset (n=184) and images from a locally obtained cohort that were obtained prior to 1/1/2018 (n=349). Evaluation data consists of the most recent cases from the local cohort obtained between 1/1/2018 and 31/8/2021 (n=205) and the EGD (n=420).

RESULTS

Subject-wise IDH classification accuracy was 93.3% and 91.5% on the local cohort and EDG, with AUC of 95.4% and 95.8%, respectively. 1p19q accuracy was 94.5% and 87.5% with AUC of 92.5% and 85.4% on the local cohort and EGD. Combined subject-wise IDH and 1p19q accuracy was 90.4% and 84.3% on the local cohort and EGD, with AUC of 92.4% and 91.2%.

CONCLUSION

s High IDH and 1p19q classification performance was achieved on the local retrospective cohort. Generalization to the EGD was robust, demonstrating the potential for clinical translation. This method is able to non-invasively predict tumor subtypes according to the WHO 2021 classification with high accuracy using readily available imaging without the need for MR spectroscopy. This may better inform patients and clinicians prior to surgery and demonstrates the high potential impact in glioma diagnostics.

CLINICAL RELEVANCE/APPLICATION

This research externally validates non-invasive IDH and 1p19q diagnosis in glioma from preoperative MRI using artificial intelligence techniques allowing tumor classification by WHO 2021 criteria.

M2-SPNR-16 Compare the Performance of MRI-based 2.5D and 3D Convolutional Neural Networks in Differential Diagnosis of High-grade Gliomas and Single Brain Metastases

Participants
Bin Zhang, (*Presenter*) Nothing to Disclose

PURPOSE

The 2.5D convolutional neural network models have unique advantages for studies with moderate sample sizes, while the 3D model can completely extract tumor and peritumoral features. To explore and compare the value of preoperative differential diagnosis of high-grade gliomas (HGG) and single brain metastases (BM) under 2.5D and 3D convolutional neural network models.

METHODS AND MATERIALS

T2WI and contrast-enhanced T1WI(CE T1WI) images of 230 patients with HGG and 111 patients with BM confirmed by surgery and pathology were retrospectively collected.The radiologist delineated the regions of interests (ROIs) of the input images of the 2.5D networks and 3D networks on the T2WI and CE T1WI axial images of the registered MRI. The slice nth with the largest tumor parenchyma area on the MRI image was determined, and then the tumor area (including tumor parenchyma and peritumoral edema area) of the slice of (n-2)th,nth and (n+2)th was delineated respectively. Define a minimum rectangular box as the ROIs of the 2.5D models that can cover all tumor areas at the three slices. Define the smallest 3D rectangular box that can completely contain the tumor area at all slices as the ROIs of the 3D models. Finally, based on DenseNet convolutional neural networks respectively build prediction models for T2WI and CE T1WI sequences under 2.5D and 3D model.The predictive performance of each model was evaluated by the receiver operating characteristic(ROC) curve, and the differences in the ROC curves of the models built by different convolutional neural networks were compared in pairs by Delong's test.

RESULTS

The best AUC values of the 3D model on CE T1WI and T2WI were 0.852 and 0.802, respectively. And the best AUC values of the 2.5D model on CE T1WI and T2WI were 0.831 and 0.784, respectively.The performance of the 3D models were better than that of the 2.5D models. Delong's test showed that the differences between the models were statistically significant ($P<0.05$).

CONCLUSION

s The MRI-based 2.5D and 3D convolutional neural network models have better diagnostic performance in differentiating HGG and single BM, and the 3D models have better diagnostic performance than 2.5D models. The deep learning model can be used to identify HGGs and BMs and assist in clinical formulation of precise treatment plans potential tool.

CLINICAL RELEVANCE/APPLICATION

The 2.5D model has better advantages in the deep learning model with a medium sample size, which can make up for the problem of the large data demand of the 3D model. While the 3D convolutional neural network structure analyzes the lesion information more completely, so it is easier to apply to clinical practice. The establishment of the prediction model will be able to differential diagnose HGG and single BM through non-invasive imaging examination.

M2-SPNR-17 Predicting the Isocitrate Dehydrogenase Wildtype in Non-enhancing or Poorly Enhancing Glioma by Conventional MRI Features and Apparent Diffusion Coefficient

Participants
Jiyoung Song, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop predictive models using clinically available MRI parameters for predicting isocitrate dehydrogenase (IDH) status of gliomas with no or poor enhancement, which is considered as a radiologically low-grade feature.

METHODS AND MATERIALS

This retrospective study included 241 patients with surgically resected and pathologically confirmed gliomas that showed no or poor enhancement (less than 5% of the entire tumor volume) in the preoperative MRI. Visual rating of imaging features (T1-weighted, T2-weighted, FLAIR, contrast-enhanced T1-weighted images, and cerebral blood volume map) was performed. Regions of interest were drawn to acquire the apparent diffusion coefficient (ADC) mean (ADCmean) and minimum (ADCmin) in tumor and ADCnawm in normal-appearing white matter. Univariable and multivariable logistic regression analyses were performed for each imaging feature

and ADC value. Then, receiver operating characteristic curve analysis was done with probability index calculated from the multivariable logistic regression model. A subgroup analysis was performed to predict IDH status in the non-enhancing gliomas.

RESULTS

In 241 non-enhancing or poorly enhancing gliomas, T2/FLAIR mismatch sign showed 100% specificity (42 of 42) to predict IDH-mutant gliomas. Among 199 gliomas with negative T2/FLAIR mismatch signs, 78 were IDH-wildtype. A predictive model incorporating age, calcification, multifocality, FLAIR homogeneity, ADCmin-to-ADCnawm ratio, and cortical involvement showed area under the curve (AUC) of 0.909 (95% CI: 0.858-0.946) with 90.8% sensitivity and 81.2% specificity. In the subgroup analysis for 116 non-enhancing tumors (46 IDH-wildtypes and 70 IDH-mutants) a predictive model that consisted of the same variables showed AUC of 0.883 (95% CI: 0.808-0.935), 82.6% sensitivity, and 88.1% specificity.

CONCLUSION

s Algorithms incorporating T2/FLAIR mismatch sign, age, calcification, multifocality, FLAIR homogeneity, ADCmin-to-ADCnawm ratio, and cortical involvement predicted IDH wild-type gliomas with radiologically low-grade feature.

CLINICAL RELEVANCE/APPLICATION

According to 2021 WHO classification for adult-type diffuse gliomas, even if a tumor seems low-grade, being IDH-wildtype satisfies a necessary condition to be diagnosed as glioblastoma. This study developed models using clinically available MRI parameters for predicting IDH status of gliomas with no or poor enhancement, which is considered as a radiologically low-grade feature.

M2-SPNR-18 High-resolution Clinical Functional MRI at 7T in Patients with Brain Tumors: Initial Assessment

Participants
Kinsey Lano, BS, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to evaluate spatial localization accuracy of a high-resolution (1.4 mm isotropic) 7T fMRI protocol and compare with a clinical 3T protocol with typical resolution (1.9 x 1.9 x 4 mm3).

METHODS AND MATERIALS

Hand motor fMRI studies of 24 patients (n=12 on 7T and 12 on 3T) were evaluated. The 7T patients included 1 with brain mets, 3 with low-grade, and 8 with high-grade gliomas. The 3T patients included 4 with low-grade and 8 with high-grade gliomas. The fMRI paradigm consisted of 6 cycles of resting and bilateral hand-motor task blocks. T2*-weighted EPI sequences were used for the fMRI at 7T (TR/TE=2000 ms/24 ms, PI=3, SMS=2, 1.4 x 1.4 x 1.4 mm3) and at 3T (TR/TE=3000 ms/25 ms, PI=2, 1.9 x 1.9 x 4.0 mm3). The fMRI pre-processing included motion correction and co-registration with 3D T1-weighted images. Functional t-value maps were then generated by the standard GLM method. The t-value maps were thresholded at two statistical levels: (1) FWE-corrected p lt 0.05 (t gt 5.5 and 6.1 for 7T and 3T, respectively), and (2) t gt 4.0. For each patient, the most relevant motor-activation cluster on the lesion side was visually determined. The smallest distance between the center of the cluster and the central sulcus was measured and categorized: (1) gt 2 mm, (2) 2-4 mm, and (3) 5-10 mm.

RESULTS

At 7T, activation clusters at expected hand motor areas were detected in 7 (58%) and 9 (75%) out of the 12 patients at the statistical level of p lt 0.05, FWE corrected, and t gt 4.0, respectively. The spatial localization accuracy was within 2 mm for all the 9 patients with detected activation clusters. At 3T, hand motor activations were detected in 11 (92%) and 12 (100%) out of the 12 patients at the two statistical levels. The spatial localization accuracy assessment found 4 (33%), 6 (50%), and 2 (17%) patients having the detected activation cluster centered at gt 2mm, 2-4 mm, and 5-10 mm, respectively, from the central sulcus.

CONCLUSION

s We demonstrated that high-resolution fMRI at 7T is feasible for mapping primary motor areas in clinical routine. More accurate functional localization was achieved using the high-resolution 7T protocol compared to our routine protocol at 3T.

CLINICAL RELEVANCE/APPLICATION

The higher fMRI sensitivity at 7T allows imaging at higher spatial resolution, which leads to improved localization accuracy for presurgical functional mapping.

M2-SPNR-19 Nomogram for Predicting Early Recurrence in Patients with High Grade Glioma

Participants
Qing Zhou, Lanzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop a nomogram to predict early recurrence of high-grade glioma (HGG) based on clinical factors, genetic factors, and MRI parameters.

METHODS AND MATERIALS

154 HGG patients were classified into recurrence and non-recurrence groups based on pathological diagnosis and RANO criteria. Clinical information included age, sex, and preoperative Karnofsky Performance Status (KPS) scores. Gene information included P53, IDH1, MGMT, and TERT status. All patients had baseline MRIs before treatment, including T1WI, T2WI, T1C, Flair and DWI examinations. The tumor location, single/multiple tumors, tumor diameter, peritumoral edema, necrotic cyst, hemorrhage, average apparent diffusion coefficient(ADC) value and minimum ADC values were evaluated. Univariate and multivariate logistic regression were used to determine the predictors of early recurrence and to build the nomogram.

RESULTS

Univariate analysis showed that the number of tumors (OR, 0.258; 95% CI: 0.104, 0.639; P = 0.003) and peritumoral edema (OR, 0.965; 95% CI 0.942, 0.988; P = 0.003; mean in the recurrence group 22.04±17.21 mm; mean in the non-recurrence group 14.22±12.84 mm) were statistically significantly different in patients with early recurrence. Genetic factors included IDH1 (OR,

4.405; 95% CI 1.874, 10.353; P= 0.001), and MGMT (OR, 2.389; 95% CI 1.234, 4.628; P= 0.010). Multivariate logistic regression analysis revealed that the number of tumors (OR, 0.227; 95% CI 0.084, 0.616; P = 0.004), peritumoral edema (OR, 0.969; 95% CI 0.945, 0.993; P = 0.013) and IDH1 (OR, 4.200; 95% CI 1.602, 10.013; P= 0.004) were independent risk factors for early recurrence. The nomogram showed the highest net benefit when the threshold probability was less than 63%.

CONCLUSION

s A nomogram prediction model based on results that are easily available before surgery can effectively aid clinical treatment decisions for newly diagnosed HGG patients.

CLINICAL RELEVANCE/APPLICATION

A nomogram prediction model can effectively aid treatment decisions in newly diagnosed HGG patients. Neurosurgeons may adjust the surgical decision on the scope of tumor resection based on the prediction model. For tumor tissues with a high risk of recurrence and high infiltration, the radiation oncologist can also upgrade the radiation dose to high-risk areas.

M2-SPNR-20 Peritumoral MR Imaging Radiomic Features Improves Identification of Circumscribed Astrocytic Gliomas and High-grade Gliomas

Participants
Shuang Li, (*Presenter*) Nothing to Disclose

PURPOSE

In the 2021 WHO classification of tumors of the central Nervous System, the terms of "diffuse" and "circumscribed" were applied to the classification of gliomas, diffuse gliomas are characterized by extensive infiltration, while circumscribed astrocytic gliomas show a solid growth pattern. The most common circumscribed astrocytic gliomas are pilocytic astrocytoma (PA) and pleomorphic xanthoastrcytoma (PXA). MR imaging findings of them can resemble high grade gliomas (HGGs). We aimed to develop an MRI-based radiomics model to distinguish circumstanced glioma from HGGs.

METHODS AND MATERIALS

Preoperative T2 fluid-attenuated inversion recovery (T2 FLAIR) and contrast-enhanced T1-weighted imaging (CE-T1WI) data were obtained from 160 patients (91 circumscribed astrocytic gliomas and 69 glioblastoma) between 2016 and 2020. 1288 features were obtained in tumor region and the 5 mm thickness peritumoral region, respectively. We up-sampled features by repeating random cases to make samples balance. Then, we applied the normalization on the feature matrix. Feature pairs with PCC values larger than 0.990 will be removed. Before build the model, we used recursive feature elimination (RFE) to select features. Support vector machine (SVM) was used as a classifier. To determine the hyper-parameter of model, we applied cross validation with 10-fold on the training data set. The hyper-parameters were set according to the model performance on the validation data set. The performance of the model was evaluated using receiver operating characteristic (ROC) curve analysis. The area under the ROC curve (AUC) was calculated for quantification. We also estimated the 95% confidence interval by bootstrape with 1000 samples.

RESULTS

Intratumor radiomic features achieved AUCs of 0.820(CE-T1WI) and 0.787(T2 FLAIR). The integrated model, incorporating intra- and peritumoral features extracted from T2 FLAIR and CE-T1WI images, improved the AUCs to 0.889 on the same test set.

CONCLUSION

s An imaging-based model combining tumor and peritumor radiomics can help to distinguish between circumscribed astrocytic gliomas and high-grade gliomas.

CLINICAL RELEVANCE/APPLICATION

Circumscribed astrocytic gliomas had better prognosis than HGGs. Correct differential diagnosis is vital for preoperative decision-making and prognostic evaluation. Radiomic features extracted from intra- and peritumoral region may help the identification.

M2-SPNR-4 Discriminative Power of Macro- And Microstructural MRI in the Differential Diagnosis of Neurodegenerative Parkinsonian Syndromes

Participants
Alexander Rau, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the discriminative performance of macro- and microstructural MRI in the differential diagnosis of neurodegenerative parkinsonian syndromes (NPS).

METHODS AND MATERIALS

We included patients with NPS according to current consensus diagnostic criteria, i.e. 136 patients with Parkinson´s disease (PD), 32 patients with progressive supranuclear palsy (PSP), 41 patients with multiple system atrophy (MSA) as well as 37 healthy controls (HC) in this monocentric retrospective cross-sectional study. Tissue probability values for gray matter, white matter and CSF were automatically obtained by CAT12. In addition, the microstructure of the patients was analyzed using a mesoscopic approach by diffusion tensor imaging (DTI) and diffusion microstructure imaging (DMI). Respective parameters were extracted using the AAL3-atlas and ROIs with great relevance for PSP. Based on this, a linear support vector machine (SVM) was trained and optimized in respect of ROC-AUC in a one-vs-rest (OVR) classifier. The diagnostic performance of SVM was compared with respect to different inputs, i.e. TPV, DTI and DMI individually.

RESULTS

Diffusion MRI outperformed the T1w derived TPV with a correct classification in 80% for DTI, 79% for DMI and 52% for TPV. The corresponding OVR-ROC-AUC of DTI was 0.92 for HC, 0.89 for PD, 0.95 for MSA and 0.93 for PSP and for DMI 0.91 (HC), 0.90 (PD), 0.96 (MSA) and 0.93 (PSP).

CONCLUSION

s Microstructural parameters as obtained in an mesoscopic approach using diffusion MRI data outperformed structural data derived

s Microstructural parameters as obtained in an mesoscopic approach using diffusion MRI data outperformed structural data derived by conventional imaging in the diagnosis of NPS. The particularly good performance of microstructural approaches in the diagnosis of PD, as a weak point in conventional MRI, underlines the potential of this approach. The introduced automatic approach might facilitate the MRI diagnosis of patients with suspected NPS.

CLINICAL RELEVANCE/APPLICATION

The developed approach might facilitate the differential diagnosis of neurodegenerative parkinsonian syndromes in an objective manner and is therefore of high clinical relevance.

M2-SPNR-6 Usefulness of 3D FIESTA in Differentiating Parkinson's Disease From Parkinson Syndrome: Volumetric Alternation of Olfactory Bulb

Participants
Ide Ide, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Parkinson's disease (PD) is a neurodegenerative disease, related with deposition of Lewy body. Braak stage of Lewy pathology shows the initiation sites are in the olfactory bulb (OB), hence, olfactory dysfunction is among the earliest nonmotor features of PD. It's sometimes difficult to differentiate PD from parkinson syndrome (PS), such as multiple system atrophy (MSA), corticobasal syndrome (CBS), and progressive supranuclear palsy (PSP) using conventional MRI and clinical symptom. It's known that olfactory loss occurs to a lesser extent or is absent in PS. Therefore, we hypothesized OB change may be useful in differential diagnosis. 3D fast imaging employing steady-state acquisition (FIESTA) results in good delineation of cranial nerves, however, no study demonstrated OB volume change between PD and PS using 3D-FIESTA. Our purpose is to determine whether OB measurement on 3D-FIESTA is useful for differentiating PD from PS.

METHODS AND MATERIALS

Sixty-four PD (mean age ± SD: 71.5 ± 9.4), 8 MSA (68.9 ± 8.9), 10 PSP (75.9 ± 8.3), and 8 CBS (73.8 ± 8.9) patients were recruited. Thirty-three healthy subjects (HS) (63.8 ± 18.6) were also recruited as normal controls. The diagnoses were made according to the diagnostic criteria by an experienced neurologist. The parameter of 3D-FIESTA is following: 3T SIGNA Premier (GE), FA 45deg, TR 4ms, TE 2ms, matrix 512×512, slice thickness 1.0mm, scan time 2:27, spatial resolution: 0.6×0.6×0.8 mm. The cross-sectional area of the OB was measured using manual ROI method, and we used maximum area of OB in coronal plane. The average of bilateral OB was calculated for each subject. We performed group comparison and diagnostic accuracy test using Welch's t test and ROC analysis, respectively. All statistics were performed with BellCurve for Excel (Social Survey Research Information Co., Ltd.).

RESULTS

The mean area of OB was significantly smaller for PD patients (mean area ± SD mm2: 4.1 ± 1.0) than for HSs (6.6 ± 1.4, plt;0.01). Moreover, that of PD were also significantly smaller than that of MSA (6.0 ± 1.4, p=.007), PSP (4.8 ± 0.9, p=.03), and CBS (5.3 ± 1.2, p=.03), respectively (Figure 1 and 2). The ROC analyses showed that good diagnostic performance, especially in analysis of PD vs MSA (AUC: 0.874, optimal cut off points: 5.6 mm2, sensitivity: 93.8%, specificity: 87.5%).

CONCLUSION

s Our results suggest the OB volume loss in PD, which may reflect degeneration due to deposition of Lewy body. OB volumetry using 3D-FIESTA can be useful to differentiate PD from PS, especially for MSA.

CLINICAL RELEVANCE/APPLICATION

OB volumetry with 3D-FIESTA may contribute precise diagnoses in PD and PS showing atypical MR findings. 3D-FIESTA is a common and widespread MR technique, which can work as clinical routine MR application in patients with Parkinsonism.

M2-SPNR-7 Altered Cerebral Blood Flow in Spinocerebellar Degeneration Patients

Participants
Bing Liu, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Spinocerebellar degeneration (SCD) comprises a multitude of disorders with sporadic and hereditary forms, including spinocerebellar ataxia (SCA), cerebellum-type of multiple system atrophy (MSA) and more complex phenotypes. Except for progressive cerebellar ataxia and structural atrophy, hemodynamic changes have also been demonstrated in SCD. This study aimed to clarify the whole-brain altered patterns of cerebral blood flow (CBF) and its correlations with disease severity and emotional abnormalities in SCD via arterial spin labeling (ASL).

METHODS AND MATERIALS

Thirty SCD patients and 30 age- and sex-matched healthy controls (HC) were prospectively recruited to undergo ASL examinations in a 3.0T MR scanner. The Scale for Assessment and Rating of Ataxia (SARA) and the International Cooperative Ataxia Rating Scale (ICARS) scores were used to reflect the disease severity in SCD patients. Additionally, the status of anxiety and depression among all patients were evaluated by the Self-Rating Anxiety Scale (SAS) and the Self-Rating Depression Scale (SDS). We compared the whole-brain CBF between SCD group and HC group at voxel level. And the ROI-based correlation analyses between CBF and disease severity as well as emotional abnormalities were performed for SCD group.

RESULTS

Compared with HC, SCD patients exhibited decreased CBF in two clusters (FWE corrected P<0.05), covering bilateral dentate and fastigii nuclei, lobule VIX, lobule VX, bilateral lobule HI-IV and lobule HIX, left lobule HVI and right lobule HVIIIb as Cluster1 and the dorsal part of raphe nucleus in midbrain as Cluster2. The CBF of Cluster 1 was negatively correlated with SARA scores (Spearman’s rho=-0.374, P=0.042) and SDS standard scores (Spearman’s rho=-0.388, P=0.034), respectively. While the CBF of Cluster2 also had negative correlations with SARA scores (Spearman’s rho=-0.370, P=0.044) and ICARS scores (Pearson r=-0.464, P=0.010).

CONCLUSION

s The SCD-related whole-brain CBF changes were mainly involved in cerebellum and midbrain, partially overlapped with hand, foot

s The SCD-related whole-brain CBF changes were mainly involved in cerebellum and midbrain, partially overlapped with hand, foot and tongue movement activations areas. Decreased CBF was related to disease severity and depression status in SCD. Therefore, CBF may be a promising neuroimaging biomarker to reflect the severity of neurodegeneration and to provide warnings for emotional changes.

CLINICAL RELEVANCE/APPLICATION

Decreased CBF in cerebellum and midbrain were associated with disease severity and depression level in SCD, which may help reflect the degree of neurodegeneration in vivo, and give early warnings for SCD-related depression.

M2-SPNR-8 Diagnostic Performance of Susceptibility Map-weighted MRI According to Acquisition Plane for Differentiating Neurodegenerative Parkinsonism

Participants
Suiji Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance of SMwI according to the acquisition plane for differentiating neurodegenerative parkinsonism.

METHODS AND MATERIALS

This retrospective, observational, single-institution study included patients who were consecutively enrolled from those who visited movement disorder clinics and underwent both brain MRI and 18F-FP-CIT with clinical symptoms of suspected parkinsonism between September 2021 and December 2021. Both oblique coronal plane (vertical to the midbrain) and anterior commissure-posterior commissure (AC-PC) plane of SMwI were acquired. Abnormality was determined when there was any hypointense area that obliterated the differentiation of the three layers and classified into 3 categories (0: normal, 1: intermediate, 2: abnormal) by two neuroradiologists. 18F-FP-CIT PET served as the reference standard. The diagnostic performance of the oblique plane and AC-PC plane of SMwI were assessed per substantia nigra and per participant. Inter-rater agreement was assessed using Cohen's kappa coefficient. McNemar's test was used to test the diagnostic performance of oblique coronal plane and AC-PC plane of SMwI.

RESULTS

Total 194 patients (mean age ± SD, 67 ±10 years, 91 men) were included. Among them, 84 patients were diagnosed with IPD, 26 with MSA, 3 with PSP, 10 with CBS, 35 with ET, 10 with DIP, 4 with NPH and 22 with others. The overall inter-rater agreement for both oblique and AC-PC plane was good (? = 0.747 and 758 for each, P < .001). In per participant analysis, the overall inter-rater agreement for both oblique and AC-PC plane was good (? = 0.747 and 758 for each, P < .001). For reader 1, the overall sensitivity of the oblique plane was 89.9% and that of the AC-PC plane was 91.7% (P = .727). The overall specificity of the oblique plane was 87.1% and that of AC-PC plane was 88.2% (P = .727). The overall accuracy of the oblique plane was 88.7% and that of AC-PC plane was 90.2%, with p-value of 0.607. Reader 2 demonstrated similar results. For both readers, there was no significant difference of sensitivity, specificity and accuracy between the oblique plane and the AC-PC plane.

CONCLUSION

s There was no significant difference of diagnostic performance between the oblique plane and the AC-PC plane of SMwI in differentiating parkinsonism.

CLINICAL RELEVANCE/APPLICATION

This study assures clinics can choose any one of MRI acquisition planes of SMwI between oblique plane and AC-PC plane according to their clinical settings in the diagnosis of parkinsonism.

M2-SPNR-9 Brain Connectivity Changes in Resting-State Functional MRI in Patients with HIV-Associated Neurocognitive Disorder (hand): A Multi-voxel Pattern Analysis (MVPA) Approach Using Mutual Connectivity Analysis (MCA)

Participants
Ali Vosoughi, Rochester, NY (*Presenter*) Nothing to Disclose

PURPOSE

To develop and evaluate a novel machine learning framework for identifying subjects with HIV-Associated Neurocognitive Disorder (HAND) using Mutual Connectivity Analysis (MCA) by capturing connectivity differences in resting-state functional MRI (rsfMRI).

METHODS AND MATERIALS

Resting-state fMRI scans (3T, EPI sequence, TR=1.65s, 250 acquisitions) were acquired in a cohort of 45 age-matched subjects (20 healthy, 25 HIV+, 16 of whom had HAND symptoms (HAND+)). After pre-processing, data was parcellated into 90 regions using the Automated Anatomical Labeling atlas. Regions were represented by their average time-series. A nonlinear machine learning connectivity analysis method (MCA [Citation blinded for review]), was used to quantify interdependence of region-specific time-series producing a 8100-element connectivity matrix. Generalized matrix learning vector quantization feature selection revealed regional connections that were most different between the groups. These were used for subsequent identification of HAND+ subjects using an adaptive boosting classifier in a Multi-Voxel Pattern Analysis (MVPA) framework. For both feature selection and classification, strict data separation (90% train/10% test) was carried out in a 100-iteration cross-validation scheme. For comparison, MCA was evaluated against the clinical standard technique of functional connectivity analysis using cross-correlating (CC) low-pass filtered fMRI time-series. Area Under the Curve (AUC) for Receiver Operator Characteristics (ROC) analysis was used to quantitatively evaluate diagnostic quality of HAND+ subject classification.

RESULTS

The MCA rsfMRI connectivity analysis method clearly outperformed the clinical standard CC technique in identifying HAND+ subjects with AUC of 0.85 ± 0.27 for MCA, and 0.71 ± 0.31 for CC, respectively. Diagnostic quality differences between both methods were statistically significant ($p<0.05$, Wilcoxon signed-rank test).

CONCLUSION

s Our results suggest that MCA significantly improves the diagnostic accuracy of identification of patients with HAND based on

s Our results suggest that MCA significantly improves the diagnostic accuracy of identification of patients with HAND based on rsfMRI neuroimaging. We conclude that, when compared to conventional CC analysis, our MVPA framework is better suited to capture disease-related brain network connectivity changes in HAND.

CLINICAL RELEVANCE/APPLICATION

The MCA method classifies HAND+ subjects and controls by identifying relevant changes in fMRI connectivity. Such changes can be useful diagnostic imaging biomarkers for HIV-related neurologic disease.

How Are We Handling All Those Fluoroscopic Guided Lumbar Puncture Requests? A Nationwide Survey of Practice Trends

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Tyler Richards, MD, Salt Lake City, UT (*Presenter*) Nothing to Disclose

PURPOSE

Our study's purpose was to determine how radiologists in different practice settings manage fluoroscopy guided lumbar puncture (FGLP) referrals.

METHODS AND MATERIALS

An online questionnaire was sent to radiologists and trainees to survey their methodology of handling FGLP requests, pre-procedural work-up including lab value and head imaging requirements, utilization of physician extenders (PEs)/trainees to perform FGLPs, among others. Odds ratio (OR) was used to compare the categories.

RESULTS

Of 131 responses, 93.9% were from the U.S. and 81.7% were from an academic practice (AP) and 18.3% from a private practice (PP). Regarding FGLP referrals, 27.5% of respondents stated it was not standard practice in their department that a bedside lumbar puncture is attempted by a clinician prior to FGLP referral, a practice 4 x more common among PP respondents (OR 4.19 (95% CI: 1.86,9.65)). Morbid obesity (80.2%), congenitally altered anatomy (71.0%), and prior lumbar surgery with hardware (61.1%) were some of the most frequent reasons respondents did not require a bedside LP attempt prior to referral for FGLP. 95.8% of PP and 84.1% of AP respondents were asked often to perform an FGLP by clinicians because the clinician does not feel competent performing LPs. Of those, 74.3% stated they will always or sometimes agree to the request; a 4.7 higher likelihood that a PP radiologist would oblige and always agree to perform the FGLP compared to an academic radiologist (OR 4.7 (95% CI: 1.3-20.5). 42.0% of respondents stated that they would always comply if a patient specifically requests an FGLP without a bedside LP attempt, 2.5 x higher likelihood for PP respondents (OR 2.5 (95%CI: 1.15-5.56)). Regarding FGLP operators, AP respondents were less likely to have PEs perform FGLPs compared to PP respondents (31.8% vs. 45.8%; (OR 0.65 (95% CI: 0.3,1.42)). In academic practices, 72.9% reported trainees perform >50% of their FGLPs. Regarding pre-procedural work up, 42.0% of respondents stated that they check coagulation labs on all patients prior to FGLP and 84.0% of respondents stated that patients should get a head CT prior to an FLGP only if there is high suspicion for increased intracranial pressure, similar between PP and AP respondents.

CONCLUSION

s This survey demonstrates that many academic and private practice radiology practitioners are relatively lenient in obliging to perform FGLPs in patients. There were many differences and some similarities in management of FGLP referrals and pre-procedural workup between academic and private practice groups.

CLINICAL RELEVANCE/APPLICATION

Our findings demonstrate the current methods of how private practice and academic radiologists handle FGLPs referrals and can be potentially used to develop guidelines of best FGLP practices.

Leptomeningeal Metastases in Glioma Revisited: High Incidence and Their Molecular Predictors based on Recent Imaging and Molecular Diagnostics

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Sung Soo Ahn, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Leptomeningeal metastases (LM) in glioma has been underestimated due to low incidence and lack of reliable imaging. This study aimed to investigate a real-world incidence of LM using a CSF-sensitive MR imaging technique and analyze molecular predictors for LM in the molecular era.

METHODS AND MATERIALS

Total 1,405 adult glioma patients underwent post-contrast fluid attenuated inversion recovery (FLAIR) imaging at initial diagnosis and during treatment monitoring between March 2001 and October 2021. Molecular data included isocitrate dehydrogenase (IDH) mutation, 1p/19q co-deletion, H3 K27M alteration, and O6-methylguanine-methyltransferase (MGMT) promoter methylation status. Multivariable logistic regression analysis for LM development was performed in molecular data, clinical data, and imaging characteristics. Median overall survival (OS) was compared between patients with and without LM using Kaplan-Meier survival curves and log-rank test.

RESULTS

LM was identified in 16.2% of glioma (228 of 1405), with 7.8% (110 of 1405) at initial diagnosis, and 8.4% (118 of 1405) at recurrence. Among molecular diagnostics, IDH-wildtype (odds ratio [OR] 3.14, P = .001) and MGMT promoter unmethylation (OR 1.43, P = .034) were independent predictors of LM. WHO grade 4 (OR 10.52, P <.001) and nonlobar location (OR 1.54, P=.048) were associated with LM at initial diagnosis, whereas IDH-wildtype (OR 5.04, P <.001) and H3 K27M alteration (OR 3.39, P =.003) were significantly associated with LM at recurrence. Patients with LM had a worse median OS than those without LM (16.7 vs. 32.0 months, log-rank test; P <.001). N

CONCLUSION

s CSF-sensitive MR imaging diagnostics aid diagnosis of LM and reduced an underdiagnosed condition in adult gliomas. Molecular markers affect LM at initial diagnosis and at recurrence, and patients with aggressive molecular markers warrant imaging surveillance of LM.

CLINICAL RELEVANCE/APPLICATION

The incidence of LM in glioma is underestimated due to lack of sensitive imaging protocol. Here, we utilized CSF-sensitive MRI with post-contrast FLAIR and discovered a high frequency of 228 (16.2%) patients diagnosed with LM in 1,405 diffuse glioma patients. Our findings emphasize the role of molecular markers in the development of LM in glioma patients. Patients with aggressive molecular markers such as IDH-wildtype and H3 K27M alteration warrant imaging surveillance of LM.

M2-SPNR-12

Use of VASARI Features for The Systematic Identification of Typical and Atypical Primary Central Nervous System Lymphomas

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Irene Dixe de Oliveira Santo, MD, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

The imaging appearance of PCNSL is highly variable with a significant proportion of cases demonstrating atypical features, frequently leading to a significant delay in diagnosis. Standardized classification of features has the potential to improve recognition of atypical variants, which is especially important given the drastically different treatment approach from the similar-appearing gliomas.

METHODS AND MATERIALS

Presurgical MR images of 71 patients with histologically-proven PCNSL were scored independently according to the VASARI (Visually Accessible Rembrandt Images) features by two different neuroradiologists. Classification into typical versus atypical PCNSL was based on enhancement pattern, presence or absence of necrosis, hemorrhage, and calcification. Age at diagnosis, gender, presenting symptoms, immune status, biochemical and molecular profile of the neoplasms, treatment, and overall survival were also recorded. The influence of visual appearance (atypical versus typical) on overall survival was analyzed using the Kaplan-Meier method and tested for significance using log-rank test (alpha=0.05).

RESULTS

Appearance of PCNSL was highly variable ranging from multiple infiltrative solid masses to ring-enhancing lesions. Periventricular and ependymal involvement were among the most common locations. Systematic scoring classified 44 (62%) patients into typical and 27 (38%) patients into atypical PCNSL. Presence of hemorrhage on SWI was often responsible for classification into atypical. Regarding survival, median OS was significantly lower for atypical (203 days) compared to typical (767 days) PCNSL (p = 0.012).

CONCLUSION

s Up to a third of our PCNSL patients demonstrated atypical MRI features, which may complicate diagnosis.

CLINICAL RELEVANCE/APPLICATION

Awareness of varying imaging presentations of PCNSL may alert the interpreting radiologist to consider lymphoma early and expedite diagnosis and treatment.

M2-SPNR-13

Usefulness of the Wave-CAIPI for the Post-contrast 3D T1-SPACE in The Evaluation of Brain Metastases

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Youngjin Heo, MD, (*Presenter*) Nothing to Disclose

PURPOSE

High-resolution post-contrast 3D T1WI is a widely used sequence for evaluating brain metastasis, despite the long scan time. This study aimed to compare highly accelerated post-contrast 3D T1-weighted sampling perfection with application-optimized contrasts by using different flip angle evolution using Wave-controlled aliasing in parallel imaging (Wave-T1-SPACE) with the commonly used standard high-resolution post-contrast 3D T1-SPACE for the evaluation of brain metastases.

METHODS AND MATERIALS

Among the 387 patients who underwent post-contrast wave-T1-SPACE and standard SPACE, 56 patients with suspected brain metastases were retrospectively included. Two neuroradiologists assessed the number of enhancing lesions according to lesion size, contrast-to-noise ratio (CNR) lesion/parenchyma, CNR white matter/gray matter, contrast ratio (CR) lesion/parenchyma, and overall image quality for the two different sequences.

RESULTS

Although there was no significant difference in the evaluation of larger enhancing lesions (>5 mm) between the two different sequences (P=0.66 for observer 1, P=0.26 for observer 2), wave-T1-SPACE showed significantly lower number of smaller enhancing lesions (<5 mm) than standard SPACE (1.61±0.29 vs 2.84±0.47 for observer 1, 1.41±0.19 vs 2.68±0.43 for observer 2). Furthermore, mean CNRlesion/parenchyma and overall image quality of wave-T1-SPACE were significantly lower than standard SPACE.

CONCLUSION

s Post-contrast wave-T1-SPACE showed comparable diagnostic performance for larger enhancing lesions (>5 mm) and marked scan time reduction as compared with standard SPACE. However, post-contrast wave-T1-SPACE showed underestimation of smaller enhancing lesions (<5 mm) and lower image quality than standard SPACE. Therefore, post-contrast wave-T1-SPACE should be interpreted carefully in the evaluation of brain metastasis.

CLINICAL RELEVANCE/APPLICATION

Recently, accelerated 3D acquisition techniques have been developed to reduce the scan time of high-resolution 3D T1WI sequences while preserving image quality. Wave-controlled aliasing in parallel imaging (Wave-CAIPI; Siemens Healthineers) is advanced parallel imaging technique that combines a corkscrew gradient trajectory with CAIPI shifts in the ky and kz directions to efficiently encode k-space and evenly spread the voxel aliasing in all dimensions. This allow to take better advantage of the 3D coil sensitivity information to provide highly accelerated parallel imaging with negligible artifacts and signal-to-noise ratio penalties. Therefore, we evaluated the diagnostic performance according to the lesion size and overall image quality of post-contrast wave-T1-SPACE for the evaluation of brain metastases.

White Matter Hyperintensities in Younger Mild Traumatic Brain Injured Patients

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Priya Santhanam, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

This study aims to identify associations between white matter hyperintensities (WMH) and the presentation and progression of post-concussive symptoms in patients 40 years and younger with mild traumatic brain injury (mTBI).

METHODS AND MATERIALS

MTBI patients (n=152; mean age=30 yrs) without preexisting head pathology were included in this study. Axial T2-weighted and T2-FLAIR sequences were performed on a 3.0 Tesla MR Signa HDxt system. Hyperintensities were regionally classified by lobe (frontal, parietal, temporal, or occipital) or cerebellum. Clinical data, including presence of several post-concussive symptoms, was obtained via retrospective chart review. Patient groups were compared by the presence or absence of WMH on imaging as well as by whether the patient had loss-of-consciousness (LOC) during injury. Interval-censored data analyses were performed to test the time to recovery between the comparison groups as recovery is only known to be between two examinations.

RESULTS

At least one WMH was present in 44% of male and 52% of female patients. Single WMH were predominantly located in the frontal lobe (84%) and more commonly in the left hemisphere (65%). LOC was more prevalent (p=0.018) in those with WMH as compared to those without WMH. While symptoms improved or resolved in both groups, a larger percentage of patients without WMH showed improvement as compared to patients with WMH. Patients with WMH also took significantly longer to recover from cognitive deficits than those without WMH (p=0.0177). Patients with LOC had a higher incidence of balance deficits as compared to patients without LOC (p=0.0391), while a larger percentage of those without LOC showed improvement or resolution of symptoms, specifically headache (p=0.0406), balance deficits (p=0.0173), and cognitive deficit (p=0.0341).

CONCLUSION

s This study revealed several significant associations between quantitative WMH findings, loss of consciousness, and clinical outcomes following mTBI. Taken together, findings suggest the presence of WMH in younger TBI patients may influence patient symptomology, while co-morbid LOC may lead to poor outcomes and recovery for affected individuals.

CLINICAL RELEVANCE/APPLICATION

The presence of white matter hyperintensities in younger patients with mild traumatic brain injury and loss of consciousness could be related to symptom prevalence, long-term outcomes, and recovery.

IDH and 1p19q Diagnosis in Diffuse Glioma from Preoperative MRI Using Artificial Intelligence

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Hugh McHugh, BMBCh, Auckland, New Zealand (*Presenter*) Clinical AI Registrar, Harrison AI Research Grant, RANZCR

PURPOSE

Isocitrate dehydrogenase (IDH) mutation and 1p19q codeletion are key molecular markers in glioma which both confer a more favorable prognosis. In the 2021 WHO classification of CNS tumours IDH and 1p19q status determine the glioma sub-categories of glioblastoma, astrocytoma and oligodendroglioma. IDH and 1p19q status is unknown until after surgery unless there is a biopsy which is uncommon. Reliable preoperative molecular characterization may facilitate tailored treatment approaches, for example if molecular status affects the optimal extent of tumor resection.Emerging research supports the potential of MRI-based IDH and 1p19q diagnosis. A limitation is the relative lack of generalization and external validation outside the widely used The Cancer Imaging Archive (TCIA) dataset. We present a combined IDH and 1p19q classification algorithm and assess performance on a local retrospective cohort and a fully independent cohort from the Erasmus Glioma Database (EGD).

METHODS AND MATERIALS

2D convolutional neural networks were trained to provide IDH and 1p19q classification. Inputs are T1 post-contrast, T2, and FLAIR sequences. Training data consists of preoperative imaging from the TCIA dataset (n=184) and images from a locally obtained cohort that were obtained prior to 1/1/2018 (n=349). Evaluation data consists of the most recent cases from the local cohort obtained between 1/1/2018 and 31/8/2021 (n=205) and the EGD (n=420).

RESULTS

Subject-wise IDH classification accuracy was 93.3% and 91.5% on the local cohort and EDG, with AUC of 95.4% and 95.8%, respectively. 1p19q accuracy was 94.5% and 87.5% with AUC of 92.5% and 85.4% on the local cohort and EGD. Combined subject-wise IDH and 1p19q accuracy was 90.4% and 84.3% on the local cohort and EGD, with AUC of 92.4% and 91.2%.

CONCLUSION

s High IDH and 1p19q classification performance was achieved on the local retrospective cohort. Generalization to the EGD was robust, demonstrating the potential for clinical translation. This method is able to non-invasively predict tumor subtypes according to the WHO 2021 classification with high accuracy using readily available imaging without the need for MR spectroscopy. This may better inform patients and clinicians prior to surgery and demonstrates the high potential impact in glioma diagnostics.

CLINICAL RELEVANCE/APPLICATION

This research externally validates non-invasive IDH and 1p19q diagnosis in glioma from preoperative MRI using artificial intelligence techniques allowing tumor classification by WHO 2021 criteria.

Compare the Performance of MRI-based 2.5D and 3D Convolutional Neural Networks in Differential Diagnosis of High-grade Gliomas and Single Brain Metastases

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Bin Zhang, (*Presenter*) Nothing to Disclose

PURPOSE

The 2.5D convolutional neural network models have unique advantages for studies with moderate sample sizes, while the 3D model can completely extract tumor and peritumoral features. To explore and compare the value of preoperative differential diagnosis of high-grade gliomas (HGG) and single brain metastases (BM) under 2.5D and 3D convolutional neural network models.

METHODS AND MATERIALS

T2WI and contrast-enhanced T1WI(CE T1WI) images of 230 patients with HGG and 111 patients with BM confirmed by surgery and pathology were retrospectively collected.The radiologist delineated the regions of interests (ROIs) of the input images of the 2.5D networks and 3D networks on the T2WI and CE T1WI axial images of the registered MRI. The slice nth with the largest tumor parenchyma area on the MRI image was determined, and then the tumor area (including tumor parenchyma and peritumoral edema area) of the slice of (n-2)th,nth and (n+2)th was delineated respectively. Define a minimum rectangular box as the ROIs of the 2.5D models that can cover all tumor areas at the three slices. Define the smallest 3D rectangular box that can completely contain the tumor area at all slices as the ROIs of the 3D models. Finally, based on DenseNet convolutional neural networks respectively build prediction models for T2WI and CE T1WI sequences under 2.5D and 3D model.The predictive performance of each model was evaluated by the receiver operating characteristic(ROC) curve, and the differences in the ROC curves of the models built by different convolutional neural networks were compared in pairs by Delong's test.

RESULTS

The best AUC values of the 3D model on CE T1WI and T2WI were 0.852 and 0.802, respectively. And the best AUC values of the 2.5D model on CE T1WI and T2WI were 0.831 and 0.784, respectively.The performance of the 3D models were better than that of the 2.5D models. Delong's test showed that the differences between the models were statistically significant ($P<0.05$).

CONCLUSION

s The MRI-based 2.5D and 3D convolutional neural network models have better diagnostic performance in differentiating HGG and single BM, and the 3D models have better diagnostic performance than 2.5D models. The deep learning model can be used to identify HGGs and BMs and assist in clinical formulation of precise treatment plans potential tool.

CLINICAL RELEVANCE/APPLICATION

The 2.5D model has better advantages in the deep learning model with a medium sample size, which can make up for the problem of the large data demand of the 3D model. While the 3D convolutional neural network structure analyzes the lesion information more completely, so it is easier to apply to clinical practice. The establishment of the prediction model will be able to differential diagnose HGG and single BM through non-invasive imaging examination.

M2-SPNR-17

Predicting the Isocitrate Dehydrogenase Wildtype in Non-enhancing or Poorly Enhancing Glioma by Conventional MRI Features and Apparent Diffusion Coefficient

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Jiyoung Song, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop predictive models using clinically available MRI parameters for predicting isocitrate dehydrogenase (IDH) status of gliomas with no or poor enhancement, which is considered as a radiologically low-grade feature.

METHODS AND MATERIALS

This retrospective study included 241 patients with surgically resected and pathologically confirmed gliomas that showed no or poor enhancement (less than 5% of the entire tumor volume) in the preoperative MRI. Visual rating of imaging features (T1-weighted, T2-weighted, FLAIR, contrast-enhanced T1-weighted images, and cerebral blood volume map) was performed. Regions of interest were drawn to acquire the apparent diffusion coefficient (ADC) mean (ADCmean) and minimum (ADCmin) in tumor and ADCnawm in normal-appearing white matter. Univariable and multivariable logistic regression analyses were performed for each imaging feature and ADC value. Then, receiver operating characteristic curve analysis was done with probability index calculated from the multivariable logistic regression model. A subgroup analysis was performed to predict IDH status in the non-enhancing gliomas.

RESULTS

In 241 non-enhancing or poorly enhancing gliomas, T2/FLAIR mismatch sign showed 100% specificity (42 of 42) to predict IDH-mutant gliomas. Among 199 gliomas with negative T2/FLAIR mismatch signs, 78 were IDH-wildtype. A predictive model incorporating age, calcification, multifocality, FLAIR homogeneity, ADCmin-to-ADCnawm ratio, and cortical involvement showed area under the curve (AUC) of 0.909 (95% CI: 0.858-0.946) with 90.8% sensitivity and 81.2% specificity. In the subgroup analysis for 116 non-enhancing tumors (46 IDH-wildtypes and 70 IDH-mutants) a predictive model that consisted of the same variables showed AUC of 0.883 (95% CI: 0.808-0.935), 82.6% sensitivity, and 88.1% specificity.

CONCLUSION

s Algorithms incorporating T2/FLAIR mismatch sign, age, calcification, multifocality, FLAIR homogeneity, ADCmin-to-ADCnawm ratio, and cortical involvement predicted IDH wild-type gliomas with radiologically low-grade feature.

CLINICAL RELEVANCE/APPLICATION

According to 2021 WHO classification for adult-type diffuse gliomas, even if a tumor seems low-grade, being IDH-wildtype satisfies a necessary condition to be diagnosed as glioblastoma. This study developed models using clinically available MRI parameters for predicting IDH status of gliomas with no or poor enhancement, which is considered as a radiologically low-grade feature.

High-resolution Clinical Functional MRI at 7T in Patients with Brain Tumors: Initial Assessment

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Kinsey Lano, BS, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to evaluate spatial localization accuracy of a high-resolution (1.4 mm isotropic) 7T fMRI protocol and compare with a clinical 3T protocol with typical resolution (1.9 x 1.9 x 4 mm3).

METHODS AND MATERIALS

Hand motor fMRI studies of 24 patients (n=12 on 7T and 12 on 3T) were evaluated. The 7T patients included 1 with brain mets, 3 with low-grade, and 8 with high-grade gliomas. The 3T patients included 4 with low-grade and 8 with high-grade gliomas. The fMRI paradigm consisted of 6 cycles of resting and bilateral hand-motor task blocks. T2*-weighted EPI sequences were used for the fMRI at 7T (TR/TE=2000 ms/24 ms, PI=3, SMS=2, 1.4 x 1.4 x 1.4 mm3) and at 3T (TR/TE=3000 ms/25 ms, PI=2, 1.9 x 1.9 x 4.0 mm3). The fMRI pre-processing included motion correction and co-registration with 3D T1-weighted images. Functional t-value maps were then generated by the standard GLM method. The t-value maps were thresholded at two statistical levels: (1) FWE-corrected p lt 0.05 (t gt 5.5 and 6.1 for 7T and 3T, respectively), and (2) t gt 4.0. For each patient, the most relevant motor-activation cluster on the lesion side was visually determined. The smallest distance between the center of the cluster and the central sulcus was measured and categorized: (1) gt 2 mm, (2) 2-4 mm, and (3) 5-10 mm.

RESULTS

At 7T, activation clusters at expected hand motor areas were detected in 7 (58%) and 9 (75%) out of the 12 patients at the statistical level of p lt 0.05, FWE corrected, and t gt 4.0, respectively. The spatial localization accuracy was within 2 mm for all the 9 patients with detected activation clusters. At 3T, hand motor activations were detected in 11 (92%) and 12 (100%) out of the 12 patients at the two statistical levels. The spatial localization accuracy assessment found 4 (33%), 6 (50%), and 2 (17%) patients having the detected activation cluster centered at gt 2mm, 2-4 mm, and 5-10 mm, respectively, from the central sulcus.

CONCLUSION

s We demonstrated that high-resolution fMRI at 7T is feasible for mapping primary motor areas in clinical routine. More accurate functional localization was achieved using the high-resolution 7T protocol compared to our routine protocol at 3T.

CLINICAL RELEVANCE/APPLICATION

The higher fMRI sensitivity at 7T allows imaging at higher spatial resolution, which leads to improved localization accuracy for presurgical functional mapping.

M2-SPNR-19

Nomogram for Predicting Early Recurrence in Patients with High Grade Glioma

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Qing Zhou, Lanzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop a nomogram to predict early recurrence of high-grade glioma (HGG) based on clinical factors, genetic factors, and MRI parameters.

METHODS AND MATERIALS

154 HGG patients were classified into recurrence and non-recurrence groups based on pathological diagnosis and RANO criteria. Clinical information included age, sex, and preoperative Karnofsky Performance Status (KPS) scores. Gene information included P53, IDH1, MGMT, and TERT status. All patients had baseline MRIs before treatment, including T1WI, T2WI, T1C, Flair and DWI examinations. The tumor location, single/multiple tumors, tumor diameter, peritumoral edema, necrotic cyst, hemorrhage, average apparent diffusion coefficient(ADC) value and minimum ADC values were evaluated. Univariate and multivariate logistic regression were used to determine the predictors of early recurrence and to build the nomogram.

RESULTS

Univariate analysis showed that the number of tumors (OR, 0.258; 95% CI: 0.104, 0.639; P = 0.003) and peritumoral edema (OR, 0.965; 95% CI 0.942, 0.988; P = 0.003; mean in the recurrence group 22.04±17.21 mm; mean in the non-recurrence group 14.22±12.84 mm) were statistically significantly different in patients with early recurrence. Genetic factors included IDH1 (OR, 4.405; 95% CI 1.874, 10.353; P= 0.001), and MGMT (OR, 2.389; 95% CI 1.234, 4.628; P= 0.010). Multivariate logistic regression analysis revealed that the number of tumors (OR, 0.227; 95% CI 0.084, 0.616; P = 0.004), peritumoral edema (OR, 0.969; 95% CI 0.945, 0.993; P = 0.013) and IDH1 (OR, 4.200; 95% CI 1.602, 10.013; P= 0.004) were independent risk factors for early recurrence. The nomogram showed the highest net benefit when the threshold probability was less than 63%.

CONCLUSION

s A nomogram prediction model based on results that are easily available before surgery can effectively aid clinical treatment decisions for newly diagnosed HGG patients.

CLINICAL RELEVANCE/APPLICATION

A nomogram prediction model can effectively aid treatment decisions in newly diagnosed HGG patients. Neurosurgeons may adjust the surgical decision on the scope of tumor resection based on the prediction model. For tumor tissues with a high risk of recurrence and high infiltration, the radiation oncologist can also upgrade the radiation dose to high-risk areas.

Peritumoral MR Imaging Radiomic Features Improves Identification of Circumscribed Astrocytic Gliomas and High-grade Gliomas

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Shuang Li, (*Presenter*) Nothing to Disclose

PURPOSE

In the 2021 WHO classification of tumors of the central Nervous System, the terms of "diffuse" and "circumscribed" were applied to the classification of gliomas, diffuse gliomas are characterized by extensive infiltration, while circumscribed astrocytic gliomas show a solid growth pattern. The most common circumscribed astrocytic gliomas are pilocytic astrocytoma (PA) and pleomorphic xanthoastrcytoma (PXA). MR imaging findings of them can resemble high grade gliomas (HGGs). We aimed to develop an MRI-based radiomics model to distinguish circumstanced glioma from HGGs.

METHODS AND MATERIALS

Preoperative T2 fluid-attenuated inversion recovery (T2 FLAIR) and contrast-enhanced T1-weighted imaging (CE-T1WI) data were obtained from 160 patients (91 circumscribed astrocytic gliomas and 69 glioblastoma) between 2016 and 2020. 1288 features were obtained in tumor region and the 5 mm thickness peritumoral region, respectively. We up-sampled features by repeating random cases to make samples balance. Then, we applied the normalization on the feature matrix. Feature pairs with PCC values larger than 0.990 will be removed. Before build the model, we used recursive feature elimination (RFE) to select features. Support vector machine (SVM) was used as a classifier. To determine the hyper-parameter of model, we applied cross validation with 10-fold on the training data set. The hyper-parameters were set according to the model performance on the validation data set. The performance of the model was evaluated using receiver operating characteristic (ROC) curve analysis. The area under the ROC curve (AUC) was calculated for quantification. We also estimated the 95% confidence interval by bootstrape with 1000 samples.

RESULTS

Intratumor radiomic features achieved AUCs of 0.820(CE-T1WI) and 0.787(T2 FLAIR). The integrated model, incorporating intra- and peritumoral features extracted from T2 FLAIR and CE-T1WI images, improved the AUCs to 0.889 on the same test set.

CONCLUSION

s An imaging-based model combining tumor and peritumor radiomics can help to distinguish between circumscribed astrocytic gliomas and high-grade gliomas.

CLINICAL RELEVANCE/APPLICATION

Circumscribed astrocytic gliomas had better prognosis than HGGs. Correct differential diagnosis is vital for preoperative decision-making and prognostic evaluation. Radiomic features extracted from intra- and peritumoral region may help the identification.

M2-SPNR-4

Discriminative Power of Macro- And Microstructural MRI in the Differential Diagnosis of Neurodegenerative Parkinsonian Syndromes

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Alexander Rau, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the discriminative performance of macro- and microstructural MRI in the differential diagnosis of neurodegenerative parkinsonian syndromes (NPS).

METHODS AND MATERIALS

We included patients with NPS according to current consensus diagnostic criteria, i.e. 136 patients with Parkinson´s disease (PD), 32 patients with progressive supranuclear palsy (PSP), 41 patients with multiple system atrophy (MSA) as well as 37 healthy controls (HC) in this monocentric retrospective cross-sectional study. Tissue probability values for gray matter, white matter and CSF were automatically obtained by CAT12. In addition, the microstructure of the patients was analyzed using a mesoscopic approach by diffusion tensor imaging (DTI) and diffusion microstructure imaging (DMI). Respective parameters were extracted using the AAL3-atlas and ROIs with great relevance for PSP. Based on this, a linear support vector machine (SVM) was trained and optimized in respect of ROC-AUC in a one-vs-rest (OVR) classifier. The diagnostic performance of SVM was compared with respect to different inputs, i.e. TPV, DTI and DMI individually.

RESULTS

Diffusion MRI outperformed the T1w derived TPV with a correct classification in 80% for DTI, 79% for DMI and 52% for TPV. The corresponding OVR-ROC-AUC of DTI was 0.92 for HC, 0.89 for PD, 0.95 for MSA and 0.93 for PSP and for DMI 0.91 (HC), 0.90 (PD), 0.96 (MSA) and 0.93 (PSP).

CONCLUSION

s Microstructural parameters as obtained in an mesoscopic approach using diffusion MRI data outperformed structural data derived by conventional imaging in the diagnosis of NPS. The particularly good performance of microstructural approaches in the diagnosis of PD, as a weak point in conventional MRI, underlines the potential of this approach. The introduced automatic approach might facilitate the MRI diagnosis of patients with suspected NPS.

CLINICAL RELEVANCE/APPLICATION

The developed approach might facilitate the differential diagnosis of neurodegenerative parkinsonian syndromes in an objective manner and is therefore of high clinical relevance.

M2-SPNR-6

Usefulness of 3D FIESTA in Differentiating Parkinson's Disease From Parkinson Syndrome: Volumetric Alternation of Olfactory Bulb

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Ide Ide, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Parkinson's disease (PD) is a neurodegenerative disease, related with deposition of Lewy body. Braak stage of Lewy pathology shows the initiation sites are in the olfactory bulb (OB), hence, olfactory dysfunction is among the earliest nonmotor features of PD. It's sometimes difficult to differentiate PD from parkinson syndrome (PS), such as multiple system atrophy (MSA), corticobasal syndrome (CBS), and progressive supranuclear palsy (PSP) using conventional MRI and clinical symptom. It's known that olfactory loss occurs to a lesser extent or is absent in PS. Therefore, we hypothesized OB change may be useful in differential diagnosis. 3D fast imaging employing steady-state acquisition (FIESTA) results in good delineation of cranial nerves, however, no study demonstrated OB volume change between PD and PS using 3D-FIESTA. Our purpose is to determine whether OB measurement on 3D-FIESTA is useful for differentiating PD from PS.

METHODS AND MATERIALS

Sixty-four PD (mean age ± SD: 71.5 ± 9.4), 8 MSA (68.9 ± 8.9), 10 PSP (75.9 ± 8.3), and 8 CBS (73.8 ± 8.9) patients were recruited. Thirty-three healthy subjects (HS) (63.8 ± 18.6) were also recruited as normal controls. The diagnoses were made according to the diagnostic criteria by an experienced neurologist. The parameter of 3D-FIESTA is following: 3T SIGNA Premier (GE), FA 45deg, TR 4ms, TE 2ms, matrix 512×512, slice thickness 1.0mm, scan time 2:27, spatial resolution: 0.6×0.6×0.8 mm. The cross-sectional area of the OB was measured using manual ROI method, and we used maximum area of OB in coronal plane. The average of bilateral OB was calculated for each subject. We performed group comparison and diagnostic accuracy test using Welch's t test and ROC analysis, respectively. All statistics were performed with BellCurve for Excel (Social Survey Research Information Co., Ltd.).

RESULTS

The mean area of OB was significantly smaller for PD patients (mean area ± SD mm2: 4.1 ± 1.0) than for HSs (6.6 ± 1.4, plt;0.01). Moreover, that of PD were also significantly smaller than that of MSA (6.0 ± 1.4, p=.007), PSP (4.8 ± 0.9, p=.03), and CBS (5.3 ± 1.2, p=.03), respectively (Figure 1 and 2). The ROC analyses showed that good diagnostic performance, especially in analysis of PD vs MSA (AUC: 0.874, optimal cut off points: 5.6 mm2, sensitivity: 93.8%, specificity: 87.5%).

CONCLUSION

s Our results suggest the OB volume loss in PD, which may reflect degeneration due to deposition of Lewy body. OB volumetry using 3D-FIESTA can be useful to differentiate PD from PS, especially for MSA.

CLINICAL RELEVANCE/APPLICATION

OB volumetry with 3D-FIESTA may contribute precise diagnoses in PD and PS showing atypical MR findings. 3D-FIESTA is a common and widespread MR technique, which can work as clinical routine MR application in patients with Parkinsonism.

M2-SPNR-7

Altered Cerebral Blood Flow in Spinocerebellar Degeneration Patients

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Bing Liu, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Spinocerebellar degeneration (SCD) comprises a multitude of disorders with sporadic and hereditary forms, including spinocerebellar ataxia (SCA), cerebellum-type of multiple system atrophy (MSA) and more complex phenotypes. Except for progressive cerebellar ataxia and structural atrophy, hemodynamic changes have also been demonstrated in SCD. This study aimed to clarify the whole-brain altered patterns of cerebral blood flow (CBF) and its correlations with disease severity and emotional abnormalities in SCD via arterial spin labeling (ASL).

METHODS AND MATERIALS

Thirty SCD patients and 30 age- and sex-matched healthy controls (HC) were prospectively recruited to undergo ASL examinations in a 3.0T MR scanner. The Scale for Assessment and Rating of Ataxia (SARA) and the International Cooperative Ataxia Rating Scale (ICARS) scores were used to reflect the disease severity in SCD patients. Additionally, the status of anxiety and depression among all patients were evaluated by the Self-Rating Anxiety Scale (SAS) and the Self-Rating Depression Scale (SDS). We compared the whole-brain CBF between SCD group and HC group at voxel level. And the ROI-based correlation analyses between CBF and disease severity as well as emotional abnormalities were performed for SCD group.

RESULTS

Compared with HC, SCD patients exhibited decreased CBF in two clusters (FWE corrected $P<0.05$), covering bilateral dentate and fastigii nuclei, lobule VIX, lobule VX, bilateral lobule HI-IV and lobule HIX, left lobule HVI and right lobule HVIIIb as Cluster1 and the dorsal part of raphe nucleus in midbrain as Cluster2. The CBF of Cluster 1 was negatively correlated with SARA scores (Spearman's rho=-0.374, P=0.042) and SDS standard scores (Spearman's rho=-0.388, P=0.034), respectively. While the CBF of Cluster2 also had negative correlations with SARA scores (Spearman's rho=-0.370, P=0.044) and ICARS scores (Pearson r=-0.464, P=0.010).

CONCLUSION

s The SCD-related whole-brain CBF changes were mainly involved in cerebellum and midbrain, partially overlapped with hand, foot and tongue movement activations areas. Decreased CBF was related to disease severity and depression status in SCD. Therefore, CBF may be a promising neuroimaging biomarker to reflect the severity of neurodegeneration and to provide warnings for emotional changes.

CLINICAL RELEVANCE/APPLICATION

Decreased CBF in cerebellum and midbrain were associated with disease severity and depression level in SCD, which may help reflect the degree of neurodegeneration in vivo, and give early warnings for SCD-related depression.

M2-SPNR-8

Diagnostic Performance of Susceptibility Map-weighted MRI According to Acquisition Plane for Differentiating Neurodegenerative Parkinsonism

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Suiji Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance of SMwI according to the acquisition plane for differentiating neurodegenerative parkinsonism.

METHODS AND MATERIALS

This retrospective, observational, single-institution study included patients who were consecutively enrolled from those who visited movement disorder clinics and underwent both brain MRI and 18F-FP-CIT with clinical symptoms of suspected parkinsonism between September 2021 and December 2021. Both oblique coronal plane (vertical to the midbrain) and anterior commissure-posterior commissure (AC-PC) plane of SMwI were acquired. Abnormality was determined when there was any hypointense area that obliterated the differentiation of the three layers and classified into 3 categories (0: normal, 1: intermediate, 2: abnormal) by two neuroradiologists. 18F-FP-CIT PET served as the reference standard. The diagnostic performance of the oblique plane and AC-PC plane of SMwI were assessed per substantia nigra and per participant. Inter-rater agreement was assessed using Cohen's kappa coefficient. McNemar's test was used to test the diagnostic performance of oblique coronal plane and AC-PC plane of SMwI.

RESULTS

Total 194 patients (mean age ± SD, 67 ±10 years, 91 men) were included. Among them, 84 patients were diagnosed with IPD, 26 with MSA, 3 with PSP, 10 with CBS, 35 with ET, 10 with DIP, 4 with NPH and 22 with others. The overall inter-rater agreement for both oblique and AC-PC plane was good (? = 0.747 and 758 for each, P < .001). In per participant analysis, the overall inter-rater agreement for both oblique and AC-PC plane was good (? = 0.747 and 758 for each, P < .001). For reader 1, the overall sensitivity of the oblique plane was 89.9% and that of the AC-PC plane was 91.7% (P = .727). The overall specificity of the oblique plane was 87.1% and that of AC-PC plane was 88.2% (P = .727). The overall accuracy of the oblique plane was 88.7% and that of AC-PC plane was 90.2%, with p-value of 0.607. Reader 2 demonstrated similar results. For both readers, there was no significant difference of sensitivity, specificity and accuracy between the oblique plane and the AC-PC plane.

CONCLUSION

s There was no significant difference of diagnostic performance between the oblique plane and the AC-PC plane of SMwI in differentiating parkinsonism.

CLINICAL RELEVANCE/APPLICATION

This study assures clinics can choose any one of MRI acquisition planes of SMwI between oblique plane and AC-PC plane according to their clinical settings in the diagnosis of parkinsonism.

Brain Connectivity Changes in Resting-State Functional MRI in Patients with HIV-Associated Neurocognitive Disorder (hand): A Multi-voxel Pattern Analysis (MVPA) Approach Using Mutual Connectivity Analysis (MCA)

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Ali Vosoughi, Rochester, NY (*Presenter*) Nothing to Disclose

PURPOSE

To develop and evaluate a novel machine learning framework for identifying subjects with HIV-Associated Neurocognitive Disorder (HAND) using Mutual Connectivity Analysis (MCA) by capturing connectivity differences in resting-state functional MRI (rsfMRI).

METHODS AND MATERIALS

Resting-state fMRI scans (3T, EPI sequence, TR=1.65s, 250 acquisitions) were acquired in a cohort of 45 age-matched subjects (20 healthy, 25 HIV+, 16 of whom had HAND symptoms (HAND+)). After pre-processing, data was parcellated into 90 regions using the Automated Anatomical Labeling atlas. Regions were represented by their average time-series. A nonlinear machine learning connectivity analysis method (MCA [Citation blinded for review]), was used to quantify interdependence of region-specific time-series producing a 8100-element connectivity matrix. Generalized matrix learning vector quantization feature selection revealed regional connections that were most different between the groups. These were used for subsequent identification of HAND+ subjects using an adaptive boosting classifier in a Multi-Voxel Pattern Analysis (MVPA) framework. For both feature selection and classification, strict data separation (90% train/10% test) was carried out in a 100-iteration cross-validation scheme. For comparison, MCA was evaluated against the clinical standard technique of functional connectivity analysis using cross-correlating (CC) low-pass filtered fMRI time-series. Area Under the Curve (AUC) for Receiver Operator Characteristics (ROC) analysis was used to quantitatively evaluate diagnostic quality of HAND+ subject classification.

RESULTS

The MCA rsfMRI connectivity analysis method clearly outperformed the clinical standard CC technique in identifying HAND+ subjects with AUC of 0.85 ± 0.27 for MCA, and 0.71 ± 0.31 for CC, respectively. Diagnostic quality differences between both methods were statistically significant ($p<0.05$, Wilcoxon signed-rank test).

CONCLUSION

s Our results suggest that MCA significantly improves the diagnostic accuracy of identification of patients with HAND based on rsfMRI neuroimaging. We conclude that, when compared to conventional CC analysis, our MVPA framework is better suited to capture disease-related brain network connectivity changes in HAND.

CLINICAL RELEVANCE/APPLICATION

The MCA method classifies HAND+ subjects and controls by identifying relevant changes in fMRI connectivity. Such changes can be useful diagnostic imaging biomarkers for HIV-related neurologic disease.

M2-SPOB-1 Assessment of Fetoplacental Unit by Intravoxel Incoherent Motion MRI: Diffusion and Perfusion Properties of Fetal Lungs and Placenta in Intrauterine Growth Restriction

Participants
Roberta Ninkova, MD, Rome, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the potential use of Intravoxel Incoherent Motion (IVIM) imaging in the study of microperfusion and microstructural characteristics of fetal lungs and placenta in IUGR fetuses, comparing IVIM parameters with those of a healthy control group.

METHODS AND MATERIALS

Eighty-eight pregnancies (26 IUGR; 62 normal) will be enrolled. MR examinations will be performed at 1.5 T, using a DWI sequence with 10 different b-values (0,10,30,50,75,100,200,400,700,1000 s/mm2). For each fetus, two bilateral ROIs will be manually placed in lung parenchyma; six ROIs will be placed on both fetal and maternal sides of each placenta. Differences of mean values of perfusion fraction f, diffusion coefficient D, and pseudo-diffusion coefficient D*and their correlation with Gestational Age (GA) and Birth Weight (BW) will be investigated in both IUGR and control group.

RESULTS

- In fetal lungs, we found a significant difference in f mean values between IUGR fetuses and the healthy control group (p= 0.0000004). No statistically significant difference was observed for D and D* values. In normal fetuses we found a positive correlation between f and GA (p<001); no correlation with GA was found in pathological fetuses.- Concerning the placenta, in the fetal side of placenta f and D* allowed to discriminate SGA (Small for Gestational Age) from real FGR (Fetal Growth Restriction) (p=0.021; p=0.036, respectively), with FGR showing lower values. SGA showed intermediate impaired perfusion pattern in terms of f and D* compared to FGR and healthy controls. A significant positive correlation was found between f and BW in IUGR fetuses. A significant negative correlation was found between D and GA in IUGR fetuses.

CONCLUSION

s Complex interactions between placental and fetal environments ensure normal fetal growth. Impairment of the fetoplacental unit may lead to Intrauterine Growth Restriction (IUGR), which is associated with perinatal morbidity and mortality, neonatal complications such as ARDS, and long-term complications, like cardiovascular disease and neurodevelopmental delay. Preliminary results show that IVIM parameters, with special regard to perfusion fraction f, may be potential in vivo biomarkers to discriminate between IUGR and healthy fetuses, and correlate with GA and BW.

CLINICAL RELEVANCE/APPLICATION

The development of new non-invasive techniques for prompt and accurate prenatal diagnosis is critical to improve the prenatal and postnatal outcomes of IUGR fetuses. The clinical significance of IVIM-MRI may lie in providing in vivo imaging biomarkers of IUGR severity useful in predicting perinatal outcome and guiding treatment decisions.

M2-SPPD-2 Radiogenomics in Pediatric Neuroblastoma: Radiomics Signature With Imaging Features Based on Computed Tomography in Predicting Segmental Chromosomal Aberrations at 1p36 and 11q23

Participants
Haoru Wang, (*Presenter*) Nothing to Disclose

PURPOSE

To build and evaluate a CT-based radiomics signature with imaging features in predicting SCAs status at 1p36 and 11q23 in pediatric neuroblastoma.

METHODS AND MATERIALS

Eighty-seven neuroblastoma patients with detection of SCAs at 1p36 and 11q23 were retrospectively enrolled and randomly stratified into training set (n=60) and test set (n=27). Clinical factors were analyzed and then selected using univariate and multivariate logistic regression analysis. Lesion regions of interest were manually delineated on three-phase CT images, and radiomics features were extracted automatically and selected. Clinical model, radiomics signature and clinical radiomics nomogram were established respectively on the basis of selected clinical factors and radiomics features. The receiver operating characteristic curve analysis and decision curve analysis were used to evaluate the predictive performance of each model.

RESULTS

The constructed radiomics signature was composed of eight radiomics features, with area under the curve (AUC) of 0.869 (95% confidence interval [CI]: 0.786, 0.941) and 0.883 (95%CI: 0.761, 0.983) in the training and test sets respectively. The nomogram incorporated of shape, ratio of mean CT values between tumor parenchyma and paraspinal muscle (Tmean/muscle) at venous phase and radiomics signature had better diagnostic efficacy in predicting SCAs compared to the clinical model for training (AUC, 0.893 vs. 0.791) and test (AUC, 0.861 vs. 0.750) sets. Decision curve analysis showed that the nomogram had better clinical practicability than the clinical model alone.

CONCLUSION

s There are certain relevance between CT imaging features and SCAs status in pediatric neuroblastoma. The CT-based radiomics signature could be helpful for predicting SCAs in neuroblastoma. The nomogram incorporated of shape, Tmean/muscle at venous phase and radiomics signature performs better than clinical model in predicting SCAs in neuroblastoma.

CLINICAL RELEVANCE/APPLICATION

We used radiomics to predict segmental chromosomal aberrations at 1p36 and 11q23 in pediatric neuroblastoma, and found that radiomics is able to predict segmental chromosomal aberrations at 1p36 and 11q23, which could provide a non-invasive method to predict genomic profiles in neuroblastoma. Meanwhile, we found imaging features based on computed tomography correlate with segmental chromosomal aberrations at 1p36 and 11q23 in neuroblastoma, and this finding is useful to direct clinical decisions and management.

M2-SPPH-1 Differentiating Patients With Diabetes Mellitus With Pancreatic Extracellular Volume Fraction and Normalized Iodine Concentration Acquired by Dual Energy CT

Participants
Xiaoyi Cai, MBBS, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the feasibility of extracellular volume (ECV) fraction and normalized iodine concentration (nIC) using dual energy CT (DECT) to evaluate diabetic patients.

METHODS AND MATERIALS

106 patients with known or suspected abdominal disease underwent abdominal precontrast CT scan (120kV) and DECT enhanced scan. Patients were divided into three groups according to the American Diabetes Association criteria: non-diabetes group (HbA1 < 5.7%, 31 patients), pre-diabetes group (5.7% = HbA1c < 6.5%, 36 patients) and diabetes group (HbA1c = 6.5%, 39 patients). Two ECV fractions(ECV-HU = (HUpancreas -equilibrium phase - HUpancreas -precontrast) /(HUabdominal aorta -equilibrium phase - HUabdominal aorta -precontrast) × (100-Hct), ECV-ID = (IDpancrease -equilibrium phase /IDabdominal aorta -equilibrium phase) × (100-Hct)) and the nIC (nIC=ICpancrease-equilibrium phase /ICabdominal aorta-equilibrium phase) of the pancreas were calculated. The correlations of pancreatic ECV-HU, ECV-ID, and nIC with HbA1c value were analyzed by Spearman rank correlation. Pancreatic ECV-HU, ECV-ID and nIC among groups were compared by one-way ANOVA. The diagnostic performance of pancreatic ECV-HU, ECV-ID, and nIC was evaluated by receiver operating characteristic (ROC) curve analysis.

RESULTS

In the whole patients, HbA1c was moderately positively correlated with ECV-HU, ECV-ID and nIC (rs =0.447, rs =0.541, rs =0.533, respectively; all P < 0.001). The pancreatic ECV-HU, ECV-ID and nIC in diabetes group were significantly higher than those in non-diabetes group and pre-diabetes group (all P < 0.001). The combination of ECV-ID and nIC has the highest area under the curve (AUC), sensitivity and specificity in differentiating non-diabetic or pre-diabetes from diabetic patients(0.876, 76.9% and 83.9%; 0.820, 71.8% and 88.9%, respectively). Furthermore, in differentiating non-diabetes or pre-diabetes from diabetes group, the AUC was superior in ECV-ID vs. ECV-HU (0.851 vs. 0.799 and 0.787 vs. 0.741, respectively).

CONCLUSION

s Combined application of pancreatic ECV-ID and nIC is a potential imaging index to evaluate diabetic patients.

CLINICAL RELEVANCE/APPLICATION

The diagnosis of diabetes mellitus was associated with pancreatic imaging biomarkers, such as ECV and nIC, which may provide new insights into clinical practice.

M2-SPPH-2 Impact of Patient Habitus and Energy-Bin Weighting on Monochromatic Image Quality for Photon-Counting CT

Participants
Paul E. Kinahan, PhD, Seattle, WA (*Presenter*) Co-founder, PET/X LLC

PURPOSE

Photon-counting x-ray computed tomography (PCCT) is a new technology that has the potential to improve clinically relevant image properties such as bias and noise. However, the image reconstruction algorithm must account for energy-dependent physical effects, including Compton scattering in the detectors for the case of silicon-based scanners. We investigated the effects of combining post-log projection data from different edge-on silicon-based PCCT energy bins to form virtual mono-energetic images by minimizing the root-mean-squared error (RMSE).

METHODS AND MATERIALS

PCCT and monochromatic images were simulated using the Catsim software package. The XCAT phantom served as a vector-based input to the simulations. Optimization of the projection data weighting and image analysis was done in MATLAB.The patient habitus was varied by modifying the XCAT fields to generate three patient sizes defined as “small”, “medium”, and “large”. For each phantom size, two Catsim simulations were performed: one having a monochromatic x-ray spectrum with standard detection, and one having a full bremsstrahlung spectrum and edge-on silicon-based PCCT detectors that included a model for Compton scatter.

Using a least-squares cost function, PCCT sinograms corresponding to different photon energies were combined to match the monochromatic sinograms at each of the three sizes. These "synthetic monochromatic sinograms" were then reconstructed. The RMSE was computed using the monochromatic images as ground truth.

RESULTS

The optimal weights for recombining multiple PCCT energy bin sinograms were object dependent. When size-specific weights were used, the RMSEs over all phantom pixels were 22, 41 and 53 HU for the three respective phantom sizes. However, if the coefficients were fixed to those optimal for the medium phantom, the RMSEs for the smaller and larger increased to 28 and 60 HU respectively. For some imaging techniques, photon starvation artifacts would appear for sub-optimal weights.

CONCLUSION

s For PCCT reconstruction algorithms that aim to estimate monochromatic CT data by simple weighting of energy bin sinograms, the use of fixed coefficients will lead to increased noise and artifacts for varying patient sizes.

CLINICAL RELEVANCE/APPLICATION

Photon-counting CT scanners have a dramatic increase in the amount of spectral (energy) information generated compared to standard energy-integrating CT scanners, even those operated in dual-kVp mode. With this rich source of energy data, there are many new parameters to be evaluated and ideally optimized. This study evaluates one such set of

M2-SPPH-3 Reporting on Methodology in Dual Energy CT Studies: A Systematic Literature Review

Participants
Nils Grosse Hokamp, MD, MBA, Koln, Germany (*Presenter*) Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Consultant, Bristol-Myers Squibb Company

PURPOSE

The objective of this study was to perform a structured literature review to assess how image acquisition parameters and technical details are reported in clinical dual-energy CT (DECT) studies.

METHODS AND MATERIALS

A structured query of the PubMed meta-database was performed that covered all studies between the years 2016 and 2020 with a potential utilization of a dual-energy system. After inclusion, the described dual-energy CT methodology was recorded in a structured approach for each study with particular attention to scanning and reconstruction parameters.

RESULTS

A total of 864 out of 2742 studies were eligible for inclusion. The DECT approach that was used was reported in 87% of all studies, while in 98% of all studies at least the vendor of the DECT system was specified. In most studies, a dual-source system was used (44%), followed by kVp switching (34%) and dual-layer systems (15%), with the remainder using multiple systems or twinbeam technology. The average number of patients included was 83 ± 213. Data on mAS was reported in 70%, data on tube voltage in 78%, data on gantry rotation time in 60%, data on collimation in 57%, and data on pitch in 60% of the studies.

CONCLUSION

s In dual-energy CT studies between 2016 and 2020, the technical parameters of image acquisition as well as reconstruction parameters are frequently only partially specified, which may significantly limit reproducibility.

CLINICAL RELEVANCE/APPLICATION

WIth the increasing complexity of technological concepts to Dual-Energy CT imaging, more caution has to be taken when describing methodology of scientific studies. Only complete details on image acquisition and image reconstruction will allow for transferability of findings among sites and from research into clinics, eventually.

M2-SPPH-5 Prior-Information-Inspired Deep Learning Noise Reduction for Coronary CT Angiography Acquired with a Photon Counting Detector CT

Participants
Shaojie Chang, PhD, ROCHESTER, MN (*Presenter*) Nothing to Disclose

PURPOSE

To develop a deep learning technique that utilizes prior information to reduce noise in high-resolution, photon-counting-detector (PCD) CT coronary CT angiography (CTA).

METHODS AND MATERIALS

Clinical coronary CTA exams acquired on a PCD-CT (NAEOTOM Alpha, Siemens Healthcare) were considered in this study. Virtual monoenergetic images (VMIs) at different energies (50, 70, 100 keV) were reconstructed using both filtered back projection (FBP) and iterative reconstruction (IR) algorithms, 0.6 mm slice thickness, and a sharp kernel (Bv68). The FBP and IR images were subtracted to generate images composed predominately of noise. The lower noise 70 keV VMI images served as the prior images. To obtain a relatively low-noise signal reference, adjacent IR images and prior images were averaged to simulate thicker slice images (1.5 mm). A convolutional neural network (CNN) was constructed based on a U-Net architecture with mean square error loss. CNN inputs consisted of (1) noise-only images superimposed onto the signal reference images and (2) the prior images. Spatial decoupling between the noise-only image and signal reference was used to avoid overfitting and reduce propagation of IR deficiencies into the CNN model. Image patches of 128x128 pixels were extracted from all available training data and standard data augmentation techniques were applied. Training targets consisted of the signal reference without added noise. Denoising strength was controlled by a weighting factor of the noise patch. The resulting CNN was applied to the original thin slice and sharp kernel FBP images.

RESULTS

FBP images showed very high noise at all VMI energies given the sharp kernel. While IR images substantially reduced image noise

compared to FBP, noise texture was altered and a patchy appearance was observed. The proposed CNN framework provided strong noise reduction, by 95 ± 1 % relative to FBP and by 60 ± 3 % relative to IR, while maintaining a natural noise texture without a patchy appearance. Additionally, image properties unique to each VMI energy were retained, with increased contrast signal at 50 keV, and decreased calcium blooming at 100 keV.

CONCLUSION

s This prior information inspired CNN framework fully utilized the PCD-CT data along the energy axis to achieve substantial noise reduction while preserving the VMI's properties.

CLINICAL RELEVANCE/APPLICATION

Improved PCD-CT coronary CTA image quality at different energies is beneficial for improving visualization of non-calcific plaques using low keV VMI and reduction of calcium/stent blooming using high keV VMI.

M2-SPPH-6 Development of a Dose- And Size- Independent Deep Learning Based Material Decomposition Algorithm Using Photon-Counting CT Images

Participants
Jayasai Rajagopal, BA, Durham, NC (*Presenter*) Nothing to Disclose

PURPOSE

To develop a material decomposition technique that can accurately characterize k-edge materials in the presence of variable dose conditions

METHODS AND MATERIALS

Image data was generated using a validated simulation platform (DukeSim, Duke University) to emulate a clinical photon-counting CT system (NAEOTOM Alpha, Siemens Healthineers) with standardized acquisition parameters (120 kV, 20-65 keV detector thresholds). 4200 cases were acquired consisting of cylindrical phantoms at variable sizes (16, 24, 32, 40 cm diameter) containing inserts of iodine and gadolinium (0.25-20 mg/mL) in various configurations including vials with single materials and mixtures and simulated at several dose levels (3.9, 5.9, 11.7 mGy CTDIvol). Dose and size parameters were selected to create variable image quality across the dataset. A convolutional neural network with a U-net architecture was trained using a subset of the cases to learn the relationship between the simulated images and the concentrations of iodine and gadolinium. The model used patch-wise training with a squared-error regression loss function. None of the material concentrations in the testing dataset were present in the training data. Model accuracy was measured by estimating bias and limits of agreement (LoA) in a Bland-Altman analysis and root-mean-square error (RMSE) of concentration estimates from the ground truth values.

RESULTS

Image noise within vial regions-of-interest increased as dose decreased (32%). Testing results showed a good performance for estimating iodine (bias: -0.1, LoA: -0.6 - 0.4 mg/mL I) and gadolinium (bias: -0.02, LoA: -0.3 - 0.3 mg/mL Gd). RMSE showed an excellent overall performance for iodine (0.1 mg/mL) and gadolinium (0.1 mg/mL).

CONCLUSION

s A deep learning based material decomposition algorithm was able to accurately characterize iodine and gadolinium as single materials and mixtures. The algorithm maintained a desirable performance under low dose conditions.

CLINICAL RELEVANCE/APPLICATION

A material decomposition technique that can reliably function at different dose levels can increase the clinical viability of material characterization for diagnostic purposes

M2-SPPH-7 Performance Evaluation of Deep Learning Image Reconstruction for Dual Energy CT - Quantitative Accuracy and Noise Characteristics of Iodine Map

Participants
Benjamin Maloney, PhD, Detroit, MI (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the performance of DLIR-GSI, a novel deep learning image reconstruction algorithm for dual energy CT, with a focus on quantitative accuracy and noise characteristics of its generated iodine maps at reduced radiation dose levels.

METHODS AND MATERIALS

An anthropomorphic lung phantom (CTP698, The Phantom Laboratory) with an inserted syringe filled with iodine solution (ISOVUE 300 and saline mix) was scanned under GSI mode on a Revolution CT scanner (GE Healthcare). Six concentrations of iodine solution (range [1.7, 12.0] mgI/ml), and five CTDIvol levels of CT scan (range [4.2, 19.0] mGy) were used in the experiment. For each scan, the iodine images were reconstructed using five different reconstruction algorithm settings, including FBP (standard), ASIR-V (40%), and DLIR (high, medium, and low strength settings). For each set of iodine images, the iodine concentration within the syringe was measured and its percentage difference relative to the reference value calculated. Also, repeated scans of the phantom without iodine inserts were performed, from which the noise power spectra (NPS) were measured from homogeneous background and the peak frequencies of their radial profiles determined.

RESULTS

For all reconstruction settings, the largest percentage difference between the measured iodine concentration and the reference value occurred at both the lowest iodine concentration and the lowest CTDIvol; the percentage differences from DLIR-GSI reconstructed images are 3.6%±0.3% (DLIR high), 3.7%±0.5% (DLIR medium), 3.9%±0.6% (DLIR low), compared to 4.3%±1.0% (FBP) and 4.3%±0.8% (ASIR-V). At the lowest CTDIvol, the peak frequencies of NPS radial profiles from DLIR-GSI reconstructed iodine images are 0.34±0.01 mm-1 (DLIR high), 0.33±0.01 mm-1 (DLIR medium), 0.34±0.01 mm-1 (DLIR low), compared to 0.34±0.01 mm-1 (FBP) and 0.30±0.01 mm-1 (ASIR-V).

CONCLUSION

s The DLIR-GSI algorithm is capable of accurate quantification of iodine at both low iodine concentration and low radiation dose while maintaining the same noise texture as the traditional analytical reconstruction algorithm.

CLINICAL RELEVANCE/APPLICATION

It provides guidance for dual energy CT protocol optimization for accurate and reliable iodine quantification in clinical applications such as perfusion defect identification and lesion characterization in lung imaging.

M2-SPPH-9 Feasibility of Small Pulmonary Nodule Detection and Characterization Using Edge-On-Irradiated Silicon Detector Photon-Counting CT

Participants
Zhye Yin, Niskayuna, NY (*Presenter*) Employee, General Electric Company

PURPOSE

Advanced high-resolution CT is effective at assessing small pulmonary nodules down to 3—5mm in size during screening and oncology exams. However, the clinical value of such findings may be unclear without further tissue characterization. Photon-counting CT (PCCT) with edge-on-irradiated silicon detectors can simultaneously offer improved spectral capability (to enable characterization) and spatial resolution (to measure size). In this study, we demonstrate the feasibility of detecting and providing quantitative spectral characterization of small peripheral pulmonary lung nodules (<5mm) in a phantom study.

METHODS AND MATERIALS

An anthropomorphic phantom (Lungman, Kyoto Kagaku) with two sets of iodine rods (diameter 2—7mm), placed longitudinally at the peripheral regions of lung, were scanned using a prototype PCCT (GE Healthcare) at 120kVp and CTDIvol of 8.72mGy. Iodine rod concentrations were 1.7mg/ml and 3.0mg/ml. Material images were generated on a 1024×1024 image grid with standard and high-resolution kernels. Quantification accuracy for various nodule sizes was obtained for regions of interest (ROI) on iodine images. Nodule sizes were measured at monochromatic images at 70 keV.

RESULTS

In the iodine images, the ROI means and standard deviations for 5mm, 4mm, 3mm, and 2mm diameter rods with 3mg/ml concentration were 3.18mg/ml[0.51mg/ml], 3.12mg/ml[0.40mg/ml], 3.21mg/ml[1.32mg/ml], and 2.56mg/ml[1.25mg/ml], respectively. The respective nodule size measurements were 5.08mm, 3.87mm, 3.05mm and 1.94mm.

CONCLUSION

s Our results indicate that this PCCT prototype can provide, from a single scan, both nodule size and iodine quantification for small lung nodule detection and characterization. Edge-on-irradiated Si-based PCCT thus has the potential to provide additional information on small pulmonary nodules and could have a role in differentiating benign and malignant nodules, obviating the need for follow up imaging or biopsy.

CLINICAL RELEVANCE/APPLICATION

PCCT with simultaneous high spatial and spectral resolution can provide supplementary information on lung nodules smaller than 3—5mm and simplify the clinical decision process.

M2-SPPH-1

Differentiating Patients With Diabetes Mellitus With Pancreatic Extracellular Volume Fraction and Normalized Iodine Concentration Acquired by Dual Energy CT

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Xiaoyi Cai, MBBS, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the feasibility of extracellular volume (ECV) fraction and normalized iodine concentration (nIC) using dual energy CT (DECT) to evaluate diabetic patients.

METHODS AND MATERIALS

106 patients with known or suspected abdominal disease underwent abdominal precontrast CT scan (120kV) and DECT enhanced scan. Patients were divided into three groups according to the American Diabetes Association criteria: non-diabetes group (HbA1 < 5.7%, 31 patients), pre-diabetes group (5.7% = HbA1c < 6.5%, 36 patients) and diabetes group (HbA1c = 6.5%, 39 patients). Two ECV fractions(ECV-HU = (HUpancreas -equilibrium phase - HUpancreas -precontrast) /(HUabdominal aorta -equilibrium phase - HUabdominal aorta -precontrast) × (100-Hct), ECV-ID = (IDpancrease -equilibrium phase /IDabdominal aorta -equilibrium phase) × (100-Hct)) and the nIC (nIC=ICpancrease-equilibrium phase /ICabdominal aorta-equilibrium phase) of the pancreas were calculated. The correlations of pancreatic ECV-HU, ECV-ID, and nIC with HbA1c value were analyzed by Spearman rank correlation. Pancreatic ECV-HU, ECV-ID and nIC among groups were compared by one-way ANOVA. The diagnostic performance of pancreatic ECV-HU, ECV-ID, and nIC was evaluated by receiver operating characteristic (ROC) curve analysis.

RESULTS

In the whole patients, HbA1c was moderately positively correlated with ECV-HU, ECV-ID and nIC (rs =0.447, rs =0.541, rs =0.533, respectively; all P < 0.001). The pancreatic ECV-HU, ECV-ID and nIC in diabetes group were significantly higher than those in non-diabetes group and pre-diabetes group (all P < 0.001). The combination of ECV-ID and nIC has the highest area under the curve (AUC), sensitivity and specificity in differentiating non-diabetic or pre-diabetes from diabetic patients(0.876, 76.9% and 83.9%; 0.820, 71.8% and 88.9%, respectively). Furthermore, in differentiating non-diabetes or pre-diabetes from diabetes group, the AUC was superior in ECV-ID vs. ECV-HU (0.851 vs. 0.799 and 0.787 vs. 0.741, respectively).

CONCLUSION

s Combined application of pancreatic ECV-ID and nIC is a potential imaging index to evaluate diabetic patients.

CLINICAL RELEVANCE/APPLICATION

The diagnosis of diabetes mellitus was associated with pancreatic imaging biomarkers, such as ECV and nIC, which may provide new insights into clinical practice.

M2-SPPH-2

Impact of Patient Habitus and Energy-Bin Weighting on Monochromatic Image Quality for Photon-Counting CT

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Paul E. Kinahan, PhD, Seattle, WA (*Presenter*) Co-founder, PET/X LLC

PURPOSE

Photon-counting x-ray computed tomography (PCCT) is a new technology that has the potential to improve clinically relevant image properties such as bias and noise. However, the image reconstruction algorithm must account for energy-dependent physical effects, including Compton scattering in the detectors for the case of silicon-based scanners. We investigated the effects of combining post-log projection data from different edge-on silicon-based PCCT energy bins to form virtual mono-energetic images by minimizing the root-mean-squared error (RMSE).

METHODS AND MATERIALS

PCCT and monochromatic images were simulated using the Catsim software package. The XCAT phantom served as a vector-based input to the simulations. Optimization of the projection data weighting and image analysis was done in MATLAB.The patient habitus was varied by modifying the XCAT fields to generate three patient sizes defined as "small", "medium", and "large". For each phantom size, two Catsim simulations were performed: one having a monochromatic x-ray spectrum with standard detection, and one having a full bremsstrahlung spectrum and edge-on silicon-based PCCT detectors that included a model for Compton scatter. Using a least-squares cost function, PCCT sinograms corresponding to different photon energies were combined to match the monochromatic sinograms at each of the three sizes. These "synthetic monochromatic sinograms" were then reconstructed. The RMSE was computed using the monochromatic images as ground truth.

RESULTS

The optimal weights for recombining multiple PCCT energy bin sinograms were object dependent. When size-specific weights were used, the RMSEs over all phantom pixels were 22, 41 and 53 HU for the three respective phantom sizes. However, if the coefficients were fixed to those optimal for the medium phantom, the RMSEs for the smaller and larger increased to 28 and 60 HU respectively. For some imaging techniques, photon starvation artifacts would appear for sub-optimal weights.

CONCLUSION

s For PCCT reconstruction algorithms that aim to estimate monochromatic CT data by simple weighting of energy bin sinograms, the use of fixed coefficients will lead to increased noise and artifacts for varying patient sizes.

CLINICAL RELEVANCE/APPLICATION

Photon-counting CT scanners have a dramatic increase in the amount of spectral (energy) information generated compared to standard energy-integrating CT scanners, even those operated in dual-kVp mode. With this rich source of energy data, there are many new parameters to be evaluated and ideally optimized. This study evaluates one such set of

Reporting on Methodology in Dual Energy CT Studies: A Systematic Literature Review

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Nils Grosse Hokamp, MD, MBA, Koln, Germany (*Presenter*) Research Grant, Koninklijke Philips NV;Speakers Bureau, Koninklijke Philips NV;Consultant, Bristol-Myers Squibb Company

PURPOSE

The objective of this study was to perform a structured literature review to assess how image acquisition parameters and technical details are reported in clinical dual-energy CT (DECT) studies.

METHODS AND MATERIALS

A structured query of the PubMed meta-database was performed that covered all studies between the years 2016 and 2020 with a potential utilization of a dual-energy system. After inclusion, the described dual-energy CT methodology was recorded in a structured approach for each study with particular attention to scanning and reconstruction parameters.

RESULTS

A total of 864 out of 2742 studies were eligible for inclusion. The DECT approach that was used was reported in 87% of all studies, while in 98% of all studies at least the vendor of the DECT system was specified. In most studies, a dual-source system was used (44%), followed by kVp switching (34%) and dual-layer systems (15%), with the remainder using multiple systems or twinbeam technology. The average number of patients included was 83 ± 213. Data on mAS was reported in 70%, data on tube voltage in 78%, data on gantry rotation time in 60%, data on collimation in 57%, and data on pitch in 60% of the studies.

CONCLUSION

s In dual-energy CT studies between 2016 and 2020, the technical parameters of image acquisition as well as reconstruction parameters are frequently only partially specified, which may significantly limit reproducibility.

CLINICAL RELEVANCE/APPLICATION

WIth the increasing complexity of technological concepts to Dual-Energy CT imaging, more caution has to be taken when describing methodology of scientific studies. Only complete details on image acquisition and image reconstruction will allow for transferability of findings among sites and from research into clinics, eventually.

M2-SPPH-5

Prior-Information-Inspired Deep Learning Noise Reduction for Coronary CT Angiography Acquired with a Photon Counting Detector CT

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Shaojie Chang, PhD, ROCHESTER, MN (*Presenter*) Nothing to Disclose

PURPOSE

To develop a deep learning technique that utilizes prior information to reduce noise in high-resolution, photon-counting-detector (PCD) CT coronary CT angiography (CTA).

METHODS AND MATERIALS

Clinical coronary CTA exams acquired on a PCD-CT (NAEOTOM Alpha, Siemens Healthcare) were considered in this study. Virtual monoenergetic images (VMIs) at different energies (50, 70, 100 keV) were reconstructed using both filtered back projection (FBP) and iterative reconstruction (IR) algorithms, 0.6 mm slice thickness, and a sharp kernel (Bv68). The FBP and IR images were subtracted to generate images composed predominately of noise. The lower noise 70 keV VMI images served as the prior images. To obtain a relatively low-noise signal reference, adjacent IR images and prior images were averaged to simulate thicker slice images (1.5 mm). A convolutional neural network (CNN) was constructed based on a U-Net architecture with mean square error loss. CNN inputs consisted of (1) noise-only images superimposed onto the signal reference images and (2) the prior images. Spatial decoupling between the noise-only image and signal reference was used to avoid overfitting and reduce propagation of IR deficiencies into the CNN model. Image patches of 128x128 pixels were extracted from all available training data and standard data augmentation techniques were applied. Training targets consisted of the signal reference without added noise. Denoising strength was controlled by a weighting factor of the noise patch. The resulting CNN was applied to the original thin slice and sharp kernel FBP images.

RESULTS

FBP images showed very high noise at all VMI energies given the sharp kernel. While IR images substantially reduced image noise compared to FBP, noise texture was altered and a patchy appearance was observed. The proposed CNN framework provided strong noise reduction, by 95 ± 1 % relative to FBP and by 60 ± 3 % relative to IR, while maintaining a natural noise texture without a patchy appearance. Additionally, image properties unique to each VMI energy were retained, with increased contrast signal at 50 keV, and decreased calcium blooming at 100 keV.

CONCLUSION

s This prior information inspired CNN framework fully utilized the PCD-CT data along the energy axis to achieve substantial noise reduction while preserving the VMI's properties.

CLINICAL RELEVANCE/APPLICATION

Improved PCD-CT coronary CTA image quality at different energies is beneficial for improving visualization of non-calcific plaques using low keV VMI and reduction of calcium/stent blooming using high keV VMI.

M2-SPPH-6

Development of a Dose- And Size- Independent Deep Learning Based Material Decomposition Algorithm Using Photon-Counting CT Images

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Jayasai Rajagopal, BA, Durham, NC (*Presenter*) Nothing to Disclose

PURPOSE

To develop a material decomposition technique that can accurately characterize k-edge materials in the presence of variable dose conditions

METHODS AND MATERIALS

Image data was generated using a validated simulation platform (DukeSim, Duke University) to emulate a clinical photon-counting CT system (NAEOTOM Alpha, Siemens Healthineers) with standardized acquisition parameters (120 kV, 20-65 keV detector thresholds). 4200 cases were acquired consisting of cylindrical phantoms at variable sizes (16, 24, 32, 40 cm diameter) containing inserts of iodine and gadolinium (0.25-20 mg/mL) in various configurations including vials with single materials and mixtures and simulated at several dose levels (3.9, 5.9, 11.7 mGy CTDIvol). Dose and size parameters were selected to create variable image quality across the dataset. A convolutional neural network with a U-net architecture was trained using a subset of the cases to learn the relationship between the simulated images and the concentrations of iodine and gadolinium. The model used patch-wise training with a squared-error regression loss function. None of the material concentrations in the testing dataset were present in the training data. Model accuracy was measured by estimating bias and limits of agreement (LoA) in a Bland-Altman analysis and root-mean-square error (RMSE) of concentration estimates from the ground truth values.

RESULTS

Image noise within vial regions-of-interest increased as dose decreased (32%). Testing results showed a good performance for estimating iodine (bias: -0.1, LoA: -0.6 - 0.4 mg/mL I) and gadolinium (bias: -0.02, LoA: -0.3 - 0.3 mg/mL Gd). RMSE showed an excellent overall performance for iodine (0.1 mg/mL) and gadolinium (0.1 mg/mL).

CONCLUSION

s A deep learning based material decomposition algorithm was able to accurately characterize iodine and gadolinium as single materials and mixtures. The algorithm maintained a desirable performance under low dose conditions.

CLINICAL RELEVANCE/APPLICATION

A material decomposition technique that can reliably function at different dose levels can increase the clinical viability of material characterization for diagnostic purposes

M2-SPPH-7

Performance Evaluation of Deep Learning Image Reconstruction for Dual Energy CT - Quantitative Accuracy and Noise Characteristics of Iodine Map

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Benjamin Maloney, PhD, Detroit, MI (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the performance of DLIR-GSI, a novel deep learning image reconstruction algorithm for dual energy CT, with a focus on quantitative accuracy and noise characteristics of its generated iodine maps at reduced radiation dose levels.

METHODS AND MATERIALS

An anthropomorphic lung phantom (CTP698, The Phantom Laboratory) with an inserted syringe filled with iodine solution (ISOVUE 300 and saline mix) was scanned under GSI mode on a Revolution CT scanner (GE Healthcare). Six concentrations of iodine solution (range [1.7, 12.0] mgI/ml), and five CTDIvol levels of CT scan (range [4.2, 19.0] mGy) were used in the experiment. For each scan, the iodine images were reconstructed using five different reconstruction algorithm settings, including FBP (standard), ASIR-V (40%), and DLIR (high, medium, and low strength settings). For each set of iodine images, the iodine concentration within the syringe was measured and its percentage difference relative to the reference value calculated. Also, repeated scans of the phantom without iodine inserts were performed, from which the noise power spectra (NPS) were measured from homogeneous background and the peak frequencies of their radial profiles determined.

RESULTS

For all reconstruction settings, the largest percentage difference between the measured iodine concentration and the reference value occurred at both the lowest iodine concentration and the lowest CTDIvol; the percentage differences from DLIR-GSI reconstructed images are 3.6%±0.3% (DLIR high), 3.7%±0.5% (DLIR medium), 3.9%±0.6% (DLIR low), compared to 4.3%±1.0% (FBP) and 4.3%±0.8% (ASIR-V). At the lowest CTDIvol, the peak frequencies of NPS radial profiles from DLIR-GSI reconstructed iodine images are 0.34±0.01 mm^{-1} (DLIR high), 0.33±0.01 mm^{-1} (DLIR medium), 0.34±0.01 mm^{-1} (DLIR low), compared to 0.34±0.01 mm^{-1} (FBP) and 0.30±0.01 mm^{-1} (ASIR-V).

CONCLUSION

s The DLIR-GSI algorithm is capable of accurate quantification of iodine at both low iodine concentration and low radiation dose while maintaining the same noise texture as the traditional analytical reconstruction algorithm.

CLINICAL RELEVANCE/APPLICATION

It provides guidance for dual energy CT protocol optimization for accurate and reliable iodine quantification in clinical applications such as perfusion defect identification and lesion characterization in lung imaging.

M2-SPPH-9

Feasibility of Small Pulmonary Nodule Detection and Characterization Using Edge-On-Irradiated Silicon Detector Photon-Counting CT

Monday, Nov. 28 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Zhye Yin, Niskayuna, NY (*Presenter*) Employee, General Electric Company

PURPOSE

Advanced high-resolution CT is effective at assessing small pulmonary nodules down to 3—5mm in size during screening and oncology exams. However, the clinical value of such findings may be unclear without further tissue characterization. Photon-counting CT (PCCT) with edge-on-irradiated silicon detectors can simultaneously offer improved spectral capability (to enable characterization) and spatial resolution (to measure size). In this study, we demonstrate the feasibility of detecting and providing quantitative spectral characterization of small peripheral pulmonary lung nodules (<5mm) in a phantom study.

METHODS AND MATERIALS

An anthropomorphic phantom (Lungman, Kyoto Kagaku) with two sets of iodine rods (diameter 2—7mm), placed longitudinally at the peripheral regions of lung, were scanned using a prototype PCCT (GE Healthcare) at 120kVp and CTDIvol of 8.72mGy. Iodine rod concentrations were 1.7mg/ml and 3.0mg/ml. Material images were generated on a 1024×1024 image grid with standard and high-resolution kernels. Quantification accuracy for various nodule sizes was obtained for regions of interest (ROI) on iodine images. Nodule sizes were measured at monochromatic images at 70 keV.

RESULTS

In the iodine images, the ROI means and standard deviations for 5mm, 4mm, 3mm, and 2mm diameter rods with 3mg/ml concentration were 3.18mg/ml[0.51mg/ml], 3.12mg/ml[0.40mg/ml], 3.21mg/ml[1.32mg/ml], and 2.56mg/ml[1.25mg/ml], respectively. The respective nodule size measurements were 5.08mm, 3.87mm, 3.05mm and 1.94mm.

CONCLUSION

s Our results indicate that this PCCT prototype can provide, from a single scan, both nodule size and iodine quantification for small lung nodule detection and characterization. Edge-on-irradiated Si-based PCCT thus has the potential to provide additional information on small pulmonary nodules and could have a role in differentiating benign and malignant nodules, obviating the need for follow up imaging or biopsy.

CLINICAL RELEVANCE/APPLICATION

PCCT with simultaneous high spatial and spectral resolution can provide supplementary information on lung nodules smaller than 3—5mm and simplify the clinical decision process.

M5A-SPBR-1 Application of Whole-Image Pixel Analysis to Contrast-Enhanced Mammography: A Potential Supplementary Tool for Evaluating Mammograms

Participants
Michael Borten, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Contrast-enhanced mammography (CEM) is an emerging breast imaging modality that has been shown to be more sensitive for detecting breast cancer than traditional mammography. This study is a pilot demonstration of whole-image pixel analysis over multiple time points and creation of a color-coded image representing contrast enhancement kinetics.

METHODS AND MATERIALS

We first identified retrospectively CEM exams that contained multiple imaging acquisitions of the same position (e.g., CC or MLO), which provided serial imaging of the same breast over several time points. After aligning these serial images using MATLAB, three techniques for overlaying the contrast distribution onto the low energy (LE) traditional mammogram were utilized: 1) direct overlay of the recombined (RC) image onto the LE image, 2) overlaying a color-coded map of change in "early phase" pixel intensity between the first and second time points, and 3) overlaying a color-coded map of "delayed phase" change in pixel intensity between the second and third time points.

RESULTS

From 2124 retrospective images of 139 patients, we identified 40 patients with 53 views for which two or more images were acquired (two or more time points). Two patients had three images acquired of the same view. Color maps were successfully created from one time point (single RC image), two time points ("early phase"), and three time points ("delayed phase"). Our imaging data demonstrate better results as the number of time points increases (Figure 1A-C). For one patient with three time points, our technique demonstrated an area of rapid uptake (Figure 1B) and mixed washout/plateau (Figure 1C) which corresponded with the area of biopsy-proven atypical ductal hyperplasia, albeit with noise from inter-acquisition movement. We also found that the mean pixel intensity across the whole breast tended to decrease around two minutes after first image acquisition (Figure 1D-E).

CONCLUSION

s Our pilot data have demonstrated the feasibility of using serial CEM acquisitions to create a kinetic color map analogous to those routinely utilized with breast MR imaging, which can demonstrate areas of washout that might correlate with suspicious breast findings. Future studies will focus on prospectively acquiring images at systematic time points to allow for more robust and conclusive data analysis.

CLINICAL RELEVANCE/APPLICATION

We apply whole-image pixel analysis to contrast-enhanced mammography (CEM) to create color-coded enhancement kinetic maps that could aid clinicians in evaluating findings suspicious for malignancy.

M5A-SPBR-2 Diagnostic Performance and Image Quality of Contrast Enhanced Spectral Mammography with Low-Dose Contrast Agents in Detecting Breast Lesions

Participants
Huizhi Cao, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

To explore the clinical value of contrast enhanced spectral mammography with low-dose contrast agents in assessing breast lesions.

METHODS AND MATERIALS

In this IRB-approved retrospective study, 223 patients undergoing CESM were randomly assigned into two protocols: 113 patients were carried out exam with conventional dose (Iohexol at 1.5ml/kg;350 mg/ml), and other 110 patients underwent exam with low dose (Iohecol at 1 ml/kg; 300-350 mg/ml). All the patients accepted MRI examination within one week. The image of CESM, MRI and the histopathological data were analyzed. The clinical value of CESM and MRI were evaluated according to the histopathological results, respectively. The ROC curve was to applied to analyzed clinical efficiency. The tumor size was measured from CESM, MRI modalities and pathological data. By using the Bland-Altman analysis, the consistency of the maximum tumor size

was assessed.

RESULTS

Histopathologic result revealed 33 benign and 67 malignant lesions in low dose group, and 35 benign and 78 malignant lesions in conventional group. CESM obtained from conventional group had similar AUC area, sensitivity, specificity, PPV, NPV to MRI imaging (0,928, 0.962, 0.846,0.783,0.821 vs. 0.903,0.974,0.809,0.805,0.856). Importantly, CESM from low dose group showed a comparison of clinical performance to MRI as well. (AUC area: 0.944 vs. 0.925; sensitivity:0.990 vs.0.941; specificity:0.825vs.0.831; PPV:0.802 vs. 0.825; NPV:0.855 vs. 0.895). For tumor size measurement, mean tumor size was 3.51 cm for CESM (conventional group) and 3.61 cm for MRI, compared with 3.38 cm on histopathological results, the average difference of diameters between CESM (conventional group), MRI and Histopathologic size was -0.02, -0.10cm, respectively. Additionally, average sizes were measured as 4.02 cm, 3.76 cm, 3.96 cm for CESM (low dose group), MRI and Histopathologic result, and the difference diameters compared to Pathologic data were -0.05, -0.08cm. Bland-Altman analysis showed best consistency on tumor size between CESM (low dose group), MRI and pathological results.

CONCLUSION

sLow doses of contrast agents used for CESM show a comparison both in diagnostic performance and tumor size assessment, compared to CESM obtained with conventional dose.

CLINICAL RELEVANCE/APPLICATION

Contrast enhanced spectral mammography performed at low dose of contrast agents can meet the clinical and imaging requirements without sacrificing diagnostic performance.

M5A-SPBR-3 Diagnostic Accuracy of Automated ACR BI-RADS Breast Density Classification using Deep Convolutional Neural Networks

Participants
Raphael Sexauer, MD, (*Presenter*) Nothing to Disclose

PURPOSE

High breast density is a well-known risk factor for breast cancer. This study aimed to develop and adapt two deep convolutional neural networks (DCNN) for the automatic classification of breast density based on the mammographic appearance of the tissue on synthetic 2D tomosynthesis craniocaudal (CC) and mediolateral oblique (MLO) projections.

METHODS AND MATERIALS

In this study, 4605 mammography tomosynthesis-based synthetic images from 1267 different patients (57 ± 37 years) were labeled according to the ACR (American College of Radiology) density (A-D) by a radiologist with 2 years of experience in breast imaging. Two DCNN with 11 convolutional layers and 3 fully connected layers were trained with 70% of the data, whereas 20% was used for validation. The remaining 10% were used as a separate test dataset with 460 images (380 patients). All mammograms in the test dataset were read blinded by two radiologists (reader 1 with two and reader 2 with 11 years of dedicated mammographic experience in mammographic imaging), and the consensus was formed as the reference standard. The inter- and intra-reader reliabilities of the density classifications were assessed by calculating Cohen’s kappa coefficients, and diagnostic accuracy measures of automated classification were evaluated.

RESULTS

Two separate models for MLO and CC projections were successfully trained and implemented in the ”b-box” artificial intelligence (AI) platform (Medical device type IIa, CE 0297). Mean sensitivity of 80.4 (95%-CI 72.2-86.9) and a specificity of 89.3 (95%-CI 85.4-92.3) in the differentiation between ACR A/B and ACR C/D. DCNN versus human and interhuman agreement was both “substantial” (Cohen’s kappa: 0.61 versus 0.63).

CONCLUSION

s The DCNN allows for accurate, standardized, and observer-independent classification of breast density based on the ACR BI-RADS system. The proposed technique is suited for tomosynthesis-based synthetic images.

CLINICAL RELEVANCE/APPLICATION

DCNNs can be used to accurately mimic human decision-making in breast density assessment for synthetic 2D tomosynthesis.

M5A-SPBR-4 Screen-detected and Interval Breast Cancer Rates are Significantly Higher in Women with Dense Breasts Across all Age Groups in a Large DBT Dataset

Participants
Giorgia Grisot, PhD, CAMBRIDGE, United Kingdom (*Presenter*) Employee, RadNet, Inc

PURPOSE

High breast density is associated with both increased breast cancer risk and decreased sensitivity of screening mammography, contributing to higher overall breast cancer rates and interval breast cancer rates. The Breast Cancer Surveillance Consortium (BCSC) previously showed that interval cancer rates are higher in women with dense breasts undergoing screening with full-field digital mammography, but little data is available for digital breast tomosynthesis (DBT). We sought to compare cancer rates by breast density on women undergoing screening with DBT using a dataset comparable to BCSC.

METHODS AND MATERIALS

Retrospective data was collected including one DBT screening mammogram from each of 559,791 women undergoing screening between 2017-2021 at over 150 clinical locations, excluding first screens, and with at least one year of follow-up. Screen-detected cancer rate and interval cancer rate were calculated per 1000 women. Analyses are separated by women with nondense (fatty or scattered fibroglandular) and dense (heterogeneously dense or very dense) breast tissue, following BI-RADS 5th Edition guidelines.

RESULTS

Across all age groups, women with dense breasts had a 1.8x higher recall rate, 1.4x higher CDR, and 2.9x higher interval cancer

Across all age groups, women with dense breasts had a 1.8x higher recall rate, 1.4x higher CDR, and 2.9x higher interval cancer rate compared to women with nondense breasts. CDR is higher in women with dense breasts in all age brackets (dense/nondense CDR: age 40-49: 2.0; 50-59: 1.8; 60-69: 1.4; 70-74: 1.4, chi-square p<0.001 for all differences). Interval cancer rate was higher in women with dense breasts in all age brackets (dense/nondense interval cancer rate: age 40-49: 2.5; 50-59: 3.2; 60-69: 2.8; 70-74: 3.7, chi-square p<0.01 for all differences). While the positive predictive value of recalls (PPV1) was similar for women with dense breasts compared to nondense breasts in age groups above 50, women ages 40-49 with dense breasts who were recalled were more likely to have cancer detected than women with nondense breasts (dense/nondense PPV1: 1.17).

CONCLUSION

s In a group of more than half a million women, women with dense breasts undergoing screening mammography with DBT show increased rates of cancer detection and interval cancer rates compared to women without dense breasts, across all age groups. Women aged 40-49 with dense breasts had a higher recall rate but also a higher likelihood of a cancer diagnosis than women without dense breasts. Mammographic breast density, even with DBT, remains associated with higher rates of cancer.

CLINICAL RELEVANCE/APPLICATION

Mammographic breast density is a strong risk factor for breast cancer and for interval breast cancers, even when DBT is used. Our results suggest women aged 40-49 with dense breasts particularly benefit from screening mammography.

M5A-SPBR-5 Density Awareness: Do Patients Know About Breast Density? What Are Factors That May Influence Breast Density Awareness?

Participants
Mary W. Yamashita, MD, South Pasadena, CA (*Presenter*) Research Grant, Delphinus Medical Technologies, Inc;Consultant, Delphinus Medical Technologies, Inc

PURPOSE

While prior studies have investigated primary or referring physician awareness of breast density and its association with breast cancer, to our knowledge, patient knowledge of breast density has not been assessed. We would like to investigate patients' awareness of breast density, specifically those patients who were previously notified of their dense breasts in the mammography result letter.

METHODS AND MATERIALS

We conducted a retrospective review of 8317 women who enrolled in the SoftVue™ Prospective Case Collection registry between December 2016 and October 2019 who had heterogeneously or extremely dense breasts. After undergoing mammography (MG) and SoftVue™ automated whole breast ultrasound tomography (SV), all participants completed a history and demographics questionnaire and an experience survey which also measured awareness of their own breast density, anxiety about breast density, and level of worry about breast cancer. We reviewed this data and determined the awareness of dense breasts in this population and its influence on self-reported anxiety about breast cancer and looked at other factors that may influence density awareness.

RESULTS

A large percentage of women are not aware of the significance of dense breasts, despite many of them having received breast density notification letters prior to participation. Patients who are aware of their breast density report higher anxiety about their breast density compared to those who are not. Non-Hispanic women are more aware of breast density than Hispanic women. Patients who underwent imaging in States where Breast Density Notification Laws were active are more likely to be aware of their breast density, however the wording of the density information letter may impact patient awareness and concern surrounding it.

CONCLUSION

s Breast density is not well understood by women who are heterogeneously dense or extremely dense. More work needs to be done to educate women with dense breasts about the increased risk of breast cancer and the need for supplementary imaging to mammography.

CLINICAL RELEVANCE/APPLICATION

Increasing breast density awareness in women with dense breasts will likely empower them to self-advocate for additional imaging for early detection of breast cancer.

M5A-SPBR-6 SOLUS - Smart Optical and Ultrasound Diagnostics of Breast Cancer: US / DOT Hybrid System for the Characterization of Breast Lesions

Participants
Elena Venturini, MD, (*Presenter*) Speaker, Bayer AG

PURPOSE

Presentation of the technology and the first clinical results of a project funded by a Grant Horizon 2020 for the development of a hybrid ultrasound and optical tomography device, created by the SOLUS consortium that unites 9 European partners experts in optical imaging, ultrasound and image processing. The purpose of the clinical study, still ongoing, is to evaluate the feasibility of the SOLUS device in the differentiation of the malignant breast nodules from the benign ones.

METHODS AND MATERIALS

The SOLUS device is a US/optical hybrid prototype that consists of a commercial Hologic Aixplorer Mach 30 US system combined with an innovative diffuse optical tomography (DOT) system. The SOLUS device includes, in a single exam, B mode ultrasound, color Doppler, share wave elastography and DOT through a probe that has a normal US transducer in the center, flanked by 8 optodes that emit and receive light in the red and infrared spectrum. The optical study allows one to measure the concentrations of water, lipids, collagen, oxygenated and deoxygenated hemoglobin, as well as to provide information on cell membranes and subcellular organelles. In the clinical study we enroll women with breast nodules = 1 cm, detectable at US, suspicious for malignancy (BI-RADS 4 or 5) or benign (BI-RADS 2 or 3) before breast biopsy, if it is clinically needed. The aim of the clinical study is to compare, in vivo, the parameters obtained from the evaluation of 20 benign and 20 malignant lesions to test the possibility of differentiating them.

RESULTS

From 10/2021 to 04/2022 we enrolled 17 women with breast nodules; overall 18 breast nodules were evaluated (5 malignant, 13 benign). The preliminary analysis performed have confirmed that the SOLUS device may depict the composition of breast tissue, differentiating breast nodules from the surrounding tissue and distinguishing malignant from benign lesions.

CONCLUSION

s The initial data collected, based mainly on DOT findings guided by US, suggest that a multiparametric analysis, adding also information from US based techniques, may have a role in the characterization of breast lesions.

CLINICAL RELEVANCE/APPLICATION

A multiparametric analysis, based mainly on DOT findings guided by US, may have a role in the characterization of breast lesions.

M5A-SPBR-7 Do as We Say, Not as We Do? Our Initial Experience with the Lateral-Arm Needle Approach for Prone Tomosynthesis Breast Biopsy.

Participants
Ethan O. Cohen, MD, Houston, TX (*Presenter*) Spouse, Consultant, Boehringer Ingelheim GmbH;Spouse, Consultant, Novo Nordisk AS;Spouse, Consultant, Eli Lilly and Company

PURPOSE

Compare conventional and lateral-arm needle approaches for prone tomosynthesis breast biopsy.

METHODS AND MATERIALS

Conventional or lateral-arm needle approach for tomosynthesis biopsy was selected based on radiologist preference during 2016-2019, and these biopsies were retrospectively reviewed after IRB approval. Procedure details and biopsy outcomes were compared with the two-sample t-test and two proportion z-tests.

RESULTS

165 patients (median age, 56 years; interquartile range 48-64) underwent 177 biopsies with a conventional needle approach, and 140 patients (median age 56 years; interquartile range 48-65) underwent 147 biopsies with a lateral-arm needle approach. All were successful. Fewer images were necessary with the lateral-arm needle approach (mean 8 versus 6, $P < 0.001$). There were no differences between needle approaches for the remaining procedure details: total procedure time, lesion targeting time, tissue sampling time, number of samples acquired, biopsy target lesion (calcifications, distortion, asymmetry, or mass), clip migration, and complications ($P = 0.06$-0.96). Outcomes for conventional-needle-approach biopsies were 99 benign (56%), 28 high-risk (16%), and 40 malignant (23%); one discordant benign lesion and two high-risk lesions were upgraded at excision. Outcomes for lateral-arm-approach biopsies were 80 benign (54%), 39 high-risk (27%), and 28 malignant (19%); one high-risk lesion was upgraded at excision. Benign and malignant outcomes were equally common with either needle approach ($P = 0.44$-0.79), but high-risk outcomes were more common with the lateral-arm needle approach (believed to be due to radiologist preference based on lesion type, $P = 0.02$). Positive predictive values were similar between approaches ($P = 0.33$).

CONCLUSION

s The lateral-arm needle approach for prone tomosynthesis breast biopsy is an acceptable alternative to conventional needle approach based on radiologist preference. Fewer images were required for the lateral-arm approach, and other procedure details were similar to the conventional needle approach.

CLINICAL RELEVANCE/APPLICATION

The lateral-arm needle approach for tomosynthesis breast biopsy is a new addition to percutaneous biopsy options, and radiologists should familiarize themselves with its benefits.

M5A-SPBR-1

Application of Whole-Image Pixel Analysis to Contrast-Enhanced Mammography: A Potential Supplementary Tool for Evaluating Mammograms

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Michael Borten, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Contrast-enhanced mammography (CEM) is an emerging breast imaging modality that has been shown to be more sensitive for detecting breast cancer than traditional mammography. This study is a pilot demonstration of whole-image pixel analysis over multiple time points and creation of a color-coded image representing contrast enhancement kinetics.

METHODS AND MATERIALS

We first identified retrospectively CEM exams that contained multiple imaging acquisitions of the same position (e.g., CC or MLO), which provided serial imaging of the same breast over several time points. After aligning these serial images using MATLAB, three techniques for overlaying the contrast distribution onto the low energy (LE) traditional mammogram were utilized: 1) direct overlay of the recombined (RC) image onto the LE image, 2) overlaying a color-coded map of change in "early phase" pixel intensity between the first and second time points, and 3) overlaying a color-coded map of "delayed phase" change in pixel intensity between the second and third time points.

RESULTS

From 2124 retrospective images of 139 patients, we identified 40 patients with 53 views for which two or more images were acquired (two or more time points). Two patients had three images acquired of the same view. Color maps were successfully created from one time point (single RC image), two time points ("early phase"), and three time points ("delayed phase"). Our imaging data demonstrate better results as the number of time points increases (Figure 1A-C). For one patient with three time points, our technique demonstrated an area of rapid uptake (Figure 1B) and mixed washout/plateau (Figure 1C) which corresponded with the area of biopsy-proven atypical ductal hyperplasia, albeit with noise from inter-acquisition movement. We also found that the mean pixel intensity across the whole breast tended to decrease around two minutes after first image acquisition (Figure 1D-E).

CONCLUSION

s Our pilot data have demonstrated the feasibility of using serial CEM acquisitions to create a kinetic color map analogous to those routinely utilized with breast MR imaging, which can demonstrate areas of washout that might correlate with suspicious breast findings. Future studies will focus on prospectively acquiring images at systematic time points to allow for more robust and conclusive data analysis.

CLINICAL RELEVANCE/APPLICATION

We apply whole-image pixel analysis to contrast-enhanced mammography (CEM) to create color-coded enhancement kinetic maps that could aid clinicians in evaluating findings suspicious for malignancy.

M5A-SPBR-2

Diagnostic Performance and Image Quality of Contrast Enhanced Spectral Mammography with Low-Dose Contrast Agents in Detecting Breast Lesions

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Huizhi Cao, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

To explore the clinical value of contrast enhanced spectral mammography with low-dose contrast agents in assessing breast lesions.

METHODS AND MATERIALS

In this IRB-approved retrospective study, 223 patients undergoing CESM were randomly assigned into two protocols: 113 patients were carried out exam with conventional dose (Iohexol at 1.5ml/kg;350 mg/ml), and other 110 patients underwent exam with low dose (Iohecol at 1 ml/kg; 300-350 mg/ml). All the patients accepted MRI examination within one week. The image of CESM, MRI and the histopathological data were analyzed. The clinical value of CESM and MRI were evaluated according to the histopathological results, respectively. The ROC curve was to applied to analyzed clinical efficiency. The tumor size was measured from CESM, MRI modalities and pathological data. By using the Bland-Altman analysis, the consistency of the maximum tumor size was assessed.

RESULTS

Histopathologic result revealed 33 benign and 67 malignant lesions in low dose group, and 35 benign and 78 malignant lesions in conventional group. CESM obtained from conventional group had similar AUC area, sensitivity, specificity, PPV, NPV to MRI imaging (0,928, 0.962, 0.846,0.783,0.821 vs. 0.903,0.974,0.809,0.805,0.856). Importantly, CESM from low dose group showed a comparison of clinical performance to MRI as well. (AUC area: 0.944 vs. 0.925; sensitivity:0.990 vs.0.941; specificity:0.825vs.0.831; PPV:0.802 vs. 0.825; NPV:0.855 vs. 0.895). For tumor size measurement, mean tumor size was 3.51 cm for CESM (conventional group) and 3.61 cm for MRI, compared with 3.38 cm on histopathological results, the average difference of diameters between CESM (conventional group), MRI and Histopathologic size was -0.02, -0.10cm, respectively. Additionally, average sizes were measured as 4.02 cm, 3.76 cm, 3.96 cm for CESM (low dose group), MRI and Histopathologic result, and the difference diameters compared to Pathologic data were -0.05, -0.08cm. Bland-Altman analysis showed best consistency on tumor size between CESM (low dose group), MRI and pathological results.

CONCLUSION

sLow doses of contrast agents used for CESM show a comparison both in diagnostic performance and tumor size assessment, compared to CESM obtained with conventional dose.

CLINICAL RELEVANCE/APPLICATION

Contrast enhanced spectral mammography performed at low dose of contrast agents can meet the clinical and imaging requirements without sacrificing diagnostic performance.

M5A-SPBR-3

Diagnostic Accuracy of Automated ACR BI-RADS Breast Density Classification using Deep Convolutional Neural Networks

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Raphael Sexauer, MD, (*Presenter*) Nothing to Disclose

PURPOSE

High breast density is a well-known risk factor for breast cancer. This study aimed to develop and adapt two deep convolutional neural networks (DCNN) for the automatic classification of breast density based on the mammographic appearance of the tissue on synthetic 2D tomosynthesis craniocaudal (CC) and mediolateral oblique (MLO) projections.

METHODS AND MATERIALS

In this study, 4605 mammography tomosynthesis-based synthetic images from 1267 different patients (57 ± 37 years) were labeled according to the ACR (American College of Radiology) density (A-D) by a radiologist with 2 years of experience in breast imaging. Two DCNN with 11 convolutional layers and 3 fully connected layers were trained with 70% of the data, whereas 20% was used for validation. The remaining 10% were used as a separate test dataset with 460 images (380 patients). All mammograms in the test dataset were read blinded by two radiologists (reader 1 with two and reader 2 with 11 years of dedicated mammographic experience in mammographic imaging), and the consensus was formed as the reference standard. The inter- and intra-reader reliabilities of the density classifications were assessed by calculating Cohen's kappa coefficients, and diagnostic accuracy measures of automated classification were evaluated.

RESULTS

Two separate models for MLO and CC projections were successfully trained and implemented in the "b-box" artificial intelligence (AI) platform (Medical device type IIa, CE 0297). Mean sensitivity of 80.4 (95%-CI 72.2-86.9) and a specificity of 89.3 (95%-CI 85.4-92.3) in the differentiation between ACR A/B and ACR C/D. DCNN versus human and interhuman agreement was both "substantial" (Cohen's kappa: 0.61 versus 0.63).

CONCLUSION

s The DCNN allows for accurate, standardized, and observer-independent classification of breast density based on the ACR BI-RADS system. The proposed technique is suited for tomosynthesis-based synthetic images.

CLINICAL RELEVANCE/APPLICATION

DCNNs can be used to accurately mimic human decision-making in breast density assessment for synthetic 2D tomosynthesis.

M5A-SPBR-4

Screen-detected and Interval Breast Cancer Rates are Significantly Higher in Women with Dense Breasts Across all Age Groups in a Large DBT Dataset

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Giorgia Grisot, PhD, CAMBRIDGE, United Kingdom (*Presenter*) Employee, RadNet, Inc

PURPOSE

High breast density is associated with both increased breast cancer risk and decreased sensitivity of screening mammography, contributing to higher overall breast cancer rates and interval breast cancer rates. The Breast Cancer Surveillance Consortium (BCSC) previously showed that interval cancer rates are higher in women with dense breasts undergoing screening with full-field digital mammography, but little data is available for digital breast tomosynthesis (DBT). We sought to compare cancer rates by breast density on women undergoing screening with DBT using a dataset comparable to BCSC.

METHODS AND MATERIALS

Retrospective data was collected including one DBT screening mammogram from each of 559,791 women undergoing screening between 2017-2021 at over 150 clinical locations, excluding first screens, and with at least one year of follow-up. Screen-detected cancer rate and interval cancer rate were calculated per 1000 women. Analyses are separated by women with nondense (fatty or scattered fibroglandular) and dense (heterogeneously dense or very dense) breast tissue, following BI-RADS 5th Edition guidelines.

RESULTS

Across all age groups, women with dense breasts had a 1.8x higher recall rate, 1.4x higher CDR, and 2.9x higher interval cancer rate compared to women with nondense breasts. CDR is higher in women with dense breasts in all age brackets (dense/nondense CDR: age 40-49: 2.0; 50-59: 1.8; 60-69: 1.4; 70-74: 1.4, chi-square $p<0.001$ for all differences). Interval cancer rate was higher in women with dense breasts in all age brackets (dense/nondense interval cancer rate: age 40-49: 2.5; 50-59: 3.2; 60-69: 2.8; 70-74: 3.7, chi-square $p<0.01$ for all differences). While the positive predictive value of recalls (PPV1) was similar for women with dense breasts compared to nondense breasts in age groups above 50, women ages 40-49 with dense breasts who were recalled were more likely to have cancer detected than women with nondense breasts (dense/nondense PPV1: 1.17).

CONCLUSION

s In a group of more than half a million women, women with dense breasts undergoing screening mammography with DBT show increased rates of cancer detection and interval cancer rates compared to women without dense breasts, across all age groups. Women aged 40-49 with dense breasts had a higher recall rate but also a higher likelihood of a cancer diagnosis than women without dense breasts. Mammographic breast density, even with DBT, remains associated with higher rates of cancer.

CLINICAL RELEVANCE/APPLICATION

Mammographic breast density is a strong risk factor for breast cancer and for interval breast cancers, even when DBT is used. Our results suggest women aged 40-49 with dense breasts particularly benefit from screening mammography.

Density Awareness: Do Patients Know About Breast Density? What Are Factors That May Influence Breast Density Awareness?

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Mary W. Yamashita, MD, South Pasadena, CA (*Presenter*) Research Grant, Delphinus Medical Technologies, Inc;Consultant, Delphinus Medical Technologies, Inc

PURPOSE

While prior studies have investigated primary or referring physician awareness of breast density and its association with breast cancer, to our knowledge, patient knowledge of breast density has not been assessed. We would like to investigate patients' awareness of breast density, specifically those patients who were previously notified of their dense breasts in the mammography result letter.

METHODS AND MATERIALS

We conducted a retrospective review of 8317 women who enrolled in the SoftVue™ Prospective Case Collection registry between December 2016 and October 2019 who had heterogeneously or extremely dense breasts. After undergoing mammography (MG) and SoftVue™ automated whole breast ultrasound tomography (SV), all participants completed a history and demographics questionnaire and an experience survey which also measured awareness of their own breast density, anxiety about breast density, and level of worry about breast cancer. We reviewed this data and determined the awareness of dense breasts in this population and its influence on self-reported anxiety about breast cancer and looked at other factors that may influence density awareness.

RESULTS

A large percentage of women are not aware of the significance of dense breasts, despite many of them having received breast density notification letters prior to participation. Patients who are aware of their breast density report higher anxiety about their breast density compared to those who are not. Non-Hispanic women are more aware of breast density than Hispanic women. Patients who underwent imaging in States where Breast Density Notification Laws were active are more likely to be aware of their breast density, however the wording of the density information letter may impact patient awareness and concern surrounding it.

CONCLUSION

s Breast density is not well understood by women who are heterogeneously dense or extremely dense. More work needs to be done to educate women with dense breasts about the increased risk of breast cancer and the need for supplementary imaging to mammography.

CLINICAL RELEVANCE/APPLICATION

Increasing breast density awareness in women with dense breasts will likely empower them to self-advocate for additional imaging for early detection of breast cancer.

Do as We Say, Not as We Do? Our Initial Experience with the Lateral-Arm Needle Approach for Prone Tomosynthesis Breast Biopsy.

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Ethan O. Cohen, MD, Houston, TX (*Presenter*) Spouse, Consultant, Boehringer Ingelheim GmbH;Spouse, Consultant, Novo Nordisk AS;Spouse, Consultant, Eli Lilly and Company

PURPOSE

Compare conventional and lateral-arm needle approaches for prone tomosynthesis breast biopsy.

METHODS AND MATERIALS

Conventional or lateral-arm needle approach for tomosynthesis biopsy was selected based on radiologist preference during 2016-2019, and these biopsies were retrospectively reviewed after IRB approval. Procedure details and biopsy outcomes were compared with the two-sample t-test and two proportion z-tests.

RESULTS

165 patients (median age, 56 years; interquartile range 48-64) underwent 177 biopsies with a conventional needle approach, and 140 patients (median age 56 years; interquartile range 48-65) underwent 147 biopsies with a lateral-arm needle approach. All were successful. Fewer images were necessary with the lateral-arm needle approach (mean 8 versus 6, $P < 0.001$). There were no differences between needle approaches for the remaining procedure details: total procedure time, lesion targeting time, tissue sampling time, number of samples acquired, biopsy target lesion (calcifications, distortion, asymmetry, or mass), clip migration, and complications ($P = 0.06$-0.96). Outcomes for conventional-needle-approach biopsies were 99 benign (56%), 28 high-risk (16%), and 40 malignant (23%); one discordant benign lesion and two high-risk lesions were upgraded at excision. Outcomes for lateral-arm-approach biopsies were 80 benign (54%), 39 high-risk (27%), and 28 malignant (19%); one high-risk lesion was upgraded at excision. Benign and malignant outcomes were equally common with either needle approach ($P = 0.44$-0.79), but high-risk outcomes were more common with the lateral-arm needle approach (believed to be due to radiologist preference based on lesion type, $P = 0.02$). Positive predictive values were similar between approaches ($P = 0.33$).

CONCLUSION

s The lateral-arm needle approach for prone tomosynthesis breast biopsy is an acceptable alternative to conventional needle approach based on radiologist preference. Fewer images were required for the lateral-arm approach, and other procedure details were similar to the conventional needle approach.

CLINICAL RELEVANCE/APPLICATION

The lateral-arm needle approach for tomosynthesis breast biopsy is a new addition to percutaneous biopsy options, and radiologists should familiarize themselves with its benefits.

Cardiac Monday Poster Discussions - A

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - CA DPS

Sub-Events

M5A-SPCA-1 Left ventricular diastolic filling pattern in competitive triathletes with and without myocardial fibrosis compared to sedentary controls by CMR imaging

Participants
Hang Chen, MD, Hamburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Endurance athletes have a higher incidence of myocardial fibrosis than the general population. However, it remains unclear whether myocardial fibrosis leads to any alterations of left ventricular (LV) diastolic function. The aim of this study was to investigate the diastolic LV filling pattern in triathletes, and the influence of myocardial fibrosis by cardiac magnetic resonance (CMR) imaging.

METHODS AND MATERIALS

101 male triathletes (age: 43±11 years) and 28 male controls (age: 41±10 years) were recruited through advertisement in local triathlon clubs. All participants underwent CMR including cine SSFP series, late gadolinium enhancement (LGE) imaging and T1 mapping. Functional and morphological ventricular parameters were obtained, including LV mass and ejection fraction (EF). Diastolic LV filling was determined by a time-volume analysis using cine series (25 phases of the cardiac cycle). Early peak-filling rates (EPFR) and atrial peak-filling rates (APFR) as well as peak-filling rate ratios (PFRR=EPFR/APFR) were determined.

RESULTS

Focal myocardial fibrosis (LGE+) was detected in 20 triathletes (20%) and in none of the controls. LVEF was similar in both triathletes and controls (61±6 vs. 62±7%; P=0.36). LGE+ triathletes had a higher LV mass (88±10 vs. 80±12 g/m²; P<0.01) and extracellular volume (ECV) (26±3 vs. 24±2%; P<0.001) compared to LGE- triathletes. EPFR was similar in LGE- triathletes and controls (216±58 vs. 224±69 ml/s/m²; P=0.52). LGE- triathletes had lower APFR (120±46 vs. 147±55 ml/s/m²; P<0.05) and higher PFRR (2.1±1 vs. 1.6±0.5; P<0.05) compared to controls. LGE+ triathletes had similar EPFR (212±73 ml/s/m²; P=0.80), higher APFR (149±50 ml/s/m²; P<0.05) and decreased PFRR (1.6±0.7, P<0.05) compared to LGE- triathletes. EPFR (P=0.52), APFR (P=0.91) and PFRR (P=0.67) were similar in LGE+ triathletes compared to controls.

CONCLUSION

s While adaptations in diastolic LV filling in LGE- triathletes are characterized by decreased APFR and increased PFRR compared to sedentary controls, LGE+ triathletes demonstrate a pseudo-normalization of APFR and PFRR.

CLINICAL RELEVANCE/APPLICATION

LGE+ triathletes show a diastolic LV filling at rest with a compensatory increase of atrial contraction rates compared to LGE- triathletes. This might suggest that diffuse myocardial fibrosis is associated with reduced passive elasticity of the hypertrophied left ventricle.

M5A-SPCA-3 Free-breathing pseudo-golden-angle bSSFP cine cardiac MRI for evaluation of biventricular function in patients with congenital heart disease

Participants
Dmitrij Kravchenko, MD, Bonn, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To compare free-breathing (FB) multi-slice respiratory-triggered pseudo-golden-angle balanced steady state free precession (bSSFP) cine cardiac MRI (CMR) to standard breath hold (BH) sequences in congenital heart disease (CHD) patients who have trouble suspending respiration.

METHODS AND MATERIALS

Twenty-five CHD patients (mean age 24±9 years, 17 males) underwent routine CMR including breath-hold (BH) 4-chamber (4C) and short axis (SA) cine imaging. FB pseudo-golden-angle bSSFP cine 4C und SA were acquired using ECG-gating and respiratory belt-triggering (at the expiratory phase with 150 ms duration for start-up excitation to drive the magnetization to steady state). Sequences were quantitively analyzed for biventricular volumes, function, signal to noise ratio (SNR), and estimated contrast to noise ratio (CNR). Qualitative image comparison was evaluated for contrast, endocardial edge definition, and artefacts, on a 5-point numeric rating scale. Statistical analysis was carried out using a two tailed paired t-Test and Bland-Altman analysis for direct comparisons.

RESULTS

No statistical differences were found between the BH and FB sequences regarding intraventricular septum thickness in diastole

No statistical differences were found between the BH and FB sequences regarding intraventricular septum thickness in diastole (IVSD, 7.4±2.0 mm vs 7.4±1.8 mm, p=.71), biventricular ejection fraction (left: 56.4±10.3 % vs 55.7±8.5 %, p=.57; right: 49.3±9.1 % vs 49.3±10.8 %, p=.93), or biventricular end diastolic volume (left: 176.3±65.8 ml vs 173.9±66.6 ml, p=.47; right: 186.6±75.8 ml vs 184.0±56.3 ml, p=.81). Average acquisition times for FB SA sequences was 9.22 min. compared to 4.26 min. for BH. Subjective image quality was comparable, yet slightly in favour of the BH sequences (BH 4C 13.9±1.8 and SA 14.7±1.0 vs FB 4C 13.4±1.8 and SA 13.6±1.6). SNR and CNR values were higher for the BH sequences compared to FB (SNR SA 1.0±0.7 and CNR SA 124.1±35.5 vs SNR SA 0.4±0.3 and CNR SA 91.7±45.7, respectively).

CONCLUSION

s FB sequences performed nearly identical to currently available BH sequences regarding ventricular volumetry and function, producing images subjectively slightly inferior to normal BH sequences while remaining diagnostic, providing sufficient data when BH could not be or were insufficiently performed.

CLINICAL RELEVANCE/APPLICATION

Free-breathing respiratory-triggered pseudo-golden-angle bSSFP imaging provides comparable diagnostic quality images to standard BH sequences in CHD patients, offering an alternative when breath-holding capacities are limited.

Left ventricular diastolic filling pattern in competitive triathletes with and without myocardial fibrosis compared to sedentary controls by CMR imaging

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - CA DPS

Participants
Hang Chen, MD, Hamburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Endurance athletes have a higher incidence of myocardial fibrosis than the general population. However, it remains unclear whether myocardial fibrosis leads to any alterations of left ventricular (LV) diastolic function. The aim of this study was to investigate the diastolic LV filling pattern in triathletes, and the influence of myocardial fibrosis by cardiac magnetic resonance (CMR) imaging.

METHODS AND MATERIALS

101 male triathletes (age: 43±11 years) and 28 male controls (age: 41±10 years) were recruited through advertisement in local triathlon clubs. All participants underwent CMR including cine SSFP series, late gadolinium enhancement (LGE) imaging and T1 mapping. Functional and morphological ventricular parameters were obtained, including LV mass and ejection fraction (EF). Diastolic LV filling was determined by a time-volume analysis using cine series (25 phases of the cardiac cycle). Early peak-filling rates (EPFR) and atrial peak-filling rates (APFR) as well as peak-filling rate ratios (PFRR=EPFR/APFR) were determined.

RESULTS

Focal myocardial fibrosis (LGE+) was detected in 20 triathletes (20%) and in none of the controls. LVEF was similar in both triathletes and controls (61±6 vs. 62±7%; P=0.36). LGE+ triathletes had a higher LV mass (88±10 vs. 80±12 g/m²; P<0.01) and extracellular volume (ECV) (26±3 vs. 24±2%; P<0.001) compared to LGE- triathletes. EPFR was similar in LGE- triathletes and controls (216±58 vs. 224±69 ml/s/m²; P=0.52). LGE- triathletes had lower APFR (120±46 vs. 147±55 ml/s/m²; P<0.05) and higher PFRR (2.1±1 vs. 1.6±0.5; P<0.05) compared to controls. LGE+ triathletes had similar EPFR (212±73 ml/s/m²; P=0.80), higher APFR (149±50 ml/s/m²; P<0.05) and decreased PFRR (1.6±0.7, P<0.05) compared to LGE- triathletes. EPFR (P=0.52), APFR (P=0.91) and PFRR (P=0.67) were similar in LGE+ triathletes compared to controls.

CONCLUSION

s While adaptations in diastolic LV filling in LGE- triathletes are characterized by decreased APFR and increased PFRR compared to sedentary controls, LGE+ triathletes demonstrate a pseudo-normalization of APFR and PFRR.

CLINICAL RELEVANCE/APPLICATION

LGE+ triathletes show a diastolic LV filling at rest with a compensatory increase of atrial contraction rates compared to LGE- triathletes. This might suggest that diffuse myocardial fibrosis is associated with reduced passive elasticity of the hypertrophied left ventricle.

M5A-SPCA-3

Free-breathing pseudo-golden-angle bSSFP cine cardiac MRI for evaluation of biventricular function in patients with congenital heart disease

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - CA DPS

Participants
Dmitrij Kravchenko, MD, Bonn, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To compare free-breathing (FB) multi-slice respiratory-triggered pseudo-golden-angle balanced steady state free precession (bSSFP) cine cardiac MRI (CMR) to standard breath hold (BH) sequences in congenital heart disease (CHD) patients who have trouble suspending respiration.

METHODS AND MATERIALS

Twenty-five CHD patients (mean age 24±9 years, 17 males) underwent routine CMR including breath-hold (BH) 4-chamber (4C) and short axis (SA) cine imaging. FB pseudo-golden-angle bSSFP cine 4C und SA were acquired using ECG-gating and respiratory belt-triggering (at the expiratory phase with 150 ms duration for start-up excitation to drive the magnetization to steady state). Sequences were quantitively analyzed for biventricular volumes, function, signal to noise ratio (SNR), and estimated contrast to noise ratio (CNR). Qualitative image comparison was evaluated for contrast, endocardial edge definition, and artefacts, on a 5-point numeric rating scale. Statistical analysis was carried out using a two tailed paired t-Test and Bland-Altman analysis for direct comparisons.

RESULTS

No statistical differences were found between the BH and FB sequences regarding intraventricular septum thickness in diastole (IVSD, 7.4±2.0 mm vs 7.4±1.8 mm, p=.71), biventricular ejection fraction (left: 56.4±10.3 % vs 55.7±8.5 %, p=.57; right: 49.3±9.1 % vs 49.3±10.8 %, p=.93), or biventricular end diastolic volume (left: 176.3±65.8 ml vs 173.9±66.6 ml, p=.47; right: 186.6±75.8 ml vs 184.0±56.3 ml, p=.81). Average acquisition times for FB SA sequences was 9.22 min. compared to 4.26 min. for BH. Subjective image quality was comparable, yet slightly in favour of the BH sequences (BH 4C 13.9±1.8 and SA 14.7±1.0 vs FB 4C 13.4±1.8 and SA 13.6±1.6). SNR and CNR values were higher for the BH sequences compared to FB (SNR SA 1.0±0.7 and CNR SA 124.1±35.5 vs SNR SA 0.4±0.3 and CNR SA 91.7±45.7, respectively).

CONCLUSION

s FB sequences performed nearly identical to currently available BH sequences regarding ventricular volumetry and function, producing images subjectively slightly inferior to normal BH sequences while remaining diagnostic, providing sufficient data when BH could not be or were insufficiently performed.

CLINICAL RELEVANCE/APPLICATION

Free-breathing respiratory-triggered pseudo-golden-angle bSSFP imaging provides comparable diagnostic quality images to standard BH sequences in CHD patients, offering an alternative when breath-holding capacities are limited.

M5A-SPCH-2 Quantitative CT and Machine Learning Classification of Fibrotic Interstitial Lung Diseases

Participants
Grace Liu, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate quantitative computed tomography (QCT) features and QCT feature-based machine learning (ML) models in classifying interstitial lung diseases (ILDs). To compare QCT-ML and deep learning (DL) models' performance.

METHODS AND MATERIALS

We retrospectively identified 1085 patients with pathologically proven usual interstitial pneumonitis (UIP), nonspecific interstitial pneumonitis (NSIP) and chronic hypersensitivity pneumonitis (CHP) who underwent peri-biopsy chest CT. Kruskal-Wallis test evaluated QCT feature associations with each ILD. QCT features, patient demographics and pulmonary function test (PFT) results trained eXtreme Gradient Boosting (training/validation set n=911) yielding 3 models: M1=QCT features only; M2=M1 plus age and sex; M3=M2 plus PFT results. A DL model was also developed. ML and DL model areas under the receiver operating characteristic curve (AUC) and 95% confidence intervals (CIs) were compared for multiclass (UIP vs. NSIP vs. CHP) and binary (UIP vs. non-UIP) classification performances.

RESULTS

The majority (69/78 [88%]) of QCT features successfully differentiated the 3 ILDs (adjusted p=0.05). All QCT-ML models achieved higher AUC than the DL model (multiclass AUC micro-averages: 0.910, 0.910, 0.925, 0.798 and macro-averages: 0.895, 0.893, 0.925, 0.779 for M1, M2, M3 and DL respectively; binary AUC: 0.880, 0.899, 0.898, 0.869 for M1, M2, M3 and DL respectively). M3 demonstrated statistically significant better performance compared to M2 (?AUC:0.015, CI:[0.002,0.029]) for multiclass prediction.

CONCLUSION

s QCT features successfully differentiated pathologically proven UIP, NSIP and CHP. While QCT-based ML models outperformed a DL model for classifying ILDs, further investigations are warranted to determine if QCT-ML, DL, or a combination will be superior in ILD classification.

CLINICAL RELEVANCE/APPLICATION

CALIPER-based ML model demonstrated high performance in classifying UIP, NSIP and CHP using pathology as reference, outperforming a DL model. While further validation is needed, a CALIPER-based ML model may mitigate the need for invasive wedge biopsies and may be useful in multidisciplinary diagnosis.

M5A-SPCH-3 Deep Learning-Based Survival Prediction in Patients with Idiopathic Pulmonary Fibrosis Using Chest Radiographs

Participants
Taehee Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Predicting prognosis in patients with idiopathic pulmonary fibrosis (IPF) is important in determining management plans and follow-up intervals. Various clinical indices including GAP index had been devised, however, chest radiographs (CXRs) were seldom utilized. We aimed to develop and validate a deep learning-based survival prediction algorithm for patients with IPF using CXRs.

METHODS AND MATERIALS

Patients diagnosed with IPF and underwent spirometry and CXR within 1 month in a single institution during 2011-2021 were retrospectively collected and split into training (n=911), validation (n=112), and internal test (n=187) datasets. A deep-learning algorithm predicting survival from CXR was trained (DLSP). For external testing, two cohorts were collected from two different institutions (EXT-A and B; n=178 [mean age 66.6 ± 10.3; 116 men] and n=101 [mean age 70.9 ± 7.5; 87 men], each). The discrimination performance of DLSP was evaluated and compared with that of forced vital capacity (FVC) using time-dependent area-under-the receiver-operating characteristic curves (TD-AUCs) for 1-year and 3-year survivals. Cox regression was performed to see if DLSP was independent prognostic factor adjusted to FVC. Goodness-of-fit was assessed using the Hosmer-Lemeshow test for model calibration. We proposed modified GAP index (GAP-CXR) which utilizes DLSP instead of DLCO: DLSP results were categorized by quartiles calculated from internal test dataset. TD-AUCs of GAP index and GAP-CXR index were compared.

RESULTS

DLSP showed 1-yr and 3-yr TD-AUCs of 0.832 and 0.753 in EXT-A cohort and 0.838 and 0.785 in EXT-B cohort, while FVC exhibited 1-yr and 3-yr TD-AUCs of 0.769 and 0.679 in EXT-A cohort and 0.568 and 0.634 in EXT-B cohort. DLSP showed significantly higher performance in predicting 1-yr (P=.03) and 3-yr survival (P=.02) in EXT-B cohort. In both external test cohorts, DLSP worked as an independent predictor when adjusted to FVC (Ps<.001) and showed good calibration (Ps>.05). When GAP index was modified to use DLSP instead of DLCO results, GAP-CXR showed comparable performance to original GAP index in EXT-A cohort (1yr TD-AUC, 0.884 vs. 0.893, P=.68; 3yr TD-AUC, 0.822 vs. 0.820, P=.95) and higher performance in EXT-B cohort (1yr TD-AUC, 0.845 vs. 0.705, P=.003; 3yr TD-AUC, 0.718 vs. 0.621, P=.03).

CONCLUSION

s DLSP using chest radiographs worked as a significant survival predictor for patients with IPF, surpassing and independent of FVC. Modified GAP index replacing DLCO by DLSP results showed comparable-to-superior performance than original GAP index.

CLINICAL RELEVANCE/APPLICATION

By predicting life expectancy of patients with IPF using easily accessible chest radiographs, personalized management could be achieved.

M5A-SPCH-5 Volumetric and Movement CT Analysis of Lung Parenchyma in Prone Positioning using Deep Neural Networks

Participants
Hyungin Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To conduct a volumetric and movement analysis of lung parenchyma in prone positioning using deep neural networks (DNNs).

METHODS AND MATERIALS

We included patients suspected of interstitial lung abnormalities or disease undergoing full-inspiratory supine and prone chest CT scans in a single institution between June 2021 and March 2022. A thoracic radiologist visually assessed the fibrosis extent in units of 10% of a total lung on supine CT images. Lobar volumes and the extent of overall fibrosis in each lobe were quantified on supine and prone CT images with the help of a previously developed 3DnnUNET. A publicly-available DNN-based deformable image registration, LungReg, was used to register supine and prone CT images: sequential affine and deformable registration. Affine registration matched patient centers and locations between supine and prone CT images. Then, we calculated pixel movement during deformable registration to calculate the x, y, z-axis, and 3-dimensional (3D) lung pixel movement of prone positioning. After registration, the radiologist visually evaluated subtraction images to check whether the registration succeeded.

RESULTS

A total of 122 CT pairs in patients (mean age, 68.1 years; 65 men) had successful CT image registration. Prone positioning significantly increased left lower (90.2±69.5 mL) and right lower lobar volumes (52.5±74.2 mL), whereas right upper (-15.5±54.4 mL) and middle lobar volumes (-33.9±44.8 mL) decreased (all p=.003). During the deformable registration, averaged maximum whole-lung pixel movements between prone and supine positions were 1.5, 1.9, 1.6, and 2.9 cm in x, y, z-axis, and 3D planes, each. Compared to patients having fibrosis <30%, those with fibrosis =30% had a smaller volume change (p<.001) and smaller maximum pixel movements in all axes between the positions (p=.000 to .007). FVC was correlated with left lower lobar volume increases (Spearman coefficient, .238) and the maximum whole-lung pixel movements in all axes (coefficients, .311 to .357).

CONCLUSION

s Prone positioning led to the expansion of lower lobes correlated with FVC, and lung fibrosis limited the lung expansion of prone positioning.

CLINICAL RELEVANCE/APPLICATION

Lower lobe recruitment in prone positioning is quantifiable on CT images and can be a new imaging biomarker for assessing lung function in interstitial lung disease.

M5A-SPCH-8 Machine Learning Based Computer-Aided Simple Triage (CAST): Capabilities for COVID-19 Pneumonia Triage based on RSNA Expert Consensus Statement and Radiological Finding Evaluations in Multi-Center Study

Participants
Yoshiharu Ohno, MD, PhD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research Grant, Daiichi Sankyo Co, Ltd;Research Grant, Ministry of Education, Culture, Sports, Science and Technology

PURPOSE

To determine the capability of machine learning (ML) based computer-aided simple triage (CAST) software based on RSNA expert consensus statement for diagnosis of COVID-19 pneumonia in multicenter study.

METHODS AND MATERIALS

174 cases underwent CT and polymerase chain reaction (PCR) test for COVID-19 (87 PCR positive and 87 PCR negative cases) were retrospectively included in this multicenter study. Then, CT data were assessed by CAST and consensus from three independent board-certified chest radiologists, and all cases were divided into three groups as follows: positive cases (i.e. typical and indeterminant appearances), atypical appearance and negative for pneumonia (i.e. latter two groups were assessed as negative cases). To determine radiological finding evaluation capability with CAST, three other board-certified chest radiologists also assessed CAST results of radiological finding including pulmonary emphysema, nodular lesion, consolidation, ground-glass opacity, reticulation and honeycombing within 156 slices selected by central reading team and classified into five criteria as follows: agree, acceptable, disagree, true negative and false positive, respectively. To determine capability of CAST, agreements between CAST and consensus were evaluated by kappa statistics with ?2 test. Then, sensitivity (SE), specificity (SP) and accuracy (AC) between CAST and PCR were compared with those between consensus and PCR by McNemar's test. To determine overall radiological finding

evaluation capability, each radiological finding accuracy of CAST (i.e. percentage of agree, acceptable and true negative lesions/ all evaluated lesions) were assessed in all readers. Moreover, overall interobserver agreements between each two readers were determined by kappa statistics with ?2 test.

RESULTS

Agreement between CAST and consensus evaluations were determined as moderate (?=0.55, p<0.0001). No significant difference of SE (88.5%) was observed between CAST and consensus, although SP (47.1%) and AC (67.8%) of CAST were significantly lower than those of consensus (SP: 79.3%, p<0.0001; AC: 83.9%, p<0.0001). Accuracies for radiological finding evaluation by CAST were determined as follows: reader A, 91.7-99.4%; reader B, 99.4-100%, reader C, 99.4-100%. Overall interobserver agreements between each two readers were assessed as substantial or almost perfect (0.65<?<0.96, p<0.0001).

CONCLUSION

s This multicenter study shows CAST is considered at least as valuable as radiologists for COVID-19 pneumonia triage with accurate radiological finding evaluations.

CLINICAL RELEVANCE/APPLICATION

CAST is considered at least as valuable as radiologists for COVID-19 pneumonia triage with accurate radiological finding evaluations.

Machine Learning Based Computer-Aided Simple Triage (CAST): Capabilities for COVID-19 Pneumonia Triage based on RSNA Expert Consensus Statement and Radiological Finding Evaluations in Multi-Center Study

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - CH DPS

Participants
Yoshiharu Ohno, MD, PhD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research Grant, Daiichi Sankyo Co, Ltd;Research Grant, Ministry of Education, Culture, Sports, Science and Technology

PURPOSE

To determine the capability of machine learning (ML) based computer-aided simple triage (CAST) software based on RSNA expert consensus statement for diagnosis of COVID-19 pneumonia in multicenter study.

METHODS AND MATERIALS

174 cases underwent CT and polymerase chain reaction (PCR) test for COVID-19 (87 PCR positive and 87 PCR negative cases) were retrospectively included in this multicenter study. Then, CT data were assessed by CAST and consensus from three independent board-certified chest radiologists, and all cases were divided into three groups as follows: positive cases (i.e. typical and indeterminant appearances), atypical appearance and negative for pneumonia (i.e. latter two groups were assessed as negative cases). To determine radiological finding evaluation capability with CAST, three other board-certified chest radiologists also assessed CAST results of radiological finding including pulmonary emphysema, nodular lesion, consolidation, ground-glass opacity, reticulation and honeycombing within 156 slices selected by central reading team and classified into five criteria as follows: agree, acceptable, disagree, true negative and false positive, respectively. To determine capability of CAST, agreements between CAST and consensus were evaluated by kappa statistics with ?2 test. Then, sensitivity (SE), specificity (SP) and accuracy (AC) between CAST and PCR were compared with those between consensus and PCR by McNemar's test. To determine overall radiological finding evaluation capability, each radiological finding accuracy of CAST (i.e. percentage of agree, acceptable and true negative lesions/ all evaluated lesions) were assessed in all readers. Moreover, overall interobserver agreements between each two readers were determined by kappa statistics with ?2 test.

RESULTS

Agreement between CAST and consensus evaluations were determined as moderate (?=0.55, p<0.0001). No significant difference of SE (88.5%) was observed between CAST and consensus, although SP (47.1%) and AC (67.8%) of CAST were significantly lower than those of consensus (SP: 79.3%, p<0.0001; AC: 83.9%, p<0.0001). Accuracies for radiological finding evaluation by CAST were determined as follows: reader A, 91.7-99.4%; reader B, 99.4-100%, reader C, 99.4-100%. Overall interobserver agreements between each two readers were assessed as substantial or almost perfect (0.65<?<0.96, p<0.0001).

CONCLUSION

s This multicenter study shows CAST is considered at least as valuable as radiologists for COVID-19 pneumonia triage with accurate radiological finding evaluations.

CLINICAL RELEVANCE/APPLICATION

CAST is considered at least as valuable as radiologists for COVID-19 pneumonia triage with accurate radiological finding evaluations.

M5A-SPER-1 Blunt Splenic Trauma: Accuracy of Automated Active Bleed and Contained Vascular Injury Detection on CT with Faster R-CNN

Participants
Alexander Upegui, Baltimore, MD (*Presenter*) Nothing to Disclose

PURPOSE

Contained vascular injury (CVI) and active bleeding (AB) are indications for intervention after blunt splenic trauma. Automated tools in this high-stakes setting require a high level of transparency and interpretability. AB and CVI are components of AAST grading and future interpretable human-centered AAST-based CAD tools will require accurate multi-feature detection. We evaluate performance of a 2D Faster-RCNN deep learning object detection framework for AB and CVI.

METHODS AND MATERIALS

An existing single institution dataset was used which included abdominal CT scans from 174 consecutively selected BSI patients archived at 1.5 mm section thickness and with voxelwise labeling of CVI on arterial images and AB on PVP images. 2D Faster-RCNN was employed given its well-known high performance for cross-sectional imaging object detection. Training and validation were performed in 5 folds with 80/20 split of the data using the most appropriate imaging phase for each task (arterial phase- CVI; PVP-active bleed). Since the 2018-AAST scoring system approaches CVI and AB in a binary fashion (intervention is typically warranted if either are present), accuracy metrics were determined at the patient level based on the highest probability box detection for each feature.

RESULTS

Of the 174 patients, 28.1% had CVI, and 14.9% had AB. The overall accuracy of Faster R-CNN for AB detection on PVP images was 86% with sens, spec, NPV PPV of 85, 85, 92, and 74%. The accuracy for CVI detection on arterial images was 84%, with sens, spec, NPV PPV of 91, 73, 94, and 61%. In patients with detected vascular lesions, intervention (either embolization or splenectomy) was performed in 88.9%.

CONCLUSION

s In this initial proof of concept study with single institution data, Faster R-CNN was useful for confident exclusion of AB or PSA (NPV 92 and 94%). As with lung nodule detection where Faster R-CNN is frequently employed, low PPV remained a challenge owing to false positives. Given the wide variability in appearances of CVI and AB, improved results are expected with large multi-institutional datasets. Further improvements could also be achieved with modifications in pre-processing (e.g., MIPs), and modifications in network architecture (e.g., residual networks) for false positive reduction.

CLINICAL RELEVANCE/APPLICATION

To our knowledge, we present the first implementation of object detection for splenic vascular lesions on CT. The method denotes lesions with box proposals and could be incorporated into interpretable automated AAST CAD grading systems in the future.

M5A-SPGI-1 Prediction of Postoperative Anastomotic Recurrence in Crohn's Disease Using Preoperative CTE Radiomic Data

Participants
Xiao Di Shen, (*Presenter*) Nothing to Disclose

PURPOSE

More than half of patients with Crohn’s disease (CD) need at least one surgery in their life, however, most patients will experience postoperative anastomotic recurrence (PAR). Stratifying them according to the risk of PAR and tailoring therapy are the most cost-effective way to manage these patients. This study aimed to develop and validate a novel preoperative clinical-radiological-radiomic model to predict the risk of PAR.

METHODS AND MATERIALS

This retrospective study included 186 CD patients (training cohort: n=103; test cohort 1: n=31; test cohort 2: n=52) who underwent CD-related surgery in one of the three centers. The presence of endoscopic, radiological, or surgical anastomotic recurrence was termed PAR. In training cohort, 106 radiomic features were extracted respectively from bowel lesions and perienteric mesenteric adipose tissues on preoperative venous-phase computed tomography enterography (CTE) images and ranked by SelectKBest to select the key features. Univariate and multivariate analyses with Cox proportional hazards regression were performed to determine the risk factors of PAR and construct the prediction model (so-call clinical-radiological-radiomic model) from various clinical-radiological and radiomic features. The prediction efficacy of clinical-radiological-radiomic model was validated in two external test cohorts.

RESULTS

Three mesenteric radiomic features were selected to develop radiomic-mesentery model and four bowel features were selected to construct radiomic-bowel model. In training cohort, radiomic-mesentery model (AUC=0.690; P<0.05) showed higher predicting efficacy than radiomic-bowel model (AUC=0.654; P<0.05) and was thus chose to integrate into the clinical-radiological-radiomic model. In training cohort and test cohorts 1 and 2, the clinical-radiological-radiomic model showed an increase in predicting performance (AUCs: 0.833, 0.778, and 0.742, respectively; all P<0.05) than clinical-radiological model (AUCs: 0.679, 0.674, and 0.687, respectively; all P<0.05). Decision curve analysis demonstrated the clinical usefulness of the clinical-radiological-radiomic model.

CONCLUSION

s The preoperative clinical-radiological-radiomic model could be a promising tool to accurately identify CD patients at high risk of PAR.

CLINICAL RELEVANCE/APPLICATION

To develop and validate a preoperative CTE-based radiomics signature to early predict postoperative anastomotic recurrence in CD.

M5A-SPGI-10 Hepatobiliary Phase Imaging in cirrhotic patients using Compressed Sensing: Comparison of Image Quality and focal Lesion Detection with the T1-Weighted Sequence using Controlled Aliasing in Parallel Imaging Results in Higher Acceleration

Participants
So Hyun Park, MD, (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to compare VIBE using compressed sensing (CS) and controlled aliasing in parallel imaging results in higher acceleration (CAIPIRINHA) in subjective and objective image quality in patients with cirrhotic liver for acquisition of single breath-hold on hepatobiliary phase images.

METHODS AND MATERIALS

We retrospectively included 244 gadoxetic acid-enhanced liver MRI in 244 patients with cirrhosis from July 2020 to December 2020. All patients underwent two hepatobiliary phases (HBP) using CS and CAIPIRINHA. Optimized resolution and scan time for CS-HBP were 0.9?×?0.9?×?1.5 mm3 and 15 s, while those for CAIPIRINHA-HBP were 1.3?×?1.8?×?3 mm3 and 15 s. Two abdominal radiologists assessed the two MRI data sets for image quality in consensus. We compared subjective and objective image quality in

two sequences.

RESULTS

CS-HBP showed significantly superior liver edge sharpness and overall image quality, and lesser respiratory motion artifact (all P <0.001), but higher non-respiratory artifact (P =0.014) compared to CAIPIRINHA-HBP. Intraclass correlation coefficients of subjective image quality in CS-HBP was 0.550-0.827 and that in CAIPIRINHA-HBP was 0.530-0.809. CS-HBP showed superior SNR in the liver to CAIPIRINHA-HBP (20.8 ± 9.1 vs. 18.8 ± 7.2; P <0.001) and liver-spleen contrast in two were similar (2.0 ± 1.1 vs. 2.1 ± 1.2, P =0.071), respectively.

CONCLUSION

s CS-HBP identified superior overall image quality, liver edge sharpness, and liver SNR and lesser respiratory motion artifact, but higher non-respiratory artifact and noise and comparable liver-spleen contrast compared to CAIPIRINHA-HBP, with same acquisition time.

CLINICAL RELEVANCE/APPLICATION

In patient with decreased liver function, HBP image showed non-clean or decreased enhancement of liver. Identification of adequate image quality on HBP applied CS in patients with cirrhosis can help to select protocol. To our knowledge, however, there have been no studies comparing image quality of HBP between CS and CAIPIRINHA in patients with liver cirrhosis.

M5A-SPGI-2 Comparison of diagnostic performance of Ultrasonography and Magnetic Resonance Enterography in assessment of active bowel lesions in patients with Crohn's disease

Participants
Dain Lee, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to evaluate and compare the diagnostic performance of ultrasonography (US) and magnetic resonance enterography (MRE) in assessing active bowel lesions in patients with Crohn’s disease (CD) through meta-analysis

METHODS AND MATERIALS

We searched PubMed and EMBASE for studies in which US and MRE were evaluated to assess active bowel lesions in CD patients. Bivariate random effect meta-analytic methods were used to estimate pooled sensitivity, specificity, and hierarchical summary receiver operating characteristic (HSROC) curves. We performed meta-regression analysis according to the characteristics of the study design, study population, reference standards, and US technique.

RESULTS

Eleven studies involving a total of 752 patients were included. US exhibited a pooled sensitivity of 87.5 % (95% confidence interval 73.7-94.6), a pooled specificity of 87.1% (95% CI 72.4-94.6), and HSROC of 0.9 in 10 studies. MRE exhibited a pooled sensitivity of 88.5% (95% CI 76.1-94.9), a pooled specificity of 87.5% (95% CI 73.1-94.8), and HSROC of 0.93 in 8 studies. In 7 studies comparing the diagnostic performance of US and MRE, summary sensitivity of US and MR were 88% (95% CI 65.3-96.6, I2=92.1) and 86% (95% CI 72.4-93.6, I2=92.3) (p=0.841) and summary specificity of US and MR were 88% (95% CI 79.7-93.1, I2=64.2%) and 84% (72.5-90.7, I2=48.9%) (p=0.431), which showed no significant differences. On meta-regression analysis, studies from Europe(p=0.002) and studies that used one kind of US probe (p=0.012) reported higher US sensitivity than those from other region and used two kind of US probe, and studies with pediatrics reported higher MR specificity than those with adult population(p=0.001>).

CONCLUSION

s Both US and MRE can diagnose active bowel lesions with comparable diagnostic accuracy in CD patients, although there was significant heterogeneity in the included studies. Study region, number of used US probe for US sensitivity and study population for MR specificity were the potential source of heterogeneity.

CLINICAL RELEVANCE/APPLICATION

Ultrasonography can be the reliable alternative to MRE in assessing active bowel lesion with free of radiation and easier accessibility in CD patients

M5A-SPGI-3 Utility of dual-layer spectral-detector CT imaging for assessing pathological tumor stages and histologic grades of colorectal adenocarcinoma

Participants
Weicui Chen, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Pathological tumor (pT) stage and histologic differentiation are the most critical factors for colorectal adenocarcinoma (CRAC) prognosis.This study aims at assessing the utility of Dual-layer spectral-detector CT (DLCT) in predicting the pT stage and histologic grade for CRAC.

METHODS AND MATERIALS

A total of 131 patients with pathologically confirmed CRAC (82 colon cancers and 49 rectal cancers; 35 pT1-2, 61 pT3, and 35 pT4; 32 high grade and 99 low grade) between May 2021 and March 2022, who received dual-phase DLCT were enrolled in this retrospective study. Normalized iodine concentration (NIC), slope of the spectral HU curve (?HU), and effective atomic number (Eff-Z) were measured for each lesion by two radiologists independently. Intraobserver reliability and interobserver agreement were assessed. The Student’s t-test, one-way analysis of variance (ANOVA), Mann-Whitney U test, or Kruskal-Wallis ANOVA test was used to compare the above quantitative parameters between two groups by histologic grades (high and low) and three groups by pT stages (pT1-2, pT3, and pT4). The correlation between the pT stages and above values were assessed by Spearman correlation analysis. ROC analyses were calculated to evaluate the diagnostic efficacy of each parameter for differentiating advanced- (pT3/4) from early-stage (pT1/2) and high- from low-grade CRAC.

RESULTS

The range of 95% confidence interval (CI) for intraobserver reliability were 0.88 to 0.99. The range of 95% CI for intreobserver agreement were 0.74 to 0.98. Eff-Z [7.21(0.09) vs 7.31 (0.10) vs 7.35 (0.19)], NICAP [0.11 (0.05) vs 0.15 (0.08) vs 0.15 (0.08)], NICVP [0.27 (0.06) vs 0.34 (0.11) vs 0.35 (0.12)], ?HUAP [1.20 (0.45) vs 1.93 (1.18) vs 2.37 (0.91)], and ?HUVP [2.07 (0.68) vs 2.35 (0.62) vs 3.09 (1.07)] were significantly different among pT stage groups (all $p<0.001$) and exhibited a positive correlation with pT stages ($r= 0.503, 0.455, 0.394, 0.512, 0.376$, respectively, all $p<0.001$). Eff-Z [7.37 (0.10) vs 7.28 (0.08)], NICAP [0.20 (0.10) vs 0.13 (0.08)], NICVP [0.35 (0.07) vs 0.31 (0.11)], and ?HUAP [2.59 (1.11) vs 1.63 (0.75)] in the high-grade group were markedly higher than those in the low-grade group (all $p<0.05$). For discriminating the advanced- from early-stage CRAC, the AUCs of Eff-Z, NICAP, NICVP, ?HUAP, and ?HUVP were 0.83, 0.80, 0.79, 0.86, and 0.68, respectively. For discriminating the high- from low-grade CRAC, the AUCs of Eff-Z, NICAP, NICVP, and ?HUAP were 0.81, 0.81, 0.64, and 0.81, respectively.

CONCLUSION

s The quantitative parameters derived from DLCT could successfully predict pT stages and histologic differentiation in CRAC.

CLINICAL RELEVANCE/APPLICATION

DLCT parameters may help characterize the aggressive CRAC.

M5A-SPGI-4 Prediction of KRAS mutations in colorectal cancer based on dual-energy and perfusion CT parameters

Participants
Xiaoqiang Lin, Lanzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the predictive value of dual-energy spectral CT (DESCT) and perfusion CT quantitative parameters for KRAS mutation in colorectal cancer, a diagnostic model was constructed and visualized as a nomogram to assist clinical preoperative treatment decisions.

METHODS AND MATERIALS

67 patients with colorectal cancer underwent "one-step" abdominal spectral and perfusion CT before surgery and were divided into two groups: group A (wild-type) and group B (mutation). Clinical baseline characteristics included age, gender, tumor location, serum tumor markers, bowel wall thickening pattern and superior rectal vein (SRV) width. A radiologist delineated the regions of interest (ROIs) on the layer of maximum tumor diameter and the nearest upper and lower layers in axial enhanced images and calculated the average value. Monoenergetic CT value, effective atomic number (Eff-Z), iodine concentration (IC) of tumor and artery were acquired to calculate normalized iodine concentration (NIC, NIC = ICtumor / ICartery). Perfusion parameters include blood flow (BF), blood volume (BV), mean slope of increase (MSI), mean transit time (MTT), positive enh integral (PEI), capillary permeability surface area product (PS) and time to peak (TTP). ?2 test, t-test and U test were used for calculated differences between groups. Then, least absolute shrinkage and selection operator (LASSO) regression and multivariate logistic regression were used to select the most discriminating features, build a predictive model and visualize the model as a nomogram. Concordance index (C-index), calibration curves and decision curves analysis (DCA) were used to evaluate prediction performance and clinical utility.

RESULTS

30 patients had KRAS mutations in 67 patients. After feature selection, the four variables included BF, BV, 130keVAP and NICAP*10 were screened by LASSO regression and multivariate logistic regression to construct the nomogram. The C-index and bootstrap C-index of the model were 0.886 (95%CI: 0.808~0.963) and 0.857, respectively. The sensitivity and specificity were 70.0% and 85.7%, respectively. The model showed good calibration, and the DCA demonstrated that the model has a higher net benefit than the best single variable.

CONCLUSION

s There were differences in LTL, CT perfusion parameters and multiple arteriovenous phases spectral CT parameters in KRAS mutation status. The nomogram based on BF, BV, 130KeVAP and NICAP*10 is helpful for the preoperative determination of KRAS mutation status in colorectal cancer.

CLINICAL RELEVANCE/APPLICATION

The nomogram is helpful for the preoperative determination of KRAS mutation status in colorectal cancer, which can assist in clinical preoperative decision-making and patient risk stratification.

M5A-SPGI-5 Noise power spectrum properties of deep learning-based reconstruction and iterative reconstruction algorithms:Phantom and clinical study

Participants
Yoshinori Funama, PhD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Recent reconstructions of computed tomography (CT) images are nonlinear in nature. Therefore, the noise power spectrum (NPS) properties of reconstructed images are likely to be clinically more relevant when measured in uniform organs of the human body, such as the bladder, with noise-level matching than the use of phantom images. This study aimed to compare the NPS properties and perform qualitative analysis of hybrid iterative reconstruction (hybrid-IR), model-based IR (MBIR), and deep learning-based IR (DLR) at a similar noise level in a clinical study based on the outcomes of a phantom study.

METHODS AND MATERIALS

A Catphan phantom with an external body ring was used in the phantom study. In the clinical study, CT examination data of 35 patients were retrospectively reviewed. NPS was calculated from DLR, hybrid IR, and MBIR images using a uniform portion of the phantom and bladder portions of the patients. The noise magnitude ratio (NMR) and central frequency ratio (CFR) were calculated from DLR, hybrid IR, and MBIR images relative to filtered back-projection (FBP) images using NPS. CFR represents the degree of lower frequency shift for NPS. Clinical CT images were independently reviewed by two board-certified general radiologists.

RESULTS

In the phantom study, DLR achieved substantial noise reduction compared to hybrid IR and MBIR with increasing strength levels. The mean NMR for DLR with a mild level was 0.49, and the noise level was similar to those of hybrid IR at 0.53 and MBIR at 0.65 with strong levels. The CFRs were 0.83, 0.60, and 0.66 for DLR, hybrid IR, and MBIR, respectively; the lower frequency shift for NPS was small level on DLR. Based on the outcomes of the phantom study, the clinical study applied DLR with mild and hybrid IR and MBIR with strong-level images. In the clinical study, the NMR and CFR were 0.39 and 0.35, 0.46 and 0.76, and 0.51 and 0.62 for DLR, hybrid IR, and MBIR, respectively. The visual inspection for DLR with mild-level images was superior to those for hybrid IR and MBIR with strong levels .

CONCLUSION

s DLR images achieved substantial noise reduction while maintaining image noise texture in the phantom and clinical studies.

CLINICAL RELEVANCE/APPLICATION

DLR images provide better clinical visibility without the lack of image texture appearance in CT.

M5A-SPGI-6 Ultra-high resolution computed tomography with deep-learning-reconstruction: Diagnostic ability in the assessment of gastric cancer and the depth of invasion

Participants
Masaya Tanabe, MD, Ube, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To assess the image quality of ultra-high-resolution CT (U-HRCT) reconstructed with improved deep-learning-reconstruction (DLR) method, the utility in the delineation of the gastric wall structure, and visibility of gastric cancer and its depth invasion.

METHODS AND MATERIALS

This study included 46 patients with resected gastric cancers who underwent preoperative contrast-enhanced U-HRCT. Image quality of U-HRCT (0.5mm, 1024x1024) reconstructed with three different methods; standard DLR (Advanced intelligent Clear-IQ Engine [AiCE]), improved DLR (AiCE-Body Sharp [BS]) and hybrid-IR (Adaptive Interactive Dose Reduction 3Dimensional [AIDR3D]) was compared for the visualization of the gastric wall. Then, the conspicuity for the three-layered structure of the gastric wall at four regions (fornix, body, angle and antrum) and the visibility of gastric cancers were compared between conventional HRCT (C-HRCT; 2mm, 512x512) and U-HRCT. Finally, the diagnostic ability of U-HRCT with improved AiCE-BS for the depth invasion of gastric cancers was assessed in comparison with actual postoperative pathology specimens.

RESULTS

The mean noise of U-HRCT with improved AiCE-BS was significantly lower than that with AIDR3D although there was no significant difference between improved AiCE-BS and standard AiCE. The mean overall image quality scores with improved AiCE-BS images were significantly higher than those with the other two methods ($p<0.001$). Regarding the comparison between C-HRCT and U-HRCT, the mean conspicuity scores for the three-layered structure of the gastric wall on U-HRCT were significantly better than those on C-HRCT in the fornix ($p<0.001$), body ($p<0.001$), angle ($p=0.007$), antrum ($p=0.007$). In addition, visibility of gastric cancer with U-HRCT was better than that with C-HRCT($p<0.001$). Correct diagnosis rate for depth invasion of gastric cancer using U-HRCT was 72%.

CONCLUSION

s U-HRCT with improved AiCE-BS is capable of depicting the three-layered structure of the gastric wall more clearly than the other two reconstruction methods, and is useful for the visualization of gastric cancers as well as for the assessment of depth invasion.

CLINICAL RELEVANCE/APPLICATION

U-HRCT using new DLR method will improve overall image quality, delineation of the three-layered structure of gastric wall, visibility of gastric cancer, and diagnostic ability for depth invasion.

M5A-SPGI-7 Low-Tube-Voltage Whole-Body CT Angiography with Extremely-Low-Iodine Dose: Comparison between Deep Learning-based and Adaptive Statistical Iterative Reconstructions

Participants
Nobuyuki Kawai, MD, Gifu, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To prospectively compare the arterial enhancement, its depiction and image quality in whole-body CT angiography (CTA) at 80 kVp with equivalent contrast material (CM) of 192 mgI/mL between deep learning image reconstruction (DLIR) and adaptive statistical iterative reconstruction Veo of 40% (ASiR-V).

METHODS AND MATERIALS

Thirty-four consecutive participants (27 men and 7 women; mean age, 74.2 years) who underwent dual phase whole-body CTA, with images obtained at 80 kVp, for evaluation of aortic diseases between January and July 2020. We used 240-mgI/mL of CM with concurrent administration of its quarter volume of saline, which is corresponding iodine concentration of 192 mgI/mL, and they were intravenously injected at 4 mL/s (iodine mass administered per unit of time; 768 mgI/s) using a commercially available power injector. Three image sets were reconstructed using the ASiR-V, DLIR with middle performance (DLIR-M), and DLIR with high performance (DLIR-H), respectively. A radiologist measured CT values of aortas, iliac arteries, and endoleaks after endovascular aortic repair (EVAR), and one standard deviation (SD) of CT value of subcutaneous fat. Signal-to-noise ratios (SNR) were calculated as CT value/ SD. Two radiologists evaluated the depiction of 25 arteries and image quality on axial, multiplanar-reformatted, and volume-rendered images.

RESULTS

Mean CM volume and iodine weight were 64.1 mL and 15.4 g, respectively. SNRs of aortas, iliac arteries, and endoleaks after EVAR were significantly higher in the order corresponding to DLIR-H, DLIR-M, and ASiR-V ($P = 0.001$, respectively). Depiction of intercostal, dorsal pancreatic, inferior phrenic, lumber, internal pudendal, and inferior epigastric arteries were significantly better in

DLIR-M and ASiR-V than those in DLIR-H (P = 0.001-0.002), however, no significant difference was found in the other arteries (P = 0.13-1.00). Image sharpness, noise, and diagnostic acceptability were significantly better in DLIR-M and DLIR-H than in ASiR-V (P = 0.001-0.005).

CONCLUSION

s DLIR significantly improved SNR and image quality compared with ASiR-V in whole-body CTA at 80 kVp with equivalent CM of 192 mgI/mL. DLIR-M seemed well-balanced algorithm compared with ASiR-V and DLIR-H.

CLINICAL RELEVANCE/APPLICATION

Deep learning image reconstruction was alternative method to adaptive statistical iterative reconstruction Veo on whole-body CT angiography at 80 kVp with equivalent contrast material of 192 mgI/mL.

M5A-SPGI-8 Is it safe to give iodine- or gadolinium-based contrast agents repeatedly on the same day?: An animal study

Participants
Heejin Bae, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate molecular and functional consequences of repeated exposures to iodine- or gadolinium-based contrast agents within 24 hours through an animal study.

METHODS AND MATERIALS

Fifty-six Sprague-Dawley male rats were equally divided into 8 groups: negative control group, positive control group with single dose administration of iodine-based CT contrast agent, and repeated administration of either CT or MRI contrast agents after 2, 4, and 24 hours from the single dose injection of CT contrast agent. Concentrations of BUN, creatinine (SCr), cystatin C (Cys C), and malondialdehyde (MDA) were measured in serum samples and mRNA of kidney injury markers including kidney injury molecule-1 (KIM-1) and neutrophil gelatinase-associated lipocalin (NGAL) were evaluated from kidney tissues. Serum KIM-1 and NGAL proteins were detected by immunoassay and quantified by ELISA.

RESULTS

Repeated exposure to CT contrast agents significantly increased SCr (0.344 - 0.411 mg/dL, P = <0.001) than negative and positive control groups (0.160; 0.207 mg/dL, respectively). SCr concentrations were not significantly different depending on various time intervals (P = >0.999). For average levels of Cys C and MDA, statistically significant differences were not observed between the positive control group (0.427 mg/L; 1.802 μM) and repeated injection groups (0.549 - 0.550, P = 0.256 - 0.362; 1.283 0 2.254, P = >0.999, respectively). Likewise, additional dose of MRI contrast agent after single dose of CT contrast agent did not affect SCr, Cys C, and MDA (0.171 - 0.230, P = >0.999; 0.4, P = 0.262; 0.770 - 1.079, P = 0.139 - 0.771, respectively). mRNA and protein levels of KIM-1 and NGAL were not significantly different among various time intervals of the additional injection of either CT or MRI contrast agents.

CONCLUSION

s More than 24 hours of interval between the repeated contrast-enhanced CT examinations may be necessary to avoid deterioration in renal function, whereas conducting contrast-enhanced MRI on the same day as contrast-enhanced CT examination may not induce clinically significant kidney injury.

CLINICAL RELEVANCE/APPLICATION

Repeated exposure to the contrast agents in a short time period is known to be a risk factor for development of contrast-induced nephropathy. However, according to ACR manual on contrast media, the evidence to avoid a repeated contrast agent injection until more than 24 hours is yet insufficient.

M5A-SPGI-9 Cross-Sectional Comparison of Serum Fib-4 and MRI-Derived Liver T1 as Noninvasive Markers of Liver Fibrosis: An Interim Analysis of the Dallas Heart Study Cohort

Participants
Sujoy Mukherjee, (*Presenter*) Nothing to Disclose

PURPOSE

Noninvasive serum (e.g. FIB-4)1 and imaging (e.g. elastography, T1 mapping)2-4 biomarkers of liver fibrosis have been validated against liver biopsy. Whether these biomarkers are correlative or complementary remains unknown. The purpose of this study is to compare serum FIB-4 and MRI-derived liver T1 in the general adult population in the US.

METHODS AND MATERIALS

This is an interim analysis of the ongoing Dallas Hearts Study (DHS) third examination, a large multiethnic sampling of adults in Dallas County, Texas. The study collects demographic data, serum laboratory tests needed to calculate FIB-4, and multiparametric liver MRI using LiverMultiScan® 3T protocol (Perspectum, Oxford, UK) to calculate mean hepatic iron-corrected T1 (cT1)5. The correlation between FIB-4 and cT1 values was assessed by scatter plots as well as Spearman and Pearson correlation coefficients. The association between FIB-4 = 1.3 and cT1 = 763 msec was assessed by odds ratio, where these thresholds were drawn from the upper limits of the low risk group6 7. This study was approved by IRB and was compliant with HIPAA.

RESULTS

279 adult participants from DHS completed liver cT1 analysis and included 107 males and 172 females, median age [interquartile range] 61 [55-67] years. The median FIB-4 and cT1 were 1.06 [0.84-1.43] and 745 [697-802] msec, with n=93 (33.3%) and n=111 (39.8%) with above-normal FIB-4 and cT1, respectively. No significant correlation was found between FIB-4 and cT1 (Figure 2) by Pearson nor Spearman methods. No significant association was found between above-normal FIB-4 and cT1, with odds ratio [95% confidence interval] of 1.14 [0.69 - 1.90].

CONCLUSION

s Serum FIB-4 and cT1 were not significantly correlated with each other in the general population. Our finding is consistent with other studies where FIB-4 had a low correlation with viscoelastic transient elastography8. Our early data suggest that FIB-4 and cT1 are not correlative, but may be complementary, in evaluating liver disease. Further research is necessary how serum and imaging biomarkers may be used in combination.

CLINICAL RELEVANCE/APPLICATION

FIB-4 was developed for viral hepatitis. Iron-corrected T1 MRI was developed for nonalcoholic fatty liver disease. While both biomarkers were validated against liver biopsies, they may generate discrepant results when applied to the general population for liver disease screening.

Prediction of Postoperative Anastomotic Recurrence in Crohn's Disease Using Preoperative CTE Radiomic Data

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Xiao Di Shen, (*Presenter*) Nothing to Disclose

PURPOSE

More than half of patients with Crohn’s disease (CD) need at least one surgery in their life, however, most patients will experience postoperative anastomotic recurrence (PAR). Stratifying them according to the risk of PAR and tailoring therapy are the most cost-effective way to manage these patients. This study aimed to develop and validate a novel preoperative clinical-radiological-radiomic model to predict the risk of PAR.

METHODS AND MATERIALS

This retrospective study included 186 CD patients (training cohort: n=103; test cohort 1: n=31; test cohort 2: n=52) who underwent CD-related surgery in one of the three centers. The presence of endoscopic, radiological, or surgical anastomotic recurrence was termed PAR. In training cohort, 106 radiomic features were extracted respectively from bowel lesions and perienteric mesenteric adipose tissues on preoperative venous-phase computed tomography enterography (CTE) images and ranked by SelectKBest to select the key features. Univariate and multivariate analyses with Cox proportional hazards regression were performed to determine the risk factors of PAR and construct the prediction model (so-call clinical-radiological-radiomic model) from various clinical-radiological and radiomic features. The prediction efficacy of clinical-radiological-radiomic model was validated in two external test cohorts.

RESULTS

Three mesenteric radiomic features were selected to develop radiomic-mesentery model and four bowel features were selected to construct radiomic-bowel model. In training cohort, radiomic-mesentery model (AUC=0.690; P<0.05) showed higher predicting efficacy than radiomic-bowel model (AUC=0.654; P<0.05) and was thus chose to integrate into the clinical-radiological-radiomic model. In training cohort and test cohorts 1 and 2, the clinical-radiological-radiomic model showed an increase in predicting performance (AUCs: 0.833, 0.778, and 0.742, respectively; all P<0.05) than clinical-radiological model (AUCs: 0.679, 0.674, and 0.687, respectively; all P<0.05). Decision curve analysis demonstrated the clinical usefulness of the clinical-radiological-radiomic model.

CONCLUSION

s The preoperative clinical-radiological-radiomic model could be a promising tool to accurately identify CD patients at high risk of PAR.

CLINICAL RELEVANCE/APPLICATION

To develop and validate a preoperative CTE-based radiomics signature to early predict postoperative anastomotic recurrence in CD.

Hepatobiliary Phase Imaging in cirrhotic patients using Compressed Sensing: Comparison of Image Quality and focal Lesion Detection with the T1-Weighted Sequence using Controlled Aliasing in Parallel Imaging Results in Higher Acceleration

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
So Hyun Park, MD, (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to compare VIBE using compressed sensing (CS) and controlled aliasing in parallel imaging results in higher acceleration (CAIPIRINHA) in subjective and objective image quality in patients with cirrhotic liver for acquisition of single breath-hold on hepatobiliary phase images.

METHODS AND MATERIALS

We retrospectively included 244 gadoxetic acid-enhanced liver MRI in 244 patients with cirrhosis from July 2020 to December 2020. All patients underwent two hepatobiliary phases (HBP) using CS and CAIPIRINHA. Optimized resolution and scan time for CS-HBP were 0.9?×?0.9?×?1.5 mm3 and 15 s, while those for CAIPIRINHA-HBP were 1.3?×?1.8?×?3 mm3 and 15 s. Two abdominal radiologists assessed the two MRI data sets for image quality in consensus. We compared subjective and objective image quality in two sequences.

RESULTS

CS-HBP showed significantly superior liver edge sharpness and overall image quality, and lesser respiratory motion artifact (all P <0.001), but higher non-respiratory artifact (P =0.014) compared to CAIPIRINHA-HBP. Intraclass correlation coefficients of subjective image quality in CS-HBP was 0.550-0.827 and that in CAIPIRINHA-HBP was 0.530-0.809. CS-HBP showed superior SNR in the liver to CAIPIRINHA-HBP (20.8 ± 9.1 vs. 18.8 ± 7.2; P <0.001) and liver-spleen contrast in two were similar (2.0 ± 1.1 vs. 2.1 ± 1.2, P =0.071), respectively.

CONCLUSION

s CS-HBP identified superior overall image quality, liver edge sharpness, and liver SNR and lesser respiratory motion artifact, but higher non-respiratory artifact and noise and comparable liver-spleen contrast compared to CAIPIRINHA-HBP, with same acquisition time.

CLINICAL RELEVANCE/APPLICATION

In patient with decreased liver function, HBP image showed non-clean or decreased enhancement of liver. Identification of adequate image quality on HBP applied CS in patients with cirrhosis can help to select protocol. To our knowledge, however, there have been no studies comparing image quality of HBP between CS and CAIPIRINHA in patients with liver cirrhosis.

Comparison of diagnostic performance of Ultrasonography and Magnetic Resonance Enterography in assessment of active bowel lesions in patients with Crohn's disease

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Dain Lee, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to evaluate and compare the diagnostic performance of ultrasonography (US) and magnetic resonance enterography (MRE) in assessing active bowel lesions in patients with Crohn's disease (CD) through meta-analysis

METHODS AND MATERIALS

We searched PubMed and EMBASE for studies in which US and MRE were evaluated to assess active bowel lesions in CD patients. Bivariate random effect meta-analytic methods were used to estimate pooled sensitivity, specificity, and hierarchical summary receiver operating characteristic (HSROC) curves. We performed meta-regression analysis according to the characteristics of the study design, study population, reference standards, and US technique.

RESULTS

Eleven studies involving a total of 752 patients were included. US exhibited a pooled sensitivity of 87.5 % (95% confidence interval 73.7-94.6), a pooled specificity of 87.1% (95% CI 72.4-94.6), and HSROC of 0.9 in 10 studies. MRE exhibited a pooled sensitivity of 88.5% (95% CI 76.1-94.9), a pooled specificity of 87.5% (95% CI 73.1-94.8), and HSROC of 0.93 in 8 studies. In 7 studies comparing the diagnostic performance of US and MRE, summary sensitivity of US and MR were 88% (95% CI 65.3-96.6, I2=92.1) and 86% (95% CI 72.4-93.6, I2=92.3) (p=0.841) and summary specificity of US and MR were 88% (95% CI 79.7-93.1, I2=64.2%) and 84% (72.5-90.7, I2=48.9%) (p=0.431), which showed no significant differences. On meta-regression analysis, studies from Europe(p=0.002) and studies that used one kind of US probe (p=0.012) reported higher US sensitivity than those from other region and used two kind of US probe, and studies with pediatrics reported higher MR specificity than those with adult population(p=0.001>).

CONCLUSION

s Both US and MRE can diagnose active bowel lesions with comparable diagnostic accuracy in CD patients, although there was significant heterogeneity in the included studies. Study region, number of used US probe for US sensitivity and study population for MR specificity were the potential source of heterogeneity.

CLINICAL RELEVANCE/APPLICATION

Ultrasonography can be the reliable alternative to MRE in assessing active bowel lesion with free of radiation and easier accessibility in CD patients

M5A-SPGI-3

Utility of dual-layer spectral-detector CT imaging for assessing pathological tumor stages and histologic grades of colorectal adenocarcinoma

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Weicui Chen, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Pathological tumor (pT) stage and histologic differentiation are the most critical factors for colorectal adenocarcinoma (CRAC) prognosis.This study aims at assessing the utility of Dual-layer spectral-detector CT (DLCT) in predicting the pT stage and histologic grade for CRAC.

METHODS AND MATERIALS

A total of 131 patients with pathologically confirmed CRAC (82 colon cancers and 49 rectal cancers; 35 pT1-2, 61 pT3, and 35 pT4; 32 high grade and 99 low grade) between May 2021 and March 2022, who received dual-phase DLCT were enrolled in this retrospective study. Normalized iodine concentration (NIC), slope of the spectral HU curve (?HU), and effective atomic number (Eff-Z) were measured for each lesion by two radiologists independently. Intraobserver reliability and interobserver agreement were assessed. The Student's t-test, one-way analysis of variance (ANOVA), Mann-Whitney U test, or Kruskal-Wallis ANOVA test was used to compare the above quantitative parameters between two groups by histologic grades (high and low) and three groups by pT stages (pT1-2, pT3, and pT4). The correlation between the pT stages and above values were assessed by Spearman correlation analysis. ROC analyses were calculated to evaluate the diagnostic efficacy of each parameter for differentiating advanced- (pT3/4) from early-stage (pT1/2) and high- from low-grade CRAC.

RESULTS

The range of 95% confidence interval (CI) for intraobserver reliability were 0.88 to 0.99. The range of 95% CI for intreobserver agreement were 0.74 to 0.98. Eff-Z [7.21(0.09) vs 7.31 (0.10) vs 7.35 (0.19)], NICAP [0.11 (0.05) vs 0.15 (0.08) vs 0.15 (0.08)], NICVP [0.27 (0.06) vs 0.34 (0.11) vs 0.35 (0.12)], ?HUAP [1.20 (0.45) vs 1.93 (1.18) vs 2.37 (0.91)], and ?HUVP [2.07 (0.68) vs 2.35 (0.62) vs 3.09 (1.07)] were significantly different among pT stage groups (all $p<0.001$) and exhibited a positive correlation with pT stages ($r= 0.503, 0.455, 0.394, 0.512, 0.376$, respectively, all $p<0.001$). Eff-Z [7.37 (0.10) vs 7.28 (0.08)], NICAP [0.20 (0.10) vs 0.13 (0.08)], NICVP [0.35 (0.07) vs 0.31 (0.11)], and ?HUAP [2.59 (1.11) vs 1.63 (0.75)] in the high-grade group were markedly higher than those in the low-grade group (all $p<0.05$). For discriminating the advanced- from early-stage CRAC, the AUCs of Eff-Z, NICAP, NICVP, ?HUAP, and ?HUVP were 0.83, 0.80, 0.79, 0.86, and 0.68, respectively. For discriminating the high- from low-grade CRAC, the AUCs of Eff-Z, NICAP, NICVP, and ?HUAP were 0.81, 0.81, 0.64, and 0.81, respectively.

CONCLUSION

s The quantitative parameters derived from DLCT could successfully predict pT stages and histologic differentiation in CRAC.

CLINICAL RELEVANCE/APPLICATION

DLCT parameters may help characterize the aggressive CRAC.

M5A-SPGI-4

Prediction of KRAS mutations in colorectal cancer based on dual-energy and perfusion CT parameters

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Xiaoqiang Lin, Lanzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the predictive value of dual-energy spectral CT (DESCT) and perfusion CT quantitative parameters for KRAS mutation in colorectal cancer, a diagnostic model was constructed and visualized as a nomogram to assist clinical preoperative treatment decisions.

METHODS AND MATERIALS

67 patients with colorectal cancer underwent "one-step" abdominal spectral and perfusion CT before surgery and were divided into two groups: group A (wild-type) and group B (mutation). Clinical baseline characteristics included age, gender, tumor location, serum tumor markers, bowel wall thickening pattern and superior rectal vein (SRV) width. A radiologist delineated the regions of interest (ROIs) on the layer of maximum tumor diameter and the nearest upper and lower layers in axial enhanced images and calculated the average value. Monoenergetic CT value, effective atomic number (Eff-Z), iodine concentration (IC) of tumor and artery were acquired to calculate normalized iodine concentration (NIC, NIC = ICtumor / ICartery). Perfusion parameters include blood flow (BF), blood volume (BV), mean slope of increase (MSI), mean transit time (MTT), positive enh integral (PEI), capillary permeability surface area product (PS) and time to peak (TTP). ?2 test, t-test and U test were used for calculated differences between groups. Then, least absolute shrinkage and selection operator (LASSO) regression and multivariate logistic regression were used to select the most discriminating features, build a predictive model and visualize the model as a nomogram. Concordance index (C-index), calibration curves and decision curves analysis (DCA) were used to evaluate prediction performance and clinical utility.

RESULTS

30 patients had KRAS mutations in 67 patients. After feature selection, the four variables included BF, BV, 130keVAP and NICAP*10 were screened by LASSO regression and multivariate logistic regression to construct the nomogram. The C-index and bootstrap C-index of the model were 0.886 (95%CI: 0.808~0.963) and 0.857, respectively. The sensitivity and specificity were 70.0% and 85.7%, respectively. The model showed good calibration, and the DCA demonstrated that the model has a higher net benefit than the best single variable.

CONCLUSION

s There were differences in LTL, CT perfusion parameters and multiple arteriovenous phases spectral CT parameters in KRAS mutation status. The nomogram based on BF, BV, 130KeVAP and NICAP*10 is helpful for the preoperative determination of KRAS mutation status in colorectal cancer.

CLINICAL RELEVANCE/APPLICATION

The nomogram is helpful for the preoperative determination of KRAS mutation status in colorectal cancer, which can assist in clinical preoperative decision-making and patient risk stratification.

M5A-SPGI-5

Noise power spectrum properties of deep learning-based reconstruction and iterative reconstruction algorithms:Phantom and clinical study

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Yoshinori Funama, PhD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Recent reconstructions of computed tomography (CT) images are nonlinear in nature. Therefore, the noise power spectrum (NPS) properties of reconstructed images are likely to be clinically more relevant when measured in uniform organs of the human body, such as the bladder, with noise-level matching than the use of phantom images. This study aimed to compare the NPS properties and perform qualitative analysis of hybrid iterative reconstruction (hybrid-IR), model-based IR (MBIR), and deep learning-based IR (DLR) at a similar noise level in a clinical study based on the outcomes of a phantom study.

METHODS AND MATERIALS

A Catphan phantom with an external body ring was used in the phantom study. In the clinical study, CT examination data of 35 patients were retrospectively reviewed. NPS was calculated from DLR, hybrid IR, and MBIR images using a uniform portion of the phantom and bladder portions of the patients. The noise magnitude ratio (NMR) and central frequency ratio (CFR) were calculated from DLR, hybrid IR, and MBIR images relative to filtered back-projection (FBP) images using NPS. CFR represents the degree of lower frequency shift for NPS. Clinical CT images were independently reviewed by two board-certified general radiologists.

RESULTS

In the phantom study, DLR achieved substantial noise reduction compared to hybrid IR and MBIR with increasing strength levels. The mean NMR for DLR with a mild level was 0.49, and the noise level was similar to those of hybrid IR at 0.53 and MBIR at 0.65 with strong levels. The CFRs were 0.83, 0.60, and 0.66 for DLR, hybrid IR, and MBIR, respectively; the lower frequency shift for NPS was small level on DLR. Based on the outcomes of the phantom study, the clinical study applied DLR with mild and hybrid IR and MBIR with strong-level images. In the clinical study, the NMR and CFR were 0.39 and 0.35, 0.46 and 0.76, and 0.51 and 0.62 for DLR, hybrid IR, and MBIR, respectively. The visual inspection for DLR with mild-level images was superior to those for hybrid IR and MBIR with strong levels .

CONCLUSION

s DLR images achieved substantial noise reduction while maintaining image noise texture in the phantom and clinical studies.

CLINICAL RELEVANCE/APPLICATION

DLR images provide better clinical visibility without the lack of image texture appearance in CT.

M5A-SPGI-6

Ultra-high resolution computed tomography with deep-learning-reconstruction: Diagnostic ability in the assessment of gastric cancer and the depth of invasion

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Masaya Tanabe, MD, Ube, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To assess the image quality of ultra-high-resolution CT (U-HRCT) reconstructed with improved deep-learning-reconstruction (DLR) method, the utility in the delineation of the gastric wall structure, and visibility of gastric cancer and its depth invasion.

METHODS AND MATERIALS

This study included 46 patients with resected gastric cancers who underwent preoperative contrast-enhanced U-HRCT. Image quality of U-HRCT (0.5mm, 1024x1024) reconstructed with three different methods; standard DLR (Advanced intelligent Clear-IQ Engine [AiCE]), improved DLR (AiCE-Body Sharp [BS]) and hybrid-IR (Adaptive Interactive Dose Reduction 3Dimensional [AIDR3D]) was compared for the visualization of the gastric wall. Then, the conspicuity for the three-layered structure of the gastric wall at four regions (fornix, body, angle and antrum) and the visibility of gastric cancers were compared between conventional HRCT (C-HRCT; 2mm, 512x512) and U-HRCT. Finally, the diagnostic ability of U-HRCT with improved AiCE-BS for the depth invasion of gastric cancers was assessed in comparison with actual postoperative pathology specimens.

RESULTS

The mean noise of U-HRCT with improved AiCE-BS was significantly lower than that with AIDR3D although there was no significant difference between improved AiCE-BS and standard AiCE. The mean overall image quality scores with improved AiCE-BS images were significantly higher than those with the other two methods ($p<0.001$). Regarding the comparison between C-HRCT and U-HRCT, the mean conspicuity scores for the three-layered structure of the gastric wall on U-HRCT were significantly better than those on C-HRCT in the fornix ($p<0.001$), body ($p<0.001$), angle ($p=0.007$), antrum ($p=0.007$). In addition, visibility of gastric cancer with U-HRCT was better than that with C-HRCT($p<0.001$). Correct diagnosis rate for depth invasion of gastric cancer using U-HRCT was 72%.

CONCLUSION

s U-HRCT with improved AiCE-BS is capable of depicting the three-layered structure of the gastric wall more clearly than the other two reconstruction methods, and is useful for the visualization of gastric cancers as well as for the assessment of depth invasion.

CLINICAL RELEVANCE/APPLICATION

U-HRCT using new DLR method will improve overall image quality, delineation of the three-layered structure of gastric wall, visibility of gastric cancer, and diagnostic ability for depth invasion.

Low-Tube-Voltage Whole-Body CT Angiography with Extremely-Low-Iodine Dose: Comparison between Deep Learning-based and Adaptive Statistical Iterative Reconstructions

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Nobuyuki Kawai, MD, Gifu, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To prospectively compare the arterial enhancement, its depiction and image quality in whole-body CT angiography (CTA) at 80 kVp with equivalent contrast material (CM) of 192 mgI/mL between deep learning image reconstruction (DLIR) and adaptive statistical iterative reconstruction Veo of 40% (ASiR-V).

METHODS AND MATERIALS

Thirty-four consecutive participants (27 men and 7 women; mean age, 74.2 years) who underwent dual phase whole-body CTA, with images obtained at 80 kVp, for evaluation of aortic diseases between January and July 2020. We used 240-mgI/mL of CM with concurrent administration of its quarter volume of saline, which is corresponding iodine concentration of 192 mgI/mL, and they were intravenously injected at 4 mL/s (iodine mass administered per unit of time; 768 mgI/s) using a commercially available power injector. Three image sets were reconstructed using the ASiR-V, DLIR with middle performance (DLIR-M), and DLIR with high performance (DLIR-H), respectively. A radiologist measured CT values of aortas, iliac arteries, and endoleaks after endovascular aortic repair (EVAR), and one standard deviation (SD) of CT value of subcutaneous fat. Signal-to-noise ratios (SNR) were calculated as CT value/ SD. Two radiologists evaluated the depiction of 25 arteries and image quality on axial, multiplanar-reformatted, and volume-rendered images.

RESULTS

Mean CM volume and iodine weight were 64.1 mL and 15.4 g, respectively. SNRs of aortas, iliac arteries, and endoleaks after EVAR were significantly higher in the order corresponding to DLIR-H, DLIR-M, and ASiR-V (P = 0.001, respectively). Depiction of intercostal, dorsal pancreatic, inferior phrenic, lumber, internal pudendal, and inferior epigastric arteries were significantly better in DLIR-M and ASiR-V than those in DLIR-H (P = 0.001-0.002), however, no significant difference was found in the other arteries (P = 0.13-1.00). Image sharpness, noise, and diagnostic acceptability were significantly better in DLIR-M and DLIR-H than in ASiR-V (P = 0.001-0.005).

CONCLUSION

s DLIR significantly improved SNR and image quality compared with ASiR-V in whole-body CTA at 80 kVp with equivalent CM of 192 mgI/mL. DLIR-M seemed well-balanced algorithm compared with ASiR-V and DLIR-H.

CLINICAL RELEVANCE/APPLICATION

Deep learning image reconstruction was alternative method to adaptive statistical iterative reconstruction Veo on whole-body CT angiography at 80 kVp with equivalent contrast material of 192 mgI/mL.

M5A-SPGI-8

Is it safe to give iodine- or gadolinium-based contrast agents repeatedly on the same day?: An animal study

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Heejin Bae, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate molecular and functional consequences of repeated exposures to iodine- or gadolinium-based contrast agents within 24 hours through an animal study.

METHODS AND MATERIALS

Fifty-six Sprague-Dawley male rats were equally divided into 8 groups: negative control group, positive control group with single dose administration of iodine-based CT contrast agent, and repeated administration of either CT or MRI contrast agents after 2, 4, and 24 hours from the single dose injection of CT contrast agent. Concentrations of BUN, creatinine (SCr), cystatin C (Cys C), and malondialdehyde (MDA) were measured in serum samples and mRNA of kidney injury markers including kidney injury molecule-1 (KIM-1) and neutrophil gelatinase-associated lipocalin (NGAL) were evaluated from kidney tissues. Serum KIM-1 and NGAL proteins were detected by immunoassay and quantified by ELISA.

RESULTS

Repeated exposure to CT contrast agents significantly increased SCr (0.344 - 0.411 mg/dL, P = <0.001) than negative and positive control groups (0.160; 0.207 mg/dL, respectively). SCr concentrations were not significantly different depending on various time intervals (P = >0.999). For average levels of Cys C and MDA, statistically significant differences were not observed between the positive control group (0.427 mg/L; 1.802 μM) and repeated injection groups (0.549 - 0.550, P = 0.256 - 0.362; 1.283 0 2.254, P = >0.999, respectively). Likewise, additional dose of MRI contrast agent after single dose of CT contrast agent did not affect SCr, Cys C, and MDA (0.171 - 0.230, P = >0.999; 0.4, P = 0.262; 0.770 - 1.079, P = 0.139 - 0.771, respectively). mRNA and protein levels of KIM-1 and NGAL were not significantly different among various time intervals of the additional injection of either CT or MRI contrast agents.

CONCLUSION

s More than 24 hours of interval between the repeated contrast-enhanced CT examinations may be necessary to avoid deterioration in renal function, whereas conducting contrast-enhanced MRI on the same day as contrast-enhanced CT examination may not induce clinically significant kidney injury.

CLINICAL RELEVANCE/APPLICATION

Repeated exposure to the contrast agents in a short time period is known to be a risk factor for development of contrast-induced nephropathy. However, according to ACR manual on contrast media, the evidence to avoid a repeated contrast agent injection until more than 24 hours is yet insufficient.

Cross-Sectional Comparison of Serum Fib-4 and MRI-Derived Liver T1 as Noninvasive Markers of Liver Fibrosis: An Interim Analysis of the Dallas Heart Study Cohort

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Sujoy Mukherjee, (*Presenter*) Nothing to Disclose

PURPOSE

Noninvasive serum (e.g. FIB-4)1 and imaging (e.g. elastography, T1 mapping)2-4 biomarkers of liver fibrosis have been validated against liver biopsy. Whether these biomarkers are correlative or complementary remains unknown. The purpose of this study is to compare serum FIB-4 and MRI-derived liver T1 in the general adult population in the US.

METHODS AND MATERIALS

This is an interim analysis of the ongoing Dallas Hearts Study (DHS) third examination, a large multiethnic sampling of adults in Dallas County, Texas. The study collects demographic data, serum laboratory tests needed to calculate FIB-4, and multiparametric liver MRI using LiverMultiScan® 3T protocol (Perspectum, Oxford, UK) to calculate mean hepatic iron-corrected T1 (cT1)5. The correlation between FIB-4 and cT1 values was assessed by scatter plots as well as Spearman and Pearson correlation coefficients. The association between FIB-4 = 1.3 and cT1 = 763 msec was assessed by odds ratio, where these thresholds were drawn from the upper limits of the low risk group6 7. This study was approved by IRB and was compliant with HIPAA.

RESULTS

279 adult participants from DHS completed liver cT1 analysis and included 107 males and 172 females, median age [interquartile range] 61 [55-67] years. The median FIB-4 and cT1 were 1.06 [0.84-1.43] and 745 [697-802] msec, with n=93 (33.3%) and n=111 (39.8%) with above-normal FIB-4 and cT1, respectively. No significant correlation was found between FIB-4 and cT1 (Figure 2) by Pearson nor Spearman methods. No significant association was found between above-normal FIB-4 and cT1, with odds ratio [95% confidence interval] of 1.14 [0.69 - 1.90].

CONCLUSION

s Serum FIB-4 and cT1 were not significantly correlated with each other in the general population. Our finding is consistent with other studies where FIB-4 had a low correlation with viscoelastic transient elastography8. Our early data suggest that FIB-4 and cT1 are not correlative, but may be complementary, in evaluating liver disease. Further research is necessary how serum and imaging biomarkers may be used in combination.

CLINICAL RELEVANCE/APPLICATION

FIB-4 was developed for viral hepatitis. Iron-corrected T1 MRI was developed for nonalcoholic fatty liver disease. While both biomarkers were validated against liver biopsies, they may generate discrepant results when applied to the general population for liver disease screening.

M5A-SPGU-1 External validation of an AI model for prostate mpMRI: a multicenter study

Participants
Kexin Wang, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the prediction efficacy of an AI model for prostate cancer using external data.

METHODS AND MATERIALS

480 cases of mpMRI were retrospectively collected from four hospitals. The pathology diagnosis was clinically significant cancer (csPCa) in 180 cases, and non-csPCa in 300 cases, with a PSA level of 17.79 [0.15,100.00]. A prior trained AI model was used to predict the existence of prostate cancer on DWI and ADC maps. 16 radiologists were asked to interpret the image without knowledge of the clinical information. Each radiologist was assigned 30 cases and interpreted the cases twice in between 1 month, with and without the aid of AI. The cases were randomly separated into 2 groups. For group 1, the case was read firstly without AI and secondly with AI. For group 2, the cases were firstly read with AI and secondly without AI. The radiologist made their diagnosis following PI-RADS v2.1. When the PI-RADS category was 3-5, the case was considered to be diagnosed as positive. On the contrary, when the PI-RADS category was 1 and 2, the case was considered to be diagnosed as negative. The reading time and diagnosis confidence were also recorded during the image interpretation.

RESULTS

The AUC for the all the radiologists were 0.791 (95%CI: 0.687-0.956) and 0.699 (95%CI: 0.565-0.773) with and without the aided of AI ($p<0.05$). The reading time shortened from 350 [27-1140]s (Median [Min, Max]) to 148 [19-948]s. The diagnosis confidence increased in 10 radiologists with the help of AI.

CONCLUSION

s This multicenter study proved that the AI model for the prediction of prostate cancer on mpMRI could be generalized, and the diagnostic accuracy of csPCa was increased.

CLINICAL RELEVANCE/APPLICATION

Validation of AI models requires large samples of external data. This study provides evidence for future practical clinical applications of the AI model for the diagnosis of prostate cancer on mpMRI.

M5A-SPGU-2 Multiparametric MR imaging for evaluating early diabetic nephropathy: Changes related to glomerular hypertension

Participants
Akira Yamamoto, MD, PhD, Kurashiki, Japan (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to identify the changes related to glomerular hypertension in multiparametric magnetic resonance imaging (MRI) findings for evaluating early diabetic nephropathy.

METHODS AND MATERIALS

The study subjects (N=58) included 35 patients with early diabetic nephropathy (hyperfiltration stage) and 23 healthy volunteers. All subjects underwent non-contrast MRI using a 3-Tesla MRI machine. Measurements were made of the renal cortex and renal medulla T1 values, T2 values, blood oxygenation level dependent (BOLD) imaging (T2* values and R2* values), intravoxel incoherent motion (IVIM) imaging (ADC, f, D* and D values), arterial spin labeling (ASL) as well as optimal inversion time (TI) (= TI of maximum corticomedullary contrast ratio (CMR = signal intensity (SI) of cortex / SI of medulla)) and inverted TI value (value of TI that inverts the renal cortex and renal medulla SI) on steady-state free precession (SSFP) with inversion recovery (IR) pulse with multi TI (TI = 1000, 1100, 1200, 1300, 1400, 1500, 1600, 1700, 1800 msec). A total 21 parameters were compared between healthy groups and early DN group.

RESULTS

A significant difference between healthy groups and early diabetic nephropathy group was seen in T2 values of cortex (mean ± SD: 101.28±9.59 msec vs. 107.76.0±11.39 msec; $p=0.041$) and parameters derived from SSFP with IR pulse with multi TI, inverted TI (mean ± SD: 1240.9±66.6 msec vs. 1278.6±62.2 msec; $p=0.029$) and optimal TI (mean ± SD: 1395.5±72.2 msec vs. 1437.1±70.0 msec; $p=0.019$). No other 18 parameters showed significant differences between healthy groups and early DN group. There was no

significant difference in renal cortical thickness, but it showed a large value in the hyperfiltration stage.

CONCLUSION

s T2 value of cortex and parameters derived from SSFP with an ssIR pulse, inverted TI and optimal TI might sensitively capture the changes in glomerular hypertension related changes of the renal cortex in early diabetic nephropathy, can be used to evaluate early diabetic nephropathy non-invasively and in a short period of time.

CLINICAL RELEVANCE/APPLICATION

MR imaging using the T2 value of cortex and parameters derived from SSFP with an ssIR pulse, inverted TI and optimal TI might be useful to evaluate glomerular hypertension in early stage of diabetic nephropathy with non-invasively and in a short period of time.

M5A-SPGU-3 Application of dual energy spectral CT in Vascular ErectileDysfunction

Participants
Xiaohu Li, MD, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

To study the value of CT angiography and CT perfusion imaging in guiding the diagnosis of vascular erectile dysfunction and indicating the clinical grading of vascular erectile dysfunction.

METHODS AND MATERIALS

60 patients with erectile dysfunction in our hospital were divided into vascular erectile dysfunction group and non-vascular erectile dysfunction group. The vascular erectile dysfunction group was divided into severe erectile dysfunction group and mild-to-moderate erectile dysfunction group according to IIEF-5. After CT scanning of hypogastrium, we completed the reconstruction of penile blood vessels and the collection of perfusion data of corpus cavernosum and penis root by using post-processing software.Then both the perfusion data and penile vascular status,including Internal pudendal artery,dorsal penile artery and cavernous artery,were analyzed statistically.

RESULTS

vascular abnormalities were found in all cases in vascular erectile dysfunction group, especially in cavernous artery; in non vascular erectile dysfunction group, there were 2 cases of dorsal penile artery and 2 cases of cavernous artery abnormalities, but no internal pudendal artery abnormalities. There were significant differences in the abnormalities of internal pudendal artery, dorsal penile artery and cavernous artery between vascular group and non vascular group ($p < 0.05$), and there was significant correlation between mild to moderate vascular erectile dysfunction group and severe group in vascular subjective score ($p < 0.05$). The BF, BV and Tmax parameters of the penile root and corpus cavernosum in the vascular erectile dysfunction group were statistically significant compared with those in the non vascular erectile dysfunction group ($p < 0.05$), but the PS parameters were not statistically significant ($p = 0.70$, $p < 0.05$).

CONCLUSION

s CT angiography can show the penile blood vessel status of patients with vascular erectile dysfunction, prompt the diseased blood vessels, assist the clinical diagnosis and treatment, and assist the clinical grading of patients with erectile dysfunction through the perfusion data obtained by post-processing software and the analysis of the degree of vascular lesions.

CLINICAL RELEVANCE/APPLICATION

The imaging data of vascular ED patients were analyzed by vascular reconstruction and perfusion parameters, and it was found that CTA can better display the penile blood vessels of patients with vascular erectile dysfunction, indicating the diseased blood vessels and their severity, which has a certain value for clinical diagnosis.

Head and Neck Monday Poster Discussions - A

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - HN DPS

Sub-Events

M5A-SPHN-1 The Clinical Feasibility of T1-based Dynamic Susceptibility Contrast Perfusion MRI in Head and Neck Cancer Patients

Participants
Ji Young Lee, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The T2*-based dynamic susceptibility contrast (DSC) perfusion MRI has been limited for clinical application in the head and neck MRI due to susceptibility or motion artifact. High temporal resolution enabled the T1-based DSC (T1-DSC) perfusion MRI which provides reliable CBV value. The purpose of this study was to assess the technical and clinical feasibility of T1-DSC perfusion MRI in patients with head and neck cancer.

METHODS AND MATERIALS

This retrospective study included twelve patients with head and neck cancer who performed the dynamic T1 gradient echo enhancement scans. The CBV maps were obtained from the T1-DSC perfusion MRI and Vp maps were obtained with the T1-DCE perfusion MRI using a commercial software. The statistical analysis was performed to evaluate the relationship between two methods. Spearman correlation and intraclass correlation coefficients (ICC) were obtained.

RESULTS

The perfusion maps were acquired for the preoperative tumor staging (n=9) and tumor treatment response (n=3). The CBV maps and Vp maps were obtained in the following locations: oral cavity (n=5), sinus cancer (n=2), hypopharynx (n=1), supraglottis (n=1), soft palate (n=1), and lymph node (n=2). The statistical analysis showed the moderate linear correlation between T1-CBV and the Vp (r= 0.67, p=0.01) The ICC was 0.80 (p=0.002).

CONCLUSION

s The relationship between T1-CBV and Vp showed moderate correlation and good reliability. T1-based DSC perfusion MRI can be feasible in head and neck oncology and it could be expected to be useful for the tumor characterization and treatment response assessment in the head and neck cancer patient.

CLINICAL RELEVANCE/APPLICATION

T1-based DSC perfusion MRI can be feasible in head and neck oncology and it could be expected to be useful for the tumor characterization and treatment response assessment in the head and neck cancer patient.

M5A-SPHN-2 Submental High Frequency Ultrasound to Evaluate the Efficacy of Acupuncture Combined with Electrical Stimulation in PD Dysphagia

Participants
Huang Meng, (*Presenter*) Nothing to Disclose

PURPOSE

To observe the effect of acupuncture combined with electrical stimulation on dysphagia in Parkinson Disease (PD) by submental high frequency ultrasound.

METHODS AND MATERIALS

A total of 64 patients with PD who were hospitalized in our hospital from April 2020 to June 2021 were enrolled in the study group and the control group after they were confirmed to have swallowing dysfunction by videofluroscopic study of swallowing (VFSS). There were 32 cases in each group. Both groups were treated with basic therapy (i.e., medopa therapy + electrical stimulation therapy). The drinking water test score and VFSS score were used to evaluate the changes of the two groups before and after treatment, and the clinical efficacy of the two groups was compared.

RESULTS

1. After treatment, the total effective rate of the research group was 90.62%, and the total effective rate of the control group was 71.87% ($p<0.05$); 2. There was no statistical difference in the overall mean of MHLA between the two groups after treatment ($p>0.05$); the research group NHLA was greater than that of the control group, and there was a difference in the overall mean of NHLA between the two groups ($p < 0.05$). 3. There was no significant correlation between MHLA and VFSS score ($p>0.05$); there was a negative correlation between NHLA and VFSS score ($p<0.05$), and a positive correlation between HLAS and ASR and VFSS score respectively ($p<0.05$) . 4. The AUCs of NHLA, HLAS and ASR for the diagnosis of dysphagia in PD were 0.893, 0.831 and

0.968, respectively. The optimal cut-off value of ASR for the diagnosis of dysphagia in PD was 41.09%, and the sensitivity and specificity were 83.65% and 100.00%, respectively.

CONCLUSION

s 1. Acupuncture combined with electrical stimulation therapy has a better effect on PD swallowing dysfunction, which can significantly improve the quality of life of patients; 2. The measurement indexes of NHLA, HLAS and ASR of submental high-frequency ultrasound can be used to evaluate the therapeutic effect of PD patients with dysphagia. ASR has high sensitivity and specificity in the diagnosis of dysphagia, and it is a reliable index to evaluate the dysphagia of PD patients.

CLINICAL RELEVANCE/APPLICATION

Acupuncture combined with electrical stimulation therapy is an effective method for the treatment of dysphagia in PD, which can significantly improve the swallowing function of patients with dysphagia in PD. Using submental high-frequency ultrasound to measure HLA can evaluate the efficacy of acupuncture combined with electrical stimulation therapy on PD dysphagia. ASR has high sensitivity and specificity in diagnosing PD dysphagia. Because of its advantages of simplicity, high repeatability, no radiation, safety and non-invasiveness, it is worthy of clinical application.

M5A-SPIN-1 Using a Single Artificial Intelligence Solution in Detecting Anatomy, View, and Orientation of X-ray Exams of Adult and Pediatric Population

Participants
Ravi Soni, (*Presenter*) Nothing to Disclose

PURPOSE

To use deep learning model in determining if an acquired X-ray image is one of many prevalent anatomies such as chest, abdomen, pelvis, hand, knee, foot, and wrist. Additionally, using the same model to identify a view and an orientation of an x-ray image. Up to 30% of Chest X-rays obtained on fixed systems have been reported as being acquired with the incorrect protocol view. This results in incorrect exposure parameters, incorrect DICOM tags being recorded, and incorrect processing algorithms. Also, radiographers must correct incorrectly orientated acquired images to a reference orientation before sending them to PACS. Across the fixed and mobile systems, we find 53% and 42% of upper and lower extremity exams respectively require manual rotation correction. We propose an AI algorithm to identify the anatomy, view, and detect the orientation of the x-rays. This model helps reduce human operating errors related to protocol mismatches and incorrect orientation.

METHODS AND MATERIALS

A convolutional neural network composed of Inception blocks for feature extraction is used to train over a large set of x-ray exams of adult and pediatric population. The size of the convolutional neural network is 5.1 million parameters. The network has multiple outputs: (1) anatomy, (2) view, (3) quadrant, (4) precise orientation. The quadrant branch outputs the coarse orientation of the x-ray image in the step of 90 degrees. While the precise orientation branch outputs the precise orientation degrees of the image. The out-of-scope or low prevalent x-ray exams are excluded and trained as the "others" class.

RESULTS

The results showed that the AI model detected the anatomy, view, and quadrant orientation with well above 90% accuracy on a large test set comprised of 13,207 images. Each image was randomly rotated multiple times to find out robustness. The quadrant orientation performance is above 99% while the performance of anatomy and view is around mid-90s%. The Matthew's Correlation Coefficient is higher than 90% for all in-scope anatomies and views.

CONCLUSION

s We demonstrated the feasibility and efficacy of artificial convolutional neural network in detecting the multiple anatomies, views, and orientations of x-rays from a large international data set. We believe this is the first time a single deep neural network is used in identifying multiple anatomies of thoracic and MSK radiographic images.

CLINICAL RELEVANCE/APPLICATION

A wide variety of x-ray exams are performed to help diagnose a variety of injuries and illnesses in most body parts. To avoid human operating errors related to protocol mismatch and to reduce time for orientation correction, an AI solution is needed to include all high prevalent anatomies and views. The proposed model offers a single solution to address this.

M5A-SPIN-2 A Novel Collaborative Self-Supervised Transformer Neural Network for Radiomic Data Classification

Participants
Zhiyuan Li, BS,MS, (*Presenter*) Nothing to Disclose

PURPOSE

To develop a novel collaborative self-supervised transformer neural network for radiomic data classification without large-scale annotated images.

METHODS AND MATERIALS

Data acquisition and pre-processing: The proposed approach was developed and validated on a prospective cohort of 392 very preterm infants, enrolled soon after birth. We used each infant's T2-weighted MRI data acquired at term-equivalent age to identify imaging prognostic features of cognitive deficits. We classified infants into one of the two groups - high-risk (Cognitive score =85) or low-risk (Cognitive score >85) for cognitive deficits based on the standardized Bayley-III Cognitive subscale at 2 years corrected age.. We segmented each T2-weighted brain image into 87 regions of interest (ROIs) and extracted 100 radiomics features from each ROI using the PyRadiomics pipeline, therefore resulting in a 87-by-100 feature map for each subject. Collaborative Self-Supervised Learning: It remains challenging to train robust deep learning models due to the lack of sufficient labeled data. As shown in Figure 1, we developed a collaborative self-supervised learning (SSL) model to solve the challenges posed by the over-dependence of labeled data, particularly for radiomic data classification. We first augmented multiple samples from each subject by

randomly masking/hiding radiomic features from several ROIs, and then we trained a transformer to learn latent features from augmented samples without human labeling by solving two collaborative pretext tasks, including 1) Reconstruction - to reconstruct the hidden radiomic features using the observable ones, and 2) Discrimination - to find similarity and dissimilarity from augmented samples, and to classify all augmented samples from the same subject into one group. Model performance was assessed using 5-fold cross-validation. This process was repeated 100 times.

RESULTS

Of the original cohort of 392 infants, 318 (81%) had Bayley III cognitive scores assessed at 2 years corrected age. Our model achieved an AUC of 0.78, outperforming the supervised Transformer (AUC=0.61) as well as several peer self-supervised models that were developed for text and/or image data, including Rotation (AUC=0.64), Moco v1 (AUC=0.69), and SimCLR (AUC=0.71). Our method achieved a balanced accuracy of 76.3%, sensitivity of 75.8%, and specificity of 76.7%.

CONCLUSION

s We showed that the proposed model outperformed peer self-supervised models for radiomic data classification in the application of the early prediction of cognitive deficit in very preterm infants.

CLINICAL RELEVANCE/APPLICATION

The proposed model is able to facilitate the deep learning-based applications in Radiomics without large-scale annotated datasets.

M5A-SPIN-3 Radiology Trainees Attitudes Towards Artificial Intelligence in Clinical Radiology and Its Implementation in Training and the Curriculum in The United Kingdom

Participants
Obaid Hashmi, MBBS, FRCR, (*Presenter*) Nothing to Disclose

PURPOSE

Artificial Intelligence (AI) and Machine learning (ML) have garnered significant interest in radiology. AI and ML have been introduced to the 2021 Royal College of Radiologists (RCR) curriculum highlighting its importance to radiology trainees in the United Kingdom (UK). The attitudes of trainees towards AI in Radiology has been reviewed in several countries, however there was no documented survey assessing the attitudes of UK radiology trainees towards AI. A national trainee led survey was created to understand the attitudes of UK radiology trainees, in particular assessing the demand for AI education. This could help guide implementation of AI teaching in radiology training programmes.

METHODS AND MATERIALS

The survey was created in the Google Forms platform and nationally distributed via email. The survey ran over a period of 2 months. All 37 training programmes in the United Kingdom were targeted. Participants were asked 4 demographic questions and 14 questions relating to the topic of AI in radiology. They were surveyed on their views relating to previous experience with AI, teaching of AI and its future within the career of a radiologist.

RESULTS

The survey was completed by 149 trainee radiologists with at least 1 response from each of the 37 UK training programmes. 83.7% said they were interested in AI use in Radiology but 71.4% had no experience of working with AI. Most, 79.9%, would like to be involved in AI based projects. Almost all respondents (98.7%) felt that AI should be taught during their training, in particular in the 1st 3 years of training, yet, only 1 respondent stated that their training programme had implemented AI teaching. Respondents indicated that basic understanding, implementation and critical appraisal of AI software should be prioritized in AI teaching. Most trainees preferred teaching to be delivered at a dearnery or training programme level. Only 12.8% of respondents said that AI would make them less likely to apply for radiology specialty training. Most responded that AI would be used in regular radiology practice in the next 5 to 10 years with 74.2% of trainees agreeing that AI will improve and enhance the job of radiologists in the next 20 years. The main concerns raised about AI in Radiology were IT/implementation and ethical/regulatory issues.

CONCLUSION

s The attitudes of UK trainees towards AI are mostly positive with many interested in being involved in AI based projects and activities. There is also clear interest and demand for AI teaching within training. However, current discussion, availability of AI based activities and AI teaching within UK training programmes is very limited.

CLINICAL RELEVANCE/APPLICATION

To help guide the RCR and UK training programmes in their implementation of AI into radiology training.

M5A-SPIN-4 A Cost-effective Multi-modality Machine Learning Framework for Prediction of Alzheimer' Disease

Participants
Jing Li, (*Presenter*) Nothing to Disclose

PURPOSE

Machine learning (ML) models integrating multi-modality datasets have shown great promise for disease diagnosis/prognosis. The acquisition costs of different data modalities vary significantly. It is not cost-effective to require all patients acquiring all data modalities. We propose a cost-effective ML framework, called the Uncertainty-driven Modality Selection (UMoS) framework, to sequentially add modalities for each patient on an as-needed basis while at the same time ensuring high diagnostic/prognostic accuracy.

METHODS AND MATERIALS

We demonstrate UMoS in an application of predicting the risk of progressing to Alzheimer's Disease (AD) for individuals with Mild Cognitive Impairment (MCI). ML models integrating MRI and PET have shown high accuracy in predicting MCI progression to AD. While MRI is used in the standard of care, PET is more costly and has less accessibility to patients. Under UMoS, a patient will be first predicted based on MRI; if the predictive uncertainty is lower than a threshold, the patient will not need PET; otherwise, the patient will need PET and be predicted by an MRI+PET model. To develop UMoS, we need to establish three building blocks: a trained MRI model, an uncertainty quantification approach for the MRI model, and a trained MRI+PET model. We establish these

building blocks and demonstrate UMoS using a dataset from ADNI, which includes 1319 T1-MRI scans from MCI patients with 612 of these MRI scans having accompanying amyloid-PET scans. We extracted regional volumetric and thickness features from MRI using FreeSurfer v7.1 and regional SUVR features from amyloid-PET using our in-house pipeline. To establish the building blocks of UMoS, we first train an MRI+PET model based on the subset of samples with both MRI and PET. Using the MRI+PET model as the teacher model, we further train an MRI model based on all samples using knowledge distillation. Predictive entropy was computed to quantify both the aleatoric and epistemic uncertainties of the MRI model.

RESULTS

Under 10-fold cross validation, UMoS achieves 0.851 AUC (0.782/0.809 sensitivity/specificity using 0.5 probability cutoff), with 46.7% of patients predicted by the MRI model and 53.3% by the MRI+PET model. If all patients are predicted by the MRI +PET model, the performances are 0.873 AUC (0.776/0.811 sensitivity/specificity).

CONCLUSION

s Under the UMoS framework, we achieve prediction performance at a similar level to the model that needs both MRI and PET for predicting MRI progression to AD, but UMoS saves 46.7% patients from needing PET.

CLINICAL RELEVANCE/APPLICATION

This study provides an ML framework that ensures high accuracy in disease diagnosis/prognosis, but saves patients from needing unnecessary data modalities thus saving diagnostic/prognostic costs.

M5A-SPIN-5 AI-based Bronchial Segmentation and Quantitation Prototype for Chest CT: Can it Help Assess Severity of Obstructive Lung Disease by Pulmonary Function Test?

Participants
Parisa Kaviani, MD, Boston, MA (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to assess if an artificial intelligence-based bronchial segmentation and quantitation prototype for assessing severity of obstructive lung disease.

METHODS AND MATERIALS

Our retrospective IRB-approved, HIPAA-compliant study comprised 222 adults (mean age 57±16 years; M:F 116: 106). A total of 107 patients with COPD had both PFT and non-contrast chest CT. The remaining 115 patients had no CT or clinical abnormality suggestive of lung disease (COPD or otherwise). The COPD severity was defined as mild, moderate, and severe based on the forced expiratory volume in 1 second (FEV1). We processed thin-section (1-1.25mm) CT images with the bronchial segmentation and quantitation prototype (Siemens Healthineers) to obtain following metrics: bronchial lumen volume, lumen diameter, lumen area, wall thickness, wall area, wall area ratio, and wall tapering) for total lung volumes and separately for each lung and lung lobe. Data were analyzed with area under the receiver operating characteristics curve (AUC) for distinguishing between mild, moderate, and severe COPD.

RESULTS

AI algorithm had an AUC of up to 0.79 (95% CI: 0.728-0.852) for differentiating mild, moderate and severe emphysema based on FEV1. The AI algorithm was able to differentiate mild COPD with AUC of 0.86 (95% CI: 0.728-0.852) for the combination of generation 2 wall thickness, generation 0 lumen volume and RUL wall thickness, moderate COPD with AUC of 0.72 (95% CI: 0.728-0.852) for the combination of generation 1 wall thickness and LLL wall area, and severe COPD with 0.79 (95% CI: 0.728-0.852) for the combination of LUL wall thickness, generation 0 lumen volume, and global volume ratio airways vs lung as the best features.

CONCLUSION

s Fully automated AI-based bronchial tree segmentation and quantitation prototype can differentiate different severity of COPD assessed with pulmonary function tests.

CLINICAL RELEVANCE/APPLICATION

The quantitative information pertaining to bronchial wall and luminal dimensions estimated from an AI-based prototype can help in diagnosis and treatment of patients with bronchial involvement in COPD.

M5A-SPIN-6 Semantic Retrieval of Similar Radiological Images using Vision Transformers: CXR and CT study

Participants
Anjali Thakrar, BS, Goleta, CA (*Presenter*) Nothing to Disclose

PURPOSE

Identifying visually and semantically similar radiological images in a database can facilitate the creation of decision support tools, teaching files, and research cohorts. Existing content based image retrieval tools are often limited to searching by pixel-wise difference or vector distance of model predictions. Vision transformers (ViT) use attention to simultaneously take into account radiological diagnosis as well as visual appearance. Here, we develop a ViT-based image retrieval framework and evaluate the algorithm on the NIH Chest Radiographs (NIH-CXR) and NLST Chest CTs.

METHODS AND MATERIALS

All 112,120 images from the NIH-CXR and 3246 randomly sampled cases from the NLST CT dataset were used. For CXR, a ViT binary classifier was trained on 4 ground truth labels (Cardiomegaly, Opacity, Emphysema, No Finding) and ensembled to produce multilabel classifications for each CXR. For CT, a regression model was trained to minimize L1 loss on the continuous ground truth labels of patient weight. The ViT image embedding layer was treated as a global image descriptor, using the L2 distance between descriptors as a similarity measure. Normalized discounted cumulative gain (nDCG) and mean average precision (mAP) were calculated from the ground truth labels. Five radiologists performed a reader performance study with random query images (25 CT and 25 CXR) and chose the 5 most similar images to the query from a set of 10 images (consisting of 5 closest to the query and 5 furthest from the query in model space). Inter-radiologist agreement and radiologist-model agreement statistics (Fleiss' and Cohen's kappa) were calculated. A t-SNE of the CT model latent space was generated to confirm clustering of similar images.

RESULTS

The CXR model achieved nDCG@5 of 0.73 ($p<0.001$) and Cardiomegaly mAP@5 of 0.76 ($p<0.001$) among other results for CXR. The CT model achieved nDCG of 16.85 ($p<0.001$). The model prediction agreed with radiologist consensus on 86% of CXR samples and 79.2% of CT samples. Inter-radiologist Fleiss Kappa of 0.51 and radiologist consensus to model Cohen's Kappa of 0.65 were observed. Full code will be made available at the time of presentation.

CONCLUSION

s We have developed and evaluated a vision transformer architecture that can retrieve visually and semantically similar radiological images.

CLINICAL RELEVANCE/APPLICATION

Our vision transformer model can identify radiological images with visual and diagnostic similarities, which may be applied to decision support, teaching file creation, and research cohort creation.

M5A-SPIN-1

Using a Single Artificial Intelligence Solution in Detecting Anatomy, View, and Orientation of X-ray Exams of Adult and Pediatric Population

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IN DPS

Participants
Ravi Soni, (*Presenter*) Nothing to Disclose

PURPOSE

To use deep learning model in determining if an acquired X-ray image is one of many prevalent anatomies such as chest, abdomen, pelvis, hand, knee, foot, and wrist. Additionally, using the same model to identify a view and an orientation of an x-ray image. Up to 30% of Chest X-rays obtained on fixed systems have been reported as being acquired with the incorrect protocol view. This results in incorrect exposure parameters, incorrect DICOM tags being recorded, and incorrect processing algorithms. Also, radiographers must correct incorrectly orientated acquired images to a reference orientation before sending them to PACS. Across the fixed and mobile systems, we find 53% and 42% of upper and lower extremity exams respectively require manual rotation correction. We propose an AI algorithm to identify the anatomy, view, and detect the orientation of the x-rays. This model helps reduce human operating errors related to protocol mismatches and incorrect orientation.

METHODS AND MATERIALS

A convolutional neural network composed of Inception blocks for feature extraction is used to train over a large set of x-ray exams of adult and pediatric population. The size of the convolutional neural network is 5.1 million parameters. The network has multiple outputs: (1) anatomy, (2) view, (3) quadrant, (4) precise orientation. The quadrant branch outputs the coarse orientation of the x-ray image in the step of 90 degrees. While the precise orientation branch outputs the precise orientation degrees of the image. The out-of-scope or low prevalent x-ray exams are excluded and trained as the “others” class.

RESULTS

The results showed that the AI model detected the anatomy, view, and quadrant orientation with well above 90% accuracy on a large test set comprised of 13,207 images. Each image was randomly rotated multiple times to find out robustness. The quadrant orientation performance is above 99% while the performance of anatomy and view is around mid-90s%. The Matthew’s Correlation Coefficient is higher than 90% for all in-scope anatomies and views.

CONCLUSION

s We demonstrated the feasibility and efficacy of artificial convolutional neural network in detecting the multiple anatomies, views, and orientations of x-rays from a large international data set. We believe this is the first time a single deep neural network is used in identifying multiple anatomies of thoracic and MSK radiographic images.

CLINICAL RELEVANCE/APPLICATION

A wide variety of x-ray exams are performed to help diagnose a variety of injuries and illnesses in most body parts. To avoid human operating errors related to protocol mismatch and to reduce time for orientation correction, an AI solution is needed to include all high prevalent anatomies and views. The proposed model offers a single solution to address this.

A Cost-effective Multi-modality Machine Learning Framework for Prediction of Alzheimer' Disease

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IN DPS

Participants
Jing Li, (*Presenter*) Nothing to Disclose

PURPOSE

Machine learning (ML) models integrating multi-modality datasets have shown great promise for disease diagnosis/prognosis. The acquisition costs of different data modalities vary significantly. It is not cost-effective to require all patients acquiring all data modalities. We propose a cost-effective ML framework, called the Uncertainty-driven Modality Selection (UMoS) framework, to sequentially add modalities for each patient on an as-needed basis while at the same time ensuring high diagnostic/prognostic accuracy.

METHODS AND MATERIALS

We demonstrate UMoS in an application of predicting the risk of progressing to Alzheimer's Disease (AD) for individuals with Mild Cognitive Impairment (MCI). ML models integrating MRI and PET have shown high accuracy in predicting MCI progression to AD. While MRI is used in the standard of care, PET is more costly and has less accessibility to patients. Under UMoS, a patient will be first predicted based on MRI; if the predictive uncertainty is lower than a threshold, the patient will not need PET; otherwise, the patient will need PET and be predicted by an MRI+PET model. To develop UMoS, we need to establish three building blocks: a trained MRI model, an uncertainty quantification approach for the MRI model, and a trained MRI+PET model. We establish these building blocks and demonstrate UMoS using a dataset from ADNI, which includes 1319 T1-MRI scans from MCI patients with 612 of these MRI scans having accompanying amyloid-PET scans. We extracted regional volumetric and thickness features from MRI using FreeSurfer v7.1 and regional SUVR features from amyloid-PET using our in-house pipeline. To establish the building blocks of UMoS, we first train an MRI+PET model based on the subset of samples with both MRI and PET. Using the MRI+PET model as the teacher model, we further train an MRI model based on all samples using knowledge distillation. Predictive entropy was computed to quantify both the aleatoric and epistemic uncertainties of the MRI model.

RESULTS

Under 10-fold cross validation, UMoS achieves 0.851 AUC (0.782/0.809 sensitivity/specificity using 0.5 probability cutoff), with 46.7% of patients predicted by the MRI model and 53.3% by the MRI+PET model. If all patients are predicted by the MRI +PET model, the performances are 0.873 AUC (0.776/0.811 sensitivity/specificity).

CONCLUSION

s Under the UMoS framework, we achieve prediction performance at a similar level to the model that needs both MRI and PET for predicting MRI progression to AD, but UMoS saves 46.7% patients from needing PET.

CLINICAL RELEVANCE/APPLICATION

This study provides an ML framework that ensures high accuracy in disease diagnosis/prognosis, but saves patients from needing unnecessary data modalities thus saving diagnostic/prognostic costs.

Semantic Retrieval of Similar Radiological Images using Vision Transformers: CXR and CT study

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IN DPS

Participants
Anjali Thakrar, BS, Goleta, CA (*Presenter*) Nothing to Disclose

PURPOSE

Identifying visually and semantically similar radiological images in a database can facilitate the creation of decision support tools, teaching files, and research cohorts. Existing content based image retrieval tools are often limited to searching by pixel-wise difference or vector distance of model predictions. Vision transformers (ViT) use attention to simultaneously take into account radiological diagnosis as well as visual appearance. Here, we develop a ViT-based image retrieval framework and evaluate the algorithm on the NIH Chest Radiographs (NIH-CXR) and NLST Chest CTs.

METHODS AND MATERIALS

All 112,120 images from the NIH-CXR and 3246 randomly sampled cases from the NLST CT dataset were used. For CXR, a ViT binary classifier was trained on 4 ground truth labels (Cardiomegaly, Opacity, Emphysema, No Finding) and ensembled to produce multilabel classifications for each CXR. For CT, a regression model was trained to minimize L1 loss on the continuous ground truth labels of patient weight. The ViT image embedding layer was treated as a global image descriptor, using the L2 distance between descriptors as a similarity measure. Normalized discounted cumulative gain (nDCG) and mean average precision (mAP) were calculated from the ground truth labels. Five radiologists performed a reader performance study with random query images (25 CT and 25 CXR) and chose the 5 most similar images to the query from a set of 10 images (consisting of 5 closest to the query and 5 furthest from the query in model space). Inter-radiologist agreement and radiologist-model agreement statistics (Fleiss' and Cohen's kappa) were calculated. A t-SNE of the CT model latent space was generated to confirm clustering of similar images.

RESULTS

The CXR model achieved nDCG@5 of 0.73 ($p<0.001$) and Cardiomegaly mAP@5 of 0.76 ($p<0.001$) among other results for CXR. The CT model achieved nDCG of 16.85 ($p<0.001$). The model prediction agreed with radiologist consensus on 86% of CXR samples and 79.2% of CT samples. Inter-radiologist Fleiss Kappa of 0.51 and radiologist consensus to model Cohen's Kappa of 0.65 were observed. Full code will be made available at the time of presentation.

CONCLUSION

s We have developed and evaluated a vision transformer architecture that can retrieve visually and semantically similar radiological images.

CLINICAL RELEVANCE/APPLICATION

Our vision transformer model can identify radiological images with visual and diagnostic similarities, which may be applied to decision support, teaching file creation, and research cohort creation.

M5A-SPIR-1 Percutaneous Transthoracic Lung Biopsy in Patients with Usual Interstitial Pneumonia Pattern in CT: Its Implication on Procedure-related Complications

Participants
Jongsoo Park, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to investigate the incidence and risk factors of major complications (pneumothorax and hemoptysis) after percutaneous transthoracic lung biopsy (PTLB) in patients with usual interstitial pneumonia (UIP) pattern on CT.

METHODS AND MATERIALS

Patients who underwent PTLB between January 2010 and December 2015 in a tertiary referral hospital were retrospectively included. UIP pattern was determined based on the pre-PTLB chest CT according to the guideline of the American Thoracic Society/European Respiratory Society/Japanese Respiratory Society/Latin American Thoracic Society by consensus reading of two thoracic radiologists. To analyze whether the UIP pattern and its traversal by the needle are the risk factors of PTLB-complications (e.i., pneumothorax, hemoptysis) or not, multivariate logistic regression analyses were performed with other pre-established risk factors.

RESULTS

A total of 4,187 patients (UIP group: 148 patients [131 men; median age, 70.1 years], non-UIP group: 4,039 patients [2,382 men; median age, 63.6 years]) were assessed in this study. UIP group had higher incidence of pneumothorax (35.1% versus 17.9%, P<0.001) and requirements of percutanes catheter drainage (PCD) (6.1% versus 1.5%) than those of non-UIP group while hemoptysis was frequently occurred in non-UIP group (2% versus 6.1%, P=0.034). Adjusted with other pre-established risk factors including emphysema, UIP pattern is associated with pneumothorax occurence (hazard ratio [HR]: 2.147, 95% confidence interval [CI]: 1.480 - 3.116, P<0.001) and event of PCD insertion for pneumothorax (HR: 3.549, 95% CI: 1.602 - 7.861, P=0.002), but not for hemoptysis after PTLB. Traversal of UIP pattern had consistent result as a risk factor for complication after PTLB (pneumothorax: HR: 5.198, 95% CI: 2.913 - 9.274, P<0.001; PCD insertion for pneumothorax: HR 9.549, 95% CI: 3.741 - 24.377, P<0.001). The duration of the PCD placement between UIP- and non-UIP groups was not different (median 3 days [range, 2 - 11 days] versus median 2 days [range, 1 - 12 days], P=0.941).

CONCLUSION

s UIP pattern on CT and traversal of this pattern by the needle are the risk factors for pneumothorax and requirements of PCD insertion after PTLB.

CLINICAL RELEVANCE/APPLICATION

When performing PTLB, the radiologists should be alert about pneumothorax occurrence in patients with UIP on CT. They avoid traversal of biopsy needle through the UIP pattern as much as possible.

M5A-SPIR-2 Feasibility of EKG gated CT-Fluoroscopy to Guide Percutaneous Biopsy of Cardiac and Pericardial Masses

Participants
Patrik Rogalla, MD, MBA, Toronto, ON (*Presenter*) Institutional Research Grant, Canon Medical Systems Corporation;Institutional Research Grant, KA Imaging

PURPOSE

Percutaneous biopsy of the heart and pericardium poses a significant challenge due to the target's continuous motion and potentially life-threatening complications. The purpose of this study was to evaluate the feasibility of an EKG gated CT-fluoroscopy approach along with various methods to minimize the risks and complications, and the clinical outcome of cardiac and pericardial mass biopsies.

METHODS AND MATERIALS

Between 2018 and 2022, 18 cardiac and pericardial mass biopsies were performed in a quaternary care referral centre after clinical consultation with the cardiac surgical team. With REB approval, the patients' charts were reviewed to extract the history, pathology, and clinical outcomes. All biopsies were performed under conscious sedation using CT-fluoroscopy guidance on a 320-slice cardiac scanner (Canon Medical Systems). The EKG was monitored and used for gated image acquisition during the intervention. Mediastinal widening and iatrogenic capnothorax techniques were applied to gain access when appropriate. Full-size 18G core samples were taken using a BioPince needle, and all samples were evaluated by a specialized cardiac pathologist. The

radiation dose and time to complete the intervention were recorded.

RESULTS

All 18 biopsies in 17 patients (F:M, 9:8; mean age, 45.8) resulted in definitive pathological diagnoses. The size of the targets ranged from 1 cm to 12 cm. Final histology reported 10 malignant (eg. synovial, spindle cell and angiosarcoma, lymphoma, thymoma) and eight benign diagnoses (eg. IgG4, hibernoma, fibroma, TB, haemangioma, fibromyxoid stroma, lipid hyperplasia). One patient developed a small hemothorax, and another patient developed a small pneumomediastinum immediately post-procedure, both of which were successfully treated conservatively. Specific cardiac-related complications, such as hemopericardium, tamponade, arrhythmia or arrest did not occur in any of the patients. The median DLP for the fluoroscopy guidance was 22.5 mGy*cm (SD, 22.3), the mean total procedure time 32 minutes. All patients left the hospital following a two-hour recovery in a medical imaging day unit.

CONCLUSION

s Percutaneous cardiac and pericardial mass biopsies can be safely performed with an acceptable clinical risk and radiation dose profile. CT-fluoroscopy with real-time non-gated and gated image visualization, a well-trained interventional care team, and the backup availability of cardiac surgery may be prerequisites to ensure the best possible patient care.

CLINICAL RELEVANCE/APPLICATION

Percutaneous cardiac and pericardial biopsies represent a minimally invasive alternative to mediastinoscopy and open cardiac surgery in a specific patient population.

M5A-SPIR-3 Histotripsy Treatment of Veins as A Mechanism of Endothelial Damage

Participants
Amanda Smolock, MD, PhD, Milwaukee, WI (*Presenter*) Consultant, HistoSonics, Inc;Shareholder, HistoSonics, Inc;Employee, NeuWave Medical, Inc;Grant, NeuWave Medical, Inc;Consultant, NeuWave Medical, Inc;;

PURPOSE

Venous insufficiency affects up to a third of the population and can cause significant complications like ulcers which are painful and costly to manage. Histotripsy is a non-invasive, non-thermal focused ultrasound method that mechanically destroys tissue through acoustic cavitation. The aim of this project was to demonstrate the feasibility of using histotripsy to cause controlled mechanical damage to the venous endothelium as a step in inducing venous occlusion for the treatment of venous insufficiency.

METHODS AND MATERIALS

Excised porcine femoral veins (n=13) were suspended in a mold of degassed 2% agarose gel and treated within 72 hours post-mortem. The mold was degassed in a vacuum overnight. Histotripsy was applied using 3-cycle pulses at 44MPa predicted peak negative pressure by a 1MHz focused ultrasound transducer along 1 cm length of vein with 4 parameter groups: 1) 1Hz pulse repetition frequency (PRF) and 200 pulses per location (ppl) (n=2), 2) 100Hz PRF and 200 ppl (n=3), 3) 100Hz PRF and 500 ppl (n=3), and 4) 100 Hz PRF and 1000 ppl (n=3). Following treatment, veins were removed from the gel mold and placed in 10% formalin. Tissue was sectioned and stained with hematoxylin and eosin. Histology was reviewed for damage to vein wall layers using a standardized scale (0 least - 4 most endothelial attenuation).

RESULTS

Histology demonstrated intact venous walls with dose-dependent damage to the venous endothelium. Frequency and severity of endothelial loss increased with increasing ppl tested at 100Hz PRF. Endothelial damage was most significant though in veins treated at a lower PRF of 1Hz with 200 ppl.

CONCLUSION

s Histotripsy causes dose-dependent damage to the endothelium of veins. Endothelial denudation is an initial step in venous thrombosis and ultimately occlusion. Additional in vivo experiments of blood-containing vein are needed to fully test dose parameters for vein histotripsy followed by longitudinal studies to assess for treatment efficacy.

CLINICAL RELEVANCE/APPLICATION

Histotripsy has the potential to provide a non-invasive and non-thermal outpatient treatment for venous insufficiency.

M5A-SPIR-4 Using a Quantitative Digital Subtraction Angiography Technique to Determine Treatment Endpoints in Partial Splenic Artery Embolization: Feasibility in an In Vivo Porcine Model

Participants
Sarvesh Periyasamy, PhD, Madison, WI (*Presenter*) Consultant, Johnson & Johnson;Consultant, HEPTA Medical;Consultant, Vector Surgical LLC

PURPOSE

Partial splenic artery embolization (PSE) is a method for treating cirrhosis-induced splenomegaly/hypersplenism and complications of portal hypertension. However, there is a direct relationship between the extent of embolization and the severity of post-procedural complications. Using quantitative metrics to determine PSE endpoints may improve procedural outcomes and decrease post-procedural complications. The objective of this study was to determine the feasibility of using a quantitative digital subtraction angiography (qDSA) technique to quantify blood velocity reduction during PSE.

METHODS AND MATERIALS

Four swine (~50 kg) underwent embolization of the proximal splenic artery using embolic particles of different sizes (100-300, 300-500, or 500-700 µm diluted in 10 mL of iohexol 300 mg I/mL). qDSAs were acquired at baseline, and after delivery of 1 mL aliquots of particles until a complete stasis angiographic endpoint was achieved. A retrospective image analysis was performed to calculate blood velocity reduction in the splenic artery using qDSA, which was correlated with time-to-peak signal in the portal vein.

RESULTS

qDSA demonstrated linear decreases in relative blood velocities from baseline (100-300 µm: 11.8%, 34.8%, 300-500 µm: 29.3%

qDSA demonstrated linear decreases in relative blood velocities from baseline (100-300 µm: 11.8%, 34.8%, 300-500 µm: 29.3%, 500-700 µm: 24.4% reduction per mL of particles) and a strong correlation with the volume of embolic particles delivered (mean R= -0.96±0.02, R2=0.93±0.04). There was a strong correlation between the percent reduction in blood velocity calculated by qDSA and the increased time-to-peak signal in the portal vein (mean R=-0.94±0.03, R2= 0.89±0.86). Embolizations performed with larger particles had larger overall post-embolization blood velocity reductions (300-500 µm: 88%, 500-700 µm: 90%) compared to embolizations performed with smaller particles (100-300 µm: 71%, 70%)

CONCLUSION

s qDSA was able to quantify intra-procedural reductions in splenic arterial blood velocity during embolization in a porcine model. Blood velocity reductions correlated with an imaging marker of reduced portal venous flow. Further investigation is warranted to evaluate qDSA use in clinical PSE procedures.

CLINICAL RELEVANCE/APPLICATION

Quantitative digital subtraction angiography may permit the determination of objective treatment endpoints for PSE, improving the safety and efficacy of the procedure.

M5A-SPIR-5 Preliminary Results from A Prospective Clinical Trial on The Immunological Effects of Locoregional Therapies in Patients with Hepatocellular Carcinoma

Participants
Robin Schmidt, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the prognostic value of periinterventional peripheral blood immune cell counts on tumor response in patients with hepatocellular carcinoma (HCC) after locoregional therapies (LRT).

METHODS AND MATERIALS

This interim report of a single-site prospective clinical trial included 76 consecutive patients with unresectable HCC between 08/2020-11/2021, who underwent LRT including high dose-rate brachytherapy alone (BT, n=59) or with prior transarterial chemoembolization (TACE/BT, n=35). Institutional review board approval and informed consent were obtained. Peripheral blood was sampled before, 24h and 8 weeks (wk) after LRT for spectral fluorescence-activated cell sorting (FACS) analysis. A 24-color multiplex staining panel was applied to quantify lymphoid and myeloid cells. Absolute cell counts were obtained by adding precision count beads. FACS data was processed using a robust gating strategy including CD45/CD66/CD16/CD14/CD3/CD4/CD8. Tumor response at 8wk was assessed on multiparametric MRI according to RECIST 1.1 and patients were grouped into responders (R) and non-responders (NR). A nonparametric ANOVA type test statistic was used.

RESULTS

FACS data at baseline, 24h, and 8wk post-TACE were available for n=84, n=84, and n=72 patients, respectively. As for BT, higher counts of T cells (TC), CD4+TC, and CD8+TC count as well as a lower CD4-to-CD8 TC ratio (p=0.093, p=0.232, p=0.095 and p=0.152, respectively) were found in R compared to NR at all timepoints. However, the opposite trend was observed in patients receiving TACE/BT, who demonstrated lower cell counts for TC, CD4+TC, CD8+TC as well as a higher CD4-to-CD8 ratio (p=0.003, p=0.003, 0.074 and p=0.801, respectively) for R compared to NR at all timepoints (Figure 1). Neutrophil-to-lymphocyte (NLR) and monocyte-to-lymphocyte (MLR) ratio were similar in R and NR after BT. However, NR after TACE/BT tended to have a lower NLR and higher MLR than R (Figure 2).

CONCLUSION

s The preliminary results of this prospective study state that different types of locoregional therapies may induce different immunological responses in HCC patients and establish the prognostic value of such quantitative inflammatory biomarkers associated with tumor response prior to LRT. Moreover, patient and tumor characteristics at baseline, that determine the assignment to the respective LRT, may potentially reflect the immunological phenotype in these patients.

CLINICAL RELEVANCE/APPLICATION

If confirmed in the complete cohort, these results may help exploit LRT-induced immune-activation and guide improved personalized monitoring and combinations with immunooncological therapies.

M5A-SPIR-6 A Phantom for Assessing Histotripsy Treatment Zones on Both Ultrasound and X-ray Imaging

Participants
Ayca Kutlu, MD, Madison, WI (*Presenter*) Nothing to Disclose

PURPOSE

Histotripsy is an emerging non-invasive, non-ionizing, and non-thermal focal tumor therapy. While targeting during histotripsy is currently based on ultrasound (US), X-ray-based fusion and targeting techniques are being developed for tumors not visible by US. The objective of this study was to validate a multi-modal phantom that enables assessment of histotripsy treatment zones on both US and X-ray imaging.

METHODS AND MATERIALS

Six cube-shaped phantoms were created by suspending sheep red blood cells (RBC) in agarose. To provide x-ray contrast, alternating layers with (~1 mm thick) and without barium sulfate (~4 mm thick) were poured in a 2 x 2 x 2 in silicone mold. During histotripsy, adjacent layers in the treatment volume mix and create a homogeneous mixture visible on US and cone beam CT (CBCT). Spherical (2.5 cm diameter) treatments were performed in each phantom and resulting treatment zones measured on US and CBCT. Treatment zone size and location (distance from phantom center) were measured in three orthogonal planes separately. In addition, signal-difference-to-noise ratio (SDNR) was calculated on CBCT images between ablation zones and untreated RBC layers.

RESULTS

In all cases, histotripsy resulted in homogeneous treatment zones with distinct x-ray attenuation and acoustic impedance, which

made segmentation of the treatment zone on both CBCT and US possible. On US, treatment zone diameters (mean±SD) were 25.5 ± 0.3, 25.0 ± 0.3 and 24.5 ± 0.4 mm on X, Y and Z planes, respectively. Similarly, on CBCT, diameters were 25.8 ± 1.1, 25.3 ± 0.4 and 24.4 ± 0.2 mm. Treatment zone center point location differed by 1.6 ± 0.9, 1.5 ± 1.1 and 2.6 ± 1.2 mm on X, Y and Z planes, respectively between CBCT and US measurements. The average SDNR between ablation zone and RBC layer was 23.1 ± 7.3.

CONCLUSION

s The proposed multimodal RBC phantom allowed visualization of histotripsy treatment zones on both US and x-ray imaging. Treatment zone diameters and center locations were similar between the two modalities. These phantoms can help validate newly developed fusion and targeting techniques for histotripsy, expanding the scope of treatable lesions.

CLINICAL RELEVANCE/APPLICATION

A multimodal RBC phantom may be used to develop and validate X-ray-based fusion and targeting techniques for histotripsy, which will facilitate treatment of tumors not visible on US.

M5A-SPIR-7 Safety and Efficacy of Serial Doxycycline Exchange Sclerotherapy for Lymphatic Malformations

Participants
Anna Gong, Baltimore, MD (*Presenter*) Nothing to Disclose

PURPOSE

To assess the efficacy of serial doxycycline exchanges (SDE) for the treatment of lymphatic malformations (LM).

METHODS AND MATERIALS

We reviewed all patients from 9/2004 to 02/2022 who received SDE after a percutaneous drain placement for an LM at our institution. After initial image-guided drainage catheter placement and sclerotherapy into the LM, the patient was admitted for SDE. Standard procedure involved bedside drainage, and infusion of doxycycline (10mg/mL) 1/3 to 1/2 of the drained volume, which was left to dwell for 4 hours before draining. This was performed twice a day, until the drained volume was sufficiently decreased as per the physician's direction, after which the patient was discharged. Charts were reviewed to assess clinical response, size changes, and complications. Symptom response was classified as resolved, improved, and stable/worsened. LM size change was calculated using difference of pre- and post- procedure MRI of the largest lesion diameter in one plane: complete response (CR, 100% reduction), partial response (PR, 30% reduction), stable disease (SD, =30% reduction or =20% enlargement), progressive disease (PD, =20% size increase). SIR classification criteria were used to classify adverse events. Fisher's Exact Tests were used for statistical analysis.

RESULTS

43 patients (58.1% M) underwent 82 image-guided sclerotherapy procedures with subsequent SDE (technical success 80/82; 97.6%). An average of 3.87 SDE sessions/admission was reported for an average extended inpatient stay of 92 hours/admission (Total: 201 exchanges). This resulted in 201/283 (71.0%) sclerotherapy sessions that were performed at the bedside. The mean patient follow-up period was 902.15 days (median: 328 days).Most common presenting symptoms were swelling/mass (25, 58.1%), pain (8, 18.6%) and trouble breathing (3, 7.0%). Sclerotherapy significantly improved symptoms with 6.1% (5/82) resolved, 47.6% (39/82) improved, and 46.3% (38/82) stable or worsened ($p < 0.0001$). Embolization also significantly decreased LM size on imaging ($p = 0.0011$). Of the 47 image-guided procedures (47/82, 57.3%) with both pre- and post- MRI imaging, zero patients saw CR, 10 patients (21.3%) experienced PR, 35 patients (74.5%) experienced SD and 2 patients (4.3%) saw PD. Early (30-day) post-procedural complications occurred after 9 of 82 procedures (10.9%), the most common of which were sensory or motor nerve injury (44.4%; 4/9) and mild in severity (44.4%; 4/9).

CONCLUSION

s SDE significantly decreases lesion size and improves clinical symptoms in LMs.

CLINICAL RELEVANCE/APPLICATION

SDE is a safe and effective treatment option for LMs that allows for multiple sclerotherapy sessions with a single fluoroscopic procedure.

M5A-SPIR-8 Silver Nanoparticles-coated Stent for Suppressing Bacterial Growth and Tissue Hyperplasia after Radiofrequency Ablation in the Rabbit Common Bile Duct

Participants
Yubeen Park, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the efficacy of silver nanoparticles (AgNPs)-coated self-expandable metal stent (SEMS) placement immediately after radiofrequency (RF) ablation in suppressing thermal damage as well as SEMS-induced bacterial growth and tissue hyperplasia in the common bile duct of rabbits.

METHODS AND MATERIALS

The release behavior and antibacterial effects of AgNPs-coated SEMSs were evaluated. A total of 12 male New Zealand White rabbits were randomly divided into two groups for verification of the efficacy of AgNPs-coated SEMS placement immediately after RF ablation: the control group received an uncoated SEMS, and the AgNPs group received an AgNPs-coated SEMS. Cholangiography was performed immediately before sacrifice in all rabbits to check the stent patency. Venous blood samples were collected before sacrifice and AST, ALT, ALP, GGT, and total bilirubin levels were analyzed to evaluate hepatobiliary functions. Histological examination was performed about the degree of inflammatory cell infiltration, thickness of submucosal fibrosis, percentage of granulation tissue area, and degree of collagen deposition. Immunohistochemistry analysis was performed about the degree of TUNEL-, HSP 70-, and a-SMA-positive areas.

RESULTS

Ag ions were rapidly released at the beginning and then showed a gradual release behavior. The AgNPs-coated SEMS significantly inhibited bacterial activity compared to the uncoated SEMS ($p < 0.05$). Stent placement immediately after RF ablation was

successfully performed without procedure-related complications in all rabbits. Jaundice was observed in 3 out of 6 (50%) rabbits in the control group. The luminal diameter in the AgNPs group was greater than that in the control group ($p < 0.05$). AST, ALT, ALP, GGT, and total bilirubin levels were all lower in the AgNPs group than in the control group. Histological examination confirmed that all evaluation results were significantly lower in the AgNPs group than in the control group (all $p < 0.05$). Immunohistochemistry analyses revealed that TUNEL-, HSP 70-, and a-SMA-positive areas were significantly lower in the AgNPs group than in the control group (all $p < 0.05$).

CONCLUSION

s The AgNPs-coated SEMS significantly inhibited tissue hyperplasia and biofilm induced by heat and mechanical damage in the rabbit common bile duct. The developed method of RF ablation with AgNPs-coated SEMS should be a promising therapeutic strategy for the prevention of RF ablation- and stent-related complications.

CLINICAL RELEVANCE/APPLICATION

AgNPs-coated SEMS placement immediately after RF ablation might be effective in preventing RF ablation and stent-related complications in patients with unresectable malignant biliary obstruction.

M5A-SPIR-9 Intragastric Satiety-Inducing Device combined with Photodynamic Therapy to Treat Obesity

Participants
Ji Won Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the efficacy and safety of the Chlorin e6-embedded intragastric satiety-inducing device (Ce6-embedded ISD) placement with photodynamic therapy (PDT) in suppressing appetite in porcine stomach.

METHODS AND MATERIALS

The ISD consisted of the lower esophageal part and disk part for the fundus of the stomach. The once dip coating technique was used for the fabrication of Ce6-embedded ISD. A total of 12 minipigs were divided into four groups. PDT group (n = 3) received single PDT using Ce6-embedded ISD. ISD group (n = 3) received ISD placement. ISD with PDT group (n = 3) received single PDT with Ce6-embedded ISD placement. The remaining three weight and age-matched healthy pigs were used as a control group. All pigs were sacrificed 4 weeks after the procedures. The outcomes were assessed by histological examinations and immunohistochemistry analysis. Body weight was monitored weekly, and the percentage of total body weight gain (%TBWG) was calculated.

RESULTS

A total of 12 minipigs were divided into four groups. PDT group (n = 3) received single PDT using Ce6-embedded ISD. ISD group (n = 3) received ISD placement. ISD with PDT group (n = 3) received single PDT with Ce6-embedded ISD placement. The remaining three weight and age-matched healthy pigs were used as a control group. Anti-ghrelin and TUNEL-positive deposition were significantly increased in PDT, ISD, and ISD with PDT groups compared to the control group (all $p < 0.001$). The weight gain was observed to decrease in the order of PDT, ISD, and ISD with PDT groups compared to the control group, and the ISD with PDT proved to be the most effective for wight loss.

CONCLUSION

s Ce6-embedded ISD was effectively decreases weight gain rate and ghrelin-producing cells in the porcine model. The simple and unique operation extends the point of view in PDT and is expected to be a novel obesity therapy.

CLINICAL RELEVANCE/APPLICATION

Ce6-embedded ISD, weight loss and stimulation of ghrelin-producing cells, will become strategy for obesity treatment.

Percutaneous Transthoracic Lung Biopsy in Patients with Usual Interstitial Pneumonia Pattern in CT: Its Implication on Procedure-related Complications

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IR DPS

Participants
Jongsoo Park, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to investigate the incidence and risk factors of major complications (pneumothorax and hemoptysis) after percutaneous transthoracic lung biopsy (PTLB) in patients with usual interstitial pneumonia (UIP) pattern on CT.

METHODS AND MATERIALS

Patients who underwent PTLB between January 2010 and December 2015 in a tertiary referral hospital were retrospectively included. UIP pattern was determined based on the pre-PTLB chest CT according to the guideline of the American Thoracic Society/European Respiratory Society/Japanese Respiratory Society/Latin American Thoracic Society by consensus reading of two thoracic radiologists. To analyze whether the UIP pattern and its traversal by the needle are the risk factors of PTLB-complications (e.i., pneumothorax, hemoptysis) or not, multivariate logistic regression analyses were performed with other pre-established risk factors.

RESULTS

A total of 4,187 patients (UIP group: 148 patients [131 men; median age, 70.1 years], non-UIP group: 4,039 patients [2,382 men; median age, 63.6 years]) were assessed in this study. UIP group had higher incidence of pneumothorax (35.1% versus 17.9%, P<0.001) and requirements of percutanes catheter drainage (PCD) (6.1% versus 1.5%) than those of non-UIP group while hemoptysis was frequently occurred in non-UIP group (2% versus 6.1%, P=0.034). Adjusted with other pre-established risk factors including emphysema, UIP pattern is associated with pneumothorax occurence (hazard ratio [HR]: 2.147, 95% confidence interval [CI]: 1.480 - 3.116, P<0.001) and event of PCD insertion for pneumothorax (HR: 3.549, 95% CI: 1.602 - 7.861, P=0.002), but not for hemoptysis after PTLB. Traversal of UIP pattern had consistent result as a risk factor for complication after PTLB (pneumothorax: HR: 5.198, 95% CI: 2.913 - 9.274, P<0.001; PCD insertion for pneumothorax: HR 9.549, 95% CI: 3.741 - 24.377, P<0.001). The duration of the PCD placement between UIP- and non-UIP groups was not different (median 3 days [range, 2 - 11 days] versus median 2 days [range, 1 - 12 days], P=0.941).

CONCLUSION

s UIP pattern on CT and traversal of this pattern by the needle are the risk factors for pneumothorax and requirements of PCD insertion after PTLB.

CLINICAL RELEVANCE/APPLICATION

When performing PTLB, the radiologists should be alert about pneumothorax occurrence in patients with UIP on CT. They avoid traversal of biopsy needle through the UIP pattern as much as possible.

Feasibility of EKG gated CT-Fluoroscopy to Guide Percutaneous Biopsy of Cardiac and Pericardial Masses

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IR DPS

Participants
Patrik Rogalla, MD, MBA, Toronto, ON (*Presenter*) Institutional Research Grant, Canon Medical Systems Corporation;Institutional Research Grant, KA Imaging

PURPOSE

Percutaneous biopsy of the heart and pericardium poses a significant challenge due to the target's continuous motion and potentially life-threatening complications. The purpose of this study was to evaluate the feasibility of an EKG gated CT-fluoroscopy approach along with various methods to minimize the risks and complications, and the clinical outcome of cardiac and pericardial mass biopsies.

METHODS AND MATERIALS

Between 2018 and 2022, 18 cardiac and pericardial mass biopsies were performed in a quaternary care referral centre after clinical consultation with the cardiac surgical team. With REB approval, the patients' charts were reviewed to extract the history, pathology, and clinical outcomes. All biopsies were performed under conscious sedation using CT-fluoroscopy guidance on a 320-slice cardiac scanner (Canon Medical Systems). The EKG was monitored and used for gated image acquisition during the intervention. Mediastinal widening and iatrogenic capnothorax techniques were applied to gain access when appropriate. Full-size 18G core samples were taken using a BioPince needle, and all samples were evaluated by a specialized cardiac pathologist. The radiation dose and time to complete the intervention were recorded.

RESULTS

All 18 biopsies in 17 patients (F:M, 9:8; mean age, 45.8) resulted in definitive pathological diagnoses. The size of the targets ranged from 1 cm to 12 cm. Final histology reported 10 malignant (eg. synovial, spindle cell and angiosarcoma, lymphoma, thymoma) and eight benign diagnoses (eg. IgG4, hibernoma, fibroma, TB, haemangioma, fibromyxoid stroma, lipid hyperplasia). One patient developed a small hemothorax, and another patient developed a small pneumomediastinum immediately post-procedure, both of which were successfully treated conservatively. Specific cardiac-related complications, such as hemopericardium, tamponade, arrhythmia or arrest did not occur in any of the patients. The median DLP for the fluoroscopy guidance was 22.5 mGy*cm (SD, 22.3), the mean total procedure time 32 minutes. All patients left the hospital following a two-hour recovery in a medical imaging day unit.

CONCLUSION

s Percutaneous cardiac and pericardial mass biopsies can be safely performed with an acceptable clinical risk and radiation dose profile. CT-fluoroscopy with real-time non-gated and gated image visualization, a well-trained interventional care team, and the backup availability of cardiac surgery may be prerequisites to ensure the best possible patient care.

CLINICAL RELEVANCE/APPLICATION

Percutaneous cardiac and pericardial biopsies represent a minimally invasive alternative to mediastinoscopy and open cardiac surgery in a specific patient population.

Histotripsy Treatment of Veins as A Mechanism of Endothelial Damage

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IR DPS

Participants
Amanda Smolock, MD, PhD, Milwaukee, WI (*Presenter*) Consultant, HistoSonics, Inc;Shareholder, HistoSonics, Inc;Employee, NeuWave Medical, Inc;Grant, NeuWave Medical, Inc;Consultant, NeuWave Medical, Inc;;

PURPOSE

Venous insufficiency affects up to a third of the population and can cause significant complications like ulcers which are painful and costly to manage. Histotripsy is a non-invasive, non-thermal focused ultrasound method that mechanically destroys tissue through acoustic cavitation. The aim of this project was to demonstrate the feasibility of using histotripsy to cause controlled mechanical damage to the venous endothelium as a step in inducing venous occlusion for the treatment of venous insufficiency.

METHODS AND MATERIALS

Excised porcine femoral veins (n=13) were suspended in a mold of degassed 2% agarose gel and treated within 72 hours post-mortem. The mold was degassed in a vacuum overnight. Histotripsy was applied using 3-cycle pulses at 44MPa predicted peak negative pressure by a 1MHz focused ultrasound transducer along 1 cm length of vein with 4 parameter groups: 1) 1Hz pulse repetition frequency (PRF) and 200 pulses per location (ppl) (n=2), 2) 100Hz PRF and 200 ppl (n=3), 3) 100Hz PRF and 500 ppl (n=3), and 4) 100 Hz PRF and 1000 ppl (n=3). Following treatment, veins were removed from the gel mold and placed in 10% formalin. Tissue was sectioned and stained with hematoxylin and eosin. Histology was reviewed for damage to vein wall layers using a standardized scale (0 least - 4 most endothelial attenuation).

RESULTS

Histology demonstrated intact venous walls with dose-dependent damage to the venous endothelium. Frequency and severity of endothelial loss increased with increasing ppl tested at 100Hz PRF. Endothelial damage was most significant though in veins treated at a lower PRF of 1Hz with 200 ppl.

CONCLUSION

s Histotripsy causes dose-dependent damage to the endothelium of veins. Endothelial denudation is an initial step in venous thrombosis and ultimately occlusion. Additional in vivo experiments of blood-containing vein are needed to fully test dose parameters for vein histotripsy followed by longitudinal studies to assess for treatment efficacy.

CLINICAL RELEVANCE/APPLICATION

Histotripsy has the potential to provide a non-invasive and non-thermal outpatient treatment for venous insufficiency.

Using a Quantitative Digital Subtraction Angiography Technique to Determine Treatment Endpoints in Partial Splenic Artery Embolization: Feasibility in an In Vivo Porcine Model

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IR DPS

Participants
Sarvesh Periyasamy, PhD, Madison, WI (*Presenter*) Consultant, Johnson & Johnson;Consultant, HEPTA Medical;Consultant, Vector Surgical LLC

PURPOSE

Partial splenic artery embolization (PSE) is a method for treating cirrhosis-induced splenomegaly/hypersplenism and complications of portal hypertension. However, there is a direct relationship between the extent of embolization and the severity of post-procedural complications. Using quantitative metrics to determine PSE endpoints may improve procedural outcomes and decrease post-procedural complications. The objective of this study was to determine the feasibility of using a quantitative digital subtraction angiography (qDSA) technique to quantify blood velocity reduction during PSE.

METHODS AND MATERIALS

Four swine (~50 kg) underwent embolization of the proximal splenic artery using embolic particles of different sizes (100-300, 300-500, or 500-700 µm diluted in 10 mL of iohexol 300 mg I/mL). qDSAs were acquired at baseline, and after delivery of 1 mL aliquots of particles until a complete stasis angiographic endpoint was achieved. A retrospective image analysis was performed to calculate blood velocity reduction in the splenic artery using qDSA, which was correlated with time-to-peak signal in the portal vein.

RESULTS

qDSA demonstrated linear decreases in relative blood velocities from baseline (100-300 µm: 11.8%, 34.8%, 300-500 µm: 29.3%, 500-700 µm: 24.4% reduction per mL of particles) and a strong correlation with the volume of embolic particles delivered (mean R= -0.96±0.02, R2=0.93±0.04). There was a strong correlation between the percent reduction in blood velocity calculated by qDSA and the increased time-to-peak signal in the portal vein (mean R=-0.94±0.03, R2= 0.89±0.86). Embolizations performed with larger particles had larger overall post-embolization blood velocity reductions (300-500 µm: 88%, 500-700 µm: 90%) compared to embolizations performed with smaller particles (100-300 µm: 71%, 70%)

CONCLUSION

s qDSA was able to quantify intra-procedural reductions in splenic arterial blood velocity during embolization in a porcine model. Blood velocity reductions correlated with an imaging marker of reduced portal venous flow. Further investigation is warranted to evaluate qDSA use in clinical PSE procedures.

CLINICAL RELEVANCE/APPLICATION

Quantitative digital subtraction angiography may permit the determination of objective treatment endpoints for PSE, improving the safety and efficacy of the procedure.

Preliminary Results from A Prospective Clinical Trial on The Immunological Effects of Locoregional Therapies in Patients with Hepatocellular Carcinoma

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IR DPS

Participants
Robin Schmidt, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the prognostic value of periinterventional peripheral blood immune cell counts on tumor response in patients with hepatocellular carcinoma (HCC) after locoregional therapies (LRT).

METHODS AND MATERIALS

This interim report of a single-site prospective clinical trial included 76 consecutive patients with unresectable HCC between 08/2020-11/2021, who underwent LRT including high dose-rate brachytherapy alone (BT, n=59) or with prior transarterial chemoembolization (TACE/BT, n=35). Institutional review board approval and informed consent were obtained. Peripheral blood was sampled before, 24h and 8 weeks (wk) after LRT for spectral fluorescence-activated cell sorting (FACS) analysis. A 24-color multiplex staining panel was applied to quantify lymphoid and myeloid cells. Absolute cell counts were obtained by adding precision count beads. FACS data was processed using a robust gating strategy including CD45/CD66/CD16/CD14/CD3/CD4/CD8. Tumor response at 8wk was assessed on multiparametric MRI according to RECIST 1.1 and patients were grouped into responders (R) and non-responders (NR). A nonparametric ANOVA type test statistic was used.

RESULTS

FACS data at baseline, 24h, and 8wk post-TACE were available for n=84, n=84, and n=72 patients, respectively. As for BT, higher counts of T cells (TC), CD4+TC, and CD8+TC count as well as a lower CD4-to-CD8 TC ratio (p=0.093, p=0.232, p=0.095 and p=0.152, respectively) were found in R compared to NR at all timepoints. However, the opposite trend was observed in patients receiving TACE/BT, who demonstrated lower cell counts for TC, CD4+TC, CD8+TC as well as a higher CD4-to-CD8 ratio (p=0.003, p=0.003, 0.074 and p=0.801, respectively) for R compared to NR at all timepoints (Figure 1). Neutrophil-to-lymphocyte (NLR) and monocyte-to-lymphocyte (MLR) ratio were similar in R and NR after BT. However, NR after TACE/BT tended to have a lower NLR and higher MLR than R (Figure 2).

CONCLUSION

s The preliminary results of this prospective study state that different types of locoregional therapies may induce different immunological responses in HCC patients and establish the prognostic value of such quantitative inflammatory biomarkers associated with tumor response prior to LRT. Moreover, patient and tumor characteristics at baseline, that determine the assignment to the respective LRT, may potentially reflect the immunological phenotype in these patients.

CLINICAL RELEVANCE/APPLICATION

If confirmed in the complete cohort, these results may help exploit LRT-induced immune-activation and guide improved personalized monitoring and combinations with immunooncological therapies.

M5A-SPIR-6

A Phantom for Assessing Histotripsy Treatment Zones on Both Ultrasound and X-ray Imaging

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IR DPS

Participants
Ayca Kutlu, MD, Madison, WI (*Presenter*) Nothing to Disclose

PURPOSE

Histotripsy is an emerging non-invasive, non-ionizing, and non-thermal focal tumor therapy. While targeting during histotripsy is currently based on ultrasound (US), X-ray-based fusion and targeting techniques are being developed for tumors not visible by US. The objective of this study was to validate a multi-modal phantom that enables assessment of histotripsy treatment zones on both US and X-ray imaging.

METHODS AND MATERIALS

Six cube-shaped phantoms were created by suspending sheep red blood cells (RBC) in agarose. To provide x-ray contrast, alternating layers with (~1 mm thick) and without barium sulfate (~4 mm thick) were poured in a 2 x 2 x 2 in silicone mold. During histotripsy, adjacent layers in the treatment volume mix and create a homogeneous mixture visible on US and cone beam CT (CBCT). Spherical (2.5 cm diameter) treatments were performed in each phantom and resulting treatment zones measured on US and CBCT. Treatment zone size and location (distance from phantom center) were measured in three orthogonal planes separately. In addition, signal-difference-to-noise ratio (SDNR) was calculated on CBCT images between ablation zones and untreated RBC layers.

RESULTS

In all cases, histotripsy resulted in homogeneous treatment zones with distinct x-ray attenuation and acoustic impedance, which made segmentation of the treatment zone on both CBCT and US possible. On US, treatment zone diameters (mean±SD) were 25.5 ± 0.3, 25.0 ± 0.3 and 24.5 ± 0.4 mm on X, Y and Z planes, respectively. Similarly, on CBCT, diameters were 25.8 ± 1.1, 25.3 ± 0.4 and 24.4 ± 0.2 mm. Treatment zone center point location differed by 1.6 ± 0.9, 1.5 ± 1.1 and 2.6 ± 1.2 mm on X, Y and Z planes, respectively between CBCT and US measurements. The average SDNR between ablation zone and RBC layer was 23.1 ± 7.3.

CONCLUSION

s The proposed multimodal RBC phantom allowed visualization of histotripsy treatment zones on both US and x-ray imaging. Treatment zone diameters and center locations were similar between the two modalities. These phantoms can help validate newly developed fusion and targeting techniques for histotripsy, expanding the scope of treatable lesions.

CLINICAL RELEVANCE/APPLICATION

A multimodal RBC phantom may be used to develop and validate X-ray-based fusion and targeting techniques for histotripsy, which will facilitate treatment of tumors not visible on US.

Safety and Efficacy of Serial Doxycycline Exchange Sclerotherapy for Lymphatic Malformations

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IR DPS

Participants
Anna Gong, Baltimore, MD (*Presenter*) Nothing to Disclose

PURPOSE

To assess the efficacy of serial doxycycline exchanges (SDE) for the treatment of lymphatic malformations (LM).

METHODS AND MATERIALS

We reviewed all patients from 9/2004 to 02/2022 who received SDE after a percutaneous drain placement for an LM at our institution. After initial image-guided drainage catheter placement and sclerotherapy into the LM, the patient was admitted for SDE. Standard procedure involved bedside drainage, and infusion of doxycycline (10mg/mL) 1/3 to 1/2 of the drained volume, which was left to dwell for 4 hours before draining. This was performed twice a day, until the drained volume was sufficiently decreased as per the physician's direction, after which the patient was discharged. Charts were reviewed to assess clinical response, size changes, and complications. Symptom response was classified as resolved, improved, and stable/worsened. LM size change was calculated using difference of pre- and post- procedure MRI of the largest lesion diameter in one plane: complete response (CR, 100% reduction), partial response (PR, 30% reduction), stable disease (SD, =30% reduction or =20% enlargement), progressive disease (PD, =20% size increase). SIR classification criteria were used to classify adverse events. Fisher's Exact Tests were used for statistical analysis.

RESULTS

43 patients (58.1% M) underwent 82 image-guided sclerotherapy procedures with subsequent SDE (technical success 80/82; 97.6%). An average of 3.87 SDE sessions/admission was reported for an average extended inpatient stay of 92 hours/admission (Total: 201 exchanges). This resulted in 201/283 (71.0%) sclerotherapy sessions that were performed at the bedside. The mean patient follow-up period was 902.15 days (median: 328 days).Most common presenting symptoms were swelling/mass (25, 58.1%), pain (8, 18.6%) and trouble breathing (3, 7.0%). Sclerotherapy significantly improved symptoms with 6.1% (5/82) resolved, 47.6% (39/82) improved, and 46.3% (38/82) stable or worsened ($p < 0.0001$). Embolization also significantly decreased LM size on imaging ($p = 0.0011$). Of the 47 image-guided procedures (47/82, 57.3%) with both pre- and post- MRI imaging, zero patients saw CR, 10 patients (21.3%) experienced PR, 35 patients (74.5%) experienced SD and 2 patients (4.3%) saw PD. Early (30-day) post-procedural complications occurred after 9 of 82 procedures (10.9%), the most common of which were sensory or motor nerve injury (44.4%; 4/9) and mild in severity (44.4%; 4/9).

CONCLUSION

s SDE significantly decreases lesion size and improves clinical symptoms in LMs.

CLINICAL RELEVANCE/APPLICATION

SDE is a safe and effective treatment option for LMs that allows for multiple sclerotherapy sessions with a single fluoroscopic procedure.

Silver Nanoparticles-coated Stent for Suppressing Bacterial Growth and Tissue Hyperplasia after Radiofrequency Ablation in the Rabbit Common Bile Duct

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IR DPS

Participants
Yubeen Park, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the efficacy of silver nanoparticles (AgNPs)-coated self-expandable metal stent (SEMS) placement immediately after radiofrequency (RF) ablation in suppressing thermal damage as well as SEMS-induced bacterial growth and tissue hyperplasia in the common bile duct of rabbits.

METHODS AND MATERIALS

The release behavior and antibacterial effects of AgNPs-coated SEMSs were evaluated. A total of 12 male New Zealand White rabbits were randomly divided into two groups for verification of the efficacy of AgNPs-coated SEMS placement immediately after RF ablation: the control group received an uncoated SEMS, and the AgNPs group received an AgNPs-coated SEMS. Cholangiography was performed immediately before sacrifice in all rabbits to check the stent patency. Venous blood samples were collected before sacrifice and AST, ALT, ALP, GGT, and total bilirubin levels were analyzed to evaluate hepatobiliary functions. Histological examination was performed about the degree of inflammatory cell infiltration, thickness of submucosal fibrosis, percentage of granulation tissue area, and degree of collagen deposition. Immunohistochemistry analysis was performed about the degree of TUNEL-, HSP 70-, and a-SMA-positive areas.

RESULTS

Ag ions were rapidly released at the beginning and then showed a gradual release behavior. The AgNPs-coated SEMS significantly inhibited bacterial activity compared to the uncoated SEMS ($p < 0.05$). Stent placement immediately after RF ablation was successfully performed without procedure-related complications in all rabbits. Jaundice was observed in 3 out of 6 (50%) rabbits in the control group. The luminal diameter in the AgNPs group was greater than that in the control group ($p < 0.05$). AST, ALT, ALP, GGT, and total bilirubin levels were all lower in the AgNPs group than in the control group. Histological examination confirmed that all evaluation results were significantly lower in the AgNPs group than in the control group (all $p < 0.05$). Immunohistochemistry analyses revealed that TUNEL-, HSP 70-, and a-SMA-positive areas were significantly lower in the AgNPs group than in the control group (all $p < 0.05$).

CONCLUSION

s The AgNPs-coated SEMS significantly inhibited tissue hyperplasia and biofilm induced by heat and mechanical damage in the rabbit common bile duct. The developed method of RF ablation with AgNPs-coated SEMS should be a promising therapeutic strategy for the prevention of RF ablation- and stent-related complications.

CLINICAL RELEVANCE/APPLICATION

AgNPs-coated SEMS placement immediately after RF ablation might be effective in preventing RF ablation and stent-related complications in patients with unresectable malignant biliary obstruction.

Intragastric Satiety-Inducing Device combined with Photodynamic Therapy to Treat Obesity

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - IR DPS

Participants
Ji Won Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the efficacy and safety of the Chlorin e6-embedded intragastric satiety-inducing device (Ce6-embedded ISD) placement with photodynamic therapy (PDT) in suppressing appetite in porcine stomach.

METHODS AND MATERIALS

The ISD consisted of the lower esophageal part and disk part for the fundus of the stomach. The once dip coating technique was used for the fabrication of Ce6-embedded ISD. A total of 12 minipigs were divided into four groups. PDT group (n = 3) received single PDT using Ce6-embedded ISD. ISD group (n = 3) received ISD placement. ISD with PDT group (n = 3) received single PDT with Ce6-embedded ISD placement. The remaining three weight and age-matched healthy pigs were used as a control group. All pigs were sacrificed 4 weeks after the procedures. The outcomes were assessed by histological examinations and immunohistochemistry analysis. Body weight was monitored weekly, and the percentage of total body weight gain (%TBWG) was calculated.

RESULTS

A total of 12 minipigs were divided into four groups. PDT group (n = 3) received single PDT using Ce6-embedded ISD. ISD group (n = 3) received ISD placement. ISD with PDT group (n = 3) received single PDT with Ce6-embedded ISD placement. The remaining three weight and age-matched healthy pigs were used as a control group. Anti-ghrelin and TUNEL-positive deposition were significantly increased in PDT, ISD, and ISD with PDT groups compared to the control group (all $p < 0.001$). The weight gain was observed to decrease in the order of PDT, ISD, and ISD with PDT groups compared to the control group, and the ISD with PDT proved to be the most effective for wight loss.

CONCLUSION

s Ce6-embedded ISD was effectively decreases weight gain rate and ghrelin-producing cells in the porcine model. The simple and unique operation extends the point of view in PDT and is expected to be a novel obesity therapy.

CLINICAL RELEVANCE/APPLICATION

Ce6-embedded ISD, weight loss and stimulation of ghrelin-producing cells, will become strategy for obesity treatment.

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - MK DPS

Sub-Events

M5A-SPMK-1 Fully Automated CT Imaging Biomarkers for Opportunistic Prediction of Future Hip Fractures

Awards
Trainee Research Prize - Medical Student

Participants
Daniel Liu, (*Presenter*) Nothing to Disclose

PURPOSE

Body CT scans are frequently acquired for many targeted indications, but potentially valuable additional biometric information often remains untapped. AI-based algorithms can automate CT-based body composition measures, which can be utilized for opportunistic screening. The purpose of this study was to assess automated CT imaging biomarkers in patients who went on to hip fracture, compared with controls.

METHODS AND MATERIALS

In this retrospective case-control study, 6926 total patients underwent initial abdominal CT over a 20-year interval at one institution, including 1308 patients (mean age at initial CT, 70.5±12.0 years; 64.4% female) who went on to hip fracture (mean time to fracture, 4.5 years) and 5618 controls (mean age, 70.25±12.0 years; 61.2% female; mean follow-up interval, 5.2 years). Validated and fully automated quantitative CT algorithms for trabecular bone attenuation (at L1), muscle attenuation (at L3), and abdominal fat area (at L1) were applied to all scans. Univariate and multivariate hazard ratios (HRs) comparing worst quartile to the other three and area under the receiver operating characteristic (AUROC) curve analyses were performed.

RESULTS

Hip fracture HRs (with 95% CI) for low trabecular bone HU, low muscle HU, and low subcutaneous adipose tissue (SAT) area were 2.09 (1.86-2.35), 1.36 (1.20-1.54), and 1.68 (1.50-1.89), respectively. Similarly, 10-year AUROC values for predicting hip fracture were 0.702, 0.603, and 0.594, respectively. Multivariate combinations of these CT biomarkers further improved the predictive value. Notably, the 10-year AUROC from combining bone, muscle, and SAT was 0.729, while combining just muscle attenuation and SAT area was 0.679.

CONCLUSION

s Automated abdominal CT-based measures of bone, muscle, and subcutaneous fat provide useful risk stratification for future hip fractures. Opportunistic use of these automated CT-based measures can identify patients at higher risk, regardless of the indication for CT imaging.

CLINICAL RELEVANCE/APPLICATION

There is growing interest in leveraging opportunistic CT data for patient benefit, and automated AI-based algorithms provide a feasible pathway for this.

M5A-SPMK-2 Can Radiomics Diagnose Cancer-associated Cachexia At An Early Stage?

Participants
Yufei Zhao, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

As one of the most common complications of non-small-cell lung cancer (NSCLC), cancer-associated cachexia (CAC) frequently present with progressive skeletal muscle and adipose tissue wasting. However, as obesity, edema, pleural and ascites fluid, tumor weight and other factors can mask the diagnosis of CAC. Radiomics is expected to be an important research and clinical tool to accurate diagnosis CAC in early stage.

METHODS AND MATERIALS

A total of 93 NSCLC patients were enrolled, abdominal and pelvic CT (Siemens SOMATOM Sensation Scanner 64 Computed Tomography) scans were collected from all patients at first diagnosis and 6 months after treatment. The complete psoas major on both sides is automatically segmented by the FCN network. Taking the starting and ending plane of the psoas major as a reference, Extraction of the subcutaneous fat(-190 HU — -30 HU) and visceral fat (-150 HU — -50HU) by threshold. The difference in the volume of the psoas muscle between the two scans was calculated, if the volume decreased by more than 3%, it was classified as a cachexia group, otherwise as non-cachexia group. All above processes were implemented with FeAture Explorer Pro (FAEPro, V 0.4.2) on Python (3.7.6), extracting features of all volume of interest separately included first order statistics, shape-based, wavelet transform, squaregray-level co-occurrence matrix and selecting 65 cases as the training data set, another 28 cases as the

independent testing data set. we used analysis of variance (ANOVA) to select features and the support vector machine (SVM) as the classifier.

RESULTS

A total of 434 features were extracted for each case and 6 features were screened out finally. There was no difference in the psoas muscle between the cachexia and non-cachexia groups at the baseline of treatment [AUC: 0.62 (95% CI: 0.36, 0.85)], but the difference between the two groups began to appear after 6 months treatment [AUC: 0.73 (95% CI: 0.51, 0.93)]. Differences in subcutaneous adipose tissue and visceral adipose tissue between cachexia [AUC: 0.83 (95% CI: 0.63, 0.97) and 0.72 (95% CI: 0.51, 0.91)] and non-cachexia groups [AUC: 0.69 (95% CI: 0.45, 0.88) and 0.70 (95% CI: 0.49, 0.88)] were present at the start of treatment and persisted 6 months later.

CONCLUSION

s For the NSCLC patients with CAC, adipose tissue changes earlier than muscle tissue, the radiomics is expected to be an effective means for early diagnosis of CAC.

CLINICAL RELEVANCE/APPLICATION

Immediate diagnosis of occult CAC by radiomics enables early intervention to slow cancer progression.

M5A-SPMK-3 AI-Detection and Auto-Reporting of Trochlear Groove Anatomic Landmarks

Participants
Justine Lee, (*Presenter*) Nothing to Disclose

PURPOSE

Total knee arthroplasty is a widely implemented, effective means applied towards the treatment of advanced osteoarthritis. One of the most frequent complications, however, lies in relation to the patellofemoral compartment which remains poorly characterized with marked variability in alignment1. With current implant designs falling short of fully restoring normal patellofemoral anatomy2, and some even exhibiting characteristics of trochlear dysplasia3, our study aimed to utilize artificial intelligence auto-detection in computed tomography (CT) imaging to identify trochlear groove anatomy, a key determinant of patellar biomechanics.

METHODS AND MATERIALS

This IRB-approved retrospective study is a collaboration between two medical institutions. A database of 219 CT scans of the knee was constructed with healthy subjects 18-40 years, excluding significant pathology such as trauma, infection, or arthroplasty. Axial CT images with bony reconstructions of the trochlear trough were reviewed by radiology and orthopedic residents, in which seven key anatomic points of the distal femur were defined (three points along the anterior femoral trochlea at the medial, central trough, and lateral aspects; two points along the most peripheral medial and lateral epicondyles; and two points at the most posterior medial and lateral condyles), in accordance with prior morphometric studies of the distal femur4. These points were subsequently labeled on a web-based viewer, with annotated images used in the creation, training, and validation of our deep learning (DL) model —a ResNet50 model pre-trained on RadImageNet5, a large multimodality radiologic dataset. These seven anatomic landmarks were auto-detected by our DL model, with mean absolute error (MAE) reported in the assessment of model performance.

RESULTS

Our RadImageNet pre-trained ResNet50 model utilized annotated CT axial images and modified the top layers to output a (14x1) vector containing predicted x and y coordinates of the seven anatomic landmarks. Within the testing dataset, the DL model achieved a MAE of 1.5 mm, successfully identifying the seven key points of the distal femur and trochlear groove as demarcated by the residents.

CONCLUSION

s Our ResNet50 model successfully achieved our primary aim of identifying seven key landmarks of the femur and trochlear groove, derived morphometric parameters of clinical interest, and auto-generated radiologic measurements targeted for clinical orthopedic use.

CLINICAL RELEVANCE/APPLICATION

This AI-based tool demonstrates value in characterizing patellofemoral anatomy, streamlining preoperative imaging measurements, and optimizing orthopedic planning of patient-specific implant selection, implant positioning, and surgical approach.

M5A-SPMK-4 Automated Machine Learning (AutoML) for MSK Radiograph Abnormality Detection: Feasibility Study of Six Codeless Platforms

Participants
Paul Yi, MD, Baltimore, MD (*Presenter*) Consultant, FH Orthopedics SAS;Consultant, BunkerHill Health

PURPOSE

Coding expertise can be a barrier for radiologists who want to apply deep learning (DL) to musculoskeletal imaging. Automated machine learning (AutoML) platforms that allow for the codeless development of DL models could bridge this gap. We evaluated the feasibility of six AutoML platforms for the development of DL models to identify radiographic abnormalities on musculoskeletal radiographs.

METHODS AND MATERIALS

We used 40,561 upper extremity radiographs from Stanford's MURA dataset labeled as abnormal or normal by board-certified radiologists. These images were split into 80/20% train/validation datasets. We evaluated 6 AutoML platforms (Amazon, Apple, Clarifai, Google, Microsoft, MedicMind) for 1) feasibility of training a functioning DL model without the need for writing code and with a cost per model <$100, and 2) performance of the DL model for identification of radiographic abnormalities as measured by F1 scores (the only metric common to all 6 platforms).

RESULTS

(1) Feasibility: All successfully trained DL models were developed using free tiers of the platforms (i.e., no cost) but only 2 of 6

(I) Feasibility: All successfully trained DL models were developed using free tiers of the platforms (i.e., no cost) but only 2 of 6 platforms allowed for truly codeless DL model development and testing (Apple and MedicMind). Three platforms required some form of coding to train and test the models (Amazon, Google, and Microsoft). One platform (Clarifai) did not successfully train a functioning model - this platform consistently crashed during model development despite numerous attempts.(II) Performance: Diagnostic performance varied between AutoML platforms and the upper extremity region analyzed, ranging from F1 0.25 to 0.99. Stratified by anatomic region, AutoML models performed best analyzing the humerus and worst in the elbow. Google and Microsoft achieved F1 scores >0.90 and >0.85, respectively, in every extremity region. The two truly codeless DL models (Apple and MedicMind) had the lowest F1 scores of the group.

CONCLUSION

s Although advertised as codeless methods to easily develop DL models, only 2 of 6 AutoML platforms allowed for truly codeless development of DL models for extremity radiograph abnormality detection. Nevertheless, some of these platforms did result in high-performing models with F1 scores as high as 0.99. Altogether, these findings suggest that AutoML platforms have promise to democratize DL for radiologists who do not have coding expertise, though there are areas for improving their useability and performance.

CLINICAL RELEVANCE/APPLICATION

AutoML has promise to democratize deep learning for radiologists who do not have coding expertise, albeit with areas for improvement.

Daniel Liu, (*Presenter*) Nothing to Disclose

PURPOSE

Body CT scans are frequently acquired for many targeted indications, but potentially valuable additional biometric information often remains untapped. AI-based algorithms can automate CT-based body composition measures, which can be utilized for opportunistic screening. The purpose of this study was to assess automated CT imaging biomarkers in patients who went on to hip fracture, compared with controls.

METHODS AND MATERIALS

In this retrospective case-control study, 6926 total patients underwent initial abdominal CT over a 20-year interval at one institution, including 1308 patients (mean age at initial CT, 70.5±12.0 years; 64.4% female) who went on to hip fracture (mean time to fracture, 4.5 years) and 5618 controls (mean age, 70.25±12.0 years; 61.2% female; mean follow-up interval, 5.2 years). Validated and fully automated quantitative CT algorithms for trabecular bone attenuation (at L1), muscle attenuation (at L3), and abdominal fat area (at L1) were applied to all scans. Univariate and multivariate hazard ratios (HRs) comparing worst quartile to the other three and area under the receiver operating characteristic (AUROC) curve analyses were performed.

RESULTS

Hip fracture HRs (with 95% CI) for low trabecular bone HU, low muscle HU, and low subcutaneous adipose tissue (SAT) area were 2.09 (1.86-2.35), 1.36 (1.20-1.54), and 1.68 (1.50-1.89), respectively. Similarly, 10-year AUROC values for predicting hip fracture were 0.702, 0.603, and 0.594, respectively. Multivariate combinations of these CT biomarkers further improved the predictive value. Notably, the 10-year AUROC from combining bone, muscle, and SAT was 0.729, while combining just muscle attenuation and SAT area was 0.679.

CONCLUSION

s Automated abdominal CT-based measures of bone, muscle, and subcutaneous fat provide useful risk stratification for future hip fractures. Opportunistic use of these automated CT-based measures can identify patients at higher risk, regardless of the indication for CT imaging.

CLINICAL RELEVANCE/APPLICATION

There is growing interest in leveraging opportunistic CT data for patient benefit, and automated AI-based algorithms provide a feasible pathway for this.

M5A-SPMK-2

Can Radiomics Diagnose Cancer-associated Cachexia At An Early Stage?

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - MK DPS

Participants
Yufei Zhao, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

As one of the most common complications of non-small-cell lung cancer (NSCLC), cancer-associated cachexia (CAC) frequently present with progressive skeletal muscle and adipose tissue wasting. However, as obesity, edema, pleural and ascites fluid, tumor weight and other factors can mask the diagnosis of CAC. Radiomics is expected to be an important research and clinical tool to accurate diagnosis CAC in early stage.

METHODS AND MATERIALS

A total of 93 NSCLC patients were enrolled, abdominal and pelvic CT (Siemens SOMATOM Sensation Scanner 64 Computed Tomography) scans were collected from all patients at first diagnosis and 6 months after treatment. The complete psoas major on both sides is automatically segmented by the FCN network. Taking the starting and ending plane of the psoas major as a reference, Extraction of the subcutaneous fat(-190 HU — -30 HU) and visceral fat (-150 HU — -50HU) by threshold. The difference in the volume of the psoas muscle between the two scans was calculated, if the volume decreased by more than 3%, it was classified as a cachexia group, otherwise as non-cachexia group. All above processes were implemented with FeAture Explorer Pro (FAEPro, V 0.4.2) on Python (3.7.6), extracting features of all volume of interest separately included first order statistics, shape-based, wavelet transform, squaregray-level co-occurrence matrix and selecting 65 cases as the training data set, another 28 cases as the independent testing data set. we used analysis of variance (ANOVA) to select features and the support vector machine (SVM) as the classifier.

RESULTS

A total of 434 features were extracted for each case and 6 features were screened out finally. There was no difference in the psoas muscle between the cachexia and non-cachexia groups at the baseline of treatment [AUC: 0.62 (95% CI: 0.36, 0.85)], but the difference between the two groups began to appear after 6 months treatment [AUC: 0.73 (95% CI: 0.51, 0.93)]. Differences in subcutaneous adipose tissue and visceral adipose tissue between cachexia [AUC: 0.83 (95% CI: 0.63, 0.97) and 0.72 (95% CI: 0.51, 0.91)] and non-cachexia groups [AUC: 0.69 (95% CI: 0.45, 0.88) and 0.70 (95% CI: 0.49, 0.88)] were present at the start of treatment and persisted 6 months later.

CONCLUSION

s For the NSCLC patients with CAC, adipose tissue changes earlier than muscle tissue, the radiomics is expected to be an effective means for early diagnosis of CAC.

CLINICAL RELEVANCE/APPLICATION

Immediate diagnosis of occult CAC by radiomics enables early intervention to slow cancer progression.

AI-Detection and Auto-Reporting of Trochlear Groove Anatomic Landmarks

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - MK DPS

Participants
Justine Lee, (*Presenter*) Nothing to Disclose

PURPOSE

Total knee arthroplasty is a widely implemented, effective means applied towards the treatment of advanced osteoarthritis. One of the most frequent complications, however, lies in relation to the patellofemoral compartment which remains poorly characterized with marked variability in alignment1. With current implant designs falling short of fully restoring normal patellofemoral anatomy2, and some even exhibiting characteristics of trochlear dysplasia3, our study aimed to utilize artificial intelligence auto-detection in computed tomography (CT) imaging to identify trochlear groove anatomy, a key determinant of patellar biomechanics.

METHODS AND MATERIALS

This IRB-approved retrospective study is a collaboration between two medical institutions. A database of 219 CT scans of the knee was constructed with healthy subjects 18-40 years, excluding significant pathology such as trauma, infection, or arthroplasty. Axial CT images with bony reconstructions of the trochlear trough were reviewed by radiology and orthopedic residents, in which seven key anatomic points of the distal femur were defined (three points along the anterior femoral trochlea at the medial, central trough, and lateral aspects; two points along the most peripheral medial and lateral epicondyles; and two points at the most posterior medial and lateral condyles), in accordance with prior morphometric studies of the distal femur4. These points were subsequently labeled on a web-based viewer, with annotated images used in the creation, training, and validation of our deep learning (DL) model —a ResNet50 model pre-trained on RadImageNet5, a large multimodality radiologic dataset. These seven anatomic landmarks were auto-detected by our DL model, with mean absolute error (MAE) reported in the assessment of model performance.

RESULTS

Our RadImageNet pre-trained ResNet50 model utilized annotated CT axial images and modified the top layers to output a (14x1) vector containing predicted x and y coordinates of the seven anatomic landmarks. Within the testing dataset, the DL model achieved a MAE of 1.5 mm, successfully identifying the seven key points of the distal femur and trochlear groove as demarcated by the residents.

CONCLUSION

s Our ResNet50 model successfully achieved our primary aim of identifying seven key landmarks of the femur and trochlear groove, derived morphometric parameters of clinical interest, and auto-generated radiologic measurements targeted for clinical orthopedic use.

CLINICAL RELEVANCE/APPLICATION

This AI-based tool demonstrates value in characterizing patellofemoral anatomy, streamlining preoperative imaging measurements, and optimizing orthopedic planning of patient-specific implant selection, implant positioning, and surgical approach.

M5A-SPMK-4

Automated Machine Learning (AutoML) for MSK Radiograph Abnormality Detection: Feasibility Study of Six Codeless Platforms

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - MK DPS

Participants
Paul Yi, MD, Baltimore, MD (*Presenter*) Consultant, FH Orthopedics SAS;Consultant, BunkerHill Health

PURPOSE

Coding expertise can be a barrier for radiologists who want to apply deep learning (DL) to musculoskeletal imaging. Automated machine learning (AutoML) platforms that allow for the codeless development of DL models could bridge this gap. We evaluated the feasibility of six AutoML platforms for the development of DL models to identify radiographic abnormalities on musculoskeletal radiographs.

METHODS AND MATERIALS

We used 40,561 upper extremity radiographs from Stanford's MURA dataset labeled as abnormal or normal by board-certified radiologists. These images were split into 80/20% train/validation datasets. We evaluated 6 AutoML platforms (Amazon, Apple, Clarifai, Google, Microsoft, MedicMind) for 1) feasibility of training a functioning DL model without the need for writing code and with a cost per model <$100, and 2) performance of the DL model for identification of radiographic abnormalities as measured by F1 scores (the only metric common to all 6 platforms).

RESULTS

(I) Feasibility: All successfully trained DL models were developed using free tiers of the platforms (i.e., no cost) but only 2 of 6 platforms allowed for truly codeless DL model development and testing (Apple and MedicMind). Three platforms required some form of coding to train and test the models (Amazon, Google, and Microsoft). One platform (Clarifai) did not successfully train a functioning model - this platform consistently crashed during model development despite numerous attempts.(II) Performance: Diagnostic performance varied between AutoML platforms and the upper extremity region analyzed, ranging from F1 0.25 to 0.99. Stratified by anatomic region, AutoML models performed best analyzing the humerus and worst in the elbow. Google and Microsoft achieved F1 scores >0.90 and >0.85, respectively, in every extremity region. The two truly codeless DL models (Apple and MedicMind) had the lowest F1 scores of the group.

CONCLUSION

s Although advertised as codeless methods to easily develop DL models, only 2 of 6 AutoML platforms allowed for truly codeless development of DL models for extremity radiograph abnormality detection. Nevertheless, some of these platforms did result in high-performing models with F1 scores as high as 0.99. Altogether, these findings suggest that AutoML platforms have promise to democratize DL for radiologists who do not have coding expertise, though there are areas for improving their useability and performance.

CLINICAL RELEVANCE/APPLICATION

AutoML has promise to democratize deep learning for radiologists who do not have coding expertise, albeit with areas for improvement.

M5A-SPNMMI-1 Role of68Ga-DOTATOC PET for Pre-operative Prediction of DAXX/ATRX Loss of Expression and Histopathological Characteristics of Pancreatic Neuroendocrine Tumors

Participants
Paola Mapelli, Milan, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the role of 68Ga-DOTATOC PET parameters in predicting PanNET characteristics of aggressiveness before surgery.

METHODS AND MATERIALS

Retrospective study including 42 patients with well-differentiated PanNET (15 females, 27 males, median age: 60 years, range: 32-80) who underwent to 68Ga-DOTATOC PET for staging purpose.SUVmax, SUV mean, somatostatin receptor density (SRD) and total lesion somatostatin receptor density (TLSRD) were extracted from primary PanNET and radiological diameter (RD) was measured for each primary PanNET. Appropriate statistical analysis (see results) investigated the ability of imaging parameters predicting DAXX/ATRX loss of expression (LoE), infiltrative growth, microvascular invasion, perineural invasion, lymph node (LN) involvement, grade and presence of liver metastases.

RESULTS

Fourteen/42 PanNET patients had DAXX/ATRX LoE and 28/42 maintained the expression.Mann-Whitney U test: SUVmean predicted perineural invasion (p=0.049) and grade (p=0.048) and RD infiltrative growth (p=0.007), DAXX/ATRX LoE (p=0.014) and presence of liver metastases (p=0.005). SRD and TLSRD correlated with Ki67 (p=0.047 and 0.028, respectively). Univariate logistic regression: SUVmax predicted LN involvement (p=0.045), SRD and TLSRD predicted DAXX/ATRX LoE (p= 0.044 and 0.0497, respectively) and presence of liver metastases (p=0.0314 and p=0.0299, respectively); RD predicted DAXX/ATRXX LoE (p=0.00614), infiltrative growth (p=0.033) and presence of liver metastases (p=0.0049). ROC curve analysis: SUVmax and SUVmean predicted perineural invasion (AUC 0.672,95%CI 0.50-0.82 and AUC 0.686, 95%CI 0.50-0.86, respectively).SUVmax was predictive of LN metastases (AUC 0.689, 95%CI: 0.52-0.84) and SUVmean of grade (AUC 0.682, 95%CI: 0.50-0.84).RD showed a role in predicting DAXX/ATRX LoE, infiltrative growth and liver metastases, with AUC of 0.735 (95%CI 0.54-0.89), 0.789 (95% CI 0.63-0.92) and 0.789 (95% CI 0.61-0.95), respectively.

CONCLUSION

s 68Ga-DOTATOC PET parameters showed predictive value in assessing DAXX/ATRX LoE and clinicopathological features of PanNET aggressiveness, thus providing additional information on PanNET behaviour in the preoperative setting.

CLINICAL RELEVANCE/APPLICATION

68Ga-DOTATOC PET parameters provide additional information on PanNET behaviour in the preoperative setting, thus improving tumour characterization.

M5A-SPNMMI-2 Prognostic Value of18F-FDG-PET/CT Radiomics Combined with Sarcopenia Status among Patients with Advanced Gastroesophageal Cancer

Participants
Ricarda Hinzpeter, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To investigate, whether 18F-FDG-PET/CT- derived radiomics combined with sarcopenia measurements improves survival prognostication among patients with advanced, metastatic gastroesophageal cancer.

METHODS AND MATERIALS

In this IRB-approved retrospective study, we included 128 consecutive patients with advanced, metastatic gastroesophageal cancer (n=128; 26 females; 102 males; mean age 63.5±11.7 years; age range: 29-91 years) undergoing 18F-FDG-PET/CT for

staging between November 2008 and December 2019. Segmentation of the primary tumor and radiomics analysis derived from PET and CT images was performed semi-automatically with a commonly used open-source software platform (LIFEX, Version 6.30, lifexsoft.org). Patients' nutritional status was determined by measuring the skeletal muscle index (SMI) at the level of L3 on the CT component. Univariable and multivariable analyses were performed to establish a survival prediction model including radiomics, clinical data, and SMI score.

RESULTS

In a univariable Cox proportional hazards model, ECOG (<0.001) and distant metastasis to the bone (p=0,028) were significant clinical parameters for overall survival (OS) and progression free survival (PFS). Age (p=0.017) was an additional prognostic factor for OS. The multivariable analysis revealed improved overall survival prognostication when adding sarcopenic status, PET and CT radiomics to the model with clinical parameter only over a clinical course of 6 to 36 months (AUC 0.67 vs. 0.82 at 15 months). Similarly, adding sarcopenia measurements, PET and CT radiomics improved the model fit for PFS (AUC 0.65 vs. 0.82 at 12 months).

CONCLUSION

s PET and CT radiomics derived from 18F-FDG-PET/CT combined with sarcopenia measurements and clinical parameters may improve survival prediction among patients with advanced, metastatic gastroesophageal cancer.

CLINICAL RELEVANCE/APPLICATION

Increasing knowledge of outcome prognostication, derived from quantitative radiomics features, has the potential for pretreatment risk stratification, allowing clinicians to deliver more patient specific treatment tailored to individual risk.

M5A-SPNMMI-3 Feasibility of in Vivo MRI Imaging of Human Placental Mesenchymal Stem Cells Labeled With Ultramicro And < Superparamagnetic Iron Oxide Nanoparticles for Targeting Colorectal Cancer

Participants
Hua He, MMedSc, MMedSc, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To transplant human placenta-zoned mesenchymal stem cells (PMSCs) labeled with USPIO-PLL protein complex into nude mice model of implanted tumor, and to explore the feasibility of in vivo MRI imaging of PMSCs.

METHODS AND MATERIALS

Nude mice were inoculated with human colon cancer cells (HT-29), and then transplanted and passaged between mice to establish a human colon cancer transplanted tumor model in nude mice. The PLL-USPIO-labeled hPMSCs at a concentration of 10 μg/ml were prepared and transplanted into the experimental group colorectal cancer animal model through the tail vein of the rat; T2WI, T2mapping and T2*mapping sequences were used to perform 3.0T magnetic resonance imaging before the injection of hPMSCs, 1, 3, 7, 10, 14 days after the injection of PMSCs, the MRI signal and tumor image changes of labeled hPMSCs in transplanted mice were dynamically observed, and the SNR, CNR and contrast (C value) of tumor tissues in each sequence were analyzed. Tumor specimens were stained with Prussian blue.

RESULTS

The morphological and functional properties of the transplanted tumor are basically similar to the primary tumor, and the transplant success rate of the transplanted tumor is 100%, the USPIO labeled hPMSCs showed low signal in all 10 nude mouse models, the image contrast of tumor T2*mapping sequence is greater than that of T2WI and T2 mapping sequence, and the display of USPIO-labeled cells is more obvious. Prussian blue staining was performed on the specimens of the experimental group: blue iron particles could be seen in the red tumor tissue.

CONCLUSION

s It is confirmed that the nude mouse model of human colon cancer can be used for MRI in vivo imaging and the T2*mapping value of the tissue can be used as a quantitative index for analysis.

CLINICAL RELEVANCE/APPLICATION

Provide basic research data for the targeted therapy of placental mesenchymal stem cells in colorectal cancer.

M5A-SPNPM-1 Diagnostic Accuracy of an Artificial Intelligence Software in Detecting Incidental Pulmonary Embolism

Participants
Madison Adams, MPH, Avon, CT (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to assess the diagnostic accuracy of an artificial intelligence-based decision support software in identifying incidental pulmonary emboli (IPE) on CT examinations of the chest and abdomen.

METHODS AND MATERIALS

This retrospective study reviewed all consecutive CT chest and CT abdomen and pelvis examinations ordered without a dedicated CT pulmonary angiogram (CTPA) protocol at one institution between September 20, 2021 and March 31, 2022. Triage and notification screening results of the IPE Module by Aidoc Medical were obtained for these non-angiographic CT examinations, indicating the presence or absence of IPE. The subsequent attending radiologists' interpretations for each of these studies were reviewed for the presence or absence of IPE, IPE laterality and location, and study indication. Sensitivity and specificity of the AI software were calculated, and descriptive statistics were used to further characterize the dataset.

RESULTS

2,651 CT examinations were analyzed within the study period, including 378 (14%) CTs of the chest and 2,273 (86%) CT scans of the abdomen and pelvis. There were 20 total IPEs (0.7%) identified by the AI software, 40% of which had concordant radiologist interpretations. There were 4 scans (0.1%) with IPEs identified by radiologists that were not detected by the AI software, including 2 scans with multiple, bilateral emboli. The software had a specificity of 0.9954 (95%CI 0.9953-0.9955) and sensitivity of 0.66 (95%CI 0.65-0.67). The 4 false-negative readings reported by the AI module were examinations ordered emergently for specific indications, including suspected aortic dissection, mesenteric ischemia, and intra-abdominal abscess.

CONCLUSION

s Preliminary data from this institution demonstrate the AI screening software had a high specificity but low sensitivity when detecting IPEs. Higher sensitivity would be ideal when detecting incidental findings, especially when the AI-undetected IPEs in this study were identified on examinations ordered for specific clinical indications, and the radiologist may be less likely to anticipate PE in these scenarios. These results support AI modules currently serve as a reinforcement rather than a replacement for radiologists, improving quality control, and peer-review initiatives.

CLINICAL RELEVANCE/APPLICATION

Our data demonstrated increasing the sensitivity of the current IPE AI module would enhance the reliability of this product in triaging patients, notifying physicians, and initiating treatment.

M5A-SPNPM-2 Reporting of Participant Demographics in Articles Published in General Radiology Journals from 2013 to 2021

Participants
Marlee Parsons, MSc, MD, Montreal, QC (*Presenter*) Nothing to Disclose

PURPOSE

Reporting research participant demographics provides insight into representativeness. No previous study has assessed how demographics are reported in radiology research. We sought (1) to determine how frequently participant age, sex and/or gender, race and/or ethnicity, and socio-economic status (SES) are reported and analyzed in randomized clinical trials (RCT) or secondary analyses of RCT published in radiology journals and (2) to evaluate associations between demographics reporting and study characteristics.

METHODS AND MATERIALS

Articles presenting RCT and secondary analyses of RCT in human subjects published in the journals Academic Radiology, American Journal of Roentgenology, British Journal of Radiology, European Journal of Radiology, European Radiology, and Radiology between

2013 and 2021 identified on PubMed were included. The continent of the first and senior author, publication year, study design (RCT/secondary analysis, prospective/retrospective), funding status, subspecialty, topic, reporting of age, sex/gender, race/ethnicity, and SES, and analysis of results according to demographics were extracted. Journal impact factors were obtained from the Journal Citation Reports. Associations between the reporting of demographics and study characteristics were analyzed using chi-squared and Mann-Whitney U test for categorical and continuous variables, respectively.

RESULTS

401 articles were included. Of those, 89% (355) reported age, 89% (358) sex/gender, 6% (23) race/ethnicity, and 3% (12) SES. Amongst articles that reported these demographics and were not specific to a population subgroup, results were analyzed by age in 14% (14/355), sex/gender in 18% (57/313), race/ethnicity in 9% (2/22), and SES in 33% (4/12). Age and sex/gender reporting was associated with first and last author continent, journal, impact factor, study design, and topic. Race/ethnicity and SES reporting was associated with first and last author continent, journal, impact factor, and funding status.

CONCLUSION

s Participant age and sex/gender are frequently reported whereas race/ethnicity and SES are rarely reported in radiology research. It remains uncertain whether the current reporting practices are optimal.

CLINICAL RELEVANCE/APPLICATION

Participant race/ethnicity and SES are rarely reported in radiology research, yet they can help inform generalizability. A consensus amongst our research community on when and how to report these demographics is needed.

M5A-SPNPM-3 Pathway to the C-Suite: A Tristate Analysis of Radiology Representation in Academic Hospital Administration

Participants

PURPOSE

To investigate the representation of radiologists within academic hospital leadership in New York, New Jersey, and Connecticut Tristate area compared to other subspecialties. Long-term, we hope this will lead to comparisons of graduate medical education (GME) to identify areas that can be modified or augmented in radiology training to encourage further representation in hospital leadership.

METHODS AND MATERIALS

New York, New Jersey, and Connecticut Hospitals were selected from the DOH Health Profiles website. Teaching hospitals (medical school and resident education). Physician credentials including medical school training, residency training, specialty, as well healthcare leadership roles were determined utilizing various publicly available databases and analyzed and categorized as demonstrated. Leadership designations/titles included CEO, CMO, CQO, CFO Physician-in-Chief, Chief-of-Staff. Given the arbitrary, non-standardized designation of leadership roles, a qualitative and limited quantitative approach was used to determine the factors associated with physician representation in institutional leadership.

RESULTS

Of the 196 hospitals sampled, 282 physicians were identified as leaders in academic medical institutions or their respective healthcare systems. Median years experience post-residency was 29.5 yrs. Most common additional degree was MBA, followed by MPH, MHCM.Primary Care: Total in Tristate workforce: 38.21%; Total in Academic Leadership: 37.94%Surgery/Surgical Sub-specialties: Total in Tristate workforce: 15.57%; Total in Academic Leadership: 16.31%Additional medical subspecialties: Total in Tristate workforce: 42.49%; Total in Academic Leadership: 43.61%Radiology: Total in Tristate workforce: 3.71%; Total in Academic Leadership: 2.13 %

CONCLUSION

s In the NY/NJ/CT tristate area, radiologists represent a small fraction of the physician workforce (3.71%) and a significantly smaller portion of academic hospital leadership (2.13%) as opposed to their primary care, surgical, and other subspecialist counterparts. When juxtaposed to primary care, surgical, and other subspecialty counterparts, there is a clear deficit in representation.

CLINICAL RELEVANCE/APPLICATION

These findings suggest that there is a significant opportunity for the field of radiology to focus on developing and training radiologists who can ascend to executive leadership positions within institutions. This is important because imaging is at the core of patient care and without adequate radiology hospital leadership representation, it may be more difficult to effectively advocate for high-quality imaging or adequate access to imaging modalities that could significantly impact patient outcomes.

Diagnostic Accuracy of an Artificial Intelligence Software in Detecting Incidental Pulmonary Embolism

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NPM DPS

Participants
Madison Adams, MPH, Avon, CT (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to assess the diagnostic accuracy of an artificial intelligence-based decision support software in identifying incidental pulmonary emboli (IPE) on CT examinations of the chest and abdomen.

METHODS AND MATERIALS

This retrospective study reviewed all consecutive CT chest and CT abdomen and pelvis examinations ordered without a dedicated CT pulmonary angiogram (CTPA) protocol at one institution between September 20, 2021 and March 31, 2022. Triage and notification screening results of the IPE Module by Aidoc Medical were obtained for these non-angiographic CT examinations, indicating the presence or absence of IPE. The subsequent attending radiologists' interpretations for each of these studies were reviewed for the presence or absence of IPE, IPE laterality and location, and study indication. Sensitivity and specificity of the AI software were calculated, and descriptive statistics were used to further characterize the dataset.

RESULTS

2,651 CT examinations were analyzed within the study period, including 378 (14%) CTs of the chest and 2,273 (86%) CT scans of the abdomen and pelvis. There were 20 total IPEs (0.7%) identified by the AI software, 40% of which had concordant radiologist interpretations. There were 4 scans (0.1%) with IPEs identified by radiologists that were not detected by the AI software, including 2 scans with multiple, bilateral emboli. The software had a specificity of 0.9954 (95%CI 0.9953-0.9955) and sensitivity of 0.66 (95%CI 0.65-0.67). The 4 false-negative readings reported by the AI module were examinations ordered emergently for specific indications, including suspected aortic dissection, mesenteric ischemia, and intra-abdominal abscess.

CONCLUSION

s Preliminary data from this institution demonstrate the AI screening software had a high specificity but low sensitivity when detecting IPEs. Higher sensitivity would be ideal when detecting incidental findings, especially when the AI-undetected IPEs in this study were identified on examinations ordered for specific clinical indications, and the radiologist may be less likely to anticipate PE in these scenarios. These results support AI modules currently serve as a reinforcement rather than a replacement for radiologists, improving quality control, and peer-review initiatives.

CLINICAL RELEVANCE/APPLICATION

Our data demonstrated increasing the sensitivity of the current IPE AI module would enhance the reliability of this product in triaging patients, notifying physicians, and initiating treatment.

M5A-SPNPM-2

Reporting of Participant Demographics in Articles Published in General Radiology Journals from 2013 to 2021

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NPM DPS

Participants
Marlee Parsons, MSc, MD, Montreal, QC (*Presenter*) Nothing to Disclose

PURPOSE

Reporting research participant demographics provides insight into representativeness. No previous study has assessed how demographics are reported in radiology research. We sought (1) to determine how frequently participant age, sex and/or gender, race and/or ethnicity, and socio-economic status (SES) are reported and analyzed in randomized clinical trials (RCT) or secondary analyses of RCT published in radiology journals and (2) to evaluate associations between demographics reporting and study characteristics.

METHODS AND MATERIALS

Articles presenting RCT and secondary analyses of RCT in human subjects published in the journals Academic Radiology, American Journal of Roentgenology, British Journal of Radiology, European Journal of Radiology, European Radiology, and Radiology between 2013 and 2021 identified on PubMed were included. The continent of the first and senior author, publication year, study design (RCT/secondary analysis, prospective/retrospective), funding status, subspecialty, topic, reporting of age, sex/gender, race/ethnicity, and SES, and analysis of results according to demographics were extracted. Journal impact factors were obtained from the Journal Citation Reports. Associations between the reporting of demographics and study characteristics were analyzed using chi-squared and Mann-Whitney U test for categorical and continuous variables, respectively.

RESULTS

401 articles were included. Of those, 89% (355) reported age, 89% (358) sex/gender, 6% (23) race/ethnicity, and 3% (12) SES. Amongst articles that reported these demographics and were not specific to a population subgroup, results were analyzed by age in 14% (14/355), sex/gender in 18% (57/313), race/ethnicity in 9% (2/22), and SES in 33% (4/12). Age and sex/gender reporting was associated with first and last author continent, journal, impact factor, study design, and topic. Race/ethnicity and SES reporting was associated with first and last author continent, journal, impact factor, and funding status.

CONCLUSION

s Participant age and sex/gender are frequently reported whereas race/ethnicity and SES are rarely reported in radiology research. It remains uncertain whether the current reporting practices are optimal.

CLINICAL RELEVANCE/APPLICATION

Participant race/ethnicity and SES are rarely reported in radiology research, yet they can help inform generalizability. A consensus amongst our research community on when and how to report these demographics is needed.

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Sub-Events

M5A-SPNR-1 Non-invasive Prediction of IDH Mutation Status in Gliomas Using Pre-operative Multi-parametric MRI Radiomics Nomogram: A Multi-center Study

Participants
Jun Lu, (*Presenter*) Nothing to Disclose

PURPOSE

Accurate identification of IDH mutation status has revolutionized our understanding of the potential for targeted therapeutics using small molecule IDH mutation inhibitors with the update of 2021 WHO classification criterion of gliomas, which might be clinically meaningful for treatment strategy and prognosis stratification of gliomas. This study aimed to establish and validate a radiomics nomogram for predicting IDH mutation status in gliomas using preoperative multiparametric MRI in a multicenter setting.

METHODS AND MATERIALS

306 gliomas patients in local institution were enrolled and randomly assigned into a training (n=214) and a test dataset (n=92). 108 patients were collected from TCGA as an independent external validation dataset. The volume of interest(VOI) was delineated manually on the map of contrast-enhanced T1-weighted (CE-T1W) and fluid attenuated inversion recovery(FLAIR). 851 radiomics features were extracted on each VOI. The features were firstly selected using Mann-Whitney U-test, followed by refining using least absolute shrinkage and selection operator (LASSO) regression combing 10-fold cross-validation. The optimal radiomics features with age and sex were processed by multivariate logistic regression to construct a prediction model, which was developed in the training dataset and assessed in the test and external validation datasets. Receiver operating characteristic(ROC), calibration curve and decision curve analysis were applied in the test and external validation datasets to evaluate the discrimination, calibration and clinical utility of prediction model.

RESULTS

Ten robust radiomics features were selected from the 1702 features(four CE-T1W and six FLAIR features). A nomogram was plotted to represent the prediction model. The accuracy and AUC of the radiomics nomogram achieved 86.96% and 0.891(0.809-0.947) and 84.26% and 0.881(0.805-0.936) in the test and external validation dataset (all $p<0.05$). The positive predictive value(PPV) and negative predictive value(NPV) were 83.72%, 87.75% and 87.81%, 82.09% in the test and external validation dataset. The Hosmer-Lemeshow test concluded that the radiomics nomogram showed goodness of fit(all $p>0.05$). Decision curve analysis demonstrated the clinical value of the radiomics nomogram.

CONCLUSION

s IDH genotypes of gliomas can be identified by preoperative multiparametric MRI radiomics nomogram and might be clinically meaningful for treatment strategy and prognosis stratification of gliomas .

CLINICAL RELEVANCE/APPLICATION

This study aimed to find imaging biomarkers for noninvasively predicting the IDH mutation status for a tailored treatment plan and prognosis stratification in glioma patients from the initial stage of the tumor diagnosis.

M5A-SPNR-10 Extent of Resection of Contrast-enhancing and Non-enhancing Tumor - Different Impacts on Survival According to Types of Adult-type Diffuse Gliomas in 2021 WHO Classification

Participants
Sung Soo Ahn, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the impact of extent of resection (EOR) of contrast-enhancing (CE) and nonenhancing (NE) tumors in the types of adult-type diffuse gliomas according to the 2021 WHO classification.

METHODS AND MATERIALS

Total 1,196 patients with adult-type diffuse gliomas diagnosed between 2001 and 2021 from a single institution were enrolled (183 patients with IDH-mutant and 1p/19q codeleted oligodendroglioma [herein oligodendroglioma], 211 patients with IDH-mutant astrocytoma, and 802 patients with IDH-wildtype glioblastoma. Multivariable Cox analyses were performed within each type to assess predictors of overall survival, including clinical, imaging data, histological grade, MGMT promoter methylation status, treatment, and EOR of CE and NE tumors. Subgroup analyses were performed in patients with CE tumor. N

RESULTS

Among 1,196 patients, 926 (77.4%) patients had CE tumors. In oligodendrogliomas, GTR of NE was not associated with survival (HR

Among 1,190 patients, 920 (77.4%) patients had CE tumors. In oligodendrogliomas, GTR of NE was not associated with survival (HR = 0.41, 95% CI 0.14-1.15, P = 0.088). In 81 (43.3%) oligodendroglioma patients with CE tumor, GTR of CE tumors was the only independent predictor of survival (HR = 0.20, 95% CI 0.05-0.85, P = 0.029) in multivariable analysis. GTR of NE and CE tumors was independently associated with better survival in IDH-mutant astrocytoma and IDH-wildtype glioblastoma (all Ps <0.05) in multivariable analyses.

CONCLUSION

s GTR of both CE and NE tumors may significantly improve survival within all types of adult-type diffuse gliomas except oligodendrogliomas. In oligodendrogliomas, the EOR of CE tumor may be crucial in survival; aggressive GTR of NE tumor may be unnecessary, whereas GTR of the CE tumor is recommended.

CLINICAL RELEVANCE/APPLICATION

This study is the first, to our knowledge, to examine the independent role of EOR in both CE and NE tumors across types in adult-type diffuse gliomas according to the 2021 WHO classification. Well-known predictors for survival such as clinical, radiological, and MGMT promoter methylation status were included in the Cox analysis, to demonstrate the independent role of EOR. Our results pave the way for rethinking surgical strategies according to types of adult-type diffuse gliomas.

M5A-SPNR-11 Application of Brain Tumour Reporting and Data System (BT-RADS) in A Large Population with High-grade Gliomas (HGG) Exhibiting Progression (PD) and Pseudo progression (PSPD) and Correlation with Survival Analysis

Participants
Ankush Jajodia, MD, MBBS, New Delhi, India (*Presenter*) Nothing to Disclose

PURPOSE

HGG accounts for approximately 60% of all primary brain tumors. BT-RADS assigns each MRI to study a score or category based on imaging findings. PsPD is an effect usually occurring in the first six months after chemoradiation (CRT), with reported incidence ranging from 2-50%. We investigated the utility of BT-RADS applications in a large population of patients with HGG with PD and PsPD.

METHODS AND MATERIALS

After institutional review board approval, a retrospective analysis was performed on 437 patients with HGG who underwent Gadolinium-enhanced MRI between 2013-and 2021. Patients were labeled as having PD or PsPD after multidisciplinary team evaluation. Typically we called pseudoprogression as progression on early scans, that stabilizes without further anti cancer therapy vs progression as continual progression. The clinical outcome (dichotomized as stable or worse) was collected from medical records. An experienced neuroradiologist did the BT-RADS category assignment. Kaplan Meier survival analysis and Chi-square test between different groups were done using MedCalc software.

RESULTS

Two hundred and thirteen patients with HGG after exclusion (Figure1) were included. PsPD (n=109) and PD (n=104) were determined in a multidisciplinary care team after evaluation of clinical information and follow-up imaging. BT-RADS category assignment between the PD and PsPD group and the final clinical outcome dichotomized group (worse and stable) was statistically significant (table). KS survival analysis of BT-RADS assignment during follow-up with the final clinical result is shown in figure 2.

CONCLUSION

s BT-RADS has a significant correlation with survival and can be an imperative tool for response assessment, especially in resource-constrained setup.

CLINICAL RELEVANCE/APPLICATION

BT-RADS implementation has the potential to increase the completeness, consistency, and comprehensibility of radiology reports in patients with glioma. This preliminary work summarizes the initial experience and emphasizes its effectiveness in a large subset of patients with HGG.

M5A-SPNR-12 Analyzing Treatment Response of Recurrent Pediatric Low-Grade Gliomas in Clinical Trials: Comparison of Volumetric and Two-Dimensional Tumor Assessment

Participants
Ryan C. Bahar, BSc, Yale School of Medicine, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

The Response Assessment in Neuro-Oncology (RANO) criteria were designed to radiologically evaluate tumor response and endpoints in clinical trials of novel treatments. These criteria estimate tumor size using the two-dimensional (2D) product of maximal perpendicular diameters on axial slices of MR images. Pediatric low-grade gliomas (pLGGs), however, are intratumorally heterogeneous with solid and cystic components. 2D measurements may therefore misevaluate pLGG tumor volume and tumor response, and ultimately affect trial outcome. This study aims to assess tumor response using volumetric assessment of recurrent and progressive pLGGs treated with everolimus. We seek to identify clinically relevant criteria that provide added value to response assessment beyond 2D measurements.

METHODS AND MATERIALS

Using multiparametric MR imaging from 44 patients in the Pediatric Neuro-Oncology Consortium (PNOC) 001 clinical trial, we performed 3D-segmentation of solid, cystic, and whole pLGGs within our PACS-framework to assess tumor response. We compared our results to those from a prior independent central imaging review which had yielded 15 (34%) patients showing progressive disease (PD), 27 (61%) stable disease (SD), 2 (5%) partial response (PR), and 0 (0%) complete response (CR).

RESULTS

8 (18%) of the 44 tumors were solid-only and 36 (82%) had a mixed solid-cystic appearance. Comparing 2D central imaging review to our volumetric tumor evaluation using the same RANO cutoff criteria, 7 (16%) cases changed from PD to SD, 3 (7%) from SD to

PD, 1 (2%) from SD to PR, and 1 (2%) from PR to SD, constituting an overall discordance in 12 (27%) cases.

CONCLUSION

s Integration of volumetrics into tumor response assessments provides additional and potentially more accurate information than strictly 2D RANO-based measurements. It is crucial to note that the above-reported changes in assessed tumor response represent numerical discrepancies as opposed to true-to-reality changes in clinical outcome. Determining representative thresholds for the deployment of volumetric measures in clinical trials will be critical. Future work will include data from the PNOC-002 clinical trial and evaluate inter-reader agreement and reader discordance.

CLINICAL RELEVANCE/APPLICATION

With the availability of PACS-based 3D tools in neuroradiology practice, well-defined volumetric criteria could be incorporated prospectively to enhance tumor response analysis in clinical trials.

M5A-SPNR-13 SMART Syndrome and Variants: From Clinical Presentation to Imaging: How to Arrive At the Diagnosis

Participants
Denver Pinto, MD, Miami, FL (*Presenter*) Nothing to Disclose

PURPOSE

SMART (Stroke-like migraine attacks after radiation therapy) syndrome is a rare clinical-radiological entity characterized by complex neurologic symptoms which may occur years following radiation therapy. The imaging features resemble a subacute infarct, hence, an incorrect diagnosis may lead to unnecessary imaging and treatment. This presentation will help the audience to identify SMART syndrome and to avoid misdiagnosis. We describe and illustrate a small series of SMART cases with the purpose of identifying the varied clinical and imaging features.

METHODS AND MATERIALS

We conducted a database search involving 3 health systems for cases of SMART syndrome and for "subacute infarcts" in patients status post radiation. We found 7 patients who could be classified as having SMART syndrome or a variant of it based on history, clinical symptoms, clinical follow-up and comparison with prior/follow-up imaging.

RESULTS

There were 5 patients with features typical of the SMART syndrome and 2 patients with atypical presentations consistent with peri-ictal pseudo-progression (PIPG). All patients had radiation therapy 1.5 years to 25 years before presentation. The most common clinical symptoms were headache (6/7) and seizures (5/7). Cranial nerve involvement (5/7), motor deficits/extremity weakness (3/7) and sensory deficits (2/7) were identified on examination. MRI findings included cortical and subcortical edema, as well as sub-arachnoid, gyriform, parenchymal and punctate contrast enhancement with elevated rCBV. Diffusion restriction in a focal or gyriform pattern was identified both in the typical presentation and in PIPG. Patients with PIPG showed more avid cortical and meningeal enhancement[RQ1] even the absence of headache (1/2). rCBV was reduced in one of our patients with PIPG. In one of our patients, the imaging changes occurred in the radiation field on the side opposite the surgery and another patient had bilateral findings. This symptom-imaging complex occurred following treatment of a wide range of benign and malignant tumors.

CONCLUSION

s SMART syndrome is a diagnostic confounder that can have undesirable downstream effects if misdiagnosed. MRI findings such as gyriform diffusion restriction, cortical and vasogenic edema as well as cortical or meningeal enhancement in a non-vascular distribution in concert with the clinical information such as the location and time since radiation delivery helps suggest the proper diagnosis.

CLINICAL RELEVANCE/APPLICATION

Decisions relative to continuing or withholding anti-neoplastic therapy may depend on recognizing this entity. Also a confident diagnosis will prevent extensive and unnecessary stroke or seizure work up because the imaging features may resemble either of these conditions.

M5A-SPNR-14 Vascular Habitats analysis Based on Preoperative Dynamic Susceptibility-weighted Contrast Perfusion MRI Predicts Recurrence Pattern in High-grade Gliomas

Participants
Hanwei Wang, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate if vascular habitats analysis based on preoperative dynamic susceptibility-weighted contrast perfusion MRI predicts recurrence pattern in high-grade gliomas (WHO grade 3-4, HGG).

METHODS AND MATERIALS

In this single-center, retrospective study, we included adults with HGG, who received chemoradiotherapy and were diagnosed with recurrence based on RANO criteria or resurgical pathology. A neurosurgeon and a neuroradiologist based on preoperative and follow-up MRI images of patients, classified recurrence patterns into local recurrence (LR) and non-local recurrence (NLR). The LR was further divided into intra-surgical cavity recurrence (ICR) and extra-surgical cavity recurrence (ECR). Kaplan-meier curves were used to analyze the PFS and OS of patients with LR and NLR, ICR recurrence and ECR. And log-rank test was used to compare the differences in patient survival. Based on ONCOhabitats platform (https://www.oncohabitats.upv.es) hemodynamic tissue signature (HTS) method automatic segmentation of vascular habitats, evaluate each vascular habitats in the 95th percentile rCBV, rCBF value. Univariate and multivariate logistic regression analysis were used to evaluate the correlation between vascular habitats parameters and recurrence patterns, and to determine the predictors. The prediction efficiency of relevant factors were computed by receiver operating characteristics curve (ROC) and the area under curve (AUC).

RESULTS

77 HGG were included in this study, of which 60 (77.92%) with LR and 17 (22.08%) with NLR. The LR was divided into ICR (30,

38.96%) and ECR (30, 38.96%). PFS and OS were longer in the LR than in the NLR (p<0.05). There was no significant difference in PFS and OS between ICR and ECR (p>0.05). In univariate logistic regression analysis, rCBVp95 at LAT (OR=2.084 ,95%CI=1.198-3.626), rCBVp95 at IPE (OR=2.840 ,95%CI=1.213-6.648), rCBVp95 at VPE (OR=3.598 ,95%CI=1.256-10.308) and rCBFp95 at VPE (OR=3.793 ,95%CI=1.172-12.270) correlated with ECR. Multivariate logistic regression analysis revealed rCBVp95 at LAT could be used as a predictor of ECR (OR=2.317,95%CI:1.264-4.246,p=0.007). ROC curve showed that the prediction efficiency is good (AUC=0.743,95%CI=0.614-0.847).

CONCLUSION

s Preoperative vascular habitats parameters can be used as noninvasive imaging markers to predict ECR, and provide reference for the management and treatment of HGG.

CLINICAL RELEVANCE/APPLICATION

Preoperative vascular habitats parameters can be used as noninvasive imaging markers to predict extra-surgical cavity recurrence, and provide reference for the management and treatment of high-grade gliomas.

M5A-SPNR-15 Neuroimaging Findings in Patients with Immune Effector Cell-associated Neurotoxicity Syndrome after CAR-T-cell Therapy

Participants
Burak Akkurt, MD, Muenster, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Chimeric antigen receptor T-cell therapy (CART) is a new immunomodulating therapy of relapsed/refractory hematological malignancies, capable of inducing an immune response against tumor cells.CART often comes with relevant organ toxicities, one of which is referred to as immune effector cell-associated neurotoxicity syndrome (ICANS). Symptoms of ICANS are heterogenous and include headache, confusion and encephalopathy.In this study we evaluated ICANS associated neuroimaging findings in cerebral magnetic resonance imaging (cMRI).

METHODS AND MATERIALS

We reviewed all patients, who received CART infusion at our university hospital between 12/2018 and 09/2021. From the initial 32 patients, 11 received cerebral imaging due to suspected or diagnosed ICANS within a follow-up time of up to 30 days after infusion.Of these 11 patients, 2 presented with ICANS grade I, 5 with ICANS grade 2, and 4 with ICANS grade 3.The routine cMRI images of patients were reviewed by two neuroradiologists with an experience of 3 and 9 years. We correlated the imaging findings with the clinical grading according to ICANS.

RESULTS

We observed FLAIR hyperintense signal alterations in most cases with pericallosal involvement (5/11, 45 %). Furthermore, we noticed FLAIR hyperintense signal changes in the forceps minor in 5 out of 11 patients (45 %). Other locations of FLAIR alterations were noticed in the capsula interna, foliae cerebelli, thalami, as well as temporal and subinsular regions (each in 1 case). We correlated the imaging findings with the clinical grading of the ICANS. According to literature, only ICANS grade =3 shows changes on MRI. However, in our cohort we observed white matter changes in all of our patients with ICANS grades =2 .

CONCLUSION

s ICANS may show subtle changes on cMRI, with FLAIR hyperintense white matter changes being the most prevalent ones.In our cohort, we found signal alterations in all patients graded ICANS =2.Our findings suggest FLAIR hyperintense signal changes in the forceps minor as a possible specific sign of neurotoxicity after CART, but further prospective evaluation with a larger cohort should be aimed at for confirmation.

CLINICAL RELEVANCE/APPLICATION

ICANS is one of the major toxicities associated with CAR-T-cell therapy and neuroimaging can help identifying ICANS and should be evaluated in suspected cases.

M5A-SPNR-16 Magnetic Resonance Imaging and Amino Acid Positron Emission Tomography in Differentiating Tumor Recurrence from Radiation Necrosis in High Grade Gliomas.

Participants
Antariksh Vijan, MBBS, Mumbai, India (*Presenter*) Nothing to Disclose

PURPOSE

Differentiating tumor recurrence (TR) from radiation necrosis (RN) in high-grade glioma (HGG) following radiotherapy can be challenging. The ability of conventional magnetic resonance imaging (MRI) to differentiate TR from post-therapeutic effects is often limited. Multiparametric advanced MRI (perfusion) and positron emission tomography (PET) with amino acid tracers, specifically 18F-Fluoroethyl-Tyrosine (FET) can provide relevant additional information on tumor metabolism, which allows for a more accurate diagnosis to differentiate tumor recurrence from radiation necrosis in HGG.

METHODS AND MATERIALS

Retrospective analysis of 69 lesions in 69 patients with HGG who underwent both MRI and FET-PET imaging within three weeks intervals was done independently by a neuroradiologist and nuclear medicine physician. The study was conducted in the department of radiodiagnosis in a tertiary care oncology center between July 2018 and August 2021. Manually segmented regions of interest were placed over the areas of maximum enhancement/suspicion on MRI and FET uptake, which were used to calculate the rCBV and tumor to white-matter ratios, respectively. Definitive diagnosis (TR versus RN) was made on clinico-radiological follow-up or histopathological report (wherever available).

RESULTS

Out of the 69 lesions that were studied, 52 and 13 had TR and RN, respectively. 4 cases were excluded from the study as they were lost to follow-up. The rCBVmean (mean relative CBV) and mean target-to-background ratios showed an accuracy of 94% and 80% for MRI and FET-PET respectively in the detection of recurrent lesions. The sensitivity and specificity for determination of TR

in HGG with conventional MRI were 98% and 77% respectively, while with FET-PET it was 79% and 85% respectively. A combination of MRI and PET parameters (mean target-to-background ratio), demonstrated an increase in diagnostic accuracy to 98%. A rCBVmax cutoff > 1.48 had a positive predictive value for recurrence of 97.92%. The sensitivity and specificity of rCBV values for determination of TR in treated cases of HGG were 90.38% and 87.50% respectively.

CONCLUSION

s Cumulative imaging with MRI and FET-PET offers a multiparametric assessment of glioma recurrence that is correlative and complimentary, with higher accuracy and clinical value.

CLINICAL RELEVANCE/APPLICATION

This study analyses the individual and combined diagnostic performance of MR and amino acid PET to distinguish recurrence from radiation necrosis in treated cases of gliomas.

M5A-SPNR-17 Critical Information Provided by PACS Based Peritumoral Edema Volumetrics in Assessment of Lung Cancer Brain Metastases after Gamma Knife Therapy

Participants
Manpreet Kaur, BSc, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

Gamma Knife (GK) has become standard of care to locally treat BM, however there is insufficient understanding of the natural posttreatment volumetric changes of peritumoral edema of BM due to paucity of tools for volumetric segmentation in neuroradiology practice. Recently PACS-integrated tools have become available in select clinical practices therefore we aimed to compare volumetric response curves of peritumoral edema to response curves of RANO-BM based measurements.

METHODS AND MATERIALS

Patients with NSCLC BM with longest diameter greater or equal to 10mm on CE-T1WI that were treated with GK were included. Volumetric measurements were performed for up to 7 follow-up studies using a PACS-integrated tool that segments the FLAIR hyperintense volume surrounding the CE lesion. The 2D and volumetric measurements were analyzed using Prism9 and clinical information including steroid timing were incorporated in the assessment.

RESULTS

41 NSCLC BM were included (59±10 years, 20 pts). The median pretreatment metastasis volume was 8.52cm3 (IQR 1.01-47.03cm3). A significant decrease was measured at 0-90 days post-GK (median 1.16cm3, IQR 0.51-6.12cm3). The time of peak median peritumoral volume increase was after 365 days post-GK (median 1.42cm3, IQR 0.37-8.12cm3). There was a significant positive correlation between longest diameter and peritumoral edema volume (r=.75). At 181-270 days post-GK 50% of BM showed an incongruent course of response curves for longest diameter and peritumoral volume. 60% of these lesions could be classified as partial response. The congruence to incongruence ratio of edema to enhancing portion of BM changed over follow-up time.

CONCLUSION

s Volumetric edema assessment of BM post-GK provides critical additional information as compared to RANO-BM based response curves.

CLINICAL RELEVANCE/APPLICATION

In the follow-up assessment of BM after GK we recommend including both volumetric response curves of peritumoral edema and CE portion of BM.

M5A-SPNR-19 Application of Electrical Properties Tomography to Ischemic Stroke: Comparison of Conductivity between Infarct and Contralateral Brain

Participants
Seong Woo Cho, Hwasun, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Ischemic stroke is one of the most important causes of neurological morbidity and mortality in the world and remains to be the leading cause of death and disability [1]. Electrical Properties Tomography (EPT) is a new MRI technique that delivers information on tissue electrical properties [2,3]. The aim of this study was to explore the feasibility of using EPT on ischemic stroke and compared the conductivity between infarct and contralateral brain.

METHODS AND MATERIALS

Twenty-seven patients who presented with acute stroke at a tertiary stroke centre were included in this study. The patients consisted of 19 males and 8 females (mean age=73.75, range=54~90). The EPT data were acquired using a balanced-Fast Field Echo (b-FFE) sequence (TR/TE = 3/1.62 ms, flip angle=30°, pixel size=1.15×1.15×2 mm) from a clinical 3T scanner (Philips, Amsterdam). The EPT data were reconstructed using the previously described method [4]. The conductivity (s) map was quantified and compared between 4 different regions: basal ganglia thalamus (n=10), cerebral hemisphere (n=11), pons (n=5), and cerebellum (n=2).

RESULTS

The ischemic lesions demonstrated a significantly higher mean conductivity value (0.93 ± 0.097 S/m) than the contralateral brain tissue (0.83 ± 0.095 S/m, p=0.00004). Both basal ganglia thalamus and cerebral hemisphere demonstrated significantly higher levels of conductivity (0.88 ± 0.1 S/m and 0.97 ± 0.097 S/m, respectively) than their contralateral normal brain tissues (0.78 ± 0.093 S/m, p=0.00009 for basal ganglia thalamus and 0.83 ± 0.046 S/m, p=0.0008 for cerebral hemisphere, respectively). The mean lesion basal ganglia thalamus (0.88 ± 0.1 S/m) conductivity value were significantly lower ($p < 0.05$) than the cerebral hemisphere (0.97 ± 0.09 S/m). The mean contralateral conductivity value in both basal ganglia thalamus (0.78 ± 0.09 S/m, p=0.009) and cerebral hemisphere (0.83 ± 0.05 S/m, p=0.04) were significantly lower than the combined pons and cerebellum (0.92 ± 0.1 S/m).

CONCLUSION

s The ischemic lesion exhibited significantly higher conductivity values than the contralateral brain tissue in the cerebral brain, while the pons and cerebellum showed similar levels of conductivity values between the lesion and contralateral brain. Interestingly, the levels of conductivity were significantly different between the contralateral normal tissue of supra- and infra-tentorial brains. The results from this study warrant further investigation of this method with a broader range of patients with stroke.

CLINICAL RELEVANCE/APPLICATION

This preliminary study demonstrated the feasibility of acquiring EPT from stroke patients and evaluating conductivities in lesion and normal brain. This new imaging contrast may provide an extra value on ischemic stroke.

M5A-SPNR-20 IDH-wild type Glioblastoma: Imaging Independent Predictors of Gross Total Resection (GTR) Using the VASARI Feature Set and Tumoral Volumetric MeasurementsVASARI Feature Set and Tumoral Volumetric Measurements

Participants
Luis Nunez, MD, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study is to assess the impact of preoperative imaging phenotypes to determine predictors of gross total resection (GTR) using the Visually Accessible Rembrandt Images lexicon (VASARI) and tumoral volumetry measurements

METHODS AND MATERIALS

A single center, retrospective study of a prospectively maintained database of 167 patients with GBMs was performed. Fourteen patients (8%) with IDH mutation and 2 subjects (1.1%) with incomplete data were excluded. Among the 146 patients, 85 (59%) were male with a mean age of 59 years (SD +/- 13.6 years). MRI findings were assessed using the VASARI feature set and semi-automated tumoral segmentation. Univariate analysis was performed using X2/Fisher's exact test with Monte Carlo simulation for categorical variables and non-parametric analysis with the Mann-Whitney U test for continuous variables. Multivariate analysis was performed using the Logistic regression analysis test and receiver operating characteristic curve (ROC)

RESULTS

In total, 79 patients (55%) underwent GTR, 15 (10%) near-total resection (NTR) and 50 (35%) subtotal resection (STR). Out of the 25 VASARI criteria, 4 characteristics were found to be associated with GTR, as follows: 39 GBMs (49%) were in non-eloquent areas (p=0.04), 59 (75%) had thick enhancing margins (p=0.04), 64 (81%) had no ependymal invasion (p=0.02) and 48 (61%) had no deep white matter invasion (p=0.03). Additionally, GBMs with GTR were found to have lower tumoral volumes (121 ml [IQR, 51.7-174 ml] versus 163.9 ml [IQR, 121.9-215.3 ml] (p<0.01), lower FLAIR volumes (98 ml [IQR, 40.2-134 ml] versus 127 ml [IQR, 87-167 ml] (p<0.01), and lower enhancing volumes (14.5 ml [IQR, 8.3-24.7 ml] versus 28.6 ml [IQR, 14.2-42 ml] (p<0.01). Logistic regression model demonstrated that thickness of enhancing margins is the only independent predictor of non-gross total resection (odds ratio: 1.57 [95% CI, 1.1-2.2]) (p=0.01). ROC analysis of our multivariate model demonstrated an AUC estimate of 0.75 with a sensitivity of 60% and a specificity of 91%

CONCLUSION

s Imaging characteristics on standard-of-care (SOC) MR scans may predict gross total resection of GBMs wild-type. Furthermore, thickness of enhancing margins was the only significant predictor of GTR after multivariate analysis. Additionally, a diagnostic model that includes a combination of the discriminating depicted features on SOC MR scans and volumetric measurements, demonstrated to have an acceptable diagnostic performance with a specificity greater than 90%

CLINICAL RELEVANCE/APPLICATION

Higher survival rates are seen among glioblastoma patients that undergo gross-total resection (GTR). Our study provides information that m will help to determine prognosis of patients with wild type glioblastomas.

M5A-SPNR-3 Study on Cranial Bone Marrow Conversion of High Altitude Polycythemia

Participants
Hai Hua Bao, Xining, China (*Presenter*) Nothing to Disclose

PURPOSE

High altitude polycythemia (HAPC) is a chronic disease caused by excessive compensatory proliferation of erythrocytes in the hypoxia environment at high altitude. The disease commonly affects multiple systems throughout the body, leading to an abnormal increase in hemoglobin concentration and red blood cell count. This study aimed to investigate the characteristics of cranial bone marrow conversion in patients with high altitude polycythemia based on conventional magnetic resonance imaging (MRI) and diffusion-weighted imaging (DWI).

METHODS AND MATERIALS

30 patients with high altitude polycythemia were included in the experimental group, aged (47.96 ±9.65) years, living at an altitude of (3155 ±736.98) m, with hemoglobin (216.57 ±11.10m) g/mL. 30 healthy subjects matched with the HAPC group in age and living altitude were included as the control group, aged (48.17±8.28) years, living altitude (3124.41±567.36) m, HGB(155.53±18.19) g/mL. The ADC values of the frontal bone, parietal bone, occipital bone and temporal bone were measured at Philips post-processing workstation, and the characteristics of cranial bone marrow conversion in patients with high altitude polycythemia were statistically analyzed.

RESULTS

There was no significant difference in age and living altitude between the two groups. Compared with the control group, the hemoglobin (HGB), red blood cell count (RBC) and hematocrit (HCT) in the HAPC group were significantly higher than those in the control group, as shown in Table 1. The ADC values of parietal bone and occipital bone in THE HAPC group were (0.88±0.30) ×10-3mm2/s and (1.37±0.27) ×10-3mm2/s, both higher than those in the control group (P<0.05), with statistical differences. The ADC values of the frontal bone and temporal bone in THE HAPC group were (1.09±0.24) ×10-3mm2/s and (1.36±0.27) ×10-3mm2/s, respectively, which were higher than those in the control group (P>0.05). The differences were not statistically significant, as shown in Table 2.

CONCLUSION

s Under the condition of long-term hypoxia in HAPC, the bone marrow of parietal bone and occipital bone was erythromedularized. This suggests that long-term chronic hypoxia may induce bone marrow erythromyelization, resulting in HAPC.

CLINICAL RELEVANCE/APPLICATION

Hypoxia is the main cause of altitude sickness. High altitude polycythemia (HAPC) is a common disease threatening people's health in the plateau, which can cause damage to multiple organs. We believe that imaging to explore cranial bone marrow conversion of HAPC patients compared with normal controls may provide an essential basis for understanding bone marrow erythromyelization induced by chronic hypoxia.

M5A-SPNR-4 Intravoxel Incoherent Motion (IVIM) May Help Distinguishing Gliomas and Solitary Brain Metastasis: A Multi-parameter Magnetic Resonance Imaging Study

Participants
Yifei Su, MS, (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study is to investigate the value of diffusion, perfusion and chemical exchange saturation transfer MR imaging in differentiating the gliomas and metastases.

METHODS AND MATERIALS

65 patients pathologically newly diagnosed gliomas or metastases were enrolled and all were conducted the diffusion weighted imaging, intravoxel incoherent motion (IVIM), and amide proton transfer-weighted (APT) imaging as well as the T1W, T2W, T2FLAIR and enhanced T1W imaging in a 3.0T MR scanner (Discovery MR 750w; GE, Milwaukee, USA). The images were imported to the iQuant software (GE Healthcare, Beijing, China) to calculate parametric maps including the apparent diffusion coefficient from DWI (ADC), diffusion coefficient (D), perfusion fraction (f), pseudo-diffusion coefficient (D*) from IVIM and the MTRasym (3.5 ppm) from APT imaging. The tumor parenchyma was delineated wherever possible in 3dslicer (https://www.slicer.org/, version 4.10). Quantitative values of 10 percentile,90 percentile, entropy, kurtosis, mean and skewness in parametric maps for region of interest (ROI)were extracted with the pyradiomics plugin and compared. Logistics regression and receiver operator curves (ROC) analysis were performed to explore the independent factors and optimal model. R packages were used for all the statistics (version 4.0.0).

RESULTS

44 patients were diagnosed as glioma (males:25, females:10, age range: 20-79y), and 21 cases were diagnosed as metastasis (males:10, females:11, age range: 34-80y) from the pathological analysis. No significant difference was observed in clinical manifestations (Table 1). There were significant differences for ADC kurtosis (6.43±5.63 vs. 4.54±3.23, p= 0.02), MTRasym (3.5ppm) 10 percentile (0.53±0.97 vs. 1.00±0.75, p= 0.05), f 90 percentile (23.07±5.14 vs. 28.67±5.51, p<0.01), f entropy (56.00±33.08 vs. 85.20±33.08, p<0.01), f kurtosis (67.56±40.75 vs. 39.08±142,84, p<0.01), and f mean (13.92±2.50 vs. 17.38±3.84, p<0.01) between gliomas and metastases groups (Table 2). The f kurtosis (OR =0.66, 95% CI 0.48-0.92, p=0.02), and f mean (OR = 1.44, 95% CI 1.16-1.18, p<0.01) were found the independent factors for metastases differentiation in logistic regression analysis (Table 3). The AUC of model combined with age, IVIM-f kurtosis and IVIM-f mean was 0.83while the AUC of model combined with IVIM-f kurtosis and IVIM-f mean with improved sensitivity was 0.81 with no significant difference under Delong test (p=0.58). (Table 4,Figure 1).

CONCLUSION

s The IVM-f kurtosis and IVM-f mean demonstrated the differences in perfusion characteristics of gliomas and metastases.

CLINICAL RELEVANCE/APPLICATION

Accurate identification of these two kinds of tumors will largely benefit the therapy.

M5A-SPNR-5 Evaluation of RANO Criteria for Assessment of Tumor Progression for Lower-grade Gliomas

Participants
Fabio Raman, MD, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

The Response Assessment in Neuro-Oncology (RANO) criteria for lower-grade gliomas (LGGs) defines tumor progression as =25% change in T2/FLAIR signal based on an operator's discretion of the perpendicular diameter of the largest tumor cross-section. Potential sources of error include limitation of 2D quantification, operator selection of both tumor cross-section and perpendicular parameters, and inability to quantify satellite tumor components. Our goal was to assess accuracy and reproducibility of RANO.

METHODS AND MATERIALS

651 FLAIR MRIs from 63 participants with LGGs at the University of Alabama at Birmingham were retrospectively analyzed by 3 blinded attending physicians and 3 blinded resident trainees using RANO, 2D visual, and 3D computer-assisted volumetric assessment. Inter- and intra-operator reproducibility was assessed using Pearson correlation, Bland Altman, and Cohen's kappa. Accuracy assessment was performed by comparing RANO to either visual or volumetric assessment, where 2/3 consensus agreement across operators was required to meet RANO and visual growth criteria for a particular tumor measurement. Volumetric assessment was performed by statistical change-of-point method. RANO assessment was performed compared to both previous and baseline scan.

RESULTS

RANO product measurements had moderate inter-operator reproducibility [r2 = 0.71 - 0.82, coefficient of variance (CV) = 81 - 110%), mean percent difference (diff) = 0.4 - 46.8%] and intra-operator reproducibility (r2 = 0.71 - 0.88, CV = 31 - 58%, diff = 0.3 - 23.9%, Figure A-B). When comparing to 2D visual gold standard, accuracy of RANO compared to previous and baseline scans were 66.7% and 65.1% with AUC of 0.67 and 0.66, respectively (Figure C). When comparing to volumetric gold standard, accuracy of RANO compared to previous and baseline scans were 21.0% and 48.4% with AUC of 0.39 and 0.55, respectively (Figure D). Median time delay at diagnosis was greater for false negative cases (RANO detected growth after volumetric) than for false positive

cases (RANO growth detected earlier) for RANO assessment compared to previous scan (2.05 > 0.50 years, p = 0.003) and baseline scan (1.08 > 0.50 years, p = 0.02, Figure E).

CONCLUSION

s RANO has moderate reproducibility and poor accuracy when comparing to either visual or volumetric gold standards.

CLINICAL RELEVANCE/APPLICATION

Limitations of the RANO criteria for LGGs suggest novel approaches, such as computer-assisted diagnostic tools, are necessary to reduce human variability and accurately assess 3D tumor progression.

M5A-SPNR-1

Non-invasive Prediction of IDH Mutation Status in Gliomas Using Pre-operative Multi-parametric MRI Radiomics Nomogram: A Multi-center Study

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Jun Lu, (*Presenter*) Nothing to Disclose

PURPOSE

Accurate identification of IDH mutation status has revolutionized our understanding of the potential for targeted therapeutics using small molecule IDH mutation inhibitors with the update of 2021 WHO classification criterion of gliomas, which might be clinically meaningful for treatment strategy and prognosis stratification of gliomas. This study aimed to establish and validate a radiomics nomogram for predicting IDH mutation status in gliomas using preoperative multiparametric MRI in a multicenter setting.

METHODS AND MATERIALS

306 gliomas patients in local institution were enrolled and randomly assigned into a training (n=214) and a test dataset (n=92). 108 patients were collected from TCGA as an independent external validation dataset. The volume of interest(VOI) was delineated manually on the map of contrast-enhanced T1-weighted (CE-T1W) and fluid attenuated inversion recovery(FLAIR). 851 radiomics features were extracted on each VOI. The features were firstly selected using Mann-Whitney U-test, followed by refining using least absolute shrinkage and selection operator (LASSO) regression combing 10-fold cross-validation. The optimal radiomics features with age and sex were processed by multivariate logistic regression to construct a prediction model, which was developed in the training dataset and assessed in the test and external validation datasets. Receiver operating characteristic(ROC), calibration curve and decision curve analysis were applied in the test and external validation datasets to evaluate the discrimination, calibration and clinical utility of prediction model.

RESULTS

Ten robust radiomics features were selected from the 1702 features(four CE-T1W and six FLAIR features). A nomogram was plotted to represent the prediction model. The accuracy and AUC of the radiomics nomogram achieved 86.96% and 0.891(0.809-0.947) and 84.26% and 0.881(0.805-0.936) in the test and external validation dataset (all $p<0.05$). The positive predictive value(PPV) and negative predictive value(NPV) were 83.72%, 87.75% and 87.81%, 82.09% in the test and external validation dataset. The Hosmer-Lemeshow test concluded that the radiomics nomogram showed goodness of fit(all $p>0.05$). Decision curve analysis demonstrated the clinical value of the radiomics nomogram.

CONCLUSION

s IDH genotypes of gliomas can be identified by preoperative multiparametric MRI radiomics nomogram and might be clinically meaningful for treatment strategy and prognosis stratification of gliomas .

CLINICAL RELEVANCE/APPLICATION

This study aimed to find imaging biomarkers for noninvasively predicting the IDH mutation status for a tailored treatment plan and prognosis stratification in glioma patients from the initial stage of the tumor diagnosis.

Extent of Resection of Contrast-enhancing and Non-enhancing Tumor - Different Impacts on Survival According to Types of Adult-type Diffuse Gliomas in 2021 WHO Classification

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Sung Soo Ahn, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the impact of extent of resection (EOR) of contrast-enhancing (CE) and nonenhancing (NE) tumors in the types of adult-type diffuse gliomas according to the 2021 WHO classification.

METHODS AND MATERIALS

Total 1,196 patients with adult-type diffuse gliomas diagnosed between 2001 and 2021 from a single institution were enrolled (183 patients with IDH-mutant and 1p/19q codeleted oligodendroglioma [herein oligodendroglioma], 211 patients with IDH-mutant astrocytoma, and 802 patients with IDH-wildtype glioblastoma. Multivariable Cox analyses were performed within each type to assess predictors of overall survival, including clinical, imaging data, histological grade, MGMT promoter methylation status, treatment, and EOR of CE and NE tumors. Subgroup analyses were performed in patients with CE tumor. N

RESULTS

Among 1,196 patients, 926 (77.4%) patients had CE tumors. In oligodendrogliomas, GTR of NE was not associated with survival (HR = 0.41, 95% CI 0.14-1.15, P = 0.088). In 81 (43.3%) oligodendroglioma patients with CE tumor, GTR of CE tumors was the only independent predictor of survival (HR = 0.20, 95% CI 0.05-0.85, P = 0.029) in multivariable analysis. GTR of NE and CE tumors was independently associated with better survival in IDH-mutant astrocytoma and IDH-wildtype glioblastoma (all Ps <0.05) in multivariable analyses.

CONCLUSION

s GTR of both CE and NE tumors may significantly improve survival within all types of adult-type diffuse gliomas except oligodendrogliomas. In oligodendrogliomas, the EOR of CE tumor may be crucial in survival; aggressive GTR of NE tumor may be unnecessary, whereas GTR of the CE tumor is recommended.

CLINICAL RELEVANCE/APPLICATION

This study is the first, to our knowledge, to examine the independent role of EOR in both CE and NE tumors across types in adult-type diffuse gliomas according to the 2021 WHO classification. Well-known predictors for survival such as clinical, radiological, and MGMT promoter methylation status were included in the Cox analysis, to demonstrate the independent role of EOR. Our results pave the way for rethinking surgical strategies according to types of adult-type diffuse gliomas.

Application of Brain Tumour Reporting and Data System (BT-RADS) in A Large Population with High-grade Gliomas (HGG) Exhibiting Progression (PD) and Pseudo progression (PSPD) and Correlation with Survival Analysis

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Ankush Jajodia, MD, MBBS, New Delhi, India (*Presenter*) Nothing to Disclose

PURPOSE

HGG accounts for approximately 60% of all primary brain tumors. BT-RADS assigns each MRI to study a score or category based on imaging findings. PsPD is an effect usually occurring in the first six months after chemoradiation (CRT), with reported incidence ranging from 2-50%. We investigated the utility of BT-RADS applications in a large population of patients with HGG with PD and PsPD.

METHODS AND MATERIALS

After institutional review board approval, a retrospective analysis was performed on 437 patients with HGG who underwent Gadolinium-enhanced MRI between 2013-and 2021. Patients were labeled as having PD or PsPD after multidisciplinary team evaluation. Typically we called pseudoprogression as progression on early scans, that stabilizes without further anti cancer therapy vs progression as continual progression. The clinical outcome (dichotomized as stable or worse) was collected from medical records. An experienced neuroradiologist did the BT-RADS category assignment. Kaplan Meier survival analysis and Chi-square test between different groups were done using MedCalc software.

RESULTS

Two hundred and thirteen patients with HGG after exclusion (Figure1) were included. PsPD (n=109) and PD (n=104) were determined in a multidisciplinary care team after evaluation of clinical information and follow-up imaging. BT-RADS category assignment between the PD and PsPD group and the final clinical outcome dichotomized group (worse and stable) was statistically significant (table). KS survival analysis of BT-RADS assignment during follow-up with the final clinical result is shown in figure 2.

CONCLUSION

s BT-RADS has a significant correlation with survival and can be an imperative tool for response assessment, especially in resource-constrained setup.

CLINICAL RELEVANCE/APPLICATION

BT-RADS implementation has the potential to increase the completeness, consistency, and comprehensibility of radiology reports in patients with glioma. This preliminary work summarizes the initial experience and emphasizes its effectiveness in a large subset of patients with HGG.

M5A-SPNR-12

Analyzing Treatment Response of Recurrent Pediatric Low-Grade Gliomas in Clinical Trials: Comparison of Volumetric and Two-Dimensional Tumor Assessment

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Ryan C. Bahar, BSc, Yale School of Medicine, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

The Response Assessment in Neuro-Oncology (RANO) criteria were designed to radiologically evaluate tumor response and endpoints in clinical trials of novel treatments. These criteria estimate tumor size using the two-dimensional (2D) product of maximal perpendicular diameters on axial slices of MR images. Pediatric low-grade gliomas (pLGGs), however, are intratumorally heterogeneous with solid and cystic components. 2D measurements may therefore misevaluate pLGG tumor volume and tumor response, and ultimately affect trial outcome. This study aims to assess tumor response using volumetric assessment of recurrent and progressive pLGGs treated with everolimus. We seek to identify clinically relevant criteria that provide added value to response assessment beyond 2D measurements.

METHODS AND MATERIALS

Using multiparametric MR imaging from 44 patients in the Pediatric Neuro-Oncology Consortium (PNOC) 001 clinical trial, we performed 3D-segmentation of solid, cystic, and whole pLGGs within our PACS-framework to assess tumor response. We compared our results to those from a prior independent central imaging review which had yielded 15 (34%) patients showing progressive disease (PD), 27 (61%) stable disease (SD), 2 (5%) partial response (PR), and 0 (0%) complete response (CR).

RESULTS

8 (18%) of the 44 tumors were solid-only and 36 (82%) had a mixed solid-cystic appearance. Comparing 2D central imaging review to our volumetric tumor evaluation using the same RANO cutoff criteria, 7 (16%) cases changed from PD to SD, 3 (7%) from SD to PD, 1 (2%) from SD to PR, and 1 (2%) from PR to SD, constituting an overall discordance in 12 (27%) cases.

CONCLUSION

s Integration of volumetrics into tumor response assessments provides additional and potentially more accurate information than strictly 2D RANO-based measurements. It is crucial to note that the above-reported changes in assessed tumor response represent numerical discrepancies as opposed to true-to-reality changes in clinical outcome. Determining representative thresholds for the deployment of volumetric measures in clinical trials will be critical. Future work will include data from the PNOC-002 clinical trial and evaluate inter-reader agreement and reader discordance.

CLINICAL RELEVANCE/APPLICATION

With the availability of PACS-based 3D tools in neuroradiology practice, well-defined volumetric criteria could be incorporated prospectively to enhance tumor response analysis in clinical trials.

M5A-SPNR-13

SMART Syndrome and Variants: From Clinical Presentation to Imaging: How to Arrive At the Diagnosis

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Denver Pinto, MD, Miami, FL (*Presenter*) Nothing to Disclose

PURPOSE

SMART (Stroke-like migraine attacks after radiation therapy) syndrome is a rare clinical-radiological entity characterized by complex neurologic symptoms which may occur years following radiation therapy. The imaging features resemble a subacute infarct, hence, an incorrect diagnosis may lead to unnecessary imaging and treatment. This presentation will help the audience to identify SMART syndrome and to avoid misdiagnosis. We describe and illustrate a small series of SMART cases with the purpose of identifying the varied clinical and imaging features.

METHODS AND MATERIALS

We conducted a database search involving 3 health systems for cases of SMART syndrome and for "subacute infarcts" in patients status post radiation. We found 7 patients who could be classified as having SMART syndrome or a variant of it based on history, clinical symptoms, clinical follow-up and comparison with prior/follow-up imaging.

RESULTS

There were 5 patients with features typical of the SMART syndrome and 2 patients with atypical presentations consistent with peri-ictal pseudo-progression (PIPG). All patients had radiation therapy 1.5 years to 25 years before presentation. The most common clinical symptoms were headache (6/7) and seizures (5/7). Cranial nerve involvement (5/7), motor deficits/extremity weakness (3/7) and sensory deficits (2/7) were identified on examination. MRI findings included cortical and subcortical edema, as well as sub-arachnoid, gyriform, parenchymal and punctate contrast enhancement with elevated rCBV. Diffusion restriction in a focal or gyriform pattern was identified both in the typical presentation and in PIPG. Patients with PIPG showed more avid cortical and meningeal enhancement[RQ1] even the absence of headache (1/2). rCBV was reduced in one of our patients with PIPG. In one of our patients, the imaging changes occurred in the radiation field on the side opposite the surgery and another patient had bilateral findings. This symptom-imaging complex occurred following treatment of a wide range of benign and malignant tumors.

CONCLUSION

s SMART syndrome is a diagnostic confounder that can have undesirable downstream effects if misdiagnosed. MRI findings such as gyriform diffusion restriction, cortical and vasogenic edema as well as cortical or meningeal enhancement in a non-vascular distribution in concert with the clinical information such as the location and time since radiation delivery helps suggest the proper diagnosis.

CLINICAL RELEVANCE/APPLICATION

Decisions relative to continuing or withholding anti-neoplastic therapy may depend on recognizing this entity. Also a confident diagnosis will prevent extensive and unnecessary stroke or seizure work up because the imaging features may resemble either of these conditions.

Vascular Habitats analysis Based on Preoperative Dynamic Susceptibility-weighted Contrast Perfusion MRI Predicts Recurrence Pattern in High-grade Gliomas

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Hanwei Wang, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate if vascular habitats analysis based on preoperative dynamic susceptibility-weighted contrast perfusion MRI predicts recurrence pattern in high-grade gliomas (WHO grade 3-4, HGG).

METHODS AND MATERIALS

In this single-center, retrospective study, we included adults with HGG, who received chemoradiotherapy and were diagnosed with recurrence based on RANO criteria or resurgical pathology. A neurosurgeon and a neuroradiologist based on preoperative and follow-up MRI images of patients, classified recurrence patterns into local recurrence (LR) and non-local recurrence (NLR). The LR was further divided into intra-surgical cavity recurrence (ICR) and extra-surgical cavity recurrence (ECR). Kaplan-meier curves were used to analyze the PFS and OS of patients with LR and NLR, ICR recurrence and ECR. And log-rank test was used to compare the differences in patient survival. Based on ONCOhabitats platform (https://www.oncohabitats.upv.es) hemodynamic tissue signature (HTS) method automatic segmentation of vascular habitats, evaluate each vascular habitats in the 95th percentile rCBV, rCBF value. Univariate and multivariate logistic regression analysis were used to evaluate the correlation between vascular habitats parameters and recurrence patterns, and to determine the predictors. The prediction efficiency of relevant factors were computed by receiver operating characteristics curve (ROC) and the area under curve (AUC).

RESULTS

77 HGG were included in this study, of which 60 (77.92%) with LR and 17 (22.08%) with NLR. The LR was divided into ICR (30, 38.96%) and ECR (30, 38.96%). PFS and OS were longer in the LR than in the NLR ($p<0.05$). There was no significant difference in PFS and OS between ICR and ECR ($p>0.05$). In univariate logistic regression analysis, rCBVp95 at LAT (OR=2.084 ,95%CI=1.198-3.626), rCBVp95 at IPE (OR=2.840 ,95%CI=1.213-6.648), rCBVp95 at VPE (OR=3.598 ,95%CI=1.256-10.308) and rCBFp95 at VPE (OR=3.793 ,95%CI=1.172-12.270) correlated with ECR. Multivariate logistic regression analysis revealed rCBVp95 at LAT could be used as a predictor of ECR (OR=2.317,95%CI:1.264-4.246,p=0.007). ROC curve showed that the prediction efficiency is good (AUC=0.743,95%CI=0.614-0.847).

CONCLUSION

s Preoperative vascular habitats parameters can be used as noninvasive imaging markers to predict ECR, and provide reference for the management and treatment of HGG.

CLINICAL RELEVANCE/APPLICATION

Preoperative vascular habitats parameters can be used as noninvasive imaging markers to predict extra-surgical cavity recurrence, and provide reference for the management and treatment of high-grade gliomas.

Neuroimaging Findings in Patients with Immune Effector Cell-associated Neurotoxicity Syndrome after CAR-T-cell Therapy

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Burak Akkurt, MD, Muenster, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Chimeric antigen receptor T-cell therapy (CART) is a new immunomodulating therapy of relapsed/refractory hematological malignancies, capable of inducing an immune response against tumor cells.CART often comes with relevant organ toxicities, one of which is referred to as immune effector cell-associated neurotoxicity syndrome (ICANS). Symptoms of ICANS are heterogenous and include headache, confusion and encephalopathy.In this study we evaluated ICANS associated neuroimaging findings in cerebral magnetic resonance imaging (cMRI).

METHODS AND MATERIALS

We reviewed all patients, who received CART infusion at our university hospital between 12/2018 and 09/2021. From the initial 32 patients, 11 received cerebral imaging due to suspected or diagnosed ICANS within a follow-up time of up to 30 days after infusion.Of these 11 patients, 2 presented with ICANS grade I, 5 with ICANS grade 2, and 4 with ICANS grade 3.The routine cMRI images of patients were reviewed by two neuroradiologists with an experience of 3 and 9 years. We correlated the imaging findings with the clinical grading according to ICANS.

RESULTS

We observed FLAIR hyperintense signal alterations in most cases with pericallosal involvement (5/11, 45 %). Furthermore, we noticed FLAIR hyperintense signal changes in the forceps minor in 5 out of 11 patients (45 %). Other locations of FLAIR alterations were noticed in the capsula interna, foliae cerebelli, thalami, as well as temporal and subinsular regions (each in 1 case). We correlated the imaging findings with the clinical grading of the ICANS. According to literature, only ICANS grade =3 shows changes on MRI. However, in our cohort we observed white matter changes in all of our patients with ICANS grades =2 .

CONCLUSION

s ICANS may show subtle changes on cMRI, with FLAIR hyperintense white matter changes being the most prevalent ones.In our cohort, we found signal alterations in all patients graded ICANS =2.Our findings suggest FLAIR hyperintense signal changes in the forceps minor as a possible specific sign of neurotoxicity after CART, but further prospective evaluation with a larger cohort should be aimed at for confirmation.

CLINICAL RELEVANCE/APPLICATION

ICANS is one of the major toxicities associated with CAR-T-cell therapy and neuroimaging can help identifying ICANS and should be evaluated in suspected cases.

Magnetic Resonance Imaging and Amino Acid Positron Emission Tomography in Differentiating Tumor Recurrence from Radiation Necrosis in High Grade Gliomas.

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Antariksh Vijan, MBBS, Mumbai, India (*Presenter*) Nothing to Disclose

PURPOSE

Differentiating tumor recurrence (TR) from radiation necrosis (RN) in high-grade glioma (HGG) following radiotherapy can be challenging. The ability of conventional magnetic resonance imaging (MRI) to differentiate TR from post-therapeutic effects is often limited. Multiparametric advanced MRI (perfusion) and positron emission tomography (PET) with amino acid tracers, specifically 18F-Fluoroethyl-Tyrosine (FET) can provide relevant additional information on tumor metabolism, which allows for a more accurate diagnosis to differentiate tumor recurrence from radiation necrosis in HGG.

METHODS AND MATERIALS

Retrospective analysis of 69 lesions in 69 patients with HGG who underwent both MRI and FET-PET imaging within three weeks intervals was done independently by a neuroradiologist and nuclear medicine physician. The study was conducted in the department of radiodiagnosis in a tertiary care oncology center between July 2018 and August 2021. Manually segmented regions of interest were placed over the areas of maximum enhancement/suspicion on MRI and FET uptake, which were used to calculate the rCBV and tumor to white-matter ratios, respectively. Definitive diagnosis (TR versus RN) was made on clinico-radiological follow-up or histopathological report (wherever available).

RESULTS

Out of the 69 lesions that were studied, 52 and 13 had TR and RN, respectively. 4 cases were excluded from the study as they were lost to follow-up. The rCBVmean (mean relative CBV) and mean target-to-background ratios showed an accuracy of 94% and 80% for MRI and FET-PET respectively in the detection of recurrent lesions. The sensitivity and specificity for determination of TR in HGG with conventional MRI were 98% and 77% respectively, while with FET-PET it was 79% and 85% respectively. A combination of MRI and PET parameters (mean target-to-background ratio), demonstrated an increase in diagnostic accuracy to 98%. A rCBVmax cutoff > 1.48 had a positive predictive value for recurrence of 97.92%. The sensitivity and specificity of rCBV values for determination of TR in treated cases of HGG were 90.38% and 87.50% respectively.

CONCLUSION

s Cumulative imaging with MRI and FET-PET offers a multiparametric assessment of glioma recurrence that is correlative and complimentary, with higher accuracy and clinical value.

CLINICAL RELEVANCE/APPLICATION

This study analyses the individual and combined diagnostic performance of MR and amino acid PET to distinguish recurrence from radiation necrosis in treated cases of gliomas.

Critical Information Provided by PACS Based Peritumoral Edema Volumetrics in Assessment of Lung Cancer Brain Metastases after Gamma Knife Therapy

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Manpreet Kaur, BSc, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

Gamma Knife (GK) has become standard of care to locally treat BM, however there is insufficient understanding of the natural posttreatment volumetric changes of peritumoral edema of BM due to paucity of tools for volumetric segmentation in neuroradiology practice. Recently PACS-integrated tools have become available in select clinical practices therefore we aimed to compare volumetric response curves of peritumoral edema to response curves of RANO-BM based measurements.

METHODS AND MATERIALS

Patients with NSCLC BM with longest diameter greater or equal to 10mm on CE-T1WI that were treated with GK were included. Volumetric measurements were performed for up to 7 follow-up studies using a PACS-integrated tool that segments the FLAIR hyperintense volume surrounding the CE lesion. The 2D and volumetric measurements were analyzed using Prism9 and clinical information including steroid timing were incorporated in the assessment.

RESULTS

41 NSCLC BM were included (59±10 years, 20 pts). The median pretreatment metastasis volume was 8.52cm3 (IQR 1.01-47.03cm3). A significant decrease was measured at 0-90 days post-GK (median 1.16cm3, IQR 0.51-6.12cm3). The time of peak median peritumoral volume increase was after 365 days post-GK (median 1.42cm3, IQR 0.37-8.12cm3). There was a significant positive correlation between longest diameter and peritumoral edema volume (r=.75). At 181-270 days post-GK 50% of BM showed an incongruent course of response curves for longest diameter and peritumoral volume. 60% of these lesions could be classified as partial response. The congruence to incongruence ratio of edema to enhancing portion of BM changed over follow-up time.

CONCLUSION

s Volumetric edema assessment of BM post-GK provides critical additional information as compared to RANO-BM based response curves.

CLINICAL RELEVANCE/APPLICATION

In the follow-up assessment of BM after GK we recommend including both volumetric response curves of peritumoral edema and CE portion of BM.

M5A-SPNR-19

Application of Electrical Properties Tomography to Ischemic Stroke: Comparison of Conductivity between Infarct and Contralateral Brain

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Seong Woo Cho, Hwasun, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Ischemic stroke is one of the most important causes of neurological morbidity and mortality in the world and remains to be the leading cause of death and disability [1]. Electrical Properties Tomography (EPT) is a new MRI technique that delivers information on tissue electrical properties [2,3]. The aim of this study was to explore the feasibility of using EPT on ischemic stroke and compared the conductivity between infarct and contralateral brain.

METHODS AND MATERIALS

Twenty-seven patients who presented with acute stroke at a tertiary stroke centre were included in this study. The patients consisted of 19 males and 8 females (mean age=73.75, range=54~90). The EPT data were acquired using a balanced-Fast Field Echo (b-FFE) sequence (TR/TE = 3/1.62 ms, flip angle=30°, pixel size=1.15×1.15×2 mm) from a clinical 3T scanner (Philips, Amsterdam). The EPT data were reconstructed using the previously described method [4]. The conductivity (s) map was quantified and compared between 4 different regions: basal ganglia thalamus (n=10), cerebral hemisphere (n=11), pons (n=5), and cerebellum (n=2).

RESULTS

The ischemic lesions demonstrated a significantly higher mean conductivity value (0.93 ± 0.097 S/m) than the contralateral brain tissue (0.83 ± 0.095 S/m, p=0.00004). Both basal ganglia thalamus and cerebral hemisphere demonstrated significantly higher levels of conductivity (0.88 ± 0.1 S/m and 0.97 ± 0.097 S/m, respectively) than their contralateral normal brain tissues (0.78 ± 0.093 S/m, p=0.00009 for basal ganglia thalamus and 0.83 ± 0.046 S/m, p=0.0008 for cerebral hemisphere, respectively). The mean lesion basal ganglia thalamus (0.88 ± 0.1 S/m) conductivity value were significantly lower ($p < 0.05$) than the cerebral hemisphere (0.97 ± 0.09 S/m). The mean contralateral conductivity value in both basal ganglia thalamus (0.78 ± 0.09 S/m, p=0.009) and cerebral hemisphere (0.83 ± 0.05 S/m, p=0.04) were significantly lower than the combined pons and cerebellum (0.92 ± 0.1 S/m).

CONCLUSION

s The ischemic lesion exhibited significantly higher conductivity values than the contralateral brain tissue in the cerebral brain, while the pons and cerebellum showed similar levels of conductivity values between the lesion and contralateral brain. Interestingly, the levels of conductivity were significantly different between the contralateral normal tissue of supra- and infra-tentorial brains. The results from this study warrant further investigation of this method with a broader range of patients with stroke.

CLINICAL RELEVANCE/APPLICATION

This preliminary study demonstrated the feasibility of acquiring EPT from stroke patients and evaluating conductivities in lesion and normal brain. This new imaging contrast may provide an extra value on ischemic stroke.

IDH-wild type Glioblastoma: Imaging Independent Predictors of Gross Total Resection (GTR) Using the VASARI Feature Set and Tumoral Volumetric MeasurementsVASARI Feature Set and Tumoral Volumetric Measurements

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Luis Nunez, MD, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study is to assess the impact of preoperative imaging phenotypes to determine predictors of gross total resection (GTR) using the Visually Accessible Rembrandt Images lexicon (VASARI) and tumoral volumetry measurements

METHODS AND MATERIALS

A single center, retrospective study of a prospectively maintained database of 167 patients with GBMs was performed. Fourteen patients (8%) with IDH mutation and 2 subjects (1.1%) with incomplete data were excluded. Among the 146 patients, 85 (59%) were male with a mean age of 59 years (SD +/- 13.6 years). MRI findings were assessed using the VASARI feature set and semi-automated tumoral segmentation. Univariate analysis was performed using X2/Fisher's exact test with Monte Carlo simulation for categorical variables and non-parametric analysis with the Mann-Whitney U test for continuous variables. Multivariate analysis was performed using the Logistic regression analysis test and receiver operating characteristic curve (ROC)

RESULTS

In total, 79 patients (55%) underwent GTR, 15 (10%) near-total resection (NTR) and 50 (35%) subtotal resection (STR). Out of the 25 VASARI criteria, 4 characteristics were found to be associated with GTR, as follows: 39 GBMs (49%) were in non-eloquent areas (p=0.04), 59 (75%) had thick enhancing margins (p=0.04), 64 (81%) had no ependymal invasion (p=0.02) and 48 (61%) had no deep white matter invasion (p=0.03). Additionally, GBMs with GTR were found to have lower tumoral volumes (121 ml [IQR, 51.7-174 ml] versus 163.9 ml [IQR, 121.9-215.3 ml] (p<0.01), lower FLAIR volumes (98 ml [IQR, 40.2-134 ml] versus 127 ml [IQR, 87-167 ml] (p<0.01), and lower enhancing volumes (14.5 ml [IQR, 8.3-24.7 ml] versus 28.6 ml [IQR, 14.2-42 ml] (p<0.01). Logistic regression model demonstrated that thickness of enhancing margins is the only independent predictor of non-gross total resection (odds ratio: 1.57 [95% CI, 1.1-2.2]) (p=0.01). ROC analysis of our multivariate model demonstrated an AUC estimate of 0.75 with a sensitivity of 60% and a specificity of 91%

CONCLUSION

s Imaging characteristics on standard-of-care (SOC) MR scans may predict gross total resection of GBMs wild-type. Furthermore, thickness of enhancing margins was the only significant predictor of GTR after multivariate analysis. Additionally, a diagnostic model that includes a combination of the discriminating depicted features on SOC MR scans and volumetric measurements, demonstrated to have an acceptable diagnostic performance with a specificity greater than 90%

CLINICAL RELEVANCE/APPLICATION

Higher survival rates are seen among glioblastoma patients that undergo gross-total resection (GTR). Our study provides information that m will help to determine prognosis of patients with wild type glioblastomas.

Study on Cranial Bone Marrow Conversion of High Altitude Polycythemia

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Hai Hua Bao, Xining, China (*Presenter*) Nothing to Disclose

PURPOSE

High altitude polycythemia (HAPC) is a chronic disease caused by excessive compensatory proliferation of erythrocytes in the hypoxia environment at high altitude. The disease commonly affects multiple systems throughout the body, leading to an abnormal increase in hemoglobin concentration and red blood cell count. This study aimed to investigate the characteristics of cranial bone marrow conversion in patients with high altitude polycythemia based on conventional magnetic resonance imaging (MRI) and diffusion-weighted imaging (DWI).

METHODS AND MATERIALS

30 patients with high altitude polycythemia were included in the experimental group, aged (47.96 ±9.65) years, living at an altitude of (3155 ±736.98) m, with hemoglobin (216.57 ±11.10m) g/mL. 30 healthy subjects matched with the HAPC group in age and living altitude were included as the control group, aged (48.17±8.28) years, living altitude (3124.41±567.36) m, HGB(155.53±18.19) g/mL. The ADC values of the frontal bone, parietal bone, occipital bone and temporal bone were measured at Philips post-processing workstation, and the characteristics of cranial bone marrow conversion in patients with high altitude polycythemia were statistically analyzed.

RESULTS

There was no significant difference in age and living altitude between the two groups. Compared with the control group, the hemoglobin (HGB), red blood cell count (RBC) and hematocrit (HCT) in the HAPC group were significantly higher than those in the control group, as shown in Table 1. The ADC values of parietal bone and occipital bone in THE HAPC group were (0.88±0.30) ×10-3mm2/s and (1.37±0.27) ×10-3mm2/s, both higher than those in the control group ($P<0.05$), with statistical differences. The ADC values of the frontal bone and temporal bone in THE HAPC group were (1.09±0.24) ×10-3mm2/s and (1.36±0.27) ×10-3mm2/s, respectively, which were higher than those in the control group ($P>0.05$). The differences were not statistically significant, as shown in Table 2.

CONCLUSION

s Under the condition of long-term hypoxia in HAPC, the bone marrow of parietal bone and occipital bone was erythromedularized. This suggests that long-term chronic hypoxia may induce bone marrow erythromyelization, resulting in HAPC.

CLINICAL RELEVANCE/APPLICATION

Hypoxia is the main cause of altitude sickness. High altitude polycythemia (HAPC) is a common disease threatening people's health in the plateau, which can cause damage to multiple organs. We believe that imaging to explore cranial bone marrow conversion of HAPC patients compared with normal controls may provide an essential basis for understanding bone marrow erythromyelization induced by chronic hypoxia.

Intravoxel Incoherent Motion (IVIM) May Help Distinguishing Gliomas and Solitary Brain Metastasis: A Multi-parameter Magnetic Resonance Imaging Study

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Yifei Su, MS, (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study is to investigate the value of diffusion, perfusion and chemical exchange saturation transfer MR imaging in differentiating the gliomas and metastases.

METHODS AND MATERIALS

65 patients pathologically newly diagnosed gliomas or metastases were enrolled and all were conducted the diffusion weighted imaging, intravoxel incoherent motion (IVIM), and amide proton transfer-weighted (APT) imaging as well as the T1W, T2W, T2FLAIR and enhanced T1W imaging in a 3.0T MR scanner (Discovery MR 750w; GE, Milwaukee, USA). The images were imported to the iQuant software (GE Healthcare, Beijing, China) to calculate parametric maps including the apparent diffusion coefficient from DWI (ADC), diffusion coefficient (D), perfusion fraction (f), pseudo-diffusion coefficient (D*) from IVIM and the MTRasym (3.5 ppm) from APT imaging. The tumor parenchyma was delineated wherever possible in 3dslicer (https://www.slicer.org/, version 4.10). Quantitative values of 10 percentile,90 percentile, entropy, kurtosis, mean and skewness in parametric maps for region of interest (ROI)were extracted with the pyradiomics plugin and compared. Logistics regression and receiver operator curves (ROC) analysis were performed to explore the independent factors and optimal model. R packages were used for all the statistics (version 4.0.0).

RESULTS

44 patients were diagnosed as glioma (males:25, females:10, age range: 20-79y), and 21 cases were diagnosed as metastasis (males:10, females:11, age range: 34-80y) from the pathological analysis. No significant difference was observed in clinical manifestations (Table 1). There were significant differences for ADC kurtosis (6.43±5.63 vs. 4.54±3.23, p= 0.02), MTRasym (3.5ppm) 10 percentile (0.53±0.97 vs. 1.00±0.75, p= 0.05), f 90 percentile (23.07±5.14 vs. 28.67±5.51, p<0.01), f entropy (56.00±33.08 vs. 85.20±33.08, p<0.01), f kurtosis (67.56±40.75 vs. 39.08±142,84, p<0.01), and f mean (13.92±2.50 vs. 17.38±3.84, p<0.01) between gliomas and metastases groups (Table 2). The f kurtosis (OR =0.66, 95% CI 0.48-0.92, p=0.02), and f mean (OR = 1.44, 95% CI 1.16-1.18, p<0.01) were found the independent factors for metastases differentiation in logistic regression analysis (Table 3). The AUC of model combined with age, IVIM-f kurtosis and IVIM-f mean was 0.83while the AUC of model combined with IVIM-f kurtosis and IVIM-f mean with improved sensitivity was 0.81 with no significant difference under Delong test (p=0.58). (Table 4,Figure 1).

CONCLUSION

s The IVM-f kurtosis and IVM-f mean demonstrated the differences in perfusion characteristics of gliomas and metastases.

CLINICAL RELEVANCE/APPLICATION

Accurate identification of these two kinds of tumors will largely benefit the therapy.

M5A-SPNR-5

Evaluation of RANO Criteria for Assessment of Tumor Progression for Lower-grade Gliomas

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - NR DPS

Participants
Fabio Raman, MD, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

The Response Assessment in Neuro-Oncology (RANO) criteria for lower-grade gliomas (LGGs) defines tumor progression as =25% change in T2/FLAIR signal based on an operator's discretion of the perpendicular diameter of the largest tumor cross-section. Potential sources of error include limitation of 2D quantification, operator selection of both tumor cross-section and perpendicular parameters, and inability to quantify satellite tumor components. Our goal was to assess accuracy and reproducibility of RANO.

METHODS AND MATERIALS

651 FLAIR MRIs from 63 participants with LGGs at the University of Alabama at Birmingham were retrospectively analyzed by 3 blinded attending physicians and 3 blinded resident trainees using RANO, 2D visual, and 3D computer-assisted volumetric assessment. Inter- and intra-operator reproducibility was assessed using Pearson correlation, Bland Altman, and Cohen's kappa. Accuracy assessment was performed by comparing RANO to either visual or volumetric assessment, where 2/3 consensus agreement across operators was required to meet RANO and visual growth criteria for a particular tumor measurement. Volumetric assessment was performed by statistical change-of-point method. RANO assessment was performed compared to both previous and baseline scan.

RESULTS

RANO product measurements had moderate inter-operator reproducibility [r2 = 0.71 - 0.82, coefficient of variance (CV) = 81 - 110%), mean percent difference (diff) = 0.4 - 46.8%] and intra-operator reproducibility (r2 = 0.71 - 0.88, CV = 31 - 58%, diff = 0.3 - 23.9%, Figure A-B). When comparing to 2D visual gold standard, accuracy of RANO compared to previous and baseline scans were 66.7% and 65.1% with AUC of 0.67 and 0.66, respectively (Figure C). When comparing to volumetric gold standard, accuracy of RANO compared to previous and baseline scans were 21.0% and 48.4% with AUC of 0.39 and 0.55, respectively (Figure D). Median time delay at diagnosis was greater for false negative cases (RANO detected growth after volumetric) than for false positive cases (RANO growth detected earlier) for RANO assessment compared to previous scan (2.05 > 0.50 years, p = 0.003) and baseline scan (1.08 > 0.50 years, p = 0.02, Figure E).

CONCLUSION

s RANO has moderate reproducibility and poor accuracy when comparing to either visual or volumetric gold standards.

CLINICAL RELEVANCE/APPLICATION

Limitations of the RANO criteria for LGGs suggest novel approaches, such as computer-assisted diagnostic tools, are necessary to reduce human variability and accurately assess 3D tumor progression.

M5A-SPOB-1 Neoadjuvant Chemotherapy Induces an Elevation of Tumor Apparent Diffusion Coefficient Values in Patients With Ovarian Cancer

Participants
Milja Reijonen, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Multiparametric magnetic resonance imaging (mMRI) is the modality of choice in the imaging of ovarian cancer (OC). We aimed to investigate the feasibility of different types of regions of interest (ROIs) in the measurement of apparent diffusion coefficient (ADC) values of diffusion-weighted imaging in OC patients treated with neoadjuvant chemotherapy (NACT).

METHODS AND MATERIALS

We retrospectively enrolled 23 consecutive patients with advanced OC who had undergone NACT and mMRI. Seventeen of them had been imaged before and after NACT. Two observers independently measured the ADC values in both ovaries and in the metastatic mass by drawing on a single slice of 1) freehand large ROIs (L-ROIs) covering the solid parts of the whole tumour and 2) three small round ROIs (S-ROIs). The side of the primary ovarian tumour was defined. We evaluated the interobserver reproducibility and statistical significance of the change in tumoural pre- and post-NACT ADC values. Each patient's disease was defined as platinum-sensitive, semi-sensitive, or resistant. The patients were deemed either responders or non-responders.

RESULTS

The interobserver reproducibility of the L-ROI and S-ROI measurements ranged from good to excellent (ICC range: 0.80-0.99). The mean ADC values were significantly higher after NACT in the primary tumour (L-ROI p lt; 0.001, S-ROIs p lt; 0.01) and the increase after NACT was associated with sensitivity to platinum-based chemotherapy. The changes in the ADC values of the omental mass were associated with a response to NACT.

CONCLUSION

s The mean ADC values in the primary tumour increased significantly after NACT in the OC patients and the amount of increase in omental mass predicted a response to platinum-based NACT. Our study indicates that quantitative analysis of ADC values with a single slice and a whole tumour ROI placement is a reproducible method that has a potential role in the evaluation of NACT response in patients with OC.

CLINICAL RELEVANCE/APPLICATION

Quantitative analysis of ADC values potentially has a role in evaluating the NACT response in patients with OC.

PURPOSE

Multiparametric magnetic resonance imaging (mMRI) is the modality of choice in the imaging of ovarian cancer (OC). We aimed to investigate the feasibility of different types of regions of interest (ROIs) in the measurement of apparent diffusion coefficient (ADC) values of diffusion-weighted imaging in OC patients treated with neoadjuvant chemotherapy (NACT).

METHODS AND MATERIALS

We retrospectively enrolled 23 consecutive patients with advanced OC who had undergone NACT and mMRI. Seventeen of them had been imaged before and after NACT. Two observers independently measured the ADC values in both ovaries and in the metastatic mass by drawing on a single slice of 1) freehand large ROIs (L-ROIs) covering the solid parts of the whole tumour and 2) three small round ROIs (S-ROIs). The side of the primary ovarian tumour was defined. We evaluated the interobserver reproducibility and statistical significance of the change in tumoural pre- and post-NACT ADC values. Each patient's disease was defined as platinum-sensitive, semi-sensitive, or resistant. The patients were deemed either responders or non-responders.

RESULTS

The interobserver reproducibility of the L-ROI and S-ROI measurements ranged from good to excellent (ICC range: 0.80-0.99). The mean ADC values were significantly higher after NACT in the primary tumour (L-ROI p lt; 0.001, S-ROIs p lt; 0.01) and the increase after NACT was associated with sensitivity to platinum-based chemotherapy. The changes in the ADC values of the omental mass were associated with a response to NACT.

CONCLUSION

s The mean ADC values in the primary tumour increased significantly after NACT in the OC patients and the amount of increase in omental mass predicted a response to platinum-based NACT. Our study indicates that quantitative analysis of ADC values with a single slice and a whole tumour ROI placement is a reproducible method that has a potential role in the evaluation of NACT response in patients with OC.

CLINICAL RELEVANCE/APPLICATION

Quantitative analysis of ADC values potentially has a role in evaluating the NACT response in patients with OC.

M5A-SPPD

Pediatric Monday Poster Discussions - A

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - PD DPS

Participants
Shailee Lala, MD, New York, NY (*Moderator*) Editor, RELX

Sub-Events

M5A-SPPD-1 Changes to Image-Defined Risk Factors Based on Computed Tomography With Neoadjuvant Chemotherapy in Pediatric Abdominal Neuroblastoma

Participants
Haoru Wang, (*Presenter*) Nothing to Disclose

PURPOSE

To observe the changes to CT-based image-defined risk factors (IDRFs) with neoadjuvant chemotherapy in pediatric abdominal neuroblastoma, and to investigate the correlation between residual IDRFs after neoadjuvant chemotherapy and surgery-related events.

METHODS AND MATERIALS

A total of forty-three patients were enrolled. Surgical and pathological data, as well as CT images at initial diagnosis and after neoadjuvant chemotherapy of all patients were retrospectively collected and analyzed.

RESULTS

The number of IDRFs at first visit was 245, and was significantly reduced to 156 after neoadjuvant chemotherapy ($p < 0.001$). The presence of most IDRFs was significantly improved after neoadjuvant chemotherapy ($p < 0.05$), while the tumor invasion of renal pedicles ($p > 0.05$) and adjacent structures other than kidney ($p > 0.05$) was the least sensitive IDRFs. The loss of IDRFs correlated with the percentage reduction of tumor volume ($p < 0.001$). IDRFs in different neuroblastoma decreased significantly after neoadjuvant chemotherapy ($p < 0.05$), while not significant in neuroblastoma with low and intermediate mitosis-karyorrhexis index ($p > 0.05$). The residual IDRFs correlated with the volume of intraoperative blood loss ($r = 0.399$, $p = 0.008$), while not with the presence of surgical complications ($r = 0.111$, $p = 0.478$).

CONCLUSION

s Neoadjuvant chemotherapy can effectively improve the majority of IDRFs in pediatric abdominal neuroblastoma. The presence of residual IDRFs after neoadjuvant chemotherapy is helpful for preoperative surgical planning, but not correlate with the occurrence of surgical complications in abdominal neuroblastoma.

CLINICAL RELEVANCE/APPLICATION

The present study focused on the changes of CT-based IDRFs with neoadjuvant chemotherapy in pediatric abdominal neuroblastoma. In general, the presence of most IDRFs in abdominal neuroblastoma could be effectively improved by neoadjuvant chemotherapy, while tumor invasion of renal pedicles and adjacent structures other than kidney was least sensitive to neoadjuvant chemotherapy. Meanwhile, we also found that IDRFs of neuroblastoma with low and intermediate MKI do not change significantly after neoadjuvant chemotherapy, and that the residual IDRFs before surgery is helpful for preoperative surgical planning but not correlate with the presence of surgical complications in abdominal neuroblastoma.

M5A-SPPH-1 Feasibility of Simultaneous Iodine and Gadolinium Imaging Using Edge-On-Irradiated Silicon Detector Photon-Counting CT

Participants
Zhye Yin, Niskayuna, NY (*Presenter*) Employee, General Electric Company

PURPOSE

Photon-counting CT (PCCT) enables novel clinical applications such as dual contrast imaging using I and Gd. PCCTs with edge-on-irradiated Si detectors may offer improved spectral capabilities due to desirable detector characteristics such as a narrow photoelectric peak, low charge-sharing and no relevant K-fluorescence. This study aims to demonstrate, in a phantom, the potential of Si-based PCCT to simultaneously image two contrast agents.

METHODS AND MATERIALS

An 20cm cylindrical phantom (Gammex, Sun Nuclear) with two configurations of I and Gd solid inserts was scanned at 120kVp using a prototype PCCT (GE Healthcare) equipped with Si sensors. First, three Gd rods (2.5, 5 and 10mg/ml concentration), and three I rods (2, 5 and 10mg/ml) were scanned in order to demonstrate the separation of I and Gd. Six Gd rods with concentrations ranging from 0.3-10mg/ml were then imaged to determine the lower limit of Gd detection. Circular regions of interest (ROI) were extracted from water and I material basis images to generate a material scatter plot. Gd images were generated by linear combination of water and I material images, and the transform weights estimated based on the scatter plot of known Gd concentrations.

RESULTS

Gd rods with concentrations ranging from 2.5-10mg/ml were consistently separated from the I rods with concentrations of 2-10mg/ml in the material scatter plot. Also, we found that Gd at as low a concentration as 1.25mg/ml can be differentiated in the material scatter plot. Literature suggests that in-vivo Gd concentrations for 1.5T MRI acquisitions range from 0-3mg/ml.

CONCLUSION

s A PCCT system using edge-on-irradiated Si detectors demonstrated separation of I and Gd. Since in vivo Gd concentration in MR acquisitions ranges from 0 to 3mg/ml, our results also suggest that this prototype edge-on-irradiated Si-based CT system can enable Gd detection at contrast dose levels typical of MR. This may enable imaging of multiple contrast agents in the same study and thus the monitoring of multiple phases of contrast enhancement.

CLINICAL RELEVANCE/APPLICATION

PCCT with high spectral capability and a high number of energy bins has the potential to support innovative cardiac and oncology applications using multiple contrast agents simultaneously.

M5A-SPPH-2 Edge-on-irradiated Si-PCCT: Spectral Imaging Performance in a Virtual Imaging Trial

Participants
Raj Kumar Panta, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the spectral imaging performance of an edge-on-irradiated Si photon-counting CT (Si-PCCT) using a virtual imaging trial platform.

METHODS AND MATERIALS

An ACR accredited CT phantom and a computational human model with liver lesions were virtually scanned with Si-PCCT under identical imaging conditions. A newly-developed projection-based maximum-likelihood material decomposition (MD) was applied on spectral sinogram domain. Accuracy of material images and virtual mono-chromatic images (VMI) of the ACR phantom were evaluated against reference values. Similarly, virtual non-contrast CT (VNC) images were generated by imaging a computational human model with iodinated contrast. The accuracy of the VNC images were compared against the true non-contrast CT (TNC) images of the computational human model without contrast-enhancement. The spectral imaging performance of Si-PCCT was further evaluated under various imaging conditions (e.g., radiation dose levels, slice thickness and reconstruction kernels).

RESULTS

Evaluation of material decomposed images revealed that estimated density of calcium and iodine highly corelated (R2 > 0.99) with ground-truth concentrations under various imaging conditions. Similarly, there was a good agreement (> 99%) between virtual monochromatic x-ray attenuation profiles and reference attenuation profiles for various materials. In addition, assessment of the in-plane and cross-plane attenuation profiles showed that mono-chromatic images had less beam-hardening artifacts compared to polychromatic grayscale images. Minor attenuation differences (few HU) were observed between VNC and TNC.

CONCLUSION

s Edge-on-irradiated Si-PCCT with projection-based MD enables quantitative material density images, and accurate VMI and VNC images under various imaging conditions of radiation dose levels, slice thickness and reconstruction kernels.

CLINICAL RELEVANCE/APPLICATION

Our virtual imaging trial demonstrates the quantitative spectral imaging performance of an edge-on-irradiated Si-PCCT under various imaging conditions and it demonstrates the promising utility in quality patient care once prototyped.

M5A-SPPH-3 Synthesizing 100 kV and 120 kV CT Images From Dual-Energy CT Data Using a Novel Ray-By-Ray Effective Energies

Participants
Xin Tie, MS, Madison, WI (*Presenter*) Nothing to Disclose

PURPOSE

Fast-kV switching-based dual-energy CT (DECT) imaging acquires data at 80 kV and 140 kV. Meanwhile, the vast majority of the clinical contrast-enhanced chest and abdominal CTs are performed at 100 or 120 kV. Reference standards for the CT numbers of cystic renal masses, adrenal masses, liver fat fractions, and other quantitative measurements were generally established based on 100 kV and 120 kV CT images. The purpose of this work was to leverage ray-specific effective energies extracted from DECT projection data along with material basis images to accurately synthesize 100 kV and 120 kV CT images desired by radiologists

METHODS AND MATERIALS

For each image object, the effective energies of each ray in the 80 kV and 140 kV acquisitions were first determined based on the line integrals of water and iodine basis images. Then, they were combined using weighting factors to estimate the effective energies of 100 kV and 120 kV acquisitions. With the estimated effective energies and DECT material basis images, 100 kV and 120 kV sinograms were synthesized. The weighting factors were learned from phantoms with known true 100 kV and 120 kV images. Once learned, the factors were fixed to synthesize 100 kV and 120 kV images from DECT data using the effective energy of each measured projection datum. Rigorous evaluations have been performed on physical phantoms (Gammex and anthropomorphic chest phantoms with various inserts) and human subjects. The quantitative accuracy was benchmarked by true 100 kV and 120 kV images of phantoms using relative root mean squared error (rRMSE) and of humans using box-whisker analysis.

RESULTS

The median ([25th, 75th percentiles]) of rRMSE were 0.38% [0.30%, 0.67%] and 0.34% [0.22%, 0.62%] for the synthesized 100 kV and 120 kV images, respectively. For the Gammex and chest phantoms, CT numbers of all inserts were accurately depicted in the synthesized images with CT number errors less than 10 HU. 20 ROIs were randomly selected on adipose tissues of human subjects and the box-whisker plot showed a zero bias between our results and true images (median [25th 75th percentile]: 0.0 [-1.0, 1.0] HU for 100 kV; 0.0 [-2.0, 1.0] HU for 120 kV images).

CONCLUSION

s Using ray-specific effective energies extracted from DECT data, virtual 100 kV and 120 kV CT images can be accurately synthesized without knowing the polychromatic spectra of each scanner.

CLINICAL RELEVANCE/APPLICATION

Even for DECT, 100 kV and 120 kV CT images are still desired by radiologists due to their training and the existing clinical standards organ CT numbers previously established based on 100 kV and 120 kV CT images. This work enables the accurate synthesis of those polychromatic images without additional data acquisitions.

M5A-SPPH-4 Performance Evaluation of Low-contrast Lesion Detectability and Potential Radiation Dose Reduction on Photon-Counting-Detector CT Compared to Energy-integrating-detector CT

Participants
Liqiang Ren, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the performance of low-contrast lesion detectability on a clinical photon-counting-detector CT (PCD-CT) and the potential of radiation dose reduction compared to a single-energy (SE) CT using an energy-integrating-detector (EID).

METHODS AND MATERIALS

Two holes with a diameter of 4 mm and 8 mm in a water-equivalent cylinder were filled with iodine solutions at a concentration of 0.5 mg/cc to mimic different sizes of lesions, and the cylinder was inserted into one of 3 abdomen phantoms (QRM, lateral widths of 30, 35 and 40 cm). The whole phantom was scanned on a clinical PCD-CT system (NAEOTOM Alpha, Siemens) at 120 kV and a 3rd generation dual-source CT (SOMATOM Force, Siemens) in a single-energy mode at the same tube potential (120 kV). The effective mAs was adjusted on PCD-CT and EID-CT to match the CTDIvol values (7.2, 12.0, and 18.4 mGy for 30, 35, and 40 cm phantom, respectively). Scans were repeated six times for each of the 6 unique conditions: 3 phantom sizes and two dose levels (100% and 75% of the routine dose). Threshold-low (T3D) images from PCD-CT and SECT images on EID-CT were reconstructed with an iterative reconstruction algorithm (Kernel/strength: Br40/3), and slice thickness/increment of 3/3.5 mm. Contrast to noise ratio (CNR) and area under the receiver operating characteristic (ROC) curve (AUC) from a calibrated channelized Hotelling observer (CHO) model observer were calculated as figures of merit for quantifying iodine detection on PCD-CT and EID-CT.

RESULTS

PCD-CT showed consistently higher iodine CNR and AUC than EID-SECT for all phantom sizes and radiation levels. Compared to EID-CT, the CNR was improved by 30-70% with PCD-CT for the 8 mm lesion. The AUC values derived for 8 mm lesion detection with all phantoms and that for 4 mm lesion with 30 cm phantom on PCD-CT were only slightly better than EID-CT as they were close to saturation. For 4 mm lesion, the AUC values were ranged in 0.96-0.98 (PCD) and 0.90-0.97 (EID) for 35 cm phantom, and 0.88-0.95 (PCD) and 0.87-0.89 (EID) for 40 cm phantom.

CONCLUSION

s For the identical low-contrast lesion detection task, PCD-CT performs better than EID-CT at all phantom sizes and radiation dose levels, which may allow up to 25% radiation dose reduction depending on lesion and patient sizes while maintaining the same lesion detectability as EID-CT.

CLINICAL RELEVANCE/APPLICATION

Low-contrast lesion detectability can be improved with PCD-CT over EID-CT or maintained as EID-CT but with a potential of up to 25% dose reduction.

M5A-SPPH-5 Evaluation of Small Coronary Stents using High-Resolution Mode Imaging with Deep Learning Imaging Reconstruction

Participants
Kazuki Ishikawa, (*Presenter*) General Electric Company

PURPOSE

Although the frequency of coronary stent restenosis has decreased with the advent of drug-eluting stents, the diagnostic accuracy of restenosis by conventional coronary CT angiography is not high. Although the high-resolution (HR) imaging seems promising for restenosis evaluation because it improves spatial resolution, increased image noise due to dedicated kernel and tube current limitations is a problem. The purpose of this study was to clarify the usefulness of noise reduction by deep learning imaging reconstruction (DLIR) in the evaluation of coronary stents using HR imaging.

METHODS AND MATERIALS

We analyzed the images of coronary stents with inner diameters of 3 mm and 2.5 mm in HR and normal (NR) modes. The images were scanned with an ECG-synchronized axial scan on a commercially available 256 MDCT scanner: tube voltage, 120 kV; current, automatic exposure control; and noise index, 26. Images were reconstructed using hybrid iterative reconstruction (HIR, strength 80%), DLIR-Low (L), -Medium (M) and -High (H), respectively. The kernels used were HD-Stand in HR mode and Stand in NR mode. The values of full width at half maximum (FWHM), standard deviation (SD) of the stent profile, and noise power spectrum (NPS) were measured to evaluate image quality.

RESULTS

The CT dose index volume for HR and NR were both 8.9 mGy. The FWHM of the stent profile in HIR, DLIR-L, DLIR-M, and DLIR-H was 1.00, 1.06, 1.05, and 1.06, respectively for HR at 2.5 mm. For NR at 2.5 mm:1.42,1.49,1.49,and 1.49, respectively. For HR at 3 mm, 0.97, 1.01, 1.01, and 1.01, respectively. For NR at 2.5 mm, 1.28,1.30,1.30,and 1.29, respectively. The FWHM between HR and NR differed significantly ($p<0.01$). The SD difference between HR and NR was 7.74, 9.61, 6.20 and 3.48, respectively. There was a significant difference among the reconstruction methods ($p<0.01$). The peak frequency of the NPS in HR mode was 0.23, 0.34, 0.28, and 0.22 cycles/mm for HIR, DLIR-L, DLIR-M, and DLIR-H, respectively, and the average frequency was 0.35, 0.42, 0.40, and 0.39 cycles/mm, respectively. Compared to the peak and average frequencies of the filtered back projection (0.54 and 0.48 cycles/mm), these results showed a noise texture change of HIR.

CONCLUSION

s The use of DLIR in combination with the HR mode improved the visibility of small-diameter coronary stents by minimizing the image noise and maintaining the image texture.

CLINICAL RELEVANCE/APPLICATION

DLIR minimizes the effects of tube current limitation and noise increase in HR mode. It enables HR mode imaging for larger patients, and can improve the imaging of smaller coronary stents.

M5A-SPPH-6 Signal-To-Noise Ratio Measurement in CT With Conventional and Textured Phantoms: Comparison of Two Deep-Learning Image Reconstruction Techniques

Participants
Hiroki Kawashima, PhD, RT, Kanazawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate signal-to-noise ratio (SNR) improvement by deep-learning image reconstruction (DLIR) techniques, with a conventional method using rod and water phantoms and a new approach using a textured phantom.

METHODS AND MATERIALS

A water-bath phantom with a diameter of 300 mm was used as a base phantom. A textured phantom with a diameter of 128 mm, made by mixing water and 12 mg/mL diluted iodine equivalent materials (IEM), was placed in the base phantom (non-uniform region). In addition, a simple rod made by IEM was placed. Thirty repeated phantom scans were performed using two CT scanners (GE, Revolution CT Apex Edition; Canon, Aquilion One PRISM Edition) at 5 and 15 mGy. Images were reconstructed with filtered back projection (FBP) and DLIR [GE, TrueFidelity (TF); Canon, Advanced intelligent Clear-IQ (AC)] for three process strengths. The task transfer function (TTF) was measured with the rod image; the noise power spectrum (NPS) was measured in the water-only region. The conventional SNR (SNRC(u)) was calculated as a square root of TTF(u)2/NPS(u). A signal spectrum (S(u)) was measured in an averaged image of the non-uniform region using a Fourier analysis, and a noise spectrum (N(u)) was estimated as an average of 30 spectra (S(u)+N(u)) minus the S(u). An SNR for the non-uniform region (SNRNU(u)) was calculated by S(u)/(N(u). The SNR improvement factor (SIF) was calculated by SNR of DLIR divided by SNR of FBP.

RESULTS

The average SIFs of SNRC with TF were 1.88 at 0.1 mm-1, 2.92 at 0.5 mm-1; those with AC were 2.52 at 0.1 mm-1, 6.20 at 0.5 mm-1. On the other hand, the SIFs of SNRNU with TF were 1.41 at 0.1 mm-1, 1.10 at 0.5 mm-1; those with AC were 1.47 at 0.1 mm-1, 1.25 at 0.5 mm-1, which were notably lower than the SIF of SNRC.

CONCLUSION

s Both DLIR techniques sufficiently improved the conventional SNR measured with the rod and water images (88-500%). However, the improvements of SNRNU were low (10-47%), which revealed limited performances for the complex structures included in the textured phantom.

CLINICAL RELEVANCE/APPLICATION

The SIFs measured using the non-uniform region are possibly more clinically relevant compared to the conventional method using simple rods and a uniform water region.

M5A-SPPH-7 Importance of Larger Reconstruction Matrix Sizes for Super-Resolution Deep Learning Reconstruction

Participants
Toru Higaki, PhD, Minami-ku, Hiroshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Recently clinically introduced super-resolution deep learning reconstruction (SR-DLR) can convert conventional- to high-resolution CT images. The matrix size of the output images can be selected as either 512×512 as conventional or 1024×1024. In this study, we investigated the effect of the output image matrix size (the pixel size in the output image) on spatial resolution.

METHODS AND MATERIALS

The SR-DLR was implemented using a super-resolution DCNN (SR-DCNN). It was trained with pairs of high-resolution- and conventional resolution images. The high-resolution images for the training target were acquired using an actual high-resolution CT scanner (Aquilion Precision, Canon Medical Systems Corp.: CMSC) which has a twice larger matrix size. We made a CCTA phantom (Fig. left-bottom) using a 3D printer (Agilista-3200, Keyence). The outer diameter of the phantom was 350×250 mm. Iodine contrast medium diluted with 20 mgI/ml was filled to the simulated left ventricle and coronary arteries. We scanned the CCTA phantom using a conventional CT scanner (Aquilion ONE GENESIS, CMSC) with standard CCTA protocol (tube voltage: 120 kV, tube current: automatic exposure control with SD 23 HU, rotation speed: 0.275 s/rot, ECG-gated volume scan). Images were reconstructed with conventional hybrid iterative reconstruction (IR) (Adaptive Iterative Dose Reduction 3D with FC14 kernel, CMSC) with 512 matrix, SR-DLR with 512 matrix, and SR-DLR with 1024 matrix. The reconstruction FoV was 200 mm, and the pixel sizes of the 512- and 1024-matrix images were 0.39 and 0.195 mm, respectively. We measured profile curves and modulation transfer functions (MTFs) using the edge of a simulated left ventricle and compared their spatial resolution.

RESULTS

The three reconstructed images shown on the left side of the figure indicate that the 1024 matrix SR-DLR image provides the sharpest edges. The edge profile curves and MTF on the right side of the figure also showed a similar trend. The actual MTF of SR-DLR exceeded the Nyquist frequency of 512 matrix images, and 1024 matrix images were required to fully utilize SR-DLR's performance.

CONCLUSION

s To fully utilize the spatial resolution of SR-DLR, it is suitable to reconstruct images with 1024 matrices.

CLINICAL RELEVANCE/APPLICATION

The SR-DLR of 1024 matrix images provides higher spatial resolution, which is useful for the visualization of fine structures such as demonstration of plaques in the coronary artery, and fine lesions in diffuse lung disease.

M5A-SPPH-8 Ranking the Relative Importance of Image Quality Features in CT by Consensus Survey

Participants
Dustin Gress, MS, (*Presenter*) Nothing to Disclose

PURPOSE

To assess consensus opinions from subspecialty radiologists and imaging physicists on the relative importance of image quality features in CT, in order to set subspecialty-informed development priorities for quantitating such features, preferably using automated methods.

METHODS AND MATERIALS

A web-based pictorial survey was created by subject matter expert radiologists and imaging physicists, requesting respondents to rank the relative importance of ten distinct imaging features in their clinical practice, using a 1 (lowest) to 10 (highest) scale. The survey was first sent to subspecialty radiologists and physicists in volunteer leadership roles in the ACR and RSNA, with such roles assumed as reasonable proxy for expertise. The survey then relied on snowball sampling, where respondents could recommend up to 3 suitable experts for invitation to complete the survey.

RESULTS

There were 66 total respondents. Median years of respondent experience for all subspecialties ranged 10-16.5 years. Overall mean rankings for features ranged 5.48-8.74; motion and streaking artifact had the highest average across all subspecialties, scored 8.74 and 8.32, respectively. Lowest overall mean score was for blooming artifact (5.48). Musculoskeletal means were highest for noise texture (9.0) and metal artifact (9.4). Emergency, neuro, pediatric, and abdominal radiologists scored motion artifact highest, with means of 9.89, 9.38, 8.5, and 9.0, respectively. Low contrast axial sharpness was second highest for abdominal radiologists (8.94), with streaking third (8.72). Imaging physicist scored low contrast axial sharpness highest and noise magnitude second highest, with means of 8.94 and 8.78, respectively.

CONCLUSION

s Specific image quality features ranked by expert subspecialty radiologists have relatively higher importance for their routine clinical practice compared to other features, and the importance of identical features also vary between subspecialties. These metrics afford an opportunity to develop targeted image quality measurement tools, especially those that are automated, which can be configurable depending on the practice domain. Limitations include those with expert opinions; responses from thoracic and cardiac radiologists are being collected.

CLINICAL RELEVANCE/APPLICATION

Automated quantification and reporting of relevant medical image quality metrics is an essential step toward enhancing the value of clinical care in medical imaging. This performance paradigm accounts for both radiation dose index management as well as objective image quality management.

M5A-SPPH-9 Detectability Index Analysis of Enterprise CT AP Protocols

Participants
Brian Hurley, MS, (*Presenter*) Nothing to Disclose

PURPOSE

With trends to move toward enterprise-wide radiology management there should be image quality standardization across a hospital system. The purpose is to develop a methodology to assess image quality uniformity for the adult abdomen and pelvis protocol across a hospital enterprise which includes a CT scanner fleet with multiple manufacturers and models.

METHODS AND MATERIALS

A dose tracking software (Radimetrics) was used to gather data on abdomen and pelvis with contrast scans across a health enterprise for the 2nd Quarter of 2021. (3,603 scans). From this dataset, the 5th, 25th, 50th, 75th, and 95th percentiles of the CTDIVol were extracted for each facility in the hospital enterprise. The ACR CT accreditation phantom was scanned at each of the facility specific CTDIVol values and these scans were assessed using the ImQuest software by Duke CIPG to obtain the detectability index (d'). To normalize the dose dependence of the image quality, the d'2/CTDIVol for the 25th, 50th and 75th percentiles were calculated and compared to evaluate the protocol performance.

RESULTS

The range of the d'2/CTDIVol for the 25th, 50th and 75th percentiles was 124 to 263, 112 to 267, and 105 to 269 respectively. The absolute differences for the 25th, 50th, and 75th were 139, 155, and 164 which corresponds to a percent difference of 72%, 82% and 88%. When comparing a single institution, the largest percent difference within the scanners at a given institution for the protocol 50th percentile of dose was found to be 29%.

CONCLUSION

s There is substantial variation in the image quality for the abdomen pelvis protocols across the hospital enterprise examined. Additionally, there is a significant variation within hospitals when multiple makes/models were utilized. Currently much effort is placed on protocol optimization in terms of dose (CTDI, DLP or Effective Dose). Though dose is a loose surrogate for image quality, with advanced applications on modern scanners and the growing push towards enterprise healthcare more focus should be placed on providing uniform image quality for a given protocol across different scanner types at a hospital enterprise. This analysis was done with a 5 mm lesion based on acrylic TTF and contrast, in the future this should be expanded to other lesion sizes and contrast levels with the potential to select the target (lesion size, contrast, etc.) based on clinical indication.

CLINICAL RELEVANCE/APPLICATION

The findings of this study can be used to help improve image quality uniformity across a large hospital system. This methodology can be applied to other adult and pediatric protocols to assess image quality uniformity across multiple CT scanners independent of make and model.

Feasibility of Simultaneous Iodine and Gadolinium Imaging Using Edge-On-Irradiated Silicon Detector Photon-Counting CT

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - PH DPS

Participants
Zhye Yin, Niskayuna, NY (*Presenter*) Employee, General Electric Company

PURPOSE

Photon-counting CT (PCCT) enables novel clinical applications such as dual contrast imaging using I and Gd. PCCTs with edge-on-irradiated Si detectors may offer improved spectral capabilities due to desirable detector characteristics such as a narrow photoelectric peak, low charge-sharing and no relevant K-fluorescence. This study aims to demonstrate, in a phantom, the potential of Si-based PCCT to simultaneously image two contrast agents.

METHODS AND MATERIALS

An 20cm cylindrical phantom (Gammex, Sun Nuclear) with two configurations of I and Gd solid inserts was scanned at 120kVp using a prototype PCCT (GE Healthcare) equipped with Si sensors. First, three Gd rods (2.5, 5 and 10mg/ml concentration), and three I rods (2, 5 and 10mg/ml) were scanned in order to demonstrate the separation of I and Gd. Six Gd rods with concentrations ranging from 0.3-10mg/ml were then imaged to determine the lower limit of Gd detection. Circular regions of interest (ROI) were extracted from water and I material basis images to generate a material scatter plot. Gd images were generated by linear combination of water and I material images, and the transform weights estimated based on the scatter plot of known Gd concentrations.

RESULTS

Gd rods with concentrations ranging from 2.5-10mg/ml were consistently separated from the I rods with concentrations of 2-10mg/ml in the material scatter plot. Also, we found that Gd at as low a concentration as 1.25mg/ml can be differentiated in the material scatter plot. Literature suggests that in-vivo Gd concentrations for 1.5T MRI acquisitions range from 0-3mg/ml.

CONCLUSION

s A PCCT system using edge-on-irradiated Si detectors demonstrated separation of I and Gd. Since in vivo Gd concentration in MR acquisitions ranges from 0 to 3mg/ml, our results also suggest that this prototype edge-on-irradiated Si-based CT system can enable Gd detection at contrast dose levels typical of MR. This may enable imaging of multiple contrast agents in the same study and thus the monitoring of multiple phases of contrast enhancement.

CLINICAL RELEVANCE/APPLICATION

PCCT with high spectral capability and a high number of energy bins has the potential to support innovative cardiac and oncology applications using multiple contrast agents simultaneously.

Edge-on-irradiated Si-PCCT: Spectral Imaging Performance in a Virtual Imaging Trial

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - PH DPS

Participants
Raj Kumar Panta, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the spectral imaging performance of an edge-on-irradiated Si photon-counting CT (Si-PCCT) using a virtual imaging trial platform.

METHODS AND MATERIALS

An ACR accredited CT phantom and a computational human model with liver lesions were virtually scanned with Si-PCCT under identical imaging conditions. A newly-developed projection-based maximum-likelihood material decomposition (MD) was applied on spectral sinogram domain. Accuracy of material images and virtual mono-chromatic images (VMI) of the ACR phantom were evaluated against reference values. Similarly, virtual non-contrast CT (VNC) images were generated by imaging a computational human model with iodinated contrast. The accuracy of the VNC images were compared against the true non-contrast CT (TNC) images of the computational human model without contrast-enhancement. The spectral imaging performance of Si-PCCT was further evaluated under various imaging conditions (e.g., radiation dose levels, slice thickness and reconstruction kernels).

RESULTS

Evaluation of material decomposed images revealed that estimated density of calcium and iodine highly corelated (R2 > 0.99) with ground-truth concentrations under various imaging conditions. Similarly, there was a good agreement (> 99%) between virtual monochromatic x-ray attenuation profiles and reference attenuation profiles for various materials. In addition, assessment of the in-plane and cross-plane attenuation profiles showed that mono-chromatic images had less beam-hardening artifacts compared to polychromatic grayscale images. Minor attenuation differences (few HU) were observed between VNC and TNC.

CONCLUSION

s Edge-on-irradiated Si-PCCT with projection-based MD enables quantitative material density images, and accurate VMI and VNC images under various imaging conditions of radiation dose levels, slice thickness and reconstruction kernels.

CLINICAL RELEVANCE/APPLICATION

Our virtual imaging trial demonstrates the quantitative spectral imaging performance of an edge-on-irradiated Si-PCCT under various imaging conditions and it demonstrates the promising utility in quality patient care once prototyped.

Synthesizing 100 kV and 120 kV CT Images From Dual-Energy CT Data Using a Novel Ray-By-Ray Effective Energies

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - PH DPS

Participants
Xin Tie, MS, Madison, WI (*Presenter*) Nothing to Disclose

PURPOSE

Fast-kV switching-based dual-energy CT (DECT) imaging acquires data at 80 kV and 140 kV. Meanwhile, the vast majority of the clinical contrast-enhanced chest and abdominal CTs are performed at 100 or 120 kV. Reference standards for the CT numbers of cystic renal masses, adrenal masses, liver fat fractions, and other quantitative measurements were generally established based on 100 kV and 120 kV CT images. The purpose of this work was to leverage ray-specific effective energies extracted from DECT projection data along with material basis images to accurately synthesize 100 kV and 120 kV CT images desired by radiologists

METHODS AND MATERIALS

For each image object, the effective energies of each ray in the 80 kV and 140 kV acquisitions were first determined based on the line integrals of water and iodine basis images. Then, they were combined using weighting factors to estimate the effective energies of 100 kV and 120 kV acquisitions. With the estimated effective energies and DECT material basis images, 100 kV and 120 kV sinograms were synthesized. The weighting factors were learned from phantoms with known true 100 kV and 120 kV images. Once learned, the factors were fixed to synthesize 100 kV and 120 kV images from DECT data using the effective energy of each measured projection datum. Rigorous evaluations have been performed on physical phantoms (Gammex and anthropomorphic chest phantoms with various inserts) and human subjects. The quantitative accuracy was benchmarked by true 100 kV and 120 kV images of phantoms using relative root mean squared error (rRMSE) and of humans using box-whisker analysis.

RESULTS

The median ([25th, 75th percentiles]) of rRMSE were 0.38% [0.30%, 0.67%] and 0.34% [0.22%, 0.62%] for the synthesized 100 kV and 120 kV images, respectively. For the Gammex and chest phantoms, CT numbers of all inserts were accurately depicted in the synthesized images with CT number errors less than 10 HU. 20 ROIs were randomly selected on adipose tissues of human subjects and the box-whisker plot showed a zero bias between our results and true images (median [25th 75th percentile]: 0.0 [-1.0, 1.0] HU for 100 kV; 0.0 [-2.0, 1.0] HU for 120 kV images).

CONCLUSION

s Using ray-specific effective energies extracted from DECT data, virtual 100 kV and 120 kV CT images can be accurately synthesized without knowing the polychromatic spectra of each scanner.

CLINICAL RELEVANCE/APPLICATION

Even for DECT, 100 kV and 120 kV CT images are still desired by radiologists due to their training and the existing clinical standards organ CT numbers previously established based on 100 kV and 120 kV CT images. This work enables the accurate synthesis of those polychromatic images without additional data acquisitions.

M5A-SPPH-4

Performance Evaluation of Low-contrast Lesion Detectability and Potential Radiation Dose Reduction on Photon-Counting-Detector CT Compared to Energy-integrating-detector CT

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - PH DPS

Participants
Liqiang Ren, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the performance of low-contrast lesion detectability on a clinical photon-counting-detector CT (PCD-CT) and the potential of radiation dose reduction compared to a single-energy (SE) CT using an energy-integrating-detector (EID).

METHODS AND MATERIALS

Two holes with a diameter of 4 mm and 8 mm in a water-equivalent cylinder were filled with iodine solutions at a concentration of 0.5 mg/cc to mimic different sizes of lesions, and the cylinder was inserted into one of 3 abdomen phantoms (QRM, lateral widths of 30, 35 and 40 cm). The whole phantom was scanned on a clinical PCD-CT system (NAEOTOM Alpha, Siemens) at 120 kV and a 3rd generation dual-source CT (SOMATOM Force, Siemens) in a single-energy mode at the same tube potential (120 kV). The effective mAs was adjusted on PCD-CT and EID-CT to match the CTDIvol values (7.2, 12.0, and 18.4 mGy for 30, 35, and 40 cm phantom, respectively). Scans were repeated six times for each of the 6 unique conditions: 3 phantom sizes and two dose levels (100% and 75% of the routine dose). Threshold-low (T3D) images from PCD-CT and SECT images on EID-CT were reconstructed with an iterative reconstruction algorithm (Kernel/strength: Br40/3), and slice thickness/increment of 3/3.5 mm. Contrast to noise ratio (CNR) and area under the receiver operating characteristic (ROC) curve (AUC) from a calibrated channelized Hotelling observer (CHO) model observer were calculated as figures of merit for quantifying iodine detection on PCD-CT and EID-CT.

RESULTS

PCD-CT showed consistently higher iodine CNR and AUC than EID-SECT for all phantom sizes and radiation levels. Compared to EID-CT, the CNR was improved by 30-70% with PCD-CT for the 8 mm lesion. The AUC values derived for 8 mm lesion detection with all phantoms and that for 4 mm lesion with 30 cm phantom on PCD-CT were only slightly better than EID-CT as they were close to saturation. For 4 mm lesion, the AUC values were ranged in 0.96-0.98 (PCD) and 0.90-0.97 (EID) for 35 cm phantom, and 0.88-0.95 (PCD) and 0.87-0.89 (EID) for 40 cm phantom.

CONCLUSION

s For the identical low-contrast lesion detection task, PCD-CT performs better than EID-CT at all phantom sizes and radiation dose levels, which may allow up to 25% radiation dose reduction depending on lesion and patient sizes while maintaining the same lesion detectability as EID-CT.

CLINICAL RELEVANCE/APPLICATION

Low-contrast lesion detectability can be improved with PCD-CT over EID-CT or maintained as EID-CT but with a potential of up to 25% dose reduction.

M5A-SPPH-5

Evaluation of Small Coronary Stents using High-Resolution Mode Imaging with Deep Learning Imaging Reconstruction

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - PH DPS

Participants
Kazuki Ishikawa, (*Presenter*) General Electric Company

PURPOSE

Although the frequency of coronary stent restenosis has decreased with the advent of drug-eluting stents, the diagnostic accuracy of restenosis by conventional coronary CT angiography is not high. Although the high-resolution (HR) imaging seems promising for restenosis evaluation because it improves spatial resolution, increased image noise due to dedicated kernel and tube current limitations is a problem. The purpose of this study was to clarify the usefulness of noise reduction by deep learning imaging reconstruction (DLIR) in the evaluation of coronary stents using HR imaging.

METHODS AND MATERIALS

We analyzed the images of coronary stents with inner diameters of 3 mm and 2.5 mm in HR and normal (NR) modes. The images were scanned with an ECG-synchronized axial scan on a commercially available 256 MDCT scanner: tube voltage, 120 kV; current, automatic exposure control; and noise index, 26. Images were reconstructed using hybrid iterative reconstruction (HIR, strength 80%), DLIR-Low (L), -Medium (M) and -High (H), respectively. The kernels used were HD-Stand in HR mode and Stand in NR mode. The values of full width at half maximum (FWHM), standard deviation (SD) of the stent profile, and noise power spectrum (NPS) were measured to evaluate image quality.

RESULTS

The CT dose index volume for HR and NR were both 8.9 mGy. The FWHM of the stent profile in HIR, DLIR-L, DLIR-M, and DLIR-H was 1.00, 1.06, 1.05, and 1.06, respectively for HR at 2.5 mm. For NR at 2.5 mm:1.42,1.49,1.49,and 1.49, respectively. For HR at 3 mm, 0.97, 1.01, 1.01, and 1.01, respectively. For NR at 2.5 mm, 1.28,1.30,1.30,and 1.29, respectively. The FWHM between HR and NR differed significantly ($p<0.01$). The SD difference between HR and NR was 7.74, 9.61, 6.20 and 3.48, respectively. There was a significant difference among the reconstruction methods ($p<0.01$). The peak frequency of the NPS in HR mode was 0.23, 0.34, 0.28, and 0.22 cycles/mm for HIR, DLIR-L, DLIR-M, and DLIR-H, respectively, and the average frequency was 0.35, 0.42, 0.40, and 0.39 cycles/mm, respectively. Compared to the peak and average frequencies of the filtered back projection (0.54 and 0.48 cycles/mm), these results showed a noise texture change of HIR.

CONCLUSION

s The use of DLIR in combination with the HR mode improved the visibility of small-diameter coronary stents by minimizing the image noise and maintaining the image texture.

CLINICAL RELEVANCE/APPLICATION

DLIR minimizes the effects of tube current limitation and noise increase in HR mode. It enables HR mode imaging for larger patients, and can improve the imaging of smaller coronary stents.

Signal-To-Noise Ratio Measurement in CT With Conventional and Textured Phantoms: Comparison of Two Deep-Learning Image Reconstruction Techniques

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - PH DPS

Participants
Hiroki Kawashima, PhD, RT, Kanazawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate signal-to-noise ratio (SNR) improvement by deep-learning image reconstruction (DLIR) techniques, with a conventional method using rod and water phantoms and a new approach using a textured phantom.

METHODS AND MATERIALS

A water-bath phantom with a diameter of 300 mm was used as a base phantom. A textured phantom with a diameter of 128 mm, made by mixing water and 12 mg/mL diluted iodine equivalent materials (IEM), was placed in the base phantom (non-uniform region). In addition, a simple rod made by IEM was placed. Thirty repeated phantom scans were performed using two CT scanners (GE, Revolution CT Apex Edition; Canon, Aquilion One PRISM Edition) at 5 and 15 mGy. Images were reconstructed with filtered back projection (FBP) and DLIR [GE, TrueFidelity (TF); Canon, Advanced intelligent Clear-IQ (AC)] for three process strengths. The task transfer function (TTF) was measured with the rod image; the noise power spectrum (NPS) was measured in the water-only region. The conventional SNR (SNRC(u)) was calculated as a square root of TTF(u)2/NPS(u). A signal spectrum (S(u)) was measured in an averaged image of the non-uniform region using a Fourier analysis, and a noise spectrum (N(u)) was estimated as an average of 30 spectra (S(u)+N(u)) minus the S(u). An SNR for the non-uniform region (SNRNU(u)) was calculated by S(u)/(N(u). The SNR improvement factor (SIF) was calculated by SNR of DLIR divided by SNR of FBP.

RESULTS

The average SIFs of SNRC with TF were 1.88 at 0.1 mm-1, 2.92 at 0.5 mm-1; those with AC were 2.52 at 0.1 mm-1, 6.20 at 0.5 mm-1. On the other hand, the SIFs of SNRNU with TF were 1.41 at 0.1 mm-1, 1.10 at 0.5 mm-1; those with AC were 1.47 at 0.1 mm-1, 1.25 at 0.5 mm-1, which were notably lower than the SIF of SNRC.

CONCLUSION

s Both DLIR techniques sufficiently improved the conventional SNR measured with the rod and water images (88-500%). However, the improvements of SNRNU were low (10-47%), which revealed limited performances for the complex structures included in the textured phantom.

CLINICAL RELEVANCE/APPLICATION

The SIFs measured using the non-uniform region are possibly more clinically relevant compared to the conventional method using simple rods and a uniform water region.

M5A-SPPH-7

Importance of Larger Reconstruction Matrix Sizes for Super-Resolution Deep Learning Reconstruction

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - PH DPS

Participants
Toru Higaki, PhD, Minami-ku, Hiroshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Recently clinically introduced super-resolution deep learning reconstruction (SR-DLR) can convert conventional- to high-resolution CT images. The matrix size of the output images can be selected as either 512×512 as conventional or 1024×1024. In this study, we investigated the effect of the output image matrix size (the pixel size in the output image) on spatial resolution.

METHODS AND MATERIALS

The SR-DLR was implemented using a super-resolution DCNN (SR-DCNN). It was trained with pairs of high-resolution- and conventional resolution images. The high-resolution images for the training target were acquired using an actual high-resolution CT scanner (Aquilion Precision, Canon Medical Systems Corp.: CMSC) which has a twice larger matrix size. We made a CCTA phantom (Fig. left-bottom) using a 3D printer (Agilista-3200, Keyence). The outer diameter of the phantom was 350×250 mm. Iodine contrast medium diluted with 20 mgI/ml was filled to the simulated left ventricle and coronary arteries. We scanned the CCTA phantom using a conventional CT scanner (Aquilion ONE GENESIS, CMSC) with standard CCTA protocol (tube voltage: 120 kV, tube current: automatic exposure control with SD 23 HU, rotation speed: 0.275 s/rot, ECG-gated volume scan). Images were reconstructed with conventional hybrid iterative reconstruction (IR) (Adaptive Iterative Dose Reduction 3D with FC14 kernel, CMSC) with 512 matrix, SR-DLR with 512 matrix, and SR-DLR with 1024 matrix. The reconstruction FoV was 200 mm, and the pixel sizes of the 512- and 1024-matrix images were 0.39 and 0.195 mm, respectively. We measured profile curves and modulation transfer functions (MTFs) using the edge of a simulated left ventricle and compared their spatial resolution.

RESULTS

The three reconstructed images shown on the left side of the figure indicate that the 1024 matrix SR-DLR image provides the sharpest edges. The edge profile curves and MTF on the right side of the figure also showed a similar trend. The actual MTF of SR-DLR exceeded the Nyquist frequency of 512 matrix images, and 1024 matrix images were required to fully utilize SR-DLR's performance.

CONCLUSION

s To fully utilize the spatial resolution of SR-DLR, it is suitable to reconstruct images with 1024 matrices.

CLINICAL RELEVANCE/APPLICATION

The SR-DLR of 1024 matrix images provides higher spatial resolution, which is useful for the visualization of fine structures such as demonstration of plaques in the coronary artery, and fine lesions in diffuse lung disease.

M5A-SPPH-8

Ranking the Relative Importance of Image Quality Features in CT by Consensus Survey

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - PH DPS

Participants
Dustin Gress, MS, (*Presenter*) Nothing to Disclose

PURPOSE

To assess consensus opinions from subspecialty radiologists and imaging physicists on the relative importance of image quality features in CT, in order to set subspecialty-informed development priorities for quantitating such features, preferably using automated methods.

METHODS AND MATERIALS

A web-based pictorial survey was created by subject matter expert radiologists and imaging physicists, requesting respondents to rank the relative importance of ten distinct imaging features in their clinical practice, using a 1 (lowest) to 10 (highest) scale. The survey was first sent to subspecialty radiologists and physicists in volunteer leadership roles in the ACR and RSNA, with such roles assumed as reasonable proxy for expertise. The survey then relied on snowball sampling, where respondents could recommend up to 3 suitable experts for invitation to complete the survey.

RESULTS

There were 66 total respondents. Median years of respondent experience for all subspecialties ranged 10-16.5 years. Overall mean rankings for features ranged 5.48-8.74; motion and streaking artifact had the highest average across all subspecialties, scored 8.74 and 8.32, respectively. Lowest overall mean score was for blooming artifact (5.48). Musculoskeletal means were highest for noise texture (9.0) and metal artifact (9.4). Emergency, neuro, pediatric, and abdominal radiologists scored motion artifact highest, with means of 9.89, 9.38, 8.5, and 9.0, respectively. Low contrast axial sharpness was second highest for abdominal radiologists (8.94), with streaking third (8.72). Imaging physicist scored low contrast axial sharpness highest and noise magnitude second highest, with means of 8.94 and 8.78, respectively.

CONCLUSION

s Specific image quality features ranked by expert subspecialty radiologists have relatively higher importance for their routine clinical practice compared to other features, and the importance of identical features also vary between subspecialties. These metrics afford an opportunity to develop targeted image quality measurement tools, especially those that are automated, which can be configurable depending on the practice domain. Limitations include those with expert opinions; responses from thoracic and cardiac radiologists are being collected.

CLINICAL RELEVANCE/APPLICATION

Automated quantification and reporting of relevant medical image quality metrics is an essential step toward enhancing the value of clinical care in medical imaging. This performance paradigm accounts for both radiation dose index management as well as objective image quality management.

Detectability Index Analysis of Enterprise CT AP Protocols

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - PH DPS

Participants
Brian Hurley, MS, (*Presenter*) Nothing to Disclose

PURPOSE

With trends to move toward enterprise-wide radiology management there should be image quality standardization across a hospital system. The purpose is to develop a methodology to assess image quality uniformity for the adult abdomen and pelvis protocol across a hospital enterprise which includes a CT scanner fleet with multiple manufacturers and models.

METHODS AND MATERIALS

A dose tracking software (Radimetrics) was used to gather data on abdomen and pelvis with contrast scans across a health enterprise for the 2nd Quarter of 2021. (3,603 scans). From this dataset, the 5th, 25th, 50th, 75th, and 95th percentiles of the CTDIVol were extracted for each facility in the hospital enterprise. The ACR CT accreditation phantom was scanned at each of the facility specific CTDIVol values and these scans were assessed using the ImQuest software by Duke CIPG to obtain the detectability index (d'). To normalize the dose dependence of the image quality, the d'2/CTDIVol for the 25th, 50th and 75th percentiles were calculated and compared to evaluate the protocol performance.

RESULTS

The range of the d'2/CTDIVol for the 25th, 50th and 75th percentiles was 124 to 263, 112 to 267, and 105 to 269 respectively. The absolute differences for the 25th, 50th, and 75th were 139, 155, and 164 which corresponds to a percent difference of 72%, 82% and 88%. When comparing a single institution, the largest percent difference within the scanners at a given institution for the protocol 50th percentile of dose was found to be 29%.

CONCLUSION

s There is substantial variation in the image quality for the abdomen pelvis protocols across the hospital enterprise examined. Additionally, there is a significant variation within hospitals when multiple makes/models were utilized. Currently much effort is placed on protocol optimization in terms of dose (CTDI, DLP or Effective Dose). Though dose is a loose surrogate for image quality, with advanced applications on modern scanners and the growing push towards enterprise healthcare more focus should be placed on providing uniform image quality for a given protocol across different scanner types at a hospital enterprise. This analysis was done with a 5 mm lesion based on acrylic TTF and contrast, in the future this should be expanded to other lesion sizes and contrast levels with the potential to select the target (lesion size, contrast, etc.) based on clinical indication.

CLINICAL RELEVANCE/APPLICATION

The findings of this study can be used to help improve image quality uniformity across a large hospital system. This methodology can be applied to other adult and pediatric protocols to assess image quality uniformity across multiple CT scanners independent of make and model.

M5A-SPRO-1 Comparison of Bladder Wall Only- and Whole Bladder Volume- Doses in Neoadjuvant Radiotherapy of Rectal Cancer

Participants
Ayse Dagli, Istanbul, Turkey (*Presenter*) Nothing to Disclose

PURPOSE

To dosimetrically compare the bladder doses obtained from whole bladder volume and bladder wall only in neoadjuvant radiotherapy of locally advanced rectal cancer (LARC).

METHODS AND MATERIALS

Treatment planning CT images of 65 LARC patients (M/F: 41/24) treated with neoadjuvant radiotherapy were used. Median patient age was 60 (33-82). CT simulation images were taken in supine position with full bladder using iv contrast, with 3.75 mm slice thickness in all patients. Tumor location was proximal rectum in 2 patients, mid-rectum in 27 and distal rectum in 36. Primary tumor was contoured as GTV. CTV-tumor was covering GTV plus 2 cm proximally and distally, and mezorectum radially. Pelvic great vessels, starting from aortic bifurcation, were contoured with a 0.8 cm margin and pre-sacral and obturator regions were included to create CTV-LNs. Whole bladder (WB) and bladder wall only (BW) were separately contoured for study purpose. Prescribed dose was 50.4 Gy in 1.8 Gy/fx for PTV-LNs and PTV-tumor. All plans were done with VMAT using two full arcs. Maximum dose (Dmax), volumes (%) receiving 40 Gy (V40), 45 Gy (V45) and 50 Gy (V50) for WB and BW were recorded and compared. Paired t-test was used for statistical analysis. $P<0.05$ was accepted statistically significant.

RESULTS

Median GTV length was 8 (5-14) cm. Median GTV and total PTV volumes were 78.4 (30.5-330) and 1133 (784-11451.2) ml, respectively. Median WB and BW volumes were 522.5 (157.7-989.6) and 129.9 (33.2-211.3) ml, respectively. Median Dmax was 53.3 (49.5-54.6) Gy in both WB and BW ($p=0.5$). V40, V45 and V50 were significantly higher for BW than WB ($p<0.0001$) (Table). Median BW/WB ratios of V40, V45 and V50 were 1.6 (1.1-2.5), 2 (1.2-3.1) and 2.6 (1.6-3.8), respectively.Table. Median (min-max) whole bladder (WB) and bladder wall only (BW) volumes (ml) and volumes receiving 40 Gy (V40), 45 Gy (V45) and 50 Gy (V50) (%).

CONCLUSION

s Except maximum bladder dose, bladder doses obtained from whole bladder volume does not represent bladder wall doses in LARC patients treated with neoadjuvant radiotherapy. Further studies are needed to evaluate clinical impact of these results.

CLINICAL RELEVANCE/APPLICATION

Whole bladder volume doses are being used for bladder dose constraints in neoadjuvant radiotherapy of locally advanced rectal cancer. However, they do not represent bladder wall doses. This may explain higher than expected bladder side effects in some patients. Bladder wall doses may be used to better predict treatment related side effects in rectal cancer patients treated with neoadjuvant radiotherapy.

Comparison of Bladder Wall Only- and Whole Bladder Volume- Doses in Neoadjuvant Radiotherapy of Rectal Cancer

Monday, Nov. 28 12:15PM - 12:45PM Room: Learning Center - RO DPS

Participants
Ayse Dagli, Istanbul, Turkey (*Presenter*) Nothing to Disclose

PURPOSE

To dosimetrically compare the bladder doses obtained from whole bladder volume and bladder wall only in neoadjuvant radiotherapy of locally advanced rectal cancer (LARC).

METHODS AND MATERIALS

Treatment planning CT images of 65 LARC patients (M/F: 41/24) treated with neoadjuvant radiotherapy were used. Median patient age was 60 (33-82). CT simulation images were taken in supine position with full bladder using iv contrast, with 3.75 mm slice thickness in all patients. Tumor location was proximal rectum in 2 patients, mid-rectum in 27 and distal rectum in 36. Primary tumor was contoured as GTV. CTV-tumor was covering GTV plus 2 cm proximally and distally, and mezorectum radially. Pelvic great vessels, starting from aortic bifurcation, were contoured with a 0.8 cm margin and pre-sacral and obturator regions were included to create CTV-LNs. Whole bladder (WB) and bladder wall only (BW) were separately contoured for study purpose. Prescribed dose was 50.4 Gy in 1.8 Gy/fx for PTV-LNs and PTV-tumor. All plans were done with VMAT using two full arcs. Maximum dose (Dmax), volumes (%) receiving 40 Gy (V40), 45 Gy (V45) and 50 Gy (V50) for WB and BW were recorded and compared. Paired t-test was used for statistical analysis. $P<0.05$ was accepted statistically significant.

RESULTS

Median GTV length was 8 (5-14) cm. Median GTV and total PTV volumes were 78.4 (30.5-330) and 1133 (784-11451.2) ml, respectively. Median WB and BW volumes were 522.5 (157.7-989.6) and 129.9 (33.2-211.3) ml, respectively. Median Dmax was 53.3 (49.5-54.6) Gy in both WB and BW ($p=0.5$). V40, V45 and V50 were significantly higher for BW than WB ($p<0.0001$) (Table). Median BW/WB ratios of V40, V45 and V50 were 1.6 (1.1-2.5), 2 (1.2-3.1) and 2.6 (1.6-3.8), respectively.Table. Median (min-max) whole bladder (WB) and bladder wall only (BW) volumes (ml) and volumes receiving 40 Gy (V40), 45 Gy (V45) and 50 Gy (V50) (%).

CONCLUSION

s Except maximum bladder dose, bladder doses obtained from whole bladder volume does not represent bladder wall doses in LARC patients treated with neoadjuvant radiotherapy. Further studies are needed to evaluate clinical impact of these results.

CLINICAL RELEVANCE/APPLICATION

Whole bladder volume doses are being used for bladder dose constraints in neoadjuvant radiotherapy of locally advanced rectal cancer. However, they do not represent bladder wall doses. This may explain higher than expected bladder side effects in some patients. Bladder wall doses may be used to better predict treatment related side effects in rectal cancer patients treated with neoadjuvant radiotherapy.

Sub-Events

M5A-SPVA-1 A Comparison of Emergency ECG-gated CT and Surgical Findings in Acute Aortic Syndrome

Participants
Makoto Orii, (*Presenter*) Nothing to Disclose

PURPOSE

The accuracy of ECG-gated CT findings in acute aortic syndrome (AAS), compared to surgical confirmation as the reference standard, remains unknown. The purpose of study is to compare the detection accuracies of ECG-gated CT for intimal tear (IT) in aortic dissection (AD) and ulcer-like projection (ULP) in intramural hematoma (IMH).

METHODS AND MATERIALS

This retrospective study was conducted from September 2005 to November 2021. The accuracies of detecting IT and ULP were compared among both diastolic- and systolic-phase, only diastolic-phase, and only systolic-phase modalities of ECG-gated CT using the Cochran's Q test.

RESULTS

Data from 81 patients (mean age±SD, 67.6 years±11.8; 41 men) who underwent emergency ECG-gated CT and subsequent open surgery or thoracic endovascular aortic repair (TEVAR) for AD (n=52) or IMH (n=29) were included. The detection accuracy for IT and ULP using both diastolic- and systolic-phase, only diastolic-phase, and only systolic-phase modalities of ECG-gated CT was 95% [95% CI: 90-97], 93% [95% CI: 87-97], and 94% [95% CI: 88-97], respectively. There were no significant differences in detection accuracy among the three modalities tested (P=0.55). There were no significant differences among both diastolic- and systolic-phase (96% [95% CI: 96-96]), only diastolic-phase (92% [95% CI: 92-97]), and only systolic-phase ECG-gated CT (94% [91% CI: 91-97], P=0.55) for the detection of IT in AD. Similarly, there were no significant differences in the accuracy of detecting ULP in IMH among both diastolic- and systolic-phase (93% [95% CI: 80-98]), only diastolic-phase (93% [95% CI: 80-98]), and only systolic-phase ECG-gated CT (93% [95% CI: 80-98], P>0.99).

CONCLUSION

s ECG-gated CT of the thorax for AAS yields highly accurate findings; however, no significant differences in the accuracy of detecting IT in AD and ULP in IMH were seen among the three modalities of ECG-gated CT.

CLINICAL RELEVANCE/APPLICATION

Recently, the detection of IT in AD and ULP in IMH has been recognized as an important factor that affects treatment selection, i.e., open surgery versus TEVAR. This is the first study to investigate the accuracy of both diastolic and systolic-phase ECG-gated CT for detecting IT and ULP with surgical confirmation as the reference standard. Emergency ECG-gated CT provides high diagnostic accuracy for detecting IT in AD and ULP in IMH. The findings of this study will sheds light on how surgeons can provide the best care for AAD patients in clinical practice.

M5B-SPBR-1 Investigating Conducive Conditions for Detecting Breast Biopsy Markers by Ultrasound Color Doppler Twinkling

Participants
Christine U. Lee, MD, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

PURPOSE

Identifying breast biopsy clips or markers, particularly in patients with breast cancer after neoadjuvant systemic therapy, is necessary for surgical management, but ultrasound detection of these markers can be challenging, if not prohibitive. This study aims to determine what optimizes color Doppler twinkling of breast biopsy markers, when present, and whether marker surface roughness is associated with their twinkling signatures.

METHODS AND MATERIALS

Thirty-five biopsy markers were evaluated using three different transducers (ML6-15, 9L, C1-6 on a Logiq E9 scanner, General Electric (GE) Healthcare, Wauwatosa, WI) in three different media (solid gel phantom, ultrasound coupling gel, and ex vivo cadaveric breasts). The twinkling signature was rated on an ordinal scale from 0 (none) to 4 (marked). Actionable ultrasound detection was defined to mean sufficiently confident detection of a target to act on it (e.g., radioactive seed localization) independent of its B-mode conspicuity. Surface roughness measurements and micro-CT images were obtained for each marker. A mixed-effects proportional odds regression model was used to examine the associations of embedding material and transducers with the twinkling scores, and a two-sided Wilcoxon rank sum test was used to compare the surface roughness measurements by twinkling rating actionability.

RESULTS

Embedding materials were associated with significantly higher twinkling ratings in both solid gel phantom ($P < 0.001$) and coupling gel media ($P = 0.002$), and there were significant pairwise differences among transducers across all media, with C1-6 > 9L > ML6-15 in solid gel phantom (all $P < 0.05$). Higher surface roughness was associated with actionable twinkling scores in cadaveric breast for both C1-6 ($P = 0.022$) and 9L transducers ($P = 0.002$).

CONCLUSION

s Color Doppler twinkling signatures of some breast biopsy markers can improve their ultrasound conspicuity. Actionable twinkling is associated with lower transducer frequencies and higher surface roughness of the markers.

CLINICAL RELEVANCE/APPLICATION

Breast ultrasound does not conventionally invoke color Doppler twinkling for marker detection, but the added twinkling information can be valuable.

M5B-SPBR-2 Localizing the Clipped Node in Patients with Node-Positive Breast Cancer Treated with Neoadjuvant Chemotherapy

Participants
Veli Süha Ozturk, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Clipping of positive axillary lymph nodes before treatment allows conservative surgery in patients with breast cancer down-staged by neoadjuvant chemotherapy (NAC). This study aimed at evaluating the feasibility and identifiability of different clips in the axilla, as well as the performance of preoperative imaging-guided localization of the clipped axillary lymph node.

METHODS AND MATERIALS

Institutional ethical committee approval was obtained. Between March 2017 and January 2022, all breast cancer patients with biopsy-confirmed breast tumor and axillary lymph node which clipped at the time of diagnosis who underwent NAC were retrospectively evaluated. Cases with 3 or more pathological lymph nodes were excluded. SenoMarc™ (Bard, Inc.) and BiomarC® (Vigeo, Inc.) were used as 2D rectangular - ribbon shaped metallic tissue markers and Twirl™ (Bard, Inc.) was used as 3D coil like round shaped metallic tissue marker. After primary systemic therapy, clipped lymph nodes were localized by a wire and then operated.

RESULTS

The study included one hundred thirty eight female breast cancer patients with clipped lymph node. There were 2D tissue markers in one hundred thirteen (81.9%) nodes. Of the clipped nodes, one hundred twenty two (88.4%) were localized under US guidance successfully (Figure 1-2). In sixteen patients, clipped nodes were not visualized by sonography, which all had 2D tissue markers. All 3D markers were detected by ultrasonography (Figure 3). The success rate of the marker placement procedure was 100%. Removals of clipped nodes were confirmed with specimen radiography.

CONCLUSION

s Ultrasound-guided wire localization of the clipped node is a feasible and useful method in clinical practice, especially with the increased detectability with 3D marker clips.

CLINICAL RELEVANCE/APPLICATION

Determination of clipped lymph nodes is the crucial part for removal with targeted axillary dissection. Despite being the primary imaging method, ultrasound fails to detect clipped node in some cases. Shape and size play an important role in sonographic visualization of the marker. Appropriate marker selection appears to increase the sensitivity of ultrasound.

M5B-SPBR-4 Whole-body [18F]FDG PET/MRI Including an Integrated Breast MRI Protocol in Breast Cancer Patients

Participants
Thiemo Van Nijnatten, Maastricht, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the feasibility of whole-body 18F-FDG PET/MRI including an integrated breast MRI protocol in breast cancer patients for locoregional and distant staging.

METHODS AND MATERIALS

Patients diagnosed with histopathologically confirmed breast cancer according to conventional imaging modalities (i.e. mammography and ultrasound) were prospectively included. All patients were considered for further examination with regard to locoregional and distant staging and underwent whole-body 18F-FDG PET/MRI including an integrated breast MRI protocol. The protocol consisted of dedicated breast MRI (prone position) and whole-body PET/MRI (supine position; including T2W, T1W post-contrast, DWI sequences and PET reconstructions) approximately 60 minutes after injection of 18F-FDG. In addition, unenhanced chest CT was performed for pulmonary lesion detection. Results of 18F-FDG PET/MRI, including integrated breast MRI, were compared to conventional imaging modalities in terms of clinical tumour (cT), nodal (cN) and distant (cM) status, according to 8th edition of TNM classification.

RESULTS

From April 2021 until April 2022, 26 breast cancer patients were included and underwent whole-body 18F-FDG PET/MRI including an integrated breast MRI protocol.According to conventional imaging, cT1-2 breast cancer was present in 22 out of 26 patients, 3 patients had cT3 and one patient cT4 breast cancer. With regard to cN status, 9 patients were considered cN0, 15 cN1 (1-3 suspicious lymph nodes) and 2 patients cN2-3 (four or more suspicious lymph nodes). Whole-body 18F-FDG PET/MRI, including an integrated breast MRI protocol, upstaged cT status in ten patients and cN status in nine patients. In addition, distant metastases were detected in three patients and a fourth patient was diagnosed with a synchronous primary tumour (lung cancer).

CONCLUSION

s Whole-body 18F-FDG PET/MRI amended by an integrated breast MRI protocol is feasible and upstages locoregional and distant status in a considerable amount of recently diagnosed breast cancer patients with an indication for whole body staging.

CLINICAL RELEVANCE/APPLICATION

Whole-body 18F-FDG PET/MRI amended by an integrated breast MRI protocol provides a promising new approach in breast cancer patients with regard to locoregional and distant staging.

M5B-SPBR-5 A Multimodal Nomogram: An Adjunct Tool for Reducing Unnecessary Biopsies of Breast Lesions with Inconsistent BI-RADS Assessments by Ultrasound and Mammography

Participants
Ziting Xu, Guangdong, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a multi-modal nomogram for the differential diagnosis of breast lesions with inconsistent assessments and to explored the practical value of the proposed model in reducing unnecessary breast lesion biopsies.

METHODS AND MATERIALS

In this retrospective study, patients with a discordant BI-RADS assessment (defined as a difference in BI-RADS classification by US and MG, where one accessed as BI-RADS 4 or 5 and the other accessed the same lesion as BI-RADS 0, 2 or 3) were eligible. Total 604 patients with discordant assessments from Center 1 were included as the training (n = 439) and internal validation (n = 175) cohorts in a ratio of 7:3 between June 2019 and June 2021. An independent cohort of 92 patients from Center 2 were allocated as the external testing (n = 92) cohort between January 2021 and June 2021. Univariate and multivariate logistic regression analyses were used to develop the nomogram. The performances of the model were assessed based on its discrimination and calibration. Receiver operating characteristic (ROC) curves analysis were performed to evaluate the diagnostic performance. The area under the curves (AUCs) were calculated and compared by using the Delong's test. The differences in sensitivities and specificities were determined by the McNemar's test.

RESULTS

Multivariate analyses indicated that age, MG features (margin, shape, density, suspicious calcifications and architectural distortion) and US features (margin, shape, and calcifications) were independent risk factors associated with breast cancer. The AUCs of the

nomogram were 0.87 (95% confidence interval [CI], 0.83-0.91) in the training, 0.91 (95% CI, 0.87-0.96) in the internal validation, and 0.92 (95% CI, 0.86 to 0.98) in the external testing cohorts. Calibration curves verified good consistency between the actual and nomogram-predicted malignancy probability. The nomogram had a significant effect improvement in diagnostic efficacy compared to MG or US alone (AUC: 0.889 vs 0448 vs 0.597, P<0.001), and the potential reduction of unnecessary biopsies was 87.1%.

CONCLUSION

s The multimodal nomogram incorporating clinical information, MG and US imaging features may improve the prediction of breast lesion with inconsistent assessments and is an adjunct reliable tool to make optimal clinical decision and avoid unnecessary biopsies.

CLINICAL RELEVANCE/APPLICATION

The multimodal nomogram can potentially serve a role in a clinical context as a decision support system to avoid unnecessary biopsies.

M5B-SPBR-6 Outcomes at Biopsy of Mammographic Architectural Distortions without Definite Ultrasound Findings

Participants
Ethan O. Cohen, MD, Houston, TX (*Presenter*) Spouse, Consultant, Boehringer Ingelheim GmbH;Spouse, Consultant, Novo Nordisk AS;Spouse, Consultant, Eli Lilly and Company

PURPOSE

To stratify outcomes for mammographic architectural distortions without definite ultrasound findings.

METHODS AND MATERIALS

Mammographically guided biopsies performed during 2016-2019 for architectural distortions without definite ultrasound correlates were retrospectively reviewed after IRB approval.

RESULTS

145 biopsies in 140 patients (median age, 54 years; interquartile range, 47-66 years) yielded the following histologies: 71 benign (49.0%), 47 high-risk (32.4%), and 27 malignant (18.6%). Eleven benign results were discordant. Stromal fibrosis (26 of 71, 36.6%) and fibrocystic changes (25 of 71, 35.2%) were the most common benign concordant lesions. Radial sclerosing lesion without atypia was the most common high-risk lesion (34 of 47, 72.3%). Malignant results were 4 ductal carcinoma in situ, 16 invasive ductal carcinoma, and 7 invasive lobular carcinoma. One benign discordant lesion, one atypical ductal hyperplasia, and one radial sclerosing lesion were upgraded to invasive carcinoma at excision, resulting in a malignancy rate of 20.7% (30 of 145). Positive predictive value for malignancy or high-risk lesion was 51.7% (75 of 145).

CONCLUSION

s In the absence of a characteristically benign etiology, architectural distortion without an ultrasound correlate warrants tissue diagnosis given the malignancy rate of 20.7%.

CLINICAL RELEVANCE/APPLICATION

Architectural distortion is an increasingly common imaging finding in the era of tomosynthesis screening. Appropriate management recommendations are necessary to ensure timely diagnosis.

M5B-SPBR-7 Assessing the Diagnostic Yield of Ultrasound, MRI, Sentinel Lymph Node Biopsy (SLNB) in the Axilla in Breast Cancer Patients: A Single Institution Experience

Participants
Alaa Alhazmi, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the diagnostic accuracy of ultrasonography (US) compared to magnetic resonance imaging (MRI) in the pre-operative assessment of metastatic disease to the axilla in breast cancer patients. This will be compared to sentinel lymph node biopsy (SLNB) results.

METHODS AND MATERIALS

Research ethics board-approved retrospective study was conducted at a single tertiary care institution. Patients who underwent a pre-operative US, MRI, and SLNB between January 2019-September 2021 were included. The US and MRI reports of these patients were reviewed. The results were then compared to the histopathology results based on the SLNB results.

RESULTS

A total of 104 female patients with primary breast cancer were included in this study. The average age was 58 (range 28-91). Of the 104 patients, 99 (95%) had unilateral breast cancer, and 5 (5%) had bilateral breast cancer. Fifty-two (50%) of patients had Invasive Ductal Carcinoma (IDC), 31 (30%) had Invasive Lobular Carcinoma (ILC), while 21 (20%) had other subtypes. The pre-operative sonographic assessment of the axillary nodes demonstrated an average long axis of 16.3 mm, a short axis of 5.7 mm, and an average cortical thickness of 2.3 mm. The pre-operative MRI assessment of the axillary nodes demonstrated an average long axis of 13.3 mm and a short axis of 7.5 mm. Correlation between the pre-operative sonographic assessment and SLNB results showed a sensitivity of 29.6%, specificity of 85.7%, positive predictive value (PPV) of 42.1%, and a negative predictive value (NPV) of 77.6%. Correlation between the MRI assessment and SLNB biopsy results showed a sensitivity of 37%, specificity of 89.6%, PPV of 55.6%, and NPV of 80.2%. There was an agreement between US and MRI in 91 cases (87.5%).

CONCLUSION

s In patients with primary breast cancer, the pre-operative evaluation of the axilla to assess for nodal metastasis utilizing US and MRI demonstrated comparable results. Both techniques demonstrated high specificity and NPV, while both had poor sensitivity and PPV. These findings should be confirmed in a larger sample of patients, as it can lead to a change in the current work-up of

patients with primary breast cancer.

CLINICAL RELEVANCE/APPLICATION

In this small sample, US and MRI were comparable in detecting axillary nodal metastasis in patients with primary breast cancer. If confirmed, this can have significant implications on patients, care providers, and the healthcare system.

M5B-SPBR-8 Semiannual Breast US and MRI for Breast Cancer Screening in Patients with Personal History of Breast Cancer

Participants
Su Min Ha, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Wide variability of screening imaging patterns in patients with personal history of breast cancer (PHBC) warrants investigation of comparative clinical effectiveness. While more intensive screening with MRI or US at intervals <1 year to supplement annual mammography would increase early stage second breast cancer detection, its benefit has not yet been established. This study investigated outcomes of semiannual multimodality screening in patients with PHBC.

METHODS AND MATERIALS

We retrospectively searched our academic medical center database for patients who underwent incidence screening with MRI or US from July-December 2019 and three subsequent semiannual screening rounds over a 2-year study period. Routine clinical care included annual screening mammography; MRI or US was performed at the discretion of referring surgeons or radiologists interpreting the prior screening examination (Figure 1). The primary outcome was second breast cancer status identified by malignant pathology by the next screening event. Examination level cancer detection and interval cancer rates were calculated.

RESULTS

Our final cohort included 3,041 asymptomatic patients (median age 53 years; interquartile range, 46-60 years) (Figure 2). Among 2,031 semiannual MRI and 6,533 semiannual US examinations, the cancer detection rate was 3.9 per 1,000 examinations (8 of 2,031; 95% CI: 2.0, 7.8) and 1.5 per 1,000 examinations (10 of 6,533; 95% CI: 0.8, 2.8), respectively. Interval cancer rates were 0 per 1,000 examinations for both MRI and US. Further, no second breast cancers were identified after negative prior semiannual MRI screening.

CONCLUSION

s Semiannual MRI or US with annual mammography eliminated interval cancers in patients with PHBC, suggesting that either modality may be used for more effective post-treatment screening.

CLINICAL RELEVANCE/APPLICATION

Semiannual MRI had higher second breast cancer detection rate than semiannual US. Further investigation is needed to establish longer term benefit such as overall survival.

Whole-body [18F]FDG PET/MRI Including an Integrated Breast MRI Protocol in Breast Cancer Patients

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - BR DPS

Participants
Thiemo Van Nijnatten, Maastricht, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the feasibility of whole-body 18F-FDG PET/MRI including an integrated breast MRI protocol in breast cancer patients for locoregional and distant staging.

METHODS AND MATERIALS

Patients diagnosed with histopathologically confirmed breast cancer according to conventional imaging modalities (i.e. mammography and ultrasound) were prospectively included. All patients were considered for further examination with regard to locoregional and distant staging and underwent whole-body 18F-FDG PET/MRI including an integrated breast MRI protocol. The protocol consisted of dedicated breast MRI (prone position) and whole-body PET/MRI (supine position; including T2W, T1W post-contrast, DWI sequences and PET reconstructions) approximately 60 minutes after injection of 18F-FDG. In addition, unenhanced chest CT was performed for pulmonary lesion detection. Results of 18F-FDG PET/MRI, including integrated breast MRI, were compared to conventional imaging modalities in terms of clinical tumour (cT), nodal (cN) and distant (cM) status, according to 8th edition of TNM classification.

RESULTS

From April 2021 until April 2022, 26 breast cancer patients were included and underwent whole-body 18F-FDG PET/MRI including an integrated breast MRI protocol.According to conventional imaging, cT1-2 breast cancer was present in 22 out of 26 patients, 3 patients had cT3 and one patient cT4 breast cancer. With regard to cN status, 9 patients were considered cN0, 15 cN1 (1-3 suspicious lymph nodes) and 2 patients cN2-3 (four or more suspicious lymph nodes). Whole-body 18F-FDG PET/MRI, including an integrated breast MRI protocol, upstaged cT status in ten patients and cN status in nine patients. In addition, distant metastases were detected in three patients and a fourth patient was diagnosed with a synchronous primary tumour (lung cancer).

CONCLUSION

s Whole-body 18F-FDG PET/MRI amended by an integrated breast MRI protocol is feasible and upstages locoregional and distant status in a considerable amount of recently diagnosed breast cancer patients with an indication for whole body staging.

CLINICAL RELEVANCE/APPLICATION

Whole-body 18F-FDG PET/MRI amended by an integrated breast MRI protocol provides a promising new approach in breast cancer patients with regard to locoregional and distant staging.

M5B-SPBR-5

A Multimodal Nomogram: An Adjunct Tool for Reducing Unnecessary Biopsies of Breast Lesions with Inconsistent BI-RADS Assessments by Ultrasound and Mammography

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - BR DPS

Participants
Ziting Xu, Guangdong, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a multi-modal nomogram for the differential diagnosis of breast lesions with inconsistent assessments and to explored the practical value of the proposed model in reducing unnecessary breast lesion biopsies.

METHODS AND MATERIALS

In this retrospective study, patients with a discordant BI-RADS assessment (defined as a difference in BI-RADS classification by US and MG, where one accessed as BI-RADS 4 or 5 and the other accessed the same lesion as BI-RADS 0, 2 or 3) were eligible. Total 604 patients with discordant assessments from Center 1 were included as the training (n = 439) and internal validation (n = 175) cohorts in a ratio of 7:3 between June 2019 and June 2021. An independent cohort of 92 patients from Center 2 were allocated as the external testing (n = 92) cohort between January 2021 and June 2021. Univariate and multivariate logistic regression analyses were used to develop the nomogram. The performances of the model were assessed based on its discrimination and calibration. Receiver operating characteristic (ROC) curves analysis were performed to evaluate the diagnostic performance. The area under the curves (AUCs) were calculated and compared by using the Delong's test. The differences in sensitivities and specificities were determined by the McNemar's test.

RESULTS

Multivariate analyses indicated that age, MG features (margin, shape, density, suspicious calcifications and architectural distortion) and US features (margin, shape, and calcifications) were independent risk factors associated with breast cancer. The AUCs of the nomogram were 0.87 (95% confidence interval [CI], 0.83-0.91) in the training, 0.91 (95% CI, 0.87-0.96) in the internal validation, and 0.92 (95% CI, 0.86 to 0.98) in the external testing cohorts. Calibration curves verified good consistency between the actual and nomogram-predicted malignancy probability. The nomogram had a significant effect improvement in diagnostic efficacy compared to MG or US alone (AUC: 0.889 vs 0448 vs 0.597, P<0.001), and the potential reduction of unnecessary biopsies was 87.1%.

CONCLUSION

s The multimodal nomogram incorporating clinical information, MG and US imaging features may improve the prediction of breast lesion with inconsistent assessments and is an adjunct reliable tool to make optimal clinical decision and avoid unnecessary biopsies.

CLINICAL RELEVANCE/APPLICATION

The multimodal nomogram can potentially serve a role in a clinical context as a decision support system to avoid unnecessary biopsies.

Outcomes at Biopsy of Mammographic Architectural Distortions without Definite Ultrasound Findings

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - BR DPS

Participants
Ethan O. Cohen, MD, Houston, TX (*Presenter*) Spouse, Consultant, Boehringer Ingelheim GmbH;Spouse, Consultant, Novo Nordisk AS;Spouse, Consultant, Eli Lilly and Company

PURPOSE

To stratify outcomes for mammographic architectural distortions without definite ultrasound findings.

METHODS AND MATERIALS

Mammographically guided biopsies performed during 2016-2019 for architectural distortions without definite ultrasound correlates were retrospectively reviewed after IRB approval.

RESULTS

145 biopsies in 140 patients (median age, 54 years; interquartile range, 47-66 years) yielded the following histologies: 71 benign (49.0%), 47 high-risk (32.4%), and 27 malignant (18.6%). Eleven benign results were discordant. Stromal fibrosis (26 of 71, 36.6%) and fibrocystic changes (25 of 71, 35.2%) were the most common benign concordant lesions. Radial sclerosing lesion without atypia was the most common high-risk lesion (34 of 47, 72.3%). Malignant results were 4 ductal carcinoma in situ, 16 invasive ductal carcinoma, and 7 invasive lobular carcinoma. One benign discordant lesion, one atypical ductal hyperplasia, and one radial sclerosing lesion were upgraded to invasive carcinoma at excision, resulting in a malignancy rate of 20.7% (30 of 145). Positive predictive value for malignancy or high-risk lesion was 51.7% (75 of 145).

CONCLUSION

s In the absence of a characteristically benign etiology, architectural distortion without an ultrasound correlate warrants tissue diagnosis given the malignancy rate of 20.7%.

CLINICAL RELEVANCE/APPLICATION

Architectural distortion is an increasingly common imaging finding in the era of tomosynthesis screening. Appropriate management recommendations are necessary to ensure timely diagnosis.

M5B-SPBR-7

Assessing the Diagnostic Yield of Ultrasound, MRI, Sentinel Lymph Node Biopsy (SLNB) in the Axilla in Breast Cancer Patients: A Single Institution Experience

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - BR DPS

Participants
Alaa Alhazmi, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the diagnostic accuracy of ultrasonography (US) compared to magnetic resonance imaging (MRI) in the pre-operative assessment of metastatic disease to the axilla in breast cancer patients. This will be compared to sentinel lymph node biopsy (SLNB) results.

METHODS AND MATERIALS

Research ethics board-approved retrospective study was conducted at a single tertiary care institution. Patients who underwent a pre-operative US, MRI, and SLNB between January 2019-September 2021 were included. The US and MRI reports of these patients were reviewed. The results were then compared to the histopathology results based on the SLNB results.

RESULTS

A total of 104 female patients with primary breast cancer were included in this study. The average age was 58 (range 28-91). Of the 104 patients, 99 (95%) had unilateral breast cancer, and 5 (5%) had bilateral breast cancer. Fifty-two (50%) of patients had Invasive Ductal Carcinoma (IDC), 31 (30%) had Invasive Lobular Carcinoma (ILC), while 21 (20%) had other subtypes. The pre-operative sonographic assessment of the axillary nodes demonstrated an average long axis of 16.3 mm, a short axis of 5.7 mm, and an average cortical thickness of 2.3 mm. The pre-operative MRI assessment of the axillary nodes demonstrated an average long axis of 13.3 mm and a short axis of 7.5 mm. Correlation between the pre-operative sonographic assessment and SLNB results showed a sensitivity of 29.6%, specificity of 85.7%, positive predictive value (PPV) of 42.1%, and a negative predictive value (NPV) of 77.6%. Correlation between the MRI assessment and SLNB biopsy results showed a sensitivity of 37%, specificity of 89.6%, PPV of 55.6%, and NPV of 80.2%. There was an agreement between US and MRI in 91 cases (87.5%).

CONCLUSION

s In patients with primary breast cancer, the pre-operative evaluation of the axilla to assess for nodal metastasis utilizing US and MRI demonstrated comparable results. Both techniques demonstrated high specificity and NPV, while both had poor sensitivity and PPV. These findings should be confirmed in a larger sample of patients, as it can lead to a change in the current work-up of patients with primary breast cancer.

CLINICAL RELEVANCE/APPLICATION

In this small sample, US and MRI were comparable in detecting axillary nodal metastasis in patients with primary breast cancer. If confirmed, this can have significant implications on patients, care providers, and the healthcare system.

M5B-SPBR-8

Semiannual Breast US and MRI for Breast Cancer Screening in Patients with Personal History of Breast Cancer

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - BR DPS

Participants
Su Min Ha, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Wide variability of screening imaging patterns in patients with personal history of breast cancer (PHBC) warrants investigation of comparative clinical effectiveness. While more intensive screening with MRI or US at intervals <1 year to supplement annual mammography would increase early stage second breast cancer detection, its benefit has not yet been established. This study investigated outcomes of semiannual multimodality screening in patients with PHBC.

METHODS AND MATERIALS

We retrospectively searched our academic medical center database for patients who underwent incidence screening with MRI or US from July-December 2019 and three subsequent semiannual screening rounds over a 2-year study period. Routine clinical care included annual screening mammography; MRI or US was performed at the discretion of referring surgeons or radiologists interpreting the prior screening examination (Figure 1). The primary outcome was second breast cancer status identified by malignant pathology by the next screening event. Examination level cancer detection and interval cancer rates were calculated.

RESULTS

Our final cohort included 3,041 asymptomatic patients (median age 53 years; interquartile range, 46-60 years) (Figure 2). Among 2,031 semiannual MRI and 6,533 semiannual US examinations, the cancer detection rate was 3.9 per 1,000 examinations (8 of 2,031; 95% CI: 2.0, 7.8) and 1.5 per 1,000 examinations (10 of 6,533; 95% CI: 0.8, 2.8), respectively. Interval cancer rates were 0 per 1,000 examinations for both MRI and US. Further, no second breast cancers were identified after negative prior semiannual MRI screening.

CONCLUSION

s Semiannual MRI or US with annual mammography eliminated interval cancers in patients with PHBC, suggesting that either modality may be used for more effective post-treatment screening.

CLINICAL RELEVANCE/APPLICATION

Semiannual MRI had higher second breast cancer detection rate than semiannual US. Further investigation is needed to establish longer term benefit such as overall survival.

M5B-SPCA-1 Myocardial radiomics texture features associated with increased coronary calcium score - First Results on a Photon-Counting-CT

Participants
Isabelle Ayx, MD, 68167 Mannheim, Germany (*Presenter*) Research Consultant, AstraZeneca PLC

PURPOSE

Coronary artery calcium score is an independent risk factor for the development of adverse cardiac events. Other cardiovascular risk factors such as tabacco use are known to influence the texture of the left ventricular myocardium in cardiac magnetic resonance imaging. The severity of coronary artery calcification may influence the myocardial texture. Due to better spatial resolution and signal-to-noise ratio, new CT technologies such as photon-counting computed tomography (PCCT) may improve the detection of texture alterations depending on the severity of coronary artery calcification.

METHODS AND MATERIALS

In this retrospective, single-center, IRB-approved study, left ventricular myocardium was segmented on axial slices semiautomatically and radiomics features were extracted using pyradiomics. Statistical analysis was performed in R statistics calculating mean and standard deviation with Pearson correlation coefficient for correlation of features. Visualization as boxplots and heatmaps was performed. For feature selection Random Forest classification was performed.

RESULTS

A total of 30 patients (26.7 % female, median age 58) were enrolled in this study. Patients were divided into two subgroups depending on the severity of coronary artery calcification (Agaston score 0 and Agatston score = 100). Random Forest feature selection was performed and a set of four higher-order features could be defined to discriminate myocardial texture between those two groups. Estimation of these radiomics features in the remaining patients (Agatston score 1-99) for validation and visualization as boxplots, confirmed an association between Agatston score severity and feature intensities.

CONCLUSION

s A subset of radiomics features texture alterations of the left ventricular myocardium was associated with the severity of coronary artery calcification estimated by Agatston score.

CLINICAL RELEVANCE/APPLICATION

Due to the implementation of PCCT with better spatial resolution and contrast-to-noise ratio, cardiac CT imaging may possibly open up new options for radiomics feature texture analysis of myocardium depending on cardiovascular risk factors.

M5B-SPCA-2 Prediction of coronary plaque progression via traditional parameters alongside radiomics based on coronary CT angiography

Participants
Yinsu Zhu, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the value of traditional plaque parameters combined with radiomics based on coronary CT angiography (CCTA) in predicting coronary plaque progression.

METHODS AND MATERIALS

The clinical data and CCTA images of 400 patients who underwent more than twice CCTA examinations between January 2009 and August 2020 were retrospectively analyzed. Traditional plaque parameters including diameter stenosis, lesion length, vessel volume, total plaque volume and burden, calcified plaque volume and burden, non-calcified plaque volume and burden (NCPB), and pericoronary fat attenuation index (FAI) were measured. Then, the 400 patients were allocated to a training cohort (n = 280) and a validation cohort (n = 120), with a proportion of 7 : 3 via a stratified random splitting method. The two cohorts were divided into plaque progression group and plaque non-progression group according to the median annual change in plaque burden (PB) (?PB/y). A random forest (RF) algorithm was used to tune the optimal radiomics model and calculate the radiomics signature. The area under the receiver operating characteristics curve (AUC) was used to evaluate the diagnostic performance of traditional parameters (model 1), radiomics (model 2), and the combination of the two (model 3).

RESULTS

For the training set, FAI and NCPB were independent risk factors for plaque progression. The RF screened out 10 important features

and the most important associated with coronary plaque progression is wavelet-HLH_first_order_Kurtosis. Likewise, the RF provided the radiomics signature, and AUC comparison revealed that model 2 showed better diagnostic performance in predicting plaque progression than model 1 (training set AUC 0.814 vs. 0.646, P < 0.001; validation set AUC 0.729 vs. 0.654, P = 0.288). Model 3 also showed better diagnostic performance than model 1 (training set AUC 0.824 vs. 0.646, P < 0.001; validation set AUC 0.758 vs. 0.654, P = 0.042).

CONCLUSION

s CCTA-based plaque radiomics signature is superior to traditional parameters in predicting coronary plaque progression, but the combination of the radiomics signature and traditional parameters is even better.

CLINICAL RELEVANCE/APPLICATION

CCTA-based radiomics signature was superior to traditional parameters in terms of predictive value of coronary plaque progression. The combined radiomics signature and traditional plaque parameters further improved its predictive power.

M5B-SPCA-3 Accelerated-whole-heart mDIXON coronary MRA using deep learning constrained compressed sensing

Participants
Xi Wu, MS, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the feasibility of using accelerated-whole-heart modified DIXON (mDIXON) coronary magnetic resonance angiography (MRA) with deep learning (DL) constrained compressed sensing (CS) and evaluate its performance against that of CS and conventional mDIXON approaches at 3 Tesla.

METHODS AND MATERIALS

Thirty healthy volunteers (15 females and 15 males; mean age of 28 ± 10 years; age range of 20-65 years) were recruited who underwent three mDIXON-based coronary MRA sequences including DL-CS, CS, and conventional sequences in a coronal orientation without contrast material. Image quality and visible coronary artery segments were evaluated for nine segments according to American Heart Association (AHA) guidelines on a four-point scale (1 = poor, 2 = fair, 3 = good, 4 = excellent). The signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of proximal coronary arteries were quantitatively measured.

RESULTS

The scan time of the DL-CS and CS methods was shorter than that of the conventional method (9.6 ± 3.1 min vs. 10.0 ± 3.4 min vs. 13.0 ± 4.9 min; p<0.001). The DL-CS sequence obtained highest overall image quality (3.83 ± 0.38 vs. 3.10 ± 0.31 vs. 2.90 ± 0.48), SNR (76.06 ± 15.93 vs. 59.24 ± 14.71 vs. 58.88 ± 16.98) and CNR (29.70 ± 8.67 vs. 19.00± 7.87 vs. 17.61 ± 7.71) (all p<0.001) compared to CS and conventional methods. Moreover, 270 coronary artery segments in thirty subjects were assessed and more segments were visualized in the DL-CS and CS methods than in the conventional method (269 [99.6%], 267 [98.9%], and 263 [97.4%], p<0.05).

CONCLUSION

s The mDIXON-based coronary MRA with the DL constrained CS technique yielded significantly shortened acquisition time compared with the conventional 3D approach and improved image quality compared with the CS and conventional approach.

CLINICAL RELEVANCE/APPLICATION

The proposed methods could provide additional fat information, and accelerate imaging of coronary arteries while preserving good image quality, which could be a viable alternative to enhance the clinical workflow of coronary MRA.

M5B-SPCH-1 Chest CT Findings of COVID-19 in Lung Transplant Recipients

Participants
Stephan Altmayer, MD, PhD, Framingham, MA (*Presenter*) Nothing to Disclose

PURPOSE

Our goal was to compare the chest computed tomography (CT) findings of COVID-19 in lung transplant recipients (LTR) and a group of controls.

METHODS AND MATERIALS

This was a retrospective study including 51 consecutive adults with a history of lung transplantation hospitalized with COVID-19 from two centers. A total of 75 consecutive controls with no history of immunosuppression were also included for the comparison. Images were classified in consensus by two chest radiologists regarding the standardized RSNA category, main pattern of attenuation, longitudinal and axial distribution. Quantitative CT analysis of the areas of high attenuation (-250 to -700 HU) was also performed using the extension Chest Imaging Platform of the open-source 3D Slicer software. Analysis was performed using chi-square tests for categorical variables and unpaired t-tests for continuous variables. The level of significance was set at 0.05. Bonferroni correction was performed when performing multiple tests.

RESULTS

There was no significant difference in mean age, gender, or days of symptoms until imaging between groups. A total of 2/51 LTR and 3/75 controls had a negative chest CT on admission. The imaging findings of COVID-19 in LTR were significantly different from controls regarding the RSNA chest CT classification (p=0.007) and the main pattern of lung attenuation (p=0.001). While a typical pattern was the most common classification in LTR and controls (0.47 vs. 0.74, adjusted-p=0.006), LTR had a significantly higher proportion of patients with an indeterminate pattern on CT (0.31 vs. 0.11, adjusted-p=0.014). The most frequent pattern of attenuation in LTR was predominantly consolidations (0.39 vs. 0.22 of controls, adjusted-p=0.144) followed by a mixed pattern of GGO and consolidation (0.37 vs. 0.20 of controls, adjusted-p=0.102). On the other hand, the most common pattern seen in controls was GGO predominant (0.58 vs. 0.24 of LTR, adjusted-p=0.001). No differences were found in the longitudinal (p=0.99) and axial distribution (p=0.717) of lesions. Both LTR and controls presented either a lower lobe predominant (0.43 vs. 0.43, respectively) or diffuse longitudinal distribution (0.57 vs. 0.56), and predominantly peripheral (0.55 vs. 0.62) or diffuse axial distribution (0.35 vs. 0.29). The percentage of lung areas with high attenuation by QCT was significantly higher in the population of LTR (0.372 ±0.08 vs. 0.148 ±0.06, p<0.001).

CONCLUSION

s The most frequent finding of COVID-19 in LTR was a predominant pattern of consolidation followed by a mixed pattern of GGO and consolidation.

CLINICAL RELEVANCE/APPLICATION

The radiologist should be aware that the presenting chest CT imaging pattern of COVID-19 in LTR is often different compared to the usual population.

M5B-SPCH-10 COV-RADS As a Classification System For the Diagnosis of COVID-19 Pneumonia in Chest Computed Tomography (CT): A Ferman Nationwide Multicenter Validation Study and Pilot Implementation of the Radiological COoperative Network (RACOON)

Participants
Marwin Jonathan Sahn, Aachen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

COV-RADS is a classification system which predicts the likelihood of the presence of COVID-19 pneumonia in chest CT and has proven high diagnostic value in a locoregional analysis. Within the German-wide Radiological Cooperative Network (RACOON) capabilities for large multicenter studies were instated. We validated COV-RADS within this nationwide consortium.

METHODS AND MATERIALS

A total of 6355 CTs were included in the analysis: Patients with confirmed SARS-CoV 2 (RT-PCR within 7 days before CT; n=1286) and CT datasets of representative pulmonary pathologies (n=4805) and a control cohort of healthy individuals (n=264). All CTs

were assessed in a blinded fashion applying the COV-RADS classification system. Test quality criteria, Clopper-Pearson confidence intervals and ROC with AUC were calculated a) for a high sensitivity setting: Patients with positive RT-PCR and COV-RADS score = 3 were considered true positive, patients with negative RT-PCR and COV-RADS score = 2 were considered true negative; b) for a high specificity setting: patients with positive RT-PCR and COV-RADS score = 4 were considered true positive, patients with negative RT-PCR and COV-RADS score = 2 were considered true negative.

RESULTS

Test quality criteria for the high sensitivity setting were: Sensitivity 86.6% [84.6-88.4%], specificity 76.0% [74.8-77.1%], PPV 47.7% [45.7-49.8%], NPV 95.7% [95.1-96.3%]. For the high specificity setting) sensitivity was 62.1% [59.4-64.8%], specificity 94.1% [93.4-94.8%], PPV 72.8% [70.1-75.4%], NPV 90.7% [89.9-91.5%]. AUC was 0.859 [0.844-0.874].

CONCLUSION

s The COV-RADS classification system provides reliable results in the diagnosis of COVID-19 pneumonia using chest CT. Overall tests criteria were acceptable. While sensitivity was high, specificity does not meet the expectations when compared to RT-PCR, even when the cutoff was shifted to aim for high specificity. Therefore, COV-RADS 3 was determined as the most reasonable cutoff in our current setting.

CLINICAL RELEVANCE/APPLICATION

In the context of lifting COVID restrictions, pandemic preparedness gains importance. Many patients undergo chest CT during routine practice, with a bias towards older patients and patients with comorbidities. Also, these patients are most vulnerable to COVID-19. Therefore, wide deployment of COV-RADS ratings can both serve as an indicator of local prevalence, bolstering pandemic preparedness, while improving patient and staff security. Future viral mutations (variants of concern) could void the effectiveness of rapid antigen tests. Wide deployment of COV-RADS could possibly overcome such a capability gap.

M5B-SPCH-2 The Impact of Vaccination on the Incidence and Severity of COVID-19 Pneumonia: Effectiveness of mRNA and Adenovirus Vector Vaccines

Participants
Simone Vicini, MD, Latina, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate and compare the incidence rate and severity of COVID-19 pneumonia on chest CT imaging in unvaccinated and fully vaccinated individuals positive for SARS-CoV-2, along with the different impact of mRNA and adenovirus vector vaccines in this context

METHODS AND MATERIALS

Retrospective single-center study. A cohort of consecutive patients positive for SARS-CoV-2 infection who underwent chest CT was evaluated and grouped by vaccination status and type. COVID-19 pneumonia severity was assessed using a semi-quantitative CT Severity Score (CT-SS) system. Morphological CT patterns were evaluated. Sex-stratified and age-stratified differences were assessedbetween groups. Logistic regression models were built to evaluate the effect of vaccination on the likelihood of presenting severe CT-SS.

RESULTS

Of the 467 patients with COVID-19 meeting inclusion criteria, 216 were not vaccinated, whereas 251 were fully vaccinated, with either BNT162b2 mRNA Vaccine (167) or ChAdOx1-S Adenovirus Vector Vaccine (84). Overall, 141 (30%) patients showed no signs of COVID-19 pneumonia on chest CT images (CTSS=0). The proportion of patients without pneumonia was higher in BNT162b2 patients (85/167, 51%) than in unvaccinated (32/216, 15%) and ChAdOx1-S (24/84, 29%) patients (p<.001). Fully vaccinated patients demonstrated a lower mean CT-SS (5.49 ± 6.06) than unvaccinated patients (9.72 ± 6.14), also considering BNT162b2 (5.15 ± 6.13) and ChAdOx1-S (6.17 ± 5.88) patients separately (p<.001). No differences were observed between BNT162b2 and ChAdOx1-S (p=0.240). Pairwise comparisons by sex and age revealed lower mean CT-SS in fully vaccinated patients. Full vaccination resulted to be associated with significantly lower risk of presenting a CT-SS predictive of ICU admission (OR=0.33).

CONCLUSION

s Fully vaccinated patients, getting either mRNA or adenovirus vector vaccines, experiencing COVID-19 breakthrough infections tend to show a lower incidence rate of COVID-19 pneumonia and less severe lung parenchymal alterations than unvaccinated patients. At the same time, vaccination status is a significant predictor associated with the need for ICU admission in patients with COVID-19.

CLINICAL RELEVANCE/APPLICATION

COVID-19 pneumonia represents the most common indication for admission to ICU and the leading risk factor of fatal outcome from COVID-19. Full vaccination against SARS-CoV-2 reduce the incidence rate and severity of COVID-19 pneumonia, having the potential to reduce lung complications caused by COVID-19, thus preventing or at least mitigating long-COVID.

M5B-SPCH-3 Invasive Pulmonary Aspergillosis in Non-onco-hematological Patients: Differential Radiological Features

Participants
Miguel Angel Gomez Bermejo, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To study the radiological manifestations of the different forms of invasive pulmonary aspergillosis (IPA) in non-oncohematological patients according to the underlying type of immunosuppression.

METHODS AND MATERIALS

A multicenter retrospective study was performed. Data were collected from non-oncohematological patients admitted to four tertiary hospitals (3 in Spain and 1 in Italy) from 1998 to 2021. Three blinded radiologists performed a consensus interpretation of the imaging findings (chest CT scans). The following IPA criteria were used according to the baseline conditions of the patients:

EORTC/MSG criteria for immunocompromised patients, Vandewoude and Blot et al criteria for critically ill patients, Bulpa et al criteria for COPD patients, and Verweij et al criteria for critically ill patients with a viral infection. Patients were divided into three immunosuppression groups: neutropenic group, severe non-neutropenic group (mostly solid organ transplant recipients), and intermediate non-neutropenic group.

RESULTS

A total of 146 patients were included: 9 (6.16%) neutropenic, 105 (71.9%) severe non-neutropenic, and 32 (21.9%) intermediate non-neutropenic. Bronchoinvasive infection signs were more frequent than angioinvasive infection signs (94.5% vs. 45.2%, p=0.023) in all patients. Bronchoinvasive infection signs were evenly distributed among all groups (neutropenic [88.9%] vs severe non-neutropenic [94.3%] vs intermediate non-neutropenic [96.9%], p=0.524). Ground glass opacities (64.5%) and bronchial wall thickening (58%) were the most frequent findings. A pure bronchoinvasive pattern was observed more frequently in less immunosuppressed patients (0% vs 41.9% vs 68.8%, p<0.0001). Classic CT angioinvasive signs (such as the halo sign) were less commonly observed in less immunosuppressed subjects (88.9% vs 45.7% vs 31.3%, p=0.008).

CONCLUSION

s Our data suggest that CT findings in less immunosuppressed patients with IPA more commonly follow a bronchoinvasive pattern. Neutropenic patients are more likely to present radiological findings of angioinvasive IPA.

CLINICAL RELEVANCE/APPLICATION

The current IPA diagnostic criteria were initially developed in oncohematological patients and do not necessarily apply to other populations. We believe that, by recognizing signs of airway invasion in less neutropenic patients (such as non-oncohematological patients), an earlier IPA diagnosis may be achieved, allowing prompt treatment.

M5B-SPCH-4 Automatically Generated CT Severity Scores for COVID-19 Predict Death or Intubation at 1-Month Follow-Up

Participants
Luuk Boulogne, MSc, (*Presenter*) Institutional Grant, Thirona Bio, Inc

PURPOSE

To evaluate the ability of CORADS-AI, an automatic system that was originally developed for scoring the presence and current extent of a COVID19 infection from chest Computed Tomography (CT), to predict death or intubation after one month for positive COVID-19 patients.

METHODS AND MATERIALS

CORADS-AI was developed in a previous study using CT scans from COVID-19 patients in the Netherlands. From a CT scan, CORADS-AI automatically segments each pulmonary lobe and produces a CT Severity Score (CTSS) at the lobe and patient level. This score is based on the percentage of affected tissue and has been used in routine clinical practice. We applied CORADS-AI to all 1205 patients that were involved in the STOIC study, had a positive COVID-19 RT-PCR result, and for which a CT scan was publicly available. 301 of them had died or had to be intubated at 1-month follow-up. We applied logistic regression with 5-fold cross validation on patient sex, age, and the patient level CTSS output of CORADS-AI to predict death or intubation after one month. We compared our method with the logistic regression model from the original STOIC study. This model received age, sex, several clinical variables, and manual CT annotations for lung disease extent as input. It was developed with all 4238 patients from the STOIC study that were positive for COVID-19 both according to RT-PCR testing and CT reading.

RESULTS

Our model obtained an AUC of 0.72±0.02 (mean±std. dev.) for predicting death or intubation after one month. When using solely the patient level CTSS output, we obtained an AUC of 0.68±0.03. In comparison, the original STOIC study reported an AUC of their model of 0.69 (95% CI: 0.67, 0.71).

CONCLUSION

s We showed that CORADS-AI can predict death or intubation after one month for positive COVID-19 patients. Adding age and sex information to the model improved its results. The performance was comparable to that of the model developed in the original STOIC study, which used additional clinical variables and manual CT annotations. This comparison should be interpreted carefully, since that model was evaluated on a different subset of the STOIC cohort.

CLINICAL RELEVANCE/APPLICATION

We showed the potential of CORADS-AI, of which the output format is already used in clinical practice, for aiding radiologists in predicting the course of a COVID-19 infection.

M5B-SPCH-5 Chest CT Findings of COVID-19 in Hospitalized Patients: A Comparison between the Delta and Omicron Variants

Participants
Jong Hyuk Lee, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

It remains underexplored whether CT manifestations of coronavirus 2019 (COVID-19) differ among variants. This study compared the chest CT findings of COVID-19 between the Delta and Omicron variants.

METHODS AND MATERIALS

The institutional review board approved this retrospective study and waived informed consent. Baseline CT images of hospitalized patients with COVID-19 were consecutively collected from a secondary referral hospital in November 2021 and February 2022, when the Delta and Omicron variants predominated, respectively. Two radiologists categorized CT images into four patterns based on the Radiological Society of North America classification system for COVID-19 and visually graded pneumonia extent. Pneumonia, pleural effusion, and intrapulmonary vessels were segmented and quantified on CT images using a priori developed neural networks, followed by reader confirmation. Multivariate logistic and linear regression analyses were performed to examine the associations

between the variants and CT category, severity, and peripheral vascularity.

RESULTS

In total, 176 patients with the Delta (n=88; 67±15 years; 46 men) and Omicron (n=88; 62±19 years; 51 men) variants were included. The Omicron variant was associated with a smaller proportion of patients with a typical CT appearance (32% versus 57%; P=.001), a lower visual pneumonia extent (5.4±6.0 versus 7.7±6.6; P=.017), similar pneumonia volume (5±10% versus 7±11%; P=.143), and a higher proportion of vessels with a cross-sectional area smaller than 5 mm2 relative to the total pulmonary blood volume (BV5%; 48±11% versus 44±8%; P=.004). When adjusted for confounders including age, comorbidities, vaccination, and infection duration, the Omicron variant was significantly associated with a non-typical appearance (P=.009) and higher BV5 (P=.010), but not with visual pneumonia extent (P=.168) or pneumonia volume (P=.666).

CONCLUSION

s The Omicron variant showed more frequent non-typical CT appearances of COVID-19 and less pulmonary vascular involvement than the Delta variant in hospitalized patients with comparable CT severity.

CLINICAL RELEVANCE/APPLICATION

The CT characteristics of Omicron may hamper radiologists from promptly recognizing COVID-19 on CT images when incidentally encountered, and this finding raises an alarm regarding the need to evaluate whether radiologic findings remain consistent or change when new variants appear.

M5B-SPCH-6 4 and 12 Months After COVID-19 Pneumonia: Clinical-Functional and Chest CT Findings

Participants
Paula Rodriguez, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Analyze whether the persistence of radiological lesions 4 and 12 months after COVID-19 pneumonia is related to the presence of residual symptoms and/or whether it has repercussions on respiratory function tests.

METHODS AND MATERIALS

Prospective study that included patients with COVID-19 pneumonia who underwent chest computed tomography (CT) 16±2 weeks and 52±2 weeks after hospital discharge.The chest CT were evaluated by 2 experienced cadiothoracic radiologists who assesed the presence of ground glass, reticulation and bronchiectasias, their distribution and the percentage of involvement of each of these findinds was quantified by lobes.Clinical, analytical and functional variables were recorded, as well as sociodemographic variables, comorbidities and data on the severity of the pneumonic process. One of the parameter to which special attention was paid was membrane diffusing capacity (DMCO) and pulmonary capillary blood volume (Vc)

RESULTS

93 patients were included, of whom 72% had lesions on chest CT. Male sex and older age are related to these lesions, but we have not found any association with the severity of the pneumonic process.At 4 months, no correlation was demonstrated between the persistence of ground glass and the sensation of dyspnea.Patients who required ICU admission had a higher prevalence of persistent ground glass, although no significant differences were obtained with respect to less severe patients.At 12 months, a decrease in the extension of the lesions was detected due to the decrease in size and/or density of the ground-glass opacities, although this was not observed in the reticulation or in the bronchiectasis. The parameter that best related with the presence of ground glass on CT was a higher DMCO/Vc

CONCLUSION

s We have observed a high prevalence of ground-glass lesions on chest CT 4 months after COVID pneumonia. The percentage of ground glass was quantified as mild and we don´t find a clear correlation with clinical, laboratory or 6-minute walk test variables. At 12 months, the improvement in respiratory function tests is related to the increase in parameters related to the vascular component of diffusion.The functional parameter that best correlates with the finding of ground glass on CT is DMCO/Vc, which is higher in patients with this radiological finding.

CLINICAL RELEVANCE/APPLICATION

d

M5B-SPCH-7 AI Denoising Improves Image Quality and Radiological Workflows In Pediatric Ultra-Low-Dose Thorax Computed Tomography Scans

Participants
Andreas Brendlin, Tuebingen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the impact of an AI denoising algorithm on image quality, diagnostic accuracy, and radiological workflows in the context of pediatric thorax ultra-low-dose CT (ULDCT).

METHODS AND MATERIALS

100 consecutive pediatric thorax ULDCT were included and reconstructed using weighted filtered back projection (wFBP), iterative reconstruction (ADMIRE 2), and AI denoising (PixelShine). Place-consistent noise measurements were used to compare objective image quality. Eight blinded readers independently rated subjective image quality on a Likert scale (1=worst to 5=best). Each reader wrote a semiquantitative report to evaluate disease severity using a score with six common pathologies. The time to diagnosis was measured for each reader to compare possible workflow benefits. Properly corrected mixed-effects analysis with posthoc subgroup tests were used. Spearman's correlation coefficient measured inter-reader agreement for the subjective image quality analysis and the severity score sheets.

RESULTS

The highest noise was measured for wFBP, followed by ADMIRE 2, and PixelShine (76.9±9.62 vs. 43.4±4.45 vs. 34.8±3.27 HU; each

The highest noise was measured for wFBP, followed by ADMIRE 2, and PixelShine (76.9±9.62 vs. 45.4±4.45 vs. 34.6±5.27 HU, each p<0.001). The highest subjective image quality was measured for PixelShine, followed by ADMIRE 2, and wFBP (4 [4-5] vs. 3 [4-5] vs. 3 [2-4], each p<0.001) with good inter-rater agreement (r=0.790; p=0.001). In diagnostic accuracy analysis, there was a good inter-rater agreement between the severity scores (r=0.764; p<0.001) without significant differences between severity score items per reconstruction mode (F (5.71;566)=0,792; p=0.570). The shortest time to diagnosis was measured for the PixelShine datasets, followed by ADMIRE 2, and wFBP (2.28±1.56 vs. 2.66±2.31 vs. 2.45±1.90minutes; F(1.000;99.00)=268.1; p<0.001).

CONCLUSION

s AI denoising significantly improves image quality in pediatric thorax ULDCT without compromising diagnostic confidence and reduces time to diagnosis substantially.

CLINICAL RELEVANCE/APPLICATION

A promising technique to minimize potentially harmful radiation exposure in pediatric thorax ultra-low-dose CT protocols is to improve the dose-effectiveness by shaping the X-ray spectrum in favor of higher energy photons. However, the typical trade-off of such approaches is lower image quality than standard protocols due to higher image noise.

M5B-SPCH-8 Chest CT Findings and Pulmonary Function Tests in the Postrecovery Phase of Mild to Severe Cases of COVID-19

Participants
Patricia Yokoo, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

To correlate follow-up chest computed tomography (CT) and pulmonary function test (PFT) findings of mild to severe COVID-19 survivors.

METHODS AND MATERIALS

This retrospective study was performed in two medical centers in Sao Paulo, Brazil. Data were collected from consecutive patients who underwent PFT and chest CT (within a maximum interval of 14 days) after recovery from COVID-19 between May and October 2021. Clinical data, spirometric parameters, diffusing capacity for carbon monoxide (DLCO), lung CT abnormalities, distribution and CT extent score were recorded. Clinical and tomographic differences between the patients with normal or abnormal PFTs were assessed by Chi-Square, Mann-Whitney or Fisher tests.

RESULTS

101 COVID-19 survivors were included (mild disease 48, moderade 40, severe 13), at a median 95 days from initial symptom onset. 33% (33/101) had persistent symptoms. Reduction of DLCO% predicted was the most common abnormality in lung function (19% of the patients). Persistence of symptoms was not associated with abnormal lung function. The presence of reticular opacities (p=0.003), bronchial dilatation (p=0.005) and architectural distortion (p<0.001) in chest CT and a CT extent score > 5 (p=0.006) were significantly more prevalent in patients with impairment of DLCO.The optimal CT score for identifyng patients with reduced DLCO% predicted was 5.5 (area under curve = 0.7), with 78.9% sensitivity and 56.1% specificity.

CONCLUSION

s The presence of reticular opacities, bronchial dilatation and architectural distortion in chest CT and the extent of lung abnormalities was associated with lung function impairment in the postrecovery phase of mild to severe cases of COVID-19.

CLINICAL RELEVANCE/APPLICATION

The anatomical and functional pulmonary sequelae of SARS-CoV-2 infection are not yet fully understood. The evaluation of late chest CT findings associated with lung function impairment can help to estabilish the role of imaging in the postrecovery phase of COVID-19 patients.

M5B-SPCH-9 Comparison of Chest CT Characteristics of COVID-19 Interstitial Pneumonia Between Patients with Different Vaccination Status

Participants
Francesco Rizzetto, MD, Milan, Italy (*Presenter*) Travel support, Bracco Group

PURPOSE

To compare the CT imaging characteristics of patients with symptomatic COVID-19 infection according to their SARS-CoV-2 vaccination status (non-vaccinated, incompletely vaccinated and fully vaccinated).

METHODS AND MATERIALS

The CT examinations performed in the Emergency Department between May and November 2021 for suspicion of COVID-19 pneumonia in patients with positive swab for SARS-CoV-2 were retrospectively included. Three reader (one 13-year experienced radiologist and two 4th-year radiology residents) independently evaluated each chest CT according to CO-RADS and ACR COVID classification and the results were compared for vaccination status.In possible COVID-19 pneumonia cases, defined as CO-RADS 3 to 5 (ACR indeterminate and typical) by each reader, high extent of pulmonary involvement (=25%) and CT patterns (presence of ground glass opacities, consolidations, crazy paving areas) were compared for vaccination status.

RESULTS

A total of 184 patients were included, 111 non-vaccinated (60%) for SARS-CoV-2 infection, 21 (11%) with an incomplete vaccination cycle, and 52 (28%) with a complete vaccination cycle (6 different vaccine types). At bivariate logistic regression, the only factor predicting the absence of pneumonia (CO-RADS 1 and ACR negative cases) for the three readers was a complete vaccination cycle (OR=12.8-13.1 compared to non-vaccinated patients, p=0.032). Both CT score and CT patterns of possible COVID-19 pneumonia showed no statistically significant correlation with vaccination status for the three readers.

CONCLUSION

s Patients with symptomatic SARS-CoV-2 infection and a complete vaccination cycle had 13-times higher odds to present with a

negative chest CT examination in ED compared to non-vaccinated patients. CT involvement and CT patterns of interstitial pneumonia showed no difference between different vaccination status.

CLINICAL RELEVANCE/APPLICATION

Symptomatic COVID-19 patient with a complete vaccination cycle may undergo a less aggressive imaging workup.

M5B-SPCH-1

Chest CT Findings of COVID-19 in Lung Transplant Recipients

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - CH DPS

Participants
Stephan Altmayer, MD, PhD, Framingham, MA (*Presenter*) Nothing to Disclose

PURPOSE

Our goal was to compare the chest computed tomography (CT) findings of COVID-19 in lung transplant recipients (LTR) and a group of controls.

METHODS AND MATERIALS

This was a retrospective study including 51 consecutive adults with a history of lung transplantation hospitalized with COVID-19 from two centers. A total of 75 consecutive controls with no history of immunosuppression were also included for the comparison. Images were classified in consensus by two chest radiologists regarding the standardized RSNA category, main pattern of attenuation, longitudinal and axial distribution. Quantitative CT analysis of the areas of high attenuation (-250 to -700 HU) was also performed using the extension Chest Imaging Platform of the open-source 3D Slicer software. Analysis was performed using chi-square tests for categorical variables and unpaired t-tests for continuous variables. The level of significance was set at 0.05. Bonferroni correction was performed when performing multiple tests.

RESULTS

There was no significant difference in mean age, gender, or days of symptoms until imaging between groups. A total of 2/51 LTR and 3/75 controls had a negative chest CT on admission. The imaging findings of COVID-19 in LTR were significantly different from controls regarding the RSNA chest CT classification (p=0.007) and the main pattern of lung attenuation (p=0.001). While a typical pattern was the most common classification in LTR and controls (0.47 vs. 0.74, adjusted-p=0.006), LTR had a significantly higher proportion of patients with an indeterminate pattern on CT (0.31 vs. 0.11, adjusted-p=0.014). The most frequent pattern of attenuation in LTR was predominantly consolidations (0.39 vs. 0.22 of controls, adjusted-p=0.144) followed by a mixed pattern of GGO and consolidation (0.37 vs. 0.20 of controls, adjusted-p=0.102). On the other hand, the most common pattern seen in controls was GGO predominant (0.58 vs. 0.24 of LTR, adjusted-p=0.001). No differences were found in the longitudinal (p=0.99) and axial distribution (p=0.717) of lesions. Both LTR and controls presented either a lower lobe predominant (0.43 vs. 0.43, respectively) or diffuse longitudinal distribution (0.57 vs. 0.56), and predominantly peripheral (0.55 vs. 0.62) or diffuse axial distribution (0.35 vs. 0.29). The percentage of lung areas with high attenuation by QCT was significantly higher in the population of LTR (0.372 ±0.08 vs. 0.148 ±0.06, p<0.001).

CONCLUSION

s The most frequent finding of COVID-19 in LTR was a predominant pattern of consolidation followed by a mixed pattern of GGO and consolidation.

CLINICAL RELEVANCE/APPLICATION

The radiologist should be aware that the presenting chest CT imaging pattern of COVID-19 in LTR is often different compared to the usual population.

M5B-SPCH-10

COV-RADS As a Classification System For the Diagnosis of COVID-19 Pneumonia in Chest Computed Tomography (CT): A Ferman Nationwide Multicenter Validation Study and Pilot Implementation of the Radiological COoperative Network (RACOON)

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - CH DPS

Participants
Marwin Jonathan Sahn, Aachen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

COV-RADS is a classification system which predicts the likelihood of the presence of COVID-19 pneumonia in chest CT and has proven high diagnostic value in a locoregional analysis. Within the German-wide Radiological Cooperative Network (RACOON) capabilities for large multicenter studies were instated. We validated COV-RADS within this nationwide consortium.

METHODS AND MATERIALS

A total of 6355 CTs were included in the analysis: Patients with confirmed SARS-CoV 2 (RT-PCR within 7 days before CT; n=1286) and CT datasets of representative pulmonary pathologies (n=4805) and a control cohort of healthy individuals (n=264). All CTs were assessed in a blinded fashion applying the COV-RADS classification system. Test quality criteria, Clopper-Pearson confidence intervals and ROC with AUC were calculated a) for a high sensitivity setting: Patients with positive RT-PCR and COV-RADS score = 3 were considered true positive, patients with negative RT-PCR and COV-RADS score = 2 were considered true negative; b) for a high specificity setting: patients with positive RT-PCR and COV-RADS score = 4 were considered true positive, patients with negative RT-PCR and COV-RADS score = 2 were considered true negative.

RESULTS

Test quality criteria for the high sensitivity setting were: Sensitivity 86.6% [84.6-88.4%], specificity 76.0% [74.8-77.1%], PPV 47.7% [45.7-49.8%], NPV 95.7% [95.1-96.3%]. For the high specificity setting) sensitivity was 62.1% [59.4-64.8%], specificity 94.1% [93.4-94.8%], PPV 72.8% [70.1-75.4%], NPV 90.7% [89.9-91.5%]. AUC was 0.859 [0.844-0.874].

CONCLUSION

s The COV-RADS classification system provides reliable results in the diagnosis of COVID-19 pneumonia using chest CT. Overall tests criteria were acceptable. While sensitivity was high, specificity does not meet the expectations when compared to RT-PCR, even when the cutoff was shifted to aim for high specificity. Therefore, COV-RADS 3 was determined as the most reasonable cutoff in our current setting.

CLINICAL RELEVANCE/APPLICATION

In the context of lifting COVID restrictions, pandemic preparedness gains importance. Many patients undergo chest CT during routine practice, with a bias towards older patients and patients with comorbidities. Also, these patients are most vulnerable to COVID-19. Therefore, wide deployment of COV-RADS ratings can both serve as an indicator of local prevalence, bolstering pandemic preparedness, while improving patient and staff security. Future viral mutations (variants of concern) could void the effectiveness of rapid antigen tests. Wide deployment of COV-RADS could possibly overcome such a capability gap.

M5B-SPCH-2

The Impact of Vaccination on the Incidence and Severity of COVID-19 Pneumonia: Effectiveness of mRNA and Adenovirus Vector Vaccines

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - CH DPS

Participants
Simone Vicini, MD, Latina, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate and compare the incidence rate and severity of COVID-19 pneumonia on chest CT imaging in unvaccinated and fully vaccinated individuals positive for SARS-CoV-2, along with the different impact of mRNA and adenovirus vector vaccines in this context

METHODS AND MATERIALS

Retrospective single-center study. A cohort of consecutive patients positive for SARS-CoV-2 infection who underwent chest CT was evaluated and grouped by vaccination status and type. COVID-19 pneumonia severity was assessed using a semi-quantitative CT Severity Score (CT-SS) system. Morphological CT patterns were evaluated. Sex-stratified and age-stratified differences were assessedbetween groups. Logistic regression models were built to evaluate the effect of vaccination on the likelihood of presenting severe CT-SS.

RESULTS

Of the 467 patients with COVID-19 meeting inclusion criteria, 216 were not vaccinated, whereas 251 were fully vaccinated, with either BNT162b2 mRNA Vaccine (167) or ChAdOx1-S Adenovirus Vector Vaccine (84). Overall, 141 (30%) patients showed no signs of COVID-19 pneumonia on chest CT images (CTSS=0). The proportion of patients without pneumonia was higher in BNT162b2 patients (85/167, 51%) than in unvaccinated (32/216, 15%) and ChAdOx1-S (24/84, 29%) patients (p<.001). Fully vaccinated patients demonstrated a lower mean CT-SS (5.49 ± 6.06) than unvaccinated patients (9.72 ± 6.14), also considering BNT162b2 (5.15 ± 6.13) and ChAdOx1-S (6.17 ± 5.88) patients separately (p<.001). No differences were observed between BNT162b2 and ChAdOx1-S (p=0.240). Pairwise comparisons by sex and age revealed lower mean CT-SS in fully vaccinated patients. Full vaccination resulted to be associated with significantly lower risk of presenting a CT-SS predictive of ICU admission (OR=0.33).

CONCLUSION

s Fully vaccinated patients, getting either mRNA or adenovirus vector vaccines, experiencing COVID-19 breakthrough infections tend to show a lower incidence rate of COVID-19 pneumonia and less severe lung parenchymal alterations than unvaccinated patients. At the same time, vaccination status is a significant predictor associated with the need for ICU admission in patients with COVID-19.

CLINICAL RELEVANCE/APPLICATION

COVID-19 pneumonia represents the most common indication for admission to ICU and the leading risk factor of fatal outcome from COVID-19. Full vaccination against SARS-CoV-2 reduce the incidence rate and severity of COVID-19 pneumonia, having the potential to reduce lung complications caused by COVID-19, thus preventing or at least mitigating long-COVID.

Invasive Pulmonary Aspergillosis in Non-onco-hematological Patients: Differential Radiological Features

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - CH DPS

Participants
Miguel Angel Gomez Bermejo, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To study the radiological manifestations of the different forms of invasive pulmonary aspergillosis (IPA) in non-oncohematological patients according to the underlying type of immunosuppression.

METHODS AND MATERIALS

A multicenter retrospective study was performed. Data were collected from non-oncohematological patients admitted to four tertiary hospitals (3 in Spain and 1 in Italy) from 1998 to 2021. Three blinded radiologists performed a consensus interpretation of the imaging findings (chest CT scans). The following IPA criteria were used according to the baseline conditions of the patients: EORTC/MSG criteria for immunocompromised patients, Vandewoude and Blot et al criteria for critically ill patients, Bulpa et al criteria for COPD patients, and Verweij et al criteria for critically ill patients with a viral infection. Patients were divided into three immunosuppression groups: neutropenic group, severe non-neutropenic group (mostly solid organ transplant recipients), and intermediate non-neutropenic group.

RESULTS

A total of 146 patients were included: 9 (6.16%) neutropenic, 105 (71.9%) severe non-neutropenic, and 32 (21.9%) intermediate non-neutropenic. Bronchoinvasive infection signs were more frequent than angioinvasive infection signs (94.5% vs. 45.2%, p=0.023) in all patients. Bronchoinvasive infection signs were evenly distributed among all groups (neutropenic [88.9%] vs severe non-neutropenic [94.3%] vs intermediate non-neutropenic [96.9%], p=0.524). Ground glass opacities (64.5%) and bronchial wall thickening (58%) were the most frequent findings. A pure bronchoinvasive pattern was observed more frequently in less immunosuppressed patients (0% vs 41.9% vs 68.8%, p<0.0001). Classic CT angioinvasive signs (such as the halo sign) were less commonly observed in less immunosuppressed subjects (88.9% vs 45.7% vs 31.3%, p=0.008).

CONCLUSION

s Our data suggest that CT findings in less immunosuppressed patients with IPA more commonly follow a bronchoinvasive pattern. Neutropenic patients are more likely to present radiological findings of angioinvasive IPA.

CLINICAL RELEVANCE/APPLICATION

The current IPA diagnostic criteria were initially developed in oncohematological patients and do not necessarily apply to other populations. We believe that, by recognizing signs of airway invasion in less neutropenic patients (such as non-oncohematological patients), an earlier IPA diagnosis may be achieved, allowing prompt treatment.

M5B-SPCH-4

Automatically Generated CT Severity Scores for COVID-19 Predict Death or Intubation at 1-Month Follow-Up

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - CH DPS

Participants
Luuk Boulogne, MSc, (*Presenter*) Institutional Grant, Thirona Bio, Inc

PURPOSE

To evaluate the ability of CORADS-AI, an automatic system that was originally developed for scoring the presence and current extent of a COVID19 infection from chest Computed Tomography (CT), to predict death or intubation after one month for positive COVID-19 patients.

METHODS AND MATERIALS

CORADS-AI was developed in a previous study using CT scans from COVID-19 patients in the Netherlands. From a CT scan, CORADS-AI automatically segments each pulmonary lobe and produces a CT Severity Score (CTSS) at the lobe and patient level. This score is based on the percentage of affected tissue and has been used in routine clinical practice. We applied CORADS-AI to all 1205 patients that were involved in the STOIC study, had a positive COVID-19 RT-PCR result, and for which a CT scan was publicly available. 301 of them had died or had to be intubated at 1-month follow-up. We applied logistic regression with 5-fold cross validation on patient sex, age, and the patient level CTSS output of CORADS-AI to predict death or intubation after one month. We compared our method with the logistic regression model from the original STOIC study. This model received age, sex, several clinical variables, and manual CT annotations for lung disease extent as input. It was developed with all 4238 patients from the STOIC study that were positive for COVID-19 both according to RT-PCR testing and CT reading.

RESULTS

Our model obtained an AUC of 0.72±0.02 (mean±std. dev.) for predicting death or intubation after one month. When using solely the patient level CTSS output, we obtained an AUC of 0.68±0.03. In comparison, the original STOIC study reported an AUC of their model of 0.69 (95% CI: 0.67, 0.71).

CONCLUSION

s We showed that CORADS-AI can predict death or intubation after one month for positive COVID-19 patients. Adding age and sex information to the model improved its results. The performance was comparable to that of the model developed in the original STOIC study, which used additional clinical variables and manual CT annotations. This comparison should be interpreted carefully, since that model was evaluated on a different subset of the STOIC cohort.

CLINICAL RELEVANCE/APPLICATION

We showed the potential of CORADS-AI, of which the output format is already used in clinical practice, for aiding radiologists in predicting the course of a COVID-19 infection.

M5B-SPCH-5

Chest CT Findings of COVID-19 in Hospitalized Patients: A Comparison between the Delta and Omicron Variants

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - CH DPS

Participants
Jong Hyuk Lee, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

It remains underexplored whether CT manifestations of coronavirus 2019 (COVID-19) differ among variants. This study compared the chest CT findings of COVID-19 between the Delta and Omicron variants.

METHODS AND MATERIALS

The institutional review board approved this retrospective study and waived informed consent. Baseline CT images of hospitalized patients with COVID-19 were consecutively collected from a secondary referral hospital in November 2021 and February 2022, when the Delta and Omicron variants predominated, respectively. Two radiologists categorized CT images into four patterns based on the Radiological Society of North America classification system for COVID-19 and visually graded pneumonia extent. Pneumonia, pleural effusion, and intrapulmonary vessels were segmented and quantified on CT images using a priori developed neural networks, followed by reader confirmation. Multivariate logistic and linear regression analyses were performed to examine the associations between the variants and CT category, severity, and peripheral vascularity.

RESULTS

In total, 176 patients with the Delta (n=88; 67±15 years; 46 men) and Omicron (n=88; 62±19 years; 51 men) variants were included. The Omicron variant was associated with a smaller proportion of patients with a typical CT appearance (32% versus 57%; P=.001), a lower visual pneumonia extent (5.4±6.0 versus 7.7±6.6; P=.017), similar pneumonia volume (5±10% versus 7±11%; P=.143), and a higher proportion of vessels with a cross-sectional area smaller than 5 mm2 relative to the total pulmonary blood volume (BV5%; 48±11% versus 44±8%; P=.004). When adjusted for confounders including age, comorbidities, vaccination, and infection duration, the Omicron variant was significantly associated with a non-typical appearance (P=.009) and higher BV5 (P=.010), but not with visual pneumonia extent (P=.168) or pneumonia volume (P=.666).

CONCLUSION

s The Omicron variant showed more frequent non-typical CT appearances of COVID-19 and less pulmonary vascular involvement than the Delta variant in hospitalized patients with comparable CT severity.

CLINICAL RELEVANCE/APPLICATION

The CT characteristics of Omicron may hamper radiologists from promptly recognizing COVID-19 on CT images when incidentally encountered, and this finding raises an alarm regarding the need to evaluate whether radiologic findings remain consistent or change when new variants appear.

M5B-SPCH-6

4 and 12 Months After COVID-19 Pneumonia: Clinical-Functional and Chest CT Findings

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - CH DPS

Participants
Paula Rodriguez, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Analyze whether the persistence of radiological lesions 4 and 12 months after COVID-19 pneumonia is related to the presence of residual symptoms and/or whether it has repercussions on respiratory function tests.

METHODS AND MATERIALS

Prospective study that included patients with COVID-19 pneumonia who underwent chest computed tomography (CT) 16±2 weeks and 52±2 weeks after hospital discharge.The chest CT were evaluated by 2 experienced cadiothoracic radiologists who assesed the presence of ground glass, reticulation and bronchiectasias, their distribution and the percentage of involvement of each of these findinds was quantified by lobes.Clinical, analytical and functional variables were recorded, as well as sociodemographic variables, comorbidities and data on the severity of the pneumonic process. One of the parameter to which special attention was paid was membrane diffusing capacity (DMCO) and pulmonary capillary blood volume (Vc)

RESULTS

93 patients were included, of whom 72% had lesions on chest CT. Male sex and older age are related to these lesions, but we have not found any association with the severity of the pneumonic process.At 4 months, no correlation was demonstrated between the persistence of ground glass and the sensation of dyspnea.Patients who required ICU admission had a higher prevalence of persistent ground glass, although no significant differences were obtained with respect to less severe patients.At 12 months, a decrease in the extension of the lesions was detected due to the decrease in size and/or density of the ground-glass opacities, although this was not observed in the reticulation or in the bronchiectasis. The parameter that best related with the presence of ground glass on CT was a higher DMCO/Vc

CONCLUSION

s We have observed a high prevalence of ground-glass lesions on chest CT 4 months after COVID pneumonia. The percentage of ground glass was quantified as mild and we don´t find a clear correlation with clinical, laboratory or 6-minute walk test variables. At 12 months, the improvement in respiratory function tests is related to the increase in parameters related to the vascular component of diffusion.The functional parameter that best correlates with the finding of ground glass on CT is DMCO/Vc, which is higher in patients with this radiological finding.

AI Denoising Improves Image Quality and Radiological Workflows In Pediatric Ultra-Low-Dose Thorax Computed Tomography Scans

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - CH DPS

Participants
Andreas Brendlin, Tuebingen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the impact of an AI denoising algorithm on image quality, diagnostic accuracy, and radiological workflows in the context of pediatric thorax ultra-low-dose CT (ULDCT).

METHODS AND MATERIALS

100 consecutive pediatric thorax ULDCT were included and reconstructed using weighted filtered back projection (wFBP), iterative reconstruction (ADMIRE 2), and AI denoising (PixelShine). Place-consistent noise measurements were used to compare objective image quality. Eight blinded readers independently rated subjective image quality on a Likert scale (1=worst to 5=best). Each reader wrote a semiquantitative report to evaluate disease severity using a score with six common pathologies. The time to diagnosis was measured for each reader to compare possible workflow benefits. Properly corrected mixed-effects analysis with posthoc subgroup tests were used. Spearman's correlation coefficient measured inter-reader agreement for the subjective image quality analysis and the severity score sheets.

RESULTS

The highest noise was measured for wFBP, followed by ADMIRE 2, and PixelShine (76.9±9.62 vs. 43.4±4.45 vs. 34.8±3.27 HU; each $p<0.001$). The highest subjective image quality was measured for PixelShine, followed by ADMIRE 2, and wFBP (4 [4-5] vs. 3 [4-5] vs. 3 [2-4], each $p<0.001$) with good inter-rater agreement ($r=0.790$; $p=0.001$). In diagnostic accuracy analysis, there was a good inter-rater agreement between the severity scores ($r=0.764$; $p<0.001$) without significant differences between severity score items per reconstruction mode ($F(5.71;566)=0,792$; $p=0.570$). The shortest time to diagnosis was measured for the PixelShine datasets, followed by ADMIRE 2, and wFBP (2.28±1.56 vs. 2.66±2.31 vs. 2.45±1.90minutes; $F(1.000;99.00)=268.1$; $p<0.001$).

CONCLUSION

s AI denoising significantly improves image quality in pediatric thorax ULDCT without compromising diagnostic confidence and reduces time to diagnosis substantially.

CLINICAL RELEVANCE/APPLICATION

A promising technique to minimize potentially harmful radiation exposure in pediatric thorax ultra-low-dose CT protocols is to improve the dose-effectiveness by shaping the X-ray spectrum in favor of higher energy photons. However, the typical trade-off of such approaches is lower image quality than standard protocols due to higher image noise.

M5B-SPCH-8

Chest CT Findings and Pulmonary Function Tests in the Postrecovery Phase of Mild to Severe Cases of COVID-19

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - CH DPS

Participants
Patricia Yokoo, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

To correlate follow-up chest computed tomography (CT) and pulmonary function test (PFT) findings of mild to severe COVID-19 survivors.

METHODS AND MATERIALS

This retrospective study was performed in two medical centers in Sao Paulo, Brazil. Data were collected from consecutive patients who underwent PFT and chest CT (within a maximum interval of 14 days) after recovery from COVID-19 between May and October 2021. Clinical data, spirometric parameters, diffusing capacity for carbon monoxide (DLCO), lung CT abnormalities, distribution and CT extent score were recorded. Clinical and tomographic differences between the patients with normal or abnormal PFTs were assessed by Chi-Square, Mann-Whitney or Fisher tests.

RESULTS

101 COVID-19 survivors were included (mild disease 48, moderade 40, severe 13), at a median 95 days from initial symptom onset. 33% (33/101) had persistent symptoms. Reduction of DLCO% predicted was the most common abnormality in lung function (19% of the patients). Persistence of symptoms was not associated with abnormal lung function. The presence of reticular opacities ($p=0.003$), bronchial dilatation ($p=0.005$) and architectural distortion ($p<0.001$) in chest CT and a CT extent score > 5 ($p=0.006$) were significantly more prevalent in patients with impairment of DLCO.The optimal CT score for identifyng patients with reduced DLCO% predicted was 5.5 (area under curve = 0.7), with 78.9% sensitivity and 56.1% specificity.

CONCLUSION

s The presence of reticular opacities, bronchial dilatation and architectural distortion in chest CT and the extent of lung abnormalities was associated with lung function impairment in the postrecovery phase of mild to severe cases of COVID-19.

CLINICAL RELEVANCE/APPLICATION

The anatomical and functional pulmonary sequelae of SARS-CoV-2 infection are not yet fully understood. The evaluation of late chest CT findings associated with lung function impairment can help to estabilish the role of imaging in the postrecovery phase of COVID-19 patients.

M5B-SPCH-9

Comparison of Chest CT Characteristics of COVID-19 Interstitial Pneumonia Between Patients with Different Vaccination Status

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - CH DPS

Participants
Francesco Rizzetto, MD, Milan, Italy (*Presenter*) Travel support, Bracco Group

PURPOSE

To compare the CT imaging characteristics of patients with symptomatic COVID-19 infection according to their SARS-CoV-2 vaccination status (non-vaccinated, incompletely vaccinated and fully vaccinated).

METHODS AND MATERIALS

The CT examinations performed in the Emergency Department between May and November 2021 for suspicion of COVID-19 pneumonia in patients with positive swab for SARS-CoV-2 were retrospectively included. Three reader (one 13-year experienced radiologist and two 4th-year radiology residents) independently evaluated each chest CT according to CO-RADS and ACR COVID classification and the results were compared for vaccination status.In possible COVID-19 pneumonia cases, defined as CO-RADS 3 to 5 (ACR indeterminate and typical) by each reader, high extent of pulmonary involvement (=25%) and CT patterns (presence of ground glass opacities, consolidations, crazy paving areas) were compared for vaccination status.

RESULTS

A total of 184 patients were included, 111 non-vaccinated (60%) for SARS-CoV-2 infection, 21 (11%) with an incomplete vaccination cycle, and 52 (28%) with a complete vaccination cycle (6 different vaccine types). At bivariate logistic regression, the only factor predicting the absence of pneumonia (CO-RADS 1 and ACR negative cases) for the three readers was a complete vaccination cycle (OR=12.8-13.1 compared to non-vaccinated patients, p=0.032). Both CT score and CT patterns of possible COVID-19 pneumonia showed no statistically significant correlation with vaccination status for the three readers.

CONCLUSION

s Patients with symptomatic SARS-CoV-2 infection and a complete vaccination cycle had 13-times higher odds to present with a negative chest CT examination in ED compared to non-vaccinated patients. CT involvement and CT patterns of interstitial pneumonia showed no difference between different vaccination status.

CLINICAL RELEVANCE/APPLICATION

Symptomatic COVID-19 patient with a complete vaccination cycle may undergo a less aggressive imaging workup.

M5B-SPGI-1 Laterality of Extracellular Volume Fraction of Liver in the Patients of the Pulmonary Hypertension

Participants
Tatsuya Nishii, MD, PhD, Suita, Japan (*Presenter*) Speakers Bureau, Guerbet SA;Speakers Bureau, General Electric Company;Speakers Bureau, Siemens AG;Research Grant, Canon Medical Systems Corporation

PURPOSE

The liver's extracellular volume fraction (ECV) has attracted attention as an imaging biomarker to measure the degree of liver parenchymal damage, and we hypothesized that it could be used for liver damage associated with pulmonary hypertension (PH). However, the left-right difference in liver ECV in PH patients has not been evaluated. This study evaluated liver ECV and right heart cath (RHC) results in first-time patients referred to a specialized PH hospital.

METHODS AND MATERIALS

We retrospectively reviewed consecutive 46 cases (35 women, median 64 years) with suspected chronic thromboembolic PH (CTEPH) who underwent dual-energy CT (DECT) of four minutes delayed phase using 192-row dual-source CT and RHC from January 2021 to March 2022. We calculated the ECV of the right and left lobe of the liver estimated from the iodine map generated via three-material decomposition using DECT images. We evaluated the correlation coefficient between the ECV of the liver (ECVtotal), obtained by averaging those of both lobes, and the results of RHC. Furthermore, patient background and RHC results were evaluated in cases in which the ECV of the left lobe was more than 5% higher than the ECV of the right lobe.

RESULTS

In 46 cases (39 CTEPH and seven others), the median (IQR) of ECVtotal, mean pulmonary artery pressure, cardiac index (CI), and pulmonary vascular resistance index was 24.2 (20.4-27.1)%, 36.5 (29-44) mmHg, 2.1 (1.8-2.5) L/min/m2 and 994 (708-1515) dys&1;s&1;cm-5&1;m2, respectively. ECVtotal moderately correlated with those results of RHC (R=0.42, -0.31, and 0.47, respectively). The median (IQR) of the ECV in left lobe were 26.9 (22.0-31.2) %, significantly higher (mean difference 2.1 [95% CI, 0.8-3.3] %, P=.001) than that of right lobe (25.3 [21.3-28.9] %). The median (IQR) CI were significantly lower (1.8 [1.6-2.1] vs. 2.2 [1.9-2.6] L/min/m2, P=.003) in cases whose ECV of left lobe were 5% higher than ECVof the right lobe.

CONCLUSION

s ECV of the liver, derived from DECT, significantly correlates with RHC measurements in PH patients. However, in cases with reduced CI, the ECV of the left lobe is measured higher than the right lobe.

CLINICAL RELEVANCE/APPLICATION

When using ECVs of the liver clinically or in research studies, radiologists need to consider that a reduction in CI can cause a significant difference in ECV measurements between the left and right lobes.

M5B-SPGI-2 Radiomics Analysis of Magnetic Resonance-Proton Density Fat Fraction for the Diagnosis of Hepatic Steatosis in Patients with Nonalcoholic Fatty Liver Disease

Participants
Hyun Jin Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To assess the diagnostic feasibility of radiomics analysis based on magnetic resonance (MR)-proton density fat fraction (PDFF) for grading of hepatic steatosis in patients with nonalcoholic fatty liver disease (NAFLD).

METHODS AND MATERIALS

One hundred-six patients with suspected NAFLD were retrospectively enrolled. All patients underwent a liver parenchymal biopsy. MR-PDFF and MR spectroscopy (MRS) were performed using a 3.0-T scanner. Following whole volume segmentation of MR-PDFF images, 834 radiomic features were analyzed using a commercial program. Radiologic features were analyzed, such as median and mean values of the volume of interest (VOIs) and variable clinical features. A random forest regressor was employed to extract important radiomic, radiological, and clinical features. It was trained using 20 repeated 10-fold cross-validation to classify the steatosis grade of NAFLD. The area under the receiver operating characteristic curve (AUROC) was evaluated using a classifier for diagnosing the steatosis stage.

RESULTS

The pathological hepatic steatosis grades were classified as low-grade steatosis (grade 0-1, n=82) and high-grade steatosis (grade 2-3, n=24). Fifteen important features were extracted from radiomics analysis, with the three most important being wavelet-LLL Neighbouring Gray Tone Difference Matrix Coarseness, original First Order Mean and 90th percentile. MRS Mean value was extracted as a more important feature than MR-PDFF Mean or Median in radiologic measures. Alanine aminotransferase has been identified as the most important clinical feature. The AUROC of the classifier using radiomics was comparable to that of radiologic measures (0.94±0.09 and 0.96±0.08, respectively).

CONCLUSION

s MR-PDFF-derived radiomics may provide a comparable alternative for the grading of hepatic steatosis in patients with NAFLD.

CLINICAL RELEVANCE/APPLICATION

Non-invasive measurement using MR-PDFF in NAFLD patients with severe steatosis is expected to be accurate and reduce unnecessary biopsies through MR-PDFF. Radiomic analysis based on MR-PDFF may provide similar diagnostic performance for hepatic steatosis and may be an alternative tool.

M5B-SPGI-3 Volume-assisted estimation of remnant liver function based on Gd-EOB-DTPA enhanced MR relaxometry: a prospective observing trial.

Participants
Niklas Verloh, MD, Freiburg, Germany (*Presenter*) Speaker, Bayer AG;Research Funded, Bayer AG

PURPOSE

This study aimed to evaluate an MR image-based liver function analysis that visualizes regional and global liver function and predicts postoperative remaining liver function.

METHODS AND MATERIALS

The study included patients (n=70) in whom MRI of the liver with Gd-EOB-DTPA was indicated as preoperative preparation before liver resection. These patients received an additional liver function test (indocyanine green clearance test) before and after liver resection. All imaging was performed on a clinical 3T system. T1 maps were obtained before and 20 minutes after contrast injection using a prototypical T1 mapping sequence. The T1 reduction rate of the segmented liver parenchyma between the two sequences was calculated and, using a previously determined formula, converted to a liver function value. Liver resection was simulated with visceral surgery, and the residual function was determined. The ICG test performed postoperatively showed liver dysfunction in 35 patients.

RESULTS

Assessment of remaining postoperative liver function by MRI was able to predict the occurrence of postoperative liver dysfunction with a sensitivity of 0.86 and a specificity of 0.74 (PPV: 0.77; NPV: 0.84; AUC: 0.80).

CONCLUSION

s In conclusion, virtual surgical planning using MRI, in addition to revealing the spatial relationships of tumors and vessels, has the potential to reduce the occurrence of small for size syndrome by calculating the postoperative liver function.

CLINICAL RELEVANCE/APPLICATION

Liver insufficiency after liver resection is often the result of an insufficient remaining functional organ ("small for size syndrome"). Currently, liver function is assessed using preoperative liver volumetry and is based on clinical and biochemical parameters. However, these conventional liver function tests are not sufficient to confidently predict postoperative liver failure. Here, modern techniques can help in surgical planning and positively impact patient care.

M5B-SPGI-4 Quantitative parameters on contrast-enhanced CT for non-invasive assessment ofclinically significantportal hypertension

Participants
Jinkui Li, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Hepatic venous pressure gradient (HVPG) is critical for diagnose portal hypertension. However, HVPG measurement is invasive. Non-invasive and accurate assessment of portal hypertension is unmet need in clinics. This study aimed to determine whether the extracellular volume fraction (ECV) of liver and spleen, and the iodine washout rate (IWR) of liver, could provide an estimate of clinically significant portal hypertension (CSPH, HVPG =10 mmHg) in patients with cirrhosis.

METHODS AND MATERIALS

101 participants (51 patients with cirrhosis who underwent HVPG measurement and 50 healthy controls who were defined to have normal portal pressure without HVPG measurement) underwent contrast-enhanced CT between January 2018 and December 2020 were retrospectively included. Absolute contrast enhancement of the liver/spleen and the abdominal aorta (subtracting unenhanced from contrast-enhanced attenuation during portal-venous phase [PVP] or delay phase [DP], ?HU) were measured. ECVliver and ECVspleen were calculated using the following equation: ECVliver/spleen = ?HUliver/spleen-DP / ?HUaorta-DP × (100-Hematocrit [%]). IWR of liver was calculated using the following equation: IWR = (1-?HUliver-DP / ?HUliver-PVP) × 100. The correlation of non-invasive parameters with HVPG was evaluated. ROC analysis was performed and the areas under the curves (AUCs) were calculated for diagnostic performance.

RESULTS

The mean of HVPG was 16.55 ± 0.67 mmHg. There were significant differences in CT parameters between cirrhotic patients and healthy controls: ECVliver ($P < 0.001$), ECVspleen ($P < 0.001$), and IWR ($P < 0.001$). Both ECVliver and ECVspleen correlated with HVPG ($P = 0.007$ and 0.001, respectively). ECVspleen and IWR were identified to be independently correlated with HVPG ($P = 0.001$ and 0.022, respectively). ECVspleen and IWR revealed perfect diagnostic performance for the identification of CSPH with AUCs of

0.984 and 0.956, respectively, and outperformed ECVliver (AUC, 0.718) (P < 0.001). The best cut-off value, ECVliver, ECVspleen, and IWR for identifying CSPH, were = 24.6%, = 38.29%, and =40.06%, respectively.

CONCLUSION

s ECVspleen and IWR were valuable non-invasive parameters for the assessment of CSPH in cirrhotic patients and outperformed ECVliver. It should be explored further across a broader range of pressure values.

CLINICAL RELEVANCE/APPLICATION

Such valuable non-invasive parameters including ECV and IWR to assess portal pressure is clinically meaningful for cirrhotic patients. ECV and IWR are easy to obtain and can be retrospectively derived from CT, since CT is routinely used to evaluate the complications of cirrhosis. Such a dual-screening strategy would further improve the cost-effectiveness of CT.

M5B-SPGI-5 Can CT Spectral Imaging Based on Multi-material Decomposition Algorithm Have Better Ability to Diagnose Chemotherapy Related Fatty Liver Disease than Liver-to-fat ratio?

Participants
Xi Huaze, (*Presenter*) Nothing to Disclose

PURPOSE

To determine whether CT multi-material decomposition (MMD) spectral examination may improve clinical diagnosis efficiency of chemotherapy related fatty liver disease (CRFLD).

METHODS AND MATERIALS

Eight one patients undergoing CT exams of abdomen (traditional unenhanced imaging enhanced spectral imaging) after chemotherapeutic treatment were retrospectively recruited. All these patients have no history of fatty liver, liver disease, liver tumors and large alcohol intake before chemotherapy. According to the results of ultrasonic or magnetic resonance examination after chemotherapy, patients were divided into clinical CRFLD group and non-CRFLD groups. On liver fat images in venous phase generated by MMD algorithm, three physicians measured liver fat fractions (LFFs) of the whole liver, left lobe and right lobe. When the average values calculated from these three doctors' measurement of the whole liver LFF or either lobe LFF exceeded 5%, the patients were considered as spectrum-CRFLD. On unenhanced CT images, the same three doctors measured CT values of spleen and liver, and calculated average values to acquirethe Liver-to-spleen ratio (LSR,LSR = CT valueliver/CT valuespleen) . When it was less than 1, the patients would be regarded as CT-CRFLD. Diagnostic efficiency of spectrum-CRFLD and CT-CRFLD was compared by using McNemar's test.

RESULTS

Thirty-four of 81 patients (mean age, 57.8 years±11.5; 23 women) were diagnosed as clinical CRFLD. The whole liver LFF showed significantly highest sensitivity, specificity, positive predictive value, negative predictive value, accuracy of diagnosing clinical CRFLD (82.4%,95.7%,93.3%,88.2% and 90.1%, respectively). The diagnostic accuracy of whole liver LFF was significantly higher than both either liver lobe LFF and LSR(both p<0.001).

CONCLUSION

s The whole liver LFF obtained by CT MMD spectral imaging is a reliable indicator to diagnose CRFLD with more accuracy and sensitivity, compared with the traditional CT liver-to-fat ratio.

CLINICAL RELEVANCE/APPLICATION

Quantitative measurement of fat fraction in the whole liver through CT spectral imaging can help detect fatty liver caused by chemotherapeutics.

M5B-SPGI-6 The value of hepatic extracellular volume fraction obtained from iodine map in evaluating liver function of patients with liver cirrhosis

Participants
Yao Wang, (*Presenter*) Nothing to Disclose

PURPOSE

To explore the correlation between hepatic extracellular volume fraction (fECV) based on iodine density and liver function in cirrhosis patients, and further investigate the diagnostic value of fECV in liver cirrhosis.

METHODS AND MATERIALS

The patients undergoing enhanced abdominal CT scan with spectral mode were categorized as group F (patients with liver cirrhosis),group F0 (patients without liver cirrhosis). According to the child-Pugh classification, group F was further divided into three subgroups: group FA (child A), group FB (child B) and group FC (child C). The latter two groups represented decompensated cirrhosis. The iodine density of liver and abdominal aorta were measured in iodine map of equilibrium phase to calculate the fECV. The formula for fecv is the iodine density of the liver multiplied by 100 minus Hct and then divided by the iodine density of the abdominal aorta.The fECV values among groups were compared by One-Way ANOVA, LSD method was used for further comparison. Pearson correlation analysis was performed to analyze the correlation between fECV and child-Pugh classification. The diagnostic performance of fECV for the differentiation of liver cirrhosis was assessed using receiver operation characteristic (ROC) curve analysis.

RESULTS

A total of 157 patients (51 in group F0, 46 in group FA, 38 in group FB, 22 in group FC) were included. The fECV fractions in from F0 to FC showed an upward trend (31.62±2.00,37.08±3.64, 43.39±6.00). There was significant difference in fECV among groups and between any two groups (all P <0.001). Strong positive correlation of fECV with child-Pugh classification was found (r=0.841). For differentiating liver cirrhosis, the sensitivity and specificity of fECV were 88.68% and 86.27%, respectively, with area under the curve (AUC) of 0.922, when the cut-off value was set at 30.26%. For differentiating decompensated cirrhosis by fECV, a cut-off value of 33.96% resulted in an AUC of 0.938, sensitivity of 90.00% and specificity of 89.13%.

CONCLUSION

s fECV from iodine map is strongly positively correlated with the Child-Pugh liver function classification, and has a high potential value in the differentiation of liver cirrhosis with different liver function grades.

CLINICAL RELEVANCE/APPLICATION

ECV measured using Hounsfield units needs precontrast phase, which has the problem of registration and increases the radiation dose. fECV obtained by dual energy spectral examination is a simple and convenient biomarker to identify different degrees of liver cirrhosis without dose compromise, which is suitable for follow-up.

M5B-SPGI-7 To Characterize Liver Fibrosis using a Four-Compartments Restriction Spectrum Imaging Model

Participants
Cai Yeyu, MD, Changsha, China (*Presenter*) Nothing to Disclose

PURPOSE

Previous studies have shown that liver fibrosis, caused by chronic liver disease, is closely associated with the progression of various types of liver disease and is a key risk factor for cirrhosis and hepatocellular carcinoma. In this study, we evaluated the feasibility of the 4-compartment RSI model to identify carbon tetrachloride (CCl4) -induced liver fibrosis in mouse model.

METHODS AND MATERIALS

A total of 38 mice in the experiment were divided into CCL4-induced liver fibrosis (LF) and control groups, respectively. MRI examinations were performed on a 3T scanner (uMR790, United Imaging Healthcare, Shanghai, China), based on the echo planar imaging sequence (EPI) with a total of 11 b-values ranging from 0-2000 s/mm2. Conventional ADC and D values for each compartment in multicompartmental RSI models were calculated on voxel wise basis. The performance of different RSI models was evaluated using the Bayesian Information Criterion. Traditional ADC values and Di values of different compartments were further compared between the LF and control groups using Mann-Whitney test, and finally, the receiver operating characteristic (ROC) curve for different parameters were performed.

RESULTS

All mice in LF group were histologically diagnosed as liver fibrosis (100%). The results showed that the best model to describe the data was the 4-compartment RSI model with the lowest ?BIC value among all RSI models. Significant differences of ADC value and D values of the different compartments in the 4-compartment RSI model were found between LF group and control group. RSI4-C3 was the best single diffusion parameter for the discrimination of liver fibrosis, with the largest AUC value. Furthermore, the AUC value was further increased when ADC and C3 were combined.

CONCLUSION

s The 4-compartment RSI model can further distinguish the alterations in the LF group from the control group during different diffusion processes. Compared with the conventional ADC values, RSI4-C3 has a better ability to discriminate liver fibrosis. The combined parameter of ADC value and RSI4-C3 can further improve the discrimination performance of liver fibrosis.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that the four-compartment RSI model can provide a better identification of liver fibrosis than conventional ADC.

M5B-SPGI-8 Non-invasive prediction of NASH by PDFF in Patients with Obesity without known Liver Disease

Participants
Nikolaos Panagiotopoulos, MD, Madison, WI (*Presenter*) Institutional Research Grant, Pfizer Inc

PURPOSE

To assess the value of PDFF, R2*, T2*, and T1 for the detection of NASH in a cohort of subject with obesity without previously known liver disease.

METHODS AND MATERIALS

This analysis is part of an ongoing study of patients with obesity undergoing weight loss surgery (WLS). Study participants underwent imaging within 1 week prior to WLS and intraoperative wedge biopsy of the liver. Imaging at 3.0T included IDEAL IQ (GE, USA) to quantify PDFF and R2* and LiverMultiscan (LMS, Perspectum, UK) for PDFF, T2*, and T1. Images were analyzed by placing ROIs in all liver segments. LMS data were analyzed by Perspectum. Liver biopsy samples were classified as normal, non-alcoholic fatty liver (NAFL, ie: steatosis only), or non-alcoholic steatohepatitis (NASH, based on a NASH activity score >5). Receiver operator characteristic (ROC) curve analysis was performed to assess the diagnostic accuracy of PDFF, R2*, T2* and T1 to differentiate NASH from non-NASH (normal or NAFL).

RESULTS

50 patients (44 female, 45±11 years, BMI: 44±6) were examined and analyzed. 24 subjects had no liver disease, 17 had NAFL and 9 had NASH. IDEAL IQ PDFF achieved separation between NASH and no NASH with an area under the curve of 0.91 (95%CI: 0.79-1). LMS PDFF achieved similarly separation between the groups with AUC=0.98 (95%CI: 0.94-1). At the same PDFF threshold of 11% for IDEAL IQ and LMS, sensitivity was 75% (95%CI: 35-97) and 83% (95%CI: 36-100), respectively, and specificity 98% (95%CI: 87-100) and 100% (95%CI: 89-100). LMS T1 achieved separation between the groups with an area under the curve of 0.83 (95%CI: 0.68-0.97). For the T1 threshold of 870ms, sensitivity was 83% (95%CI: 36-100) and specificity was 73% (95%CI: 55-87). Neither R2* nor T2* could distinguish between NASH and non-NASH.

CONCLUSION

s We observed promising performance of PDFF for the detection of NASH in a cohort of patients with obesity without previously known liver disease, in stark contrast to current knowledge. The results support our hypothesis that PDFF can differentiate NASH from NAFL in a cohort of patients with early-stage NASH where the severity of liver fat deposition is still present and relevant. A major limitation of this work is the limited number of patients with NASH to date.

CLINICAL RELEVANCE/APPLICATION

If confirmed, these results would constitute a paradigm change in the early detection of NASH.

M5B-SPGI-9 a fully automated hybrid approach to assessing liver fibrosis and necroinflammation on conventional MRI: a multi-center study

Participants
Junhao Zha, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a combined radiomics-clinic model by a fully automated hybrid approach to diagnosing clinically significant liver fibrosis (=F2) and necroinflammatory activity (=G2), respectively

METHODS AND MATERIALS

In this retrospective multi-center study, a total of 537 patients were included. From May 2015 to December 2018, 394 patients were randomly distributed in a training (n=276) or internal test (n=118) set at a ratio of 7:3 at center 1. From January 2019 to August 2020, 96 patients considered eligible at center 1 were placed in a temporal test set. An independent external test set from center 2 was used to validate the proposed models. All patients underwent abdominal MRI with pathologically proven liver fibrosis and necroinflammation. An interactive deep learning approach was developed to achieve better automated whole liver segmentation performance of ResUnet. 2880 radiomics features extracted from VOIT2FS, VOIT1delay were analyzed separately to form the radiomics scores (R-scores). The optimal R-scores and clinical biomarkers were integrated into the combined radiomics-clinic model (CRC model) for assessing =F2 or =G2, respectively. The performance of the models was assessed and compared with FIB-4 and APRI

RESULTS

For staging =F2, AUCs of CRC model are 0.83, 0.79, 0.82, 0.83 in the training, internal test, temporal test, and external test set respectively. CRC model (AUC 0.79) significantly outperformed radiomics model (AUC 0.75; $P < .05$) in the internal test set, and significantly outperformed FIB-4 (AUC 0.69, 0.67, 0.63; $P < .05$), and APRI (AUC 0.69, 0.68, 0.62; $P < .05$) in the internal test, temporal test, and external test set. By using the cutoffs, the CRC model had sensitivities and specificities as follows: 72.4% / 82.1%, 73.1% / 62.5%, 82.4% / 71.1%, 91.4% / 75.0% in the training, internal test, temporal test, and external test set for diagnosing =F2. For classifying =G2, the training, internal test, temporal test, and external test set results of the CRC model were AUC 0.88, 0.86, 0.79, and 0.89, sensitivity 74.6%, 71.4%, 61.5%, and 80.0%, and specificity 85.6%, 90.3%, 82.5%, and 87.1%, respectively. CRC model (AUC 0.86, 0.79, 0.89) significantly outperformed radiomics model (AUC 0.67, 0.69, 0.67; $P < .05$) , FIB-4 (AUC 0.67, 0.69, 0.73; $P < .05$), and APRI (AUC 0.74, 0.70, 0.63; $P < .05$) in the internal test, temporal test, and external test set for staging =G2

CONCLUSION

s The CRC models provide a promising approach for diagnosing liver fibrosis (=F2) and necroinflammatory activity (=G2)

CLINICAL RELEVANCE/APPLICATION

Traditional MR tissue texture, and routine clinical biomarkers, should be taken into consideration to develop the CRC model, and this mimics the diagnosis in real clinical scenarios.

M5B-SPGI-1

Laterality of Extracellular Volume Fraction of Liver in the Patients of the Pulmonary Hypertension

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - GI DPS

Participants
Tatsuya Nishii, MD, PhD, Suita, Japan (*Presenter*) Speakers Bureau, Guerbet SA;Speakers Bureau, General Electric Company;Speakers Bureau, Siemens AG;Research Grant, Canon Medical Systems Corporation

PURPOSE

The liver's extracellular volume fraction (ECV) has attracted attention as an imaging biomarker to measure the degree of liver parenchymal damage, and we hypothesized that it could be used for liver damage associated with pulmonary hypertension (PH). However, the left-right difference in liver ECV in PH patients has not been evaluated. This study evaluated liver ECV and right heart cath (RHC) results in first-time patients referred to a specialized PH hospital.

METHODS AND MATERIALS

We retrospectively reviewed consecutive 46 cases (35 women, median 64 years) with suspected chronic thromboembolic PH (CTEPH) who underwent dual-energy CT (DECT) of four minutes delayed phase using 192-row dual-source CT and RHC from January 2021 to March 2022. We calculated the ECV of the right and left lobe of the liver estimated from the iodine map generated via three-material decomposition using DECT images. We evaluated the correlation coefficient between the ECV of the liver (ECVtotal), obtained by averaging those of both lobes, and the results of RHC. Furthermore, patient background and RHC results were evaluated in cases in which the ECV of the left lobe was more than 5% higher than the ECV of the right lobe.

RESULTS

In 46 cases (39 CTEPH and seven others), the median (IQR) of ECVtotal, mean pulmonary artery pressure, cardiac index (CI), and pulmonary vascular resistance index was 24.2 (20.4-27.1)%, 36.5 (29-44) mmHg, 2.1 (1.8-2.5) L/min/m2 and 994 (708-1515) dys&1;s&1;cm-5&1;m2, respectively. ECVtotal moderately correlated with those results of RHC (R=0.42, -0.31, and 0.47, respectively). The median (IQR) of the ECV in left lobe were 26.9 (22.0-31.2) %, significantly higher (mean difference 2.1 [95% CI, 0.8-3.3] %, P=.001) than that of right lobe (25.3 [21.3-28.9] %). The median (IQR) CI were significantly lower (1.8 [1.6-2.1] vs. 2.2 [1.9-2.6] L/min/m2, P=.003) in cases whose ECV of left lobe were 5% higher than ECVof the right lobe.

CONCLUSION

s ECV of the liver, derived from DECT, significantly correlates with RHC measurements in PH patients. However, in cases with reduced CI, the ECV of the left lobe is measured higher than the right lobe.

CLINICAL RELEVANCE/APPLICATION

When using ECVs of the liver clinically or in research studies, radiologists need to consider that a reduction in CI can cause a significant difference in ECV measurements between the left and right lobes.

M5B-SPGI-2

Radiomics Analysis of Magnetic Resonance-Proton Density Fat Fraction for the Diagnosis of Hepatic Steatosis in Patients with Nonalcoholic Fatty Liver Disease

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - GI DPS

Participants
Hyun Jin Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To assess the diagnostic feasibility of radiomics analysis based on magnetic resonance (MR)-proton density fat fraction (PDFF) for grading of hepatic steatosis in patients with nonalcoholic fatty liver disease (NAFLD).

METHODS AND MATERIALS

One hundred-six patients with suspected NAFLD were retrospectively enrolled. All patients underwent a liver parenchymal biopsy. MR-PDFF and MR spectroscopy (MRS) were performed using a 3.0-T scanner. Following whole volume segmentation of MR-PDFF images, 834 radiomic features were analyzed using a commercial program. Radiologic features were analyzed, such as median and mean values of the volume of interest (VOIs) and variable clinical features. A random forest regressor was employed to extract important radiomic, radiological, and clinical features. It was trained using 20 repeated 10-fold cross-validation to classify the steatosis grade of NAFLD. The area under the receiver operating characteristic curve (AUROC) was evaluated using a classifier for diagnosing the steatosis stage.

RESULTS

The pathological hepatic steatosis grades were classified as low-grade steatosis (grade 0-1, n=82) and high-grade steatosis (grade 2-3, n=24). Fifteen important features were extracted from radiomics analysis, with the three most important being wavelet-LLL Neighbouring Gray Tone Difference Matrix Coarseness, original First Order Mean and 90th percentile. MRS Mean value was extracted as a more important feature than MR-PDFF Mean or Median in radiologic measures. Alanine aminotransferase has been identified as the most important clinical feature. The AUROC of the classifier using radiomics was comparable to that of radiologic measures (0.94±0.09 and 0.96±0.08, respectively).

CONCLUSION

s MR-PDFF-derived radiomics may provide a comparable alternative for the grading of hepatic steatosis in patients with NAFLD.

CLINICAL RELEVANCE/APPLICATION

Non-invasive measurement using MR-PDFF in NAFLD patients with severe steatosis is expected to be accurate and reduce unnecessary biopsies through MR-PDFF. Radiomic analysis based on MR-PDFF may provide similar diagnostic performance for hepatic steatosis and may be an alternative tool.

M5B-SPGI-3

Volume-assisted estimation of remnant liver function based on Gd-EOB-DTPA enhanced MR relaxometry: a prospective observing trial.

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - GI DPS

Participants
Niklas Verloh, MD, Freiburg, Germany (*Presenter*) Speaker, Bayer AG;Research Funded, Bayer AG

PURPOSE

This study aimed to evaluate an MR image-based liver function analysis that visualizes regional and global liver function and predicts postoperative remaining liver function.

METHODS AND MATERIALS

The study included patients (n=70) in whom MRI of the liver with Gd-EOB-DTPA was indicated as preoperative preparation before liver resection. These patients received an additional liver function test (indocyanine green clearance test) before and after liver resection. All imaging was performed on a clinical 3T system. T1 maps were obtained before and 20 minutes after contrast injection using a prototypical T1 mapping sequence. The T1 reduction rate of the segmented liver parenchyma between the two sequences was calculated and, using a previously determined formula, converted to a liver function value. Liver resection was simulated with visceral surgery, and the residual function was determined. The ICG test performed postoperatively showed liver dysfunction in 35 patients.

RESULTS

Assessment of remaining postoperative liver function by MRI was able to predict the occurrence of postoperative liver dysfunction with a sensitivity of 0.86 and a specificity of 0.74 (PPV: 0.77; NPV: 0.84; AUC: 0.80).

CONCLUSION

s In conclusion, virtual surgical planning using MRI, in addition to revealing the spatial relationships of tumors and vessels, has the potential to reduce the occurrence of small for size syndrome by calculating the postoperative liver function.

CLINICAL RELEVANCE/APPLICATION

Liver insufficiency after liver resection is often the result of an insufficient remaining functional organ ("small for size syndrome"). Currently, liver function is assessed using preoperative liver volumetry and is based on clinical and biochemical parameters. However, these conventional liver function tests are not sufficient to confidently predict postoperative liver failure. Here, modern techniques can help in surgical planning and positively impact patient care.

M5B-SPGI-4

Quantitative parameters on contrast-enhanced CT for non-invasive assessment ofclinically significantportal hypertension

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - GI DPS

Participants
Jinkui Li, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Hepatic venous pressure gradient (HVPG) is critical for diagnose portal hypertension. However, HVPG measurement is invasive. Non-invasive and accurate assessment of portal hypertension is unmet need in clinics. This study aimed to determine whether the extracellular volume fraction (ECV) of liver and spleen, and the iodine washout rate (IWR) of liver, could provide an estimate of clinically significant portal hypertension (CSPH, HVPG =10 mmHg) in patients with cirrhosis.

METHODS AND MATERIALS

101 participants (51 patients with cirrhosis who underwent HVPG measurement and 50 healthy controls who were defined to have normal portal pressure without HVPG measurement) underwent contrast-enhanced CT between January 2018 and December 2020 were retrospectively included. Absolute contrast enhancement of the liver/spleen and the abdominal aorta (subtracting unenhanced from contrast-enhanced attenuation during portal-venous phase [PVP] or delay phase [DP], ?HU) were measured. ECVliver and ECVspleen were calculated using the following equation: ECVliver/spleen = ?HUliver/spleen-DP / ?HUaorta-DP × (100-Hematocrit [%]). IWR of liver was calculated using the following equation: IWR = (1-?HUliver-DP / ?HUliver-PVP) × 100. The correlation of non-invasive parameters with HVPG was evaluated. ROC analysis was performed and the areas under the curves (AUCs) were calculated for diagnostic performance.

RESULTS

The mean of HVPG was 16.55 ± 0.67 mmHg. There were significant differences in CT parameters between cirrhotic patients and healthy controls: ECVliver ($P < 0.001$), ECVspleen ($P < 0.001$), and IWR ($P < 0.001$). Both ECVliver and ECVspleen correlated with HVPG ($P = 0.007$ and 0.001, respectively). ECVspleen and IWR were identified to be independently correlated with HVPG ($P = 0.001$ and 0.022, respectively). ECVspleen and IWR revealed perfect diagnostic performance for the identification of CSPH with AUCs of 0.984 and 0.956, respectively, and outperformed ECVliver (AUC, 0.718) ($P < 0.001$). The best cut-off value, ECVliver, ECVspleen, and IWR for identifying CSPH, were = 24.6%, = 38.29%, and =40.06%, respectively.

CONCLUSION

s ECVspleen and IWR were valuable non-invasive parameters for the assessment of CSPH in cirrhotic patients and outperformed ECVliver. It should be explored further across a broader range of pressure values.

CLINICAL RELEVANCE/APPLICATION

Such valuable non-invasive parameters including ECV and IWR to assess portal pressure is clinically meaningful for cirrhotic patients. ECV and IWR are easy to obtain and can be retrospectively derived from CT, since CT is routinely used to evaluate the complications of cirrhosis. Such a dual-screening strategy would further improve the cost-effectiveness of CT.

M5B-SPGI-5

Can CT Spectral Imaging Based on Multi-material Decomposition Algorithm Have Better Ability to Diagnose Chemotherapy Related Fatty Liver Disease than Liver-to-fat ratio?

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - GI DPS

Participants
Xi Huaze, (*Presenter*) Nothing to Disclose

PURPOSE

To determine whether CT multi-material decomposition (MMD) spectral examination may improve clinical diagnosis efficiency of chemotherapy related fatty liver disease (CRFLD).

METHODS AND MATERIALS

Eight one patients undergoing CT exams of abdomen (traditional unenhanced imaging enhanced spectral imaging) after chemotherapeutic treatment were retrospectively recruited. All these patients have no history of fatty liver, liver disease, liver tumors and large alcohol intake before chemotherapy. According to the results of ultrasonic or magnetic resonance examination after chemotherapy, patients were divided into clinical CRFLD group and non-CRFLD groups. On liver fat images in venous phase generated by MMD algorithm, three physicians measured liver fat fractions (LFFs) of the whole liver, left lobe and right lobe. When the average values calculated from these three doctors' measurement of the whole liver LFF or either lobe LFF exceeded 5%, the patients were considered as spectrum-CRFLD. On unenhanced CT images, the same three doctors measured CT values of spleen and liver, and calculated average values to acquirethe Liver-to-spleen ratio (LSR,LSR = CT valueliver/CT valuespleen) . When it was less than 1, the patients would be regarded as CT-CRFLD. Diagnostic efficiency of spectrum-CRFLD and CT-CRFLD was compared by using McNemar's test.

RESULTS

Thirty-four of 81 patients (mean age, 57.8 years±11.5; 23 women) were diagnosed as clinical CRFLD. The whole liver LFF showed significantly highest sensitivity, specificity, positive predictive value, negative predictive value, accuracy of diagnosing clinical CRFLD (82.4%,95.7%,93.3%,88.2% and 90.1%, respectively). The diagnostic accuracy of whole liver LFF was significantly higher than both either liver lobe LFF and LSR(both $p<0.001$).

CONCLUSION

s The whole liver LFF obtained by CT MMD spectral imaging is a reliable indicator to diagnose CRFLD with more accuracy and sensitivity, compared with the traditional CT liver-to-fat ratio.

CLINICAL RELEVANCE/APPLICATION

Quantitative measurement of fat fraction in the whole liver through CT spectral imaging can help detect fatty liver caused by chemotherapeutics.

M5B-SPGI-6

The value of hepatic extracellular volume fraction obtained from iodine map in evaluating liver function of patients with liver cirrhosis

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - GI DPS

Participants
Yao Wang, (*Presenter*) Nothing to Disclose

PURPOSE

To explore the correlation between hepatic extracellular volume fraction (fECV) based on iodine density and liver function in cirrhosis patients, and further investigate the diagnostic value of fECV in liver cirrhosis.

METHODS AND MATERIALS

The patients undergoing enhanced abdominal CT scan with spectral mode were categorized as group F (patients with liver cirrhosis),group F0 (patients without liver cirrhosis). According to the child-Pugh classification, group F was further divided into three subgroups: group FA (child A), group FB (child B) and group FC (child C). The latter two groups represented decompensated cirrhosis. The iodine density of liver and abdominal aorta were measured in iodine map of equilibrium phase to calculate the fECV. The formula for fecv is the iodine density of the liver multiplied by 100 minus Hct and then divided by the iodine density of the abdominal aorta.The fECV values among groups were compared by One-Way ANOVA, LSD method was used for further comparison. Pearson correlation analysis was performed to analyze the correlation between fECV and child-Pugh classification. The diagnostic performance of fECV for the differentiation of liver cirrhosis was assessed using receiver operation characteristic (ROC) curve analysis.

RESULTS

A total of 157 patients (51 in group F0, 46 in group FA, 38 in group FB, 22 in group FC) were included. The fECV fractions in from F0 to FC showed an upward trend (31.62±2.00,37.08±3.64, 43.39±6.00). There was significant difference in fECV among groups and between any two groups (all P <0.001). Strong positive correlation of fECV with child-Pugh classification was found (r=0.841). For differentiating liver cirrhosis, the sensitivity and specificity of fECV were 88.68% and 86.27%, respectively, with area under the curve (AUC) of 0.922, when the cut-off value was set at 30.26%. For differentiating decompensated cirrhosis by fECV, a cut-off value of 33.96% resulted in an AUC of 0.938, sensitivity of 90.00% and specificity of 89.13%.

CONCLUSION

s fECV from iodine map is strongly positively correlated with the Child-Pugh liver function classification, and has a high potential value in the differentiation of liver cirrhosis with different liver function grades.

CLINICAL RELEVANCE/APPLICATION

ECV measured using Hounsfield units needs precontrast phase, which has the problem of registration and increases the radiation dose. fECV obtained by dual energy spectral examination is a simple and convenient biomarker to identify different degrees of liver cirrhosis without dose compromise, which is suitable for follow-up.

To Characterize Liver Fibrosis using a Four-Compartments Restriction Spectrum Imaging Model

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - GI DPS

Participants
Cai Yeyu, MD, Changsha, China (*Presenter*) Nothing to Disclose

PURPOSE

Previous studies have shown that liver fibrosis, caused by chronic liver disease, is closely associated with the progression of various types of liver disease and is a key risk factor for cirrhosis and hepatocellular carcinoma. In this study, we evaluated the feasibility of the 4-compartment RSI model to identify carbon tetrachloride (CCl4) -induced liver fibrosis in mouse model.

METHODS AND MATERIALS

A total of 38 mice in the experiment were divided into CCL4-induced liver fibrosis (LF) and control groups, respectively. MRI examinations were performed on a 3T scanner (uMR790, United Imaging Healthcare, Shanghai, China), based on the echo planar imaging sequence (EPI) with a total of 11 b-values ranging from 0-2000 s/mm2. Conventional ADC and D values for each compartment in multicompartmental RSI models were calculated on voxel wise basis. The performance of different RSI models was evaluated using the Bayesian Information Criterion. Traditional ADC values and Di values of different compartments were further compared between the LF and control groups using Mann-Whitney test, and finally, the receiver operating characteristic (ROC) curve for different parameters were performed.

RESULTS

All mice in LF group were histologically diagnosed as liver fibrosis (100%). The results showed that the best model to describe the data was the 4-compartment RSI model with the lowest ?BIC value among all RSI models. Significant differences of ADC value and D values of the different compartments in the 4-compartment RSI model were found between LF group and control group. RSI4-C3 was the best single diffusion parameter for the discrimination of liver fibrosis, with the largest AUC value. Furthermore, the AUC value was further increased when ADC and C3 were combined.

CONCLUSION

s The 4-compartment RSI model can further distinguish the alterations in the LF group from the control group during different diffusion processes. Compared with the conventional ADC values, RSI4-C3 has a better ability to discriminate liver fibrosis. The combined parameter of ADC value and RSI4-C3 can further improve the discrimination performance of liver fibrosis.

CLINICAL RELEVANCE/APPLICATION

This study demonstrates that the four-compartment RSI model can provide a better identification of liver fibrosis than conventional ADC.

Non-invasive prediction of NASH by PDFF in Patients with Obesity without known Liver Disease

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - GI DPS

Participants
Nikolaos Panagiotopoulos, MD, Madison, WI (*Presenter*) Institutional Research Grant, Pfizer Inc

PURPOSE

To assess the value of PDFF, R2*, T2*, and T1 for the detection of NASH in a cohort of subject with obesity without previously known liver disease.

METHODS AND MATERIALS

This analysis is part of an ongoing study of patients with obesity undergoing weight loss surgery (WLS). Study participants underwent imaging within 1 week prior to WLS and intraoperative wedge biopsy of the liver. Imaging at 3.0T included IDEAL IQ (GE, USA) to quantify PDFF and R2* and LiverMultiscan (LMS, Perspectum, UK) for PDFF, T2*, and T1. Images were analyzed by placing ROIs in all liver segments. LMS data were analyzed by Perspectum. Liver biopsy samples were classified as normal, non-alcoholic fatty liver (NAFL, ie: steatosis only), or non-alcoholic steatohepatitis (NASH, based on a NASH activity score >5). Receiver operator characteristic (ROC) curve analysis was performed to assess the diagnostic accuracy of PDFF, R2*, T2* and T1 to differentiate NASH from non-NASH (normal or NAFL).

RESULTS

50 patients (44 female, 45±11 years, BMI: 44±6) were examined and analyzed. 24 subjects had no liver disease, 17 had NAFL and 9 had NASH. IDEAL IQ PDFF achieved separation between NASH and no NASH with an area under the curve of 0.91 (95%CI: 0.79-1). LMS PDFF achieved similarly separation between the groups with AUC=0.98 (95%CI: 0.94-1). At the same PDFF threshold of 11% for IDEAL IQ and LMS, sensitivity was 75% (95%CI: 35-97) and 83% (95%CI: 36-100), respectively, and specificity 98% (95%CI: 87-100) and 100% (95%CI: 89-100). LMS T1 achieved separation between the groups with an area under the curve of 0.83 (95%CI: 0.68-0.97). For the T1 threshold of 870ms, sensitivity was 83% (95%CI: 36-100) and specificity was 73% (95%CI: 55-87). Neither R2* nor T2* could distinguish between NASH and non-NASH.

CONCLUSION

s We observed promising performance of PDFF for the detection of NASH in a cohort of patients with obesity without previously known liver disease, in stark contrast to current knowledge. The results support our hypothesis that PDFF can differentiate NASH from NAFL in a cohort of patients with early-stage NASH where the severity of liver fat deposition is still present and relevant. A major limitation of this work is the limited number of patients with NASH to date.

CLINICAL RELEVANCE/APPLICATION

If confirmed, these results would constitute a paradigm change in the early detection of NASH.

M5B-SPGI-9

a fully automated hybrid approach to assessing liver fibrosis and necroinflammation on conventional MRI: a multi-center study

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - GI DPS

Participants
Junhao Zha, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a combined radiomics-clinic model by a fully automated hybrid approach to diagnosing clinically significant liver fibrosis (=F2) and necroinflammatory activity (=G2), respectively

METHODS AND MATERIALS

In this retrospective multi-center study, a total of 537 patients were included. From May 2015 to December 2018, 394 patients were randomly distributed in a training (n=276) or internal test (n=118) set at a ratio of 7:3 at center 1. From January 2019 to August 2020, 96 patients considered eligible at center 1 were placed in a temporal test set. An independent external test set from center 2 was used to validate the proposed models. All patients underwent abdominal MRI with pathologically proven liver fibrosis and necroinflammation. An interactive deep learning approach was developed to achieve better automated whole liver segmentation performance of ResUnet. 2880 radiomics features extracted from VOIT2FS, VOIT1delay were analyzed separately to form the radiomics scores (R-scores). The optimal R-scores and clinical biomarkers were integrated into the combined radiomics-clinic model (CRC model) for assessing =F2 or =G2, respectively. The performance of the models was assessed and compared with FIB-4 and APRI

RESULTS

For staging =F2, AUCs of CRC model are 0.83, 0.79, 0.82, 0.83 in the training, internal test, temporal test, and external test set respectively. CRC model (AUC 0.79) significantly outperformed radiomics model (AUC 0.75; $P < .05$) in the internal test set, and significantly outperformed FIB-4 (AUC 0.69, 0.67, 0.63; $P < .05$), and APRI (AUC 0.69, 0.68, 0.62; $P < .05$) in the internal test, temporal test, and external test set. By using the cutoffs, the CRC model had sensitivities and specificities as follows: 72.4% / 82.1%, 73.1% / 62.5%, 82.4% / 71.1%, 91.4% / 75.0% in the training, internal test, temporal test, and external test set for diagnosing =F2. For classifying =G2, the training, internal test, temporal test, and external test set results of the CRC model were AUC 0.88, 0.86, 0.79, and 0.89, sensitivity 74.6%, 71.4%, 61.5%, and 80.0%, and specificity 85.6%, 90.3%, 82.5%, and 87.1%, respectively. CRC model (AUC 0.86, 0.79, 0.89) significantly outperformed radiomics model (AUC 0.67, 0.69, 0.67; $P < .05$) , FIB-4 (AUC 0.67, 0.69, 0.73; $P < .05$), and APRI (AUC 0.74, 0.70, 0.63; $P < .05$) in the internal test, temporal test, and external test set for staging =G2

CONCLUSION

s The CRC models provide a promising approach for diagnosing liver fibrosis (=F2) and necroinflammatory activity (=G2)

CLINICAL RELEVANCE/APPLICATION

Traditional MR tissue texture, and routine clinical biomarkers, should be taken into consideration to develop the CRC model, and this mimics the diagnosis in real clinical scenarios.

Genitourinary Monday Poster Discussions - B

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - GU DPS

Sub-Events

M5B-SPGU-2 Diffusion Weighted Imaging as a Dominant Sequence for Evaluating Transitional Zone Prostate Cancer: Comparison with Current Prostate Imaging-Reporting Data System (PI-RADS) version 2.1.

Participants
Myoung Seok Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To explore the performance of Diffusion-weighted imaging (DWI) as a dominant sequence for detecting Transitional-zone Prostate Cancer (TZPCa) compared to current PI-RADS, which designate T2-weighted imaging (T2WI) as a dominant sequence for TZPCa.

METHODS AND MATERIALS

Forty patients confirmed as TZPCa and forty age-matched patients confirmed as BPH without TZPCa by radical prostatectomy. Two radiologists recorded every significant prostate cancer (Gleason score(GS)=6, maximal diameter=1cm) on pathologic mapping sheet, and per lesion-base, one-to-one correlation between mapping sheet and corresponding MRI was conducted by consensus of a pathologist and aforementioned radiologist. Another three radiologists independently reviewed MRIs of the patients, and recorded the PI-RADS scores for the case where the DWI was the dominant sequence and the case where the T2WI was the dominant score, with 4 weeks of time interval. The sensitivity, specificity, PPV, NPV and interobserver agreement for the two cases were statistically compared.

RESULTS

When the PI-RADS score of 3 or higher is considered to be lesion-positive, the overall specificity, PPV and NPV were significantly higher when DWI was a dominant sequence than when T2WI was a dominant sequence (0.896 vs 0.542, 0.764 vs 0.439, 0.853 vs 0.759, respectively). The sensitivity was similar in the two cases (0.687 vs 0.676). When the PI-RADS score of 4 and 5 were considered as cancer-positive, the specificity and PPV were also higher when regarding DWI as a dominant score (0.986 vs 0.944, 0.943 and 0.810, respectively), however the sensitivity and NPV showed no statistical difference (0.468 vs 0.468, 0.785 vs 0.776, respectively). The interobserver agreement was significantly higher when DWI was a dominant sequence, regardless of the cutoff value of PI-RADS score.

CONCLUSION

s Regarding DWI as a dominant score for TZPCa improves specificity, PPV and importantly, interobserver agreement without impairment of test sensitivity, compared to current PI-RADS which is using T2WI as a dominant score for TZPCa.

CLINICAL RELEVANCE/APPLICATION

Using DWI as a dominant sequence for evaluating transitional zone is supposed to improve specificity and PPV of current PI-RADS. Importantly, the interobserver agreement, one of the problems of PI-RADS, may be improved when using DWI as a dominant sequence. It is thought to be a consideration when revising PI-RADS.

M5B-SPGU-4 Automated Kidney Segmentation in contrast-enhanced Computed Tomography with patch-based 3D UNets on different anatomical planes

Participants
Konstantinos Koukoutegos, (*Presenter*) Nothing to Disclose

PURPOSE

Renal volumetric measurements are a critical radiological task, as Total Kidney Volume is a biomarker for assessing the risk of renal insufficiency. This study attempts to develop and validate a CNN-based method for measuring the volume of kidney parenchyma, excluding the collecting system, in contrast-enhanced CT.

METHODS AND MATERIALS

A cohort of 89 pre-transplant abdomen CT sequences and their corresponding segmentation masks were used in this retrospective study and split in 62, 14 and 13 for training, validation and testing respectively. A 3D residual UNet variant was used to train 3 separate patch-based models in the coronal, axial and sagittal anatomical views and their results were mutually compared and then combined. Extensive data augmentation techniques (such as intensity shift, Gaussian noise, image dropout) were implemented to increase the training population and offer additional regularization to the neural networks. The network training was performed using PyTorch 1.10 and MONAI 0.80.

RESULTS

Each model was trained for 400 epochs in 2 NVIDIA GeForce 1080Ti GPUs for 6 hours. The best-performing coronal, axial and

Each model was trained for 400 epochs in 2 NVIDIA GeForce 1080Ti GPUs for 6 hours. The best-performing coronal, axial and sagittal models achieved an average Dice coefficient of 0.929, 0.926 and 0.925 for the left kidney and 0.924, 0.925 and 0.921 for the right kidney respectively. Their ensemble prediction achieved a Dice of 0.934 for left and 0.936 for right kidney, making the latter the most robust amongst all methods, with paired t-test p values of 0.001, 0.0007 and 0.02 for the coronal, axial and sagittal models versus the combined method. A Volumetric Similarity of 0.981 ± 0.014 and 0.985 ± 0.013 (left and right) as compared with the ground truth data was achieved. The difference in volumetric agreement between manual delineation and predicted volumes is within the 95% confidence intervals for the whole test set with a mean of 4.53cm3. The average prediction time measured for a whole abdomen CT is 19.91 ± 2.77 secs.

CONCLUSION

s Combination of models trained in different anatomical planes can better capture the information of the 3D contrast-enhanced CT sequences and was shown to provide accurate measurements of kidney parenchyma.

CLINICAL RELEVANCE/APPLICATION

Robust AI models that perform with near-human accuracy can help as decision support system to achieve faster and more accurate disease diagnosis and treatment planning. We obtained promising results to facilitate the quantification of changes in kidney volume during a specified timeline, upon transplantation or at partial nephrectomy.

M5B-SPHN-1 Lateral Rectus Muscle Displacement in Sagging Eye Syndrome

Participants
Rouzbeh Mashayekhi, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Sagging Eye Syndrome (SES) is strabismus caused by degeneration of orbital connective tissue predominantly among the elderly. There has been ongoing research to find objective measurements to evaluate SES on Magnetic Resonance Imaging (MRI). Our study examines the vertical displacement angle between the midpoint of the lateral and medial rectus muscles to find an objective tool for SES evaluation.

METHODS AND MATERIALS

This is a retrospective study of 11 subjects who had radiologic and clinical confirmation of SES. 11 subjects who had undergone MRI orbital study for multiple sclerosis (MS) were selected as control subjects. Coronal oblique reconstructions were done of the axial 3D gradient echo sequence with the plane parallel to the insertion of the optic nerve and crossing the lacrimal crest to zygomatic arch. The vertical angle difference between the midpoint of the lateral and medial rectus muscles was measured. The Mann Whitney U test was performed to compare the angle measurements between the subjects with SES and the subjects with MS.

RESULTS

The 11 subjects with SES had an average age of 69 and 73% were female. The 11 MS subjects had an average age of 60 and 64% were female. The lateral rectus muscle midpoint was on average 3.4 degrees vertically lower relative to the medial rectus muscle midpoint among the SES subjects and 0.3 degrees among the MS subjects. The results showed statistically significant vertical inferior displacement of the lateral rectus muscle relative to the medial rectus muscle ($P < 0.01$).

CONCLUSION

s This study demonstrates that vertical displacement angle between the midpoint of the lateral and medial rectus muscles may be a useful tool for objectively evaluating for SES on MRI.

CLINICAL RELEVANCE/APPLICATION

Strabismus occurs from a variety of conditions including Sagging Eye Syndrome. We examined an ocular muscle angle measurement to provide radiologists with a tool to better evaluate for SES on MRI.

M5B-SPHN-2 Multi-Parametric Diffusion Tensor Imaging of The Optic Nerve for Detection of Dysthyroid Optic Neuropathy in Patients with Thyroid-Associated Ophthalmopathy

Awards
Trainee Research Prize - Medical Student

Participants
Ping Liu, MS, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the microstructural changes of the orbital optic nerve in thyroid-associated ophthalmopathy (TAO) patients with or without dysthyroid optic neuropathy (DON) using diffusion tensor imaging (DTI) and investigate whether DTI can be used to detect DON.

METHODS AND MATERIALS

59 bilateral TAO patients with (n= 23) and without DON (non-DON, n= 36) who underwent pretreatment DTI were included and 118 orbits were analyzed. The clinical features of all patients were collected. DTI parameters, including mean, axial, and radial diffusivity (MD, AD, and RD, respectively) and fractional anisotropy (FA) of the intra-orbital optic nerve for each orbit were calculated and compared between the DON and non-DON groups. ROC curves were generated to evaluate the diagnostic performance of single or combined DTI parameters. Correlations between DTI parameters and ophthalmological characteristics were analyzed using correlation analysis.

RESULTS

Compared with non-DON, the DON group showed decreased FA and increased MD, RD, and AD ($P < 0.01$). In the differentiation of

DON from non-DON, the MD was optimal individually, and the combination of the four parameters had the best diagnostic performance. There were significant correlations between the optic nerve's four DTI metrics and the visual acuity and clinical active score ($P < 0.05$). In addition, optic nerve FA was significantly associated with the amplitude of visual evoked potentials ($P = 0.022$).

CONCLUSION

s DTI is a promising technique in assessing microstructural changes of optic nerve in patients with DON, and it facilitates differentiation of DON from non-DON eyes in patients with TAO.

CLINICAL RELEVANCE/APPLICATION

We recommend DTI as a convenient and noninvasive tool for early detection of DON, and as a conventional examination in the clinical pipeline of TAO. Thus, facilitating timely diagnosis and initiation of medical treatment and enabling a better management of DON.

M5B-SPHN-3 Evaluation of The Efficacy of Postoperative Treatment in Obstructive Sleep Apnea Hypoventilation Syndrome

Participants
Wenwen Wang, Xian, China (*Presenter*) Nothing to Disclose

PURPOSE

This study aims to compare the role of CT and MR in assessing the stability of the upper respiratory tract in patients with obstructive sleep apnea syndrome (OSAHS), and to provide evidence for the evaluation of the postoperative treatment effect.

METHODS AND MATERIALS

A total of 61 patients (mean age: 36.62±7.99 years, range 22-51 years) were diagnosed as OSAHS through the Polysomnography(PSG).All the patients were treated with modified uvulopalatopharyngoplasty. The upper airway anatomy in all patents was evaluated by CT and MRI pre-operation, and 33 patients were followed-up post-operation. The upper airway parameters such as the thickness of lateral pharyngeal wall, the length of the tongue, the length and thickness of the soft palate and the cross-sectional areas of the soft palate on midsagittal planes were measured and compared, and a two-tailed p-value of less than 0.05 was considered statistically significant.

RESULTS

The minimum area of cross section of the upper airway (77.50±41.92mm2) on CT was significantly higher than the MR image (34.64±19.93mm2) ($p < 0.05$).In 31 patients with self-control, the soft palate thickness measured on nuclear magnetic images before and after surgery were(9.67±2.34vs11.24±2.41,$P<0.05$).The soft palate length, soft palate thickness, and minimum area of upper airway cross section measured on CT images were (37.38±7.86vs33.62±5.92,10.01±2.11vs11.34±2.43,78.40±40.93vs145.55±78.49)(all P value <0.05).

CONCLUSION

s Imageological examinationmay objectively evaluate the improvement of postoperative airway stenosis.In the evaluation of upper respiratory tract stenosis in OSAHS patients, MR and CT imaging findings were differently significant.Compared with preoperative, MR and CT showed increased thickness of the soft palate and decreased soft palate thickness on post-operative; the cross-sectional areas of the soft palate was not changed. with.

CLINICAL RELEVANCE/APPLICATION

CT and MR examination can effectively evaluate the upper airway status of patients, providing more basis for the diagnosis of OSAHS, the severity of the disease and the treatment effect evaluation.

The minimum area of cross section of the upper airway (77.50±41.92mm2) on CT was significantly higher than the MR image (34.64±19.93mm2) (p <0.05).In 31 patients with self-control, the soft palate thickness measured on nuclear magnetic images before and after surgery were(9.67±2.34vs11.24±2.41,P<0.05).The soft palate length, soft palate thickness, and minimum area of upper airway cross section measured on CT images were (37.38±7.86vs33.62±5.92,10.01±2.11vs11.34±2.43,78.40±40.93vs145.55±78.49)(all P value <0.05).

CONCLUSION

s Imageological examinationmay objectively evaluate the improvement of postoperative airway stenosis.In the evaluation of upper respiratory tract stenosis in OSAHS patients, MR and CT imaging findings were differently significant.Compared with preoperative, MR and CT showed increased thickness of the soft palate and decreased soft palate thickness on post-operative; the cross-sectional areas of the soft palate was not changed. with.

CLINICAL RELEVANCE/APPLICATION

CT and MR examination can effectively evaluate the upper airway status of patients, providing more basis for the diagnosis of OSAHS, the severity of the disease and the treatment effect evaluation.

M5B-SPIN-2 A Combined Risk Model Using Imaging and Clinical Parameters in COVID-19 Patients From a Nationwide German Cohort to Predict Disease Progression

Participants
Rebecca Armbruster, Bad Rippoldsau-Schapbach, Germany (*Presenter*) Nothing to Disclose

PURPOSE

COVID-19 infections are on a steep rise in early 2022 and new mutations are spreading rapidly. Machine learning models predicting severe courses of disease remain of interest to efficiently allocate limited medical resources. Our analysis is based on the large scale network infrastructure of the RACOON project spanning across all University Radiology Departements in Germany.

METHODS AND MATERIALS

In RACOON a representative dataset consisting of image-based and complementary non-image based standardized structured reports of COVID patients and COVID-mimics was created in 2021 and 2022 containing more than 6 million datapoints. In this analysis, we included 551 PCR-confirmed COVID-cases from 10 university hospitals out of a nationwide collection of 3065 COVID-cases across all 36 German university hospitals (age: 60.62±14.87, female/male: 172/372, known comorbidities: 1.68±1.47 [min-max: 0-7]). We combined outcome variables in a binary disease severity-score and trained predictors for severe disease progression. Our cohort included 129 severe (ICU admission and invasive ventilation) and 422 non-severe cases. We leveraged 31 structured CT reporting items per patient. Complementary clinical parameters included 18 additional features as input variables (9 anamnestic parameters, 4 vital parameters, oxygen therapy type, IL-6, lymphocyte-count, CRP and d-dimers).We generated classifiers (RandomForest, GradientBoosting) to estimate likelihood of severe outcomes for hospitalized patients and additionally for all location-specific folds to test generalizability.

RESULTS

Predicting the highest treatment status, we achieve an accuracy of 73.19% and increase this by 15pp when predicting the highest ventilatory needs (88.41%). By combining these two metrics, we achieve an accuracy of 94.93%. Compared to models trained on image-derived parameters only, we improve by 8pp. Location-specific train/test-folds achieve an averaged accuracy of 94.64±0.03% and show that our model generalizes among clinical settings.

CONCLUSION

s Our model accurately predicts patients COVID-19 progression at the time of the first CT scan after hospital admission by using baseline parameters complementary to image analysis. Our tool will be made available for public use. This analysis can be expanded to include datasets of further centers of the nationwide RACOON network.

CLINICAL RELEVANCE/APPLICATION

Predictive models can be used in clinical setting to predict necessity of intensive care treatment. Our novel large scale national research infrastructure project could create a representative dataset promptly within the pandemic and can be leveraged to continously address pandemic preparedness and public health research questions.

M5B-SPIN-3 Autonomous Machine Learning: Validating the Approach on Use-case for Classifying Clavicle Fractures

Participants
Giridhar Dasegowda, MBBS, Boston, MA (*Presenter*) Nothing to Disclose

PURPOSE

We created an infrastructure for autonomous machine learning (AML) platform for the non-programming physicians to create AML algorithms for different clinical applications. We tested the autonomous platform by creating an AML for classifying radiographs for presence and absence of clavicle fractures.

METHODS AND MATERIALS

Our IRB approved retrospective study included 972 clavicle radiographs from 486 patients (mean age 53 ± 19 years, M:F 249:237) from 5 hospitals (three community and two quaternary care hospitals). Most patient had two-view radiographs with axial and anterior-posterior projections. The positive radiographs had either displaced or non-displaced clavicle fractures. Radiographs with incomplete coverage of clavicles were excluded. The AML platform automatically retrieves imaging exams using series UID from the hospital VNA via WADO. The platform then autonomously trains a model until the validation loss plateaus. For training, the images are resized to 512 x 512 matrix. A DenseNet201 model (pretrained on ImageNet) is used for training with the following types of data augmentation - random rotation, random zoom, and random elastic deformation using splines. Once the testing is complete, the

platform provides the receiver operating characteristics curve and confusion matrix for estimating sensitivity, specificity, and accuracy.

RESULTS

The AML infrastructure was successful in retrieving radiographs from 5 of 7 sites. The retrieved datasets were successfully parsed for creating an ML classifier with 871 radiographs for the training dataset, 40 radiographs for cross-validation, and 100 radiographs for testing (46 with clavicle fracture, 54 without clavicle fracture). The algorithm identified clavicle fracture with 91% sensitivity, 72% specificity, and 81% accuracy with an AUC of 0.88.

CONCLUSION

s A fully autonomous ML platform can help physicians create and test successful machine learning models from multicenter imaging datasets such as the one in our study for classifying radiographs based on presence of clavicle fracture.

CLINICAL RELEVANCE/APPLICATION

A fully autonomous ML platform can help create self-learning ML algorithm with local datasets and high model performance for some tasks such as in classification of imaging tests for presence of specific findings.

M5B-SPIN-4 Artificial Intelligence-generated Auto-impression from 9.8-Million Radiology Reports as Training Datasets from Multiple Sites and Imaging Modalities

Awards
Trainee Research Prize - Fellow

Participants
Parisa Kaviani, MD, Boston, MA (*Presenter*) Nothing to Disclose

PURPOSE

We developed an artificial intelligence-generated auto-impression from a training dataset of 9.8-million radiology reports for multiple imaging modalities, radiology subspecialities, and sites. We evaluated the relationship, content, and accuracy of an AI-generated auto-impression (AAI) against the radiologists' reported findings and impression (RI).

METHODS AND MATERIALS

We developed and trained an AAI algorithm (Nuance Communications, Inc.) with 9.8 million radiology reports from multiple sites to generate AAI based on information including protocol name and the radiologists-dictated findings section of radiology reports. In an ongoing evaluation of a separate dataset of 10,000 radiology reports of multiple imaging modalities and from multiple US imaging sites, we assessed if AAI can accurately reproduce the RI in terms of number of clinically significant findings and radiologists' style of reporting, while avoiding potential mismatch (with the findings section in terms of size, location, or side). Separately we recorded the word count for AAI and RI. Data were analyzed with Pearson correlation and paired t-tests.

RESULTS

AAI reports were deemed either perfect (82.5%) or acceptable (17.5%) for stylistic concurrence with RI. Both AAI (mismatched Haller's Index) and RI (mismatched nodule size) had one mismatch each. There was no difference between the word counts of AAI (mean 43±25 words/impression) and RI (mean 41±24 words/impression) ($p>0.1$). Overall, there was an excellent correlation ($r=0.96$) between AAI and RI for the trajectory of findings (negative vs. stable vs. new or increasing vs. resolved or decreasing findings). The AAI output (<4%) requiring major changes pertained to reports with multiple impression items, and those where differential diagnosis or disease trajectories were not described in radiologists' findings section.

CONCLUSION

s Our AI-generated auto-impression has strong content and stylistic correlation with the radiologists-dictated impression of radiology reports from multiple sites and multiple imaging modalities.

CLINICAL RELEVANCE/APPLICATION

In clinical settings of radiology exam interpretation, the AI generated auto-impression assessed in our study can save interpretation time; a comprehensive findings section results in best AAI output.

M5B-SPIN-5 Enhancing Generalizability of a Non-Linear Deep Learning Model by Adjusting Linear Confounding Variables for Bone Age Estimation in Pediatric Hand X-rays

Participants
Sunggu Kyung, MS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To present the differences in performance and generalizability of non-linear deep learning models according to the method of adjusting linear confounding variables.

METHODS AND MATERIALS

RSNA Pediatric Bone Age Challenge (2017) dataset was used for training deep learning models. Test dataset of RSNA dataset and 227 pediatric hand X-ray images of a tertiary hospital from South Korea were used for the evaluation. Three different deep learning models were developed. Baseline model was simple CNN which takes input values of image and sex for estimating bone age. A double-task model with U-Net based encoder-decoder architecture has been developed, which takes input values of image, sex for estimating bone age and adjusts image related confounding variables by reconstructing the input image. Finally, a U-Net based triple-task model has been developed, which only takes input of image for estimating bone age and adjusts biological confounding variables by predicting sex and adjusts image related confounding variables by reconstructing the input image. The mean average error (MAE) and Pearson's correlation coefficient (r) between radiologist-labeled bone age and model prediction was evaluated and compared. In addition, attention map which highlights the region for bone age estimation was averaged and compared according to pubertal stage and sex. Paired t-test was used for statistical comparison

RESULTS

In test dataset of RSNA dataset, MAEs were 6.77, 5.43, and 7.61, respectively for the baseline, double-task, and triple-task models. The r values were 0.976, 0.988, and 0.972, respectively. There were statistical differences between baseline and double-task model ($P<0.001$) but not between double-task model and triple task model ($P=0.222$). In the tertiary hospital dataset, MAEs were 9.41, 9.10, and 8.35 respectively for the baseline, double-task, and triple-task models. The r values were 0.978, 0.978, and 0.983 respectively. There were statistical differences between triple-task and the other models (baseline, $P<0.001$; double-task, $P=0.037$). The averaged attention maps highlighted proper regions in all models.

CONCLUSION

s Adjusting linear confounding variables by additional input value can enhance internal performance of deep learning model but may deteriorate generalizability. Adjusting linear confounding variable by predicting it can enhance the generalizability of the deep learning model.

CLINICAL RELEVANCE/APPLICATION

For developing the model with better performance and muti-ethnic generalizability, the differences in adjustment strategies were used, which could be applicable to real world computer-aided diagnosis practice.

M5B-SPIR-1 Novel Stent-based Electrode for Radiofrequency Ablation in the Rat Esophagus: A Preliminary Study

Participants
Dong-Sung Won, BS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Endoluminal radiofrequency (RF) electrodes have been developed for the management of inoperable biliopancreatic ductal cancers and Barrett's esophagus but, the formation of a uniform ablation zone is still challenging. The purpose of this study was to investigate technical feasibility and efficacy of RF ablation with use of a novel monopolar stent-based electrode (SE) in the rat esophagus.

METHODS AND MATERIALS

RF protocol was determined to the exposed rat esophagus reached at 70 °C at 30, 40, and 50 W, respectively. Eighteen of 21 male Sprague-Dawley rats were divided into three groups and received stent-based RF ablation at 40 W, and the remaining three rats received a sham procedure. Histological changes including the thickness of the submucosal fibrosis, thickness of the epithelial layer, degree of inflammatory cell infiltration, and degree of collagen deposition were analyzed and compared with sham control at immediately (n = 6), 1 week (n = 6), and 2 weeks (n = 6). Additionally, TUNEL and HSP70-positive deposition were investigated.

RESULTS

The optimal RF protocol was at 40 W and 480 kHz for 60 sec. The stent-based RF ablation was successful in 16 (88.8%) of the 18 rats. Two rats died of dyspnea due to thicker delivery system and were excluded in this study. The degrees of RF-induced fibrotic changes and inflammatory cell infiltration in the RF-ablated rat esophagus were significantly and gradually increased compared with the sham control at 1 and 2 weeks (all $p < 0.05$). The thickness of epithelial layer was significantly lower at immediately ($p < 0.05$) but, gradually increased at 1 and 2 weeks (all $p < 0.001$) compared with the sham control. TUNEL-positive deposition was significantly increased immediately after RF ablation ($p < 0.001$) and gradually decreased. The HSP70-positive deposition was significantly increased compared with sham control at immediately, 1 and 2 weeks (all $p < 0.001$)

CONCLUSION

s The SE can maximize the RF ablation-induced therapeutic effects by fully contacting the inner wall of the rat esophagus. The stent-based RF ablation is technically feasible and effective to evenly induce thermal damages in the rat esophagus.

CLINICAL RELEVANCE/APPLICATION

The stent-based RF system might represent a promising new approach for the treatment of endoluminal malignancies in non-vascular luminal organs.

M5B-SPIR-2 Efficacy of Thermoplastic Polyurethane and Gelatin blended Nanofibers-coated Stent-graft in the Porcine Iliac Artery

Participants
Dae Sung Ryu, BS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Stent-grafts composed of expanded polytetrafluoroethylene, polyethylene terephthalate and polyurethane are characterized by poor endothelialization, high modulus, and low compliance, leading to thrombosis and intimal hyperplasia. A composite synthetic/natural matrix is thought to be a promising alternative to conventional synthetic stent-grafts. The purpose of this study was investigated the efficacy of thermoplastic polyurethane (TPU) and gelatin (GL) blended nanofibers (NFs) coated stent-graft in the porcine iliac artery.

METHODS AND MATERIALS

The TPU and GL blended NFs membrane was constructed using ES techniques on surface of the stent with 6 mm in diameter and 30 mm in length. A total of twelve Yorkshire domestic pigs were randomly sacrificed 7 days (n = 6) and 28 days (n = 6) after stent-graft placement in the left iliac artery. The efficacy of the TPU and GL blended NFs-coated stent-graft was assessed by comparing the results of follow-up angiography, the degree of thrombosis, and histological examinations.

RESULTS

TPU and GL blended NFs-coated stent-grafts were successfully placed in all pigs without procedure-related complications. The mean (± SD) luminal diameters at 28 days follow-up angiography (2.8 ± 0.34 mm) were significantly lower than those at 7 days

follow-up (4.6 ± 0.39 mm, p < 0.001) and post-procedure (5.1 ± 0.24 mm, p < 0.001) angiographies. The mean (± SD) thrombogenicity score was significantly increased at 28 days than at 7 days (2.67 ± 0.51 vs. 1.33 ± 0.51, p < 0.001). The mean (± SD) thickness of neointimal hyperplasia, degree of inflammatory cell infiltration, and degree of collagen deposition were all significantly higher at 28 days than at 7 days (847.8 ± 162.6 μm vs. 373.7 ± 53.25 μm, 3.66 ± 0.51 vs. 1.83 ± 0.40, 3.50 ± 0.83 vs. 1.33 ± 0.51, respectively; all p < 0.001).

CONCLUSION

s The TPU and GL blended NFs -coated stent-grafts successfully maintained the patency for 28 days in the porcine iliac artery. Although thrombosis with neointimal tissue were observed, there were no subsequent occlusion of the stent- graft until the end of the study. Further preclinical studies are needed to investigate the its efficacy and safety.

CLINICAL RELEVANCE/APPLICATION

A composite synthetic/natural matrix-coated stent-graft using electrospinning may be promising for prolonged stent-graft patency.

M5B-SPIR-3 A New Paradigm in Procedure Simulation Using 3D Printing and CT Scans

Participants
Eugene Moon, MD, MS, (*Presenter*) Nothing to Disclose

PURPOSE

Our purpose is to determine the cost-effectiveness of 3D printing vasculature models for procedure simulation and training. We aim to delineate the process of converting an abdominal computed tomography angiogram (CTA) into a 3D printed model for simulations like splenic artery embolization.

METHODS AND MATERIALS

CTA image was converted into a 3D digital model and saved as a .stl file using GE Healthcare AW Volumeshare 7. A free automated computer-aided design software, Autodesk MeshMixer, was used to hollow out the arterial model and erase artifacts created during the conversion. The final digital version was then printed on Formlabs Form3 3D printer using Elastic 50A resin. The 3D printed models were further processed by manually removing support structures, washing residual resin off with 100% isopropanol, and treating in UV light at 60°C for 20 min.

RESULTS

A segment of descending aorta with its celiac vessels was 3D printed using an abdominal CTA image. The 3D printed model was hollow, elastic, and transparent with varying vessel sizes. We found that the minimum limit of the vascular wall thickness and the lumen diameter was approximately 1 mm and 2 mm, respectively. The Form3 printer at the price of $3,499 printed our model at a resolution of 100 um layer thickness using a total resin volume of 52 mL. With the current price of resin at $0.15/mL, our single print costed about $7.80 of resin.

CONCLUSION

s We were able to 3D print a high-fidelity model of descending aorta and its celiac vessels at a significantly less cost than many models sold for simulation training. Our hollowed and transparent model provides both haptic and visual feedback for catheter and wire advancement simulation. We specifically aimed to 3D print a model for splenic artery embolization simulation because it demonstrates its ability to accurately create both large and small vessels (i.e., aorta and splenic artery).

CLINICAL RELEVANCE/APPLICATION

Procedure practice provides increased retention, proficiency, and confidence in the trainees that ultimately improves patient outcome. Despite the overwhelming benefits, training opportunities are limited by the cost and availability. However, 3D printed models for simulation overcomes those hurdles. Additionally, diverse models of patient-specific anatomy can be made using different CT images, and a finished 3D printable computer file can be reprinted or shared with different institutions.

M5B-SPIR-4 Sirolimus-loaded Stent Coated with Flexible 3D Nanonetworked Silica Film for Suppressing Tissue Hyperplasia in Rat Esophagus

Participants
Chu Hui Zeng, MMEd, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the safety and efficacy of a newly developed flexible three-dimensional sirolimus-loaded nano-networked silica film (NSF)-covered stent for suppressing stent-induced tissue hyperplasia in rat esophagus.

METHODS AND MATERIALS

A total of 30 Sprague-Dawley rats (300-350 g; 9 weeks old) were randomly allocated to three groups with 10 rats in each: Group A received control self-expandable metallic stent (SEMS), Group B received NSF-covered SEMS, and Group C received sirolimus-loaded NSF-covered SEMS. Hematoxylin and eosin staining was performed to determine the degree of submucosal inflammatory cell infiltration, number of epithelial layers, thickness of submucosal fibrosis, and percentage of tissue-hyperplasia area. Masson's trichrome staining was used for the degrees of inflammatory cell infiltration and collagen deposition. The degrees of a-SMA-, Ki-67-, and TUNEL-positive deposition were subjectively determined by immunohistochemistry.

RESULTS

Stent placement was successful in all rats. Four of the 30 rats experienced procedure-related death (n = 3; 10%) or stent migration (n = 1; 3.3%), while the remaining 26 (86.7%) rats survived until the end of study without stent-related complications. Compared with Groups A and B, the mean percentage of tissue-hyperplasia area, mean number of epithelial layers, mean thickness of submucosal fibrosis, and mean degrees of collagen, a-SMA-, and Ki-67-positive deposition were all significantly lower in Group C (all P < 0.05), but no difference was detected in TUNEL-stained tissues among the groups.

CONCLUSION

s This newly developed flexible three-dimensional sirolimus-loaded NSF-covered stent effectively suppressed stent-induced tissue

s This newly developed flexible three-dimensional sirolimus-loaded NSF-covered stent effectively suppressed stent-induced tissue hyperplasia in rat esophagus. Thus, the developed NSF is a promising polymer-free drug delivery platform to effectively treat esophageal stricture.

CLINICAL RELEVANCE/APPLICATION

This new flexible 3D nanonetworked silica film may serve as a promising polymer-free drug delivery platform for suppressing stent-induced tissue hyperplasia in the esophagus and other luminal organs.

M5B-SPIR-5 Differentiation Between Arterial and Venous Lines on Virtual Chest Radiographs: Deep Learning vs. Radiologists

Participants
Akihiro Inoue, BA, Kawadacho Shinjuku-Ku, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Arterial misinsertion of central venous catheter can cause lethal complications, while it is rare. The purpose of this study is to compare the performances of differentiating between arterial and venous lines on virtual chest radiographs simulating right internal jugular venous (IJV) catheter placement between radiologists and deep learning (DL).

METHODS AND MATERIALS

Virtual chest radiographs of seven directions at 5° intervals were developed from contrast-enhanced CT images using raysum reconstruction on a 3D workstation in 130 patients. Virtual venous and arterial lines were drawn from the right IJV to the superior vena cava or aorta at the tracheal bifurcation level using curved planar reconstruction function, respectively. Two DL models, object detection and image classification, were developed using IBM Maximo Visual Inspection in 100 cases. The performances of the DL models and three radiologists in differentiating arterial and venous lines were evaluated using 60 virtual chest radiographs in 30 patients and compared using the area under the receiver operating characteristic curve (AUC).

RESULTS

The sensitivity, specificity, and AUC using confidence scores in the DL model with image classification were 96.7%, 100%, and 1.000, respectively. Those in the DL model with object detection were 100%, 96.7%, and 1.000, respectively. Those of the radiologists were 93.3-100%, 100%, and 0.964-1.000, respectively. Limited to the frontal images, the DL model showed higher or equivalent AUCs (1.000) compared to the radiologists (0.964-1.000, P = 0.139-1.000).

CONCLUSION

s The diagnostic performances of the DL models are equivalent to or greater than those of radiologists in differentiating between arterial and venous lines from the right IJV on virtual chest radiographs. The DL models can contribute to patient safety by detecting arterial misinsertion which can cause serious complications.

CLINICAL RELEVANCE/APPLICATION

The deep learning models can contribute to patient safety by detecting arterial misinsertion from the right internal jugular vein, which can cause serious complications, on chest radiographs.

M5B-SPIR-6 Radiomics-based Prediction Model for Outcomes of Radioembolization in Metastatic Colorectal Cancer

Participants
Philipp Schindler, MD, Muenster, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the benefit of a radiomics-based model for predicting response and survival of patients with colorectal liver metastases treated with Yttrium-90 transarterial radioembolization (TARE).

METHODS AND MATERIALS

In this single center retrospective study fifty-one patients undergoing TARE were included. Treatment response was assessed by the Response Evaluation Criteria in Solid Tumors (RECIST) at follow-up after 3 months. Patients were stratified into responder (complete/partial response and disease control, n=24) and non-responder (progressive disease, n=27). Radiomic features (RF) were extracted from baseline CT after segmenting liver tumor volume. A radiomics-based model was built based on a radiomics signature consisting of reliable RFs that allow classification of response using multivariate logistic regression. Decision curve analysis was performed to evaluate the clinical benefit of the prediction model. According to a cutoff determined in the model, patients were assigned to either high- or low-risk groups for disease progression. Kaplan-Meier analysis was performed to analyze survival between high- and low-risk groups.

RESULTS

Two independent radiomic features differentiated well between responders and non-responders. For predicting treatment response, the area under the receiver operating characteristic curve of the radiomics-based model was 0.75 (95% CI, 0.48-1), providing larger net benefit than without radiomics-based model as determined by decision curve analysis. The high-risk group revealed shorter overall survival than the low-risk group (3.4 vs. 6.4 months, p<0.001).

CONCLUSION

s The radiomics-based model may predict the response and survival outcome in patients treated with TARE for colorectal liver metastases.

CLINICAL RELEVANCE/APPLICATION

This radiomics-based approach may provide an important decision tool for planning TARE and hereby optimize patient selection.

M5B-SPIR-7 Defining a Radiomics Feature Selection Method for Predicting Response to Transarterial Chemoembolization in Hepatocellular Carcinoma Patients

Participants
Amanda Laguna, BS, Laguna Niguel, CA (*Presenter*) Nothing to Disclose

PURPOSE

Defining reliable machine learning methods to predict treatment success in hepatocellular carcinoma (HCC) represents a key step in the management of this disease. In this work, we compared 18 existing radiomics feature selection methods to assess utility in predicting response to transarterial chemoembolization (TACE) when applied to a non-linear support vector machine (SVM) with a Gaussian kernel.

METHODS AND MATERIALS

136 paired MR T1-weighted contrast-enhanced abdominal images with liver tumor masks before and after TACE formed our dataset. Tumors were manually segmented by an experienced radiologist with seven years of experience. Using RECIST and mRECIST criteria, a combined manual label of either CR/PR or SD/PD was applied to each image pair to classify it as demonstrating a TACE-based reduction in tumor size or not, respectively. 100D feature vectors respected to first-order, shape and textual features were generated for the paired tumor areas before and after TACE. Subtracted feature vectors for each pre/post-TACE image pair were obtained. 18 existing methods of feature selection were employed to select the top-k features to train and test a non-linear SVM with a Gaussian kernel. A five-cross validation was performed to identify the highest performing feature selection method.

RESULTS

For images classified with mRECIST criteria that were analyzed with the highest performing feature selection method, the ACC, AUC, and F1-score were 74.29%±11.34%, 71.50%±15.67%, and 81.00%±7.74%, respectively. For images classified with RECIST criteria that were analyzed with the highest performing feature selection method, the ACC, AUC, and F1-score were 75.03%±6.46%, 75.04%±8.66%, and 80.46%±5.08%, respectively.

CONCLUSION

s An L0-based method that selects the top-5 most important features predicted TACE response in HCC patients with the highest accuracy under both RECIST and mRECIST criteria.

CLINICAL RELEVANCE/APPLICATION

TACE is the first-line treatment option for patients with intermediate-stage HCC. However, difficulty arises when managing these patients. Differences in patient characteristics, liver function, tumor burden, and other disease specificities result in only a subset of these patients benefiting from TACE. Therefore, developing a clinical decision making tool for selecting TACE candidates is critical in improving care of HCC patients. The present study suggests that an L0-based machine learning method that selects the top-5 most important radiomic features to predict TACE response may aid in TACE candidate selection.

M5B-SPIR-8 A Machine Learning Approach to Procedure-Related Mortality Prediction in Patients Undergoing Lower Extremity Endovascular Interventions

Participants
Meredith Cox, Durham, NC (*Presenter*) Nothing to Disclose

PURPOSE

A risk assessment for procedure-related mortality following lower extremity endovascular procedures can help clinicians identify optimal treatment plans and set realistic patient expectations. We develop a machine learning model using multi-hospital data to predict risk of death in patients with peripheral artery disease (PAD) undergoing lower extremity endovascular interventions and interpret the model to identify predictive factors for procedure-related mortality.

METHODS AND MATERIALS

Our study included 14,444 patients who underwent lower extremity endovascular procedures for PAD between 2011 and 2018 extracted from the American College of Surgeons National Surgical Quality Improvement Program (ACS NSQIP) database. Missing values were imputed using Optimal Imputation, and we selected an optimal feature set using Minimum Redundancy Maximum Relevance (mRMR). We trained a random forest model to predict 30-day mortality using 9,407 cases from 2011-2016 balanced with random oversampling of the minority class, and the model was tested using 5,037 independent cases from 2017-2018. We used Gini Importance and SHapley Additive exPlanations (SHAP) to understand the features that most significantly influenced model output. We tested for algorithmic fairness by calculating performance metrics across different races, sexes, and age groups.

RESULTS

The 20 predictive variables selected using mRMR were physiologic high-risk factors, elective surgery, functional status, creatinine, INR, BUN, diabetes, claudication, HCT, renal failure, albumin, dyspnea, pulmonary comorbidities, WBC, asymptomatic status, alkaline phosphatase, platelet count, SGOT, PTT, and bilirubin. Using these features, the random forest model achieved an AUC of 0.75 and an accuracy of 0.87 on the testing set. The model performed equally well on white and nonwhite patients (Delong p-value = 0.295), male and female patients (Delong p-value = 0.960), and patients under age 65 and patients age 65 and older (Delong p-value = 0.650).

CONCLUSION

s We present a machine learning model that predicts 30-day mortality outcomes in PAD patients undergoing lower extremity endovascular procedures that is both interpretable and fair. This model may aid in clinical decision-making to reduce procedure-related mortality in patients with PAD.

CLINICAL RELEVANCE/APPLICATION

Our machine learning model performs well for risk stratification in patients undergoing lower-extremity endovascular interventions, which may aid in optimizing patient outcomes.

Novel Stent-based Electrode for Radiofrequency Ablation in the Rat Esophagus: A Preliminary Study

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - IR DPS

Participants
Dong-Sung Won, BS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Endoluminal radiofrequency (RF) electrodes have been developed for the management of inoperable biliopancreatic ductal cancers and Barrett's esophagus but, the formation of a uniform ablation zone is still challenging. The purpose of this study was to investigate technical feasibility and efficacy of RF ablation with use of a novel monopolar stent-based electrode (SE) in the rat esophagus.

METHODS AND MATERIALS

RF protocol was determined to the exposed rat esophagus reached at 70 °C at 30, 40, and 50 W, respectively. Eighteen of 21 male Sprague-Dawley rats were divided into three groups and received stent-based RF ablation at 40 W, and the remaining three rats received a sham procedure. Histological changes including the thickness of the submucosal fibrosis, thickness of the epithelial layer, degree of inflammatory cell infiltration, and degree of collagen deposition were analyzed and compared with sham control at immediately (n = 6), 1 week (n = 6), and 2 weeks (n = 6). Additionally, TUNEL and HSP70-positive deposition were investigated.

RESULTS

The optimal RF protocol was at 40 W and 480 kHz for 60 sec. The stent-based RF ablation was successful in 16 (88.8%) of the 18 rats. Two rats died of dyspnea due to thicker delivery system and were excluded in this study. The degrees of RF-induced fibrotic changes and inflammatory cell infiltration in the RF-ablated rat esophagus were significantly and gradually increased compared with the sham control at 1 and 2 weeks (all $p < 0.05$). The thickness of epithelial layer was significantly lower at immediately ($p < 0.05$) but, gradually increased at 1 and 2 weeks (all $p < 0.001$) compared with the sham control. TUNEL-positive deposition was significantly increased immediately after RF ablation ($p < 0.001$) and gradually decreased. The HSP70-positive deposition was significantly increased compared with sham control at immediately, 1 and 2 weeks (all $p < 0.001$)

CONCLUSION

s The SE can maximize the RF ablation-induced therapeutic effects by fully contacting the inner wall of the rat esophagus. The stent-based RF ablation is technically feasible and effective to evenly induce thermal damages in the rat esophagus.

CLINICAL RELEVANCE/APPLICATION

The stent-based RF system might represent a promising new approach for the treatment of endoluminal malignancies in non-vascular luminal organs.

Efficacy of Thermoplastic Polyurethane and Gelatin blended Nanofibers-coated Stent-graft in the Porcine Iliac Artery

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - IR DPS

Participants
Dae Sung Ryu, BS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Stent-grafts composed of expanded polytetrafluoroethylene, polyethylene terephthalate and polyurethane are characterized by poor endothelialization, high modulus, and low compliance, leading to thrombosis and intimal hyperplasia. A composite synthetic/natural matrix is thought to be a promising alternative to conventional synthetic stent-grafts. The purpose of this study was investigated the efficacy of thermoplastic polyurethane (TPU) and gelatin (GL) blended nanofibers (NFs) coated stent-graft in the porcine iliac artery.

METHODS AND MATERIALS

The TPU and GL blended NFs membrane was constructed using ES techniques on surface of the stent with 6 mm in diameter and 30 mm in length. A total of twelve Yorkshire domestic pigs were randomly sacrificed 7 days (n = 6) and 28 days (n = 6) after stent-graft placement in the left iliac artery. The efficacy of the TPU and GL blended NFs-coated stent-graft was assessed by comparing the results of follow-up angiography, the degree of thrombosis, and histological examinations.

RESULTS

TPU and GL blended NFs-coated stent-grafts were successfully placed in all pigs without procedure-related complications. The mean (± SD) luminal diameters at 28 days follow-up angiography (2.8 ± 0.34 mm) were significantly lower than those at 7 days follow-up (4.6 ± 0.39 mm, $p < 0.001$) and post-procedure (5.1 ± 0.24 mm, $p < 0.001$) angiographies. The mean (± SD) thrombogenicity score was significantly increased at 28 days than at 7 days (2.67 ± 0.51 vs. 1.33 ± 0.51, $p < 0.001$). The mean (± SD) thickness of neointimal hyperplasia, degree of inflammatory cell infiltration, and degree of collagen deposition were all significantly higher at 28 days than at 7 days (847.8 ± 162.6 μm vs. 373.7 ± 53.25 μm, 3.66 ± 0.51 vs. 1.83 ± 0.40, 3.50 ± 0.83 vs. 1.33 ± 0.51, respectively; all $p < 0.001$).

CONCLUSION

s The TPU and GL blended NFs -coated stent-grafts successfully maintained the patency for 28 days in the porcine iliac artery. Although thrombosis with neointimal tissue were observed, there were no subsequent occlusion of the stent- graft until the end of the study. Further preclinical studies are needed to investigate the its efficacy and safety.

CLINICAL RELEVANCE/APPLICATION

A composite synthetic/natural matrix-coated stent-graft using electrospinning may be promising for prolonged stent-graft patency.

A New Paradigm in Procedure Simulation Using 3D Printing and CT Scans

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - IR DPS

Participants
Eugene Moon, MD, MS, (*Presenter*) Nothing to Disclose

PURPOSE

Our purpose is to determine the cost-effectiveness of 3D printing vasculature models for procedure simulation and training. We aim to delineate the process of converting an abdominal computed tomography angiogram (CTA) into a 3D printed model for simulations like splenic artery embolization.

METHODS AND MATERIALS

CTA image was converted into a 3D digital model and saved as a .stl file using GE Healthcare AW Volumeshare 7. A free automated computer-aided design software, Autodesk MeshMixer, was used to hollow out the arterial model and erase artifacts created during the conversion. The final digital version was then printed on Formlabs Form3 3D printer using Elastic 50A resin. The 3D printed models were further processed by manually removing support structures, washing residual resin off with 100% isopropanol, and treating in UV light at 60°C for 20 min.

RESULTS

A segment of descending aorta with its celiac vessels was 3D printed using an abdominal CTA image. The 3D printed model was hollow, elastic, and transparent with varying vessel sizes. We found that the minimum limit of the vascular wall thickness and the lumen diameter was approximately 1 mm and 2 mm, respectively. The Form3 printer at the price of $3,499 printed our model at a resolution of 100 um layer thickness using a total resin volume of 52 mL. With the current price of resin at $0.15/mL, our single print costed about $7.80 of resin.

CONCLUSION

s We were able to 3D print a high-fidelity model of descending aorta and its celiac vessels at a significantly less cost than many models sold for simulation training. Our hollowed and transparent model provides both haptic and visual feedback for catheter and wire advancement simulation. We specifically aimed to 3D print a model for splenic artery embolization simulation because it demonstrates its ability to accurately create both large and small vessels (i.e., aorta and splenic artery).

CLINICAL RELEVANCE/APPLICATION

Procedure practice provides increased retention, proficiency, and confidence in the trainees that ultimately improves patient outcome. Despite the overwhelming benefits, training opportunities are limited by the cost and availability. However, 3D printed models for simulation overcomes those hurdles. Additionally, diverse models of patient-specific anatomy can be made using different CT images, and a finished 3D printable computer file can be reprinted or shared with different institutions.

Sirolimus-loaded Stent Coated with Flexible 3D Nanonetworked Silica Film for Suppressing Tissue Hyperplasia in Rat Esophagus

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - IR DPS

Participants
Chu Hui Zeng, MMEd, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the safety and efficacy of a newly developed flexible three-dimensional sirolimus-loaded nano-networked silica film (NSF)-covered stent for suppressing stent-induced tissue hyperplasia in rat esophagus.

METHODS AND MATERIALS

A total of 30 Sprague-Dawley rats (300-350 g; 9 weeks old) were randomly allocated to three groups with 10 rats in each: Group A received control self-expandable metallic stent (SEMS), Group B received NSF-covered SEMS, and Group C received sirolimus-loaded NSF-covered SEMS. Hematoxylin and eosin staining was performed to determine the degree of submucosal inflammatory cell infiltration, number of epithelial layers, thickness of submucosal fibrosis, and percentage of tissue-hyperplasia area. Masson's trichrome staining was used for the degrees of inflammatory cell infiltration and collagen deposition. The degrees of a-SMA-, Ki-67-, and TUNEL-positive deposition were subjectively determined by immunohistochemistry.

RESULTS

Stent placement was successful in all rats. Four of the 30 rats experienced procedure-related death (n = 3; 10%) or stent migration (n = 1; 3.3%), while the remaining 26 (86.7%) rats survived until the end of study without stent-related complications. Compared with Groups A and B, the mean percentage of tissue-hyperplasia area, mean number of epithelial layers, mean thickness of submucosal fibrosis, and mean degrees of collagen, a-SMA-, and Ki-67-positive deposition were all significantly lower in Group C (all $P < 0.05$), but no difference was detected in TUNEL-stained tissues among the groups.

CONCLUSION

s This newly developed flexible three-dimensional sirolimus-loaded NSF-covered stent effectively suppressed stent-induced tissue hyperplasia in rat esophagus. Thus, the developed NSF is a promising polymer-free drug delivery platform to effectively treat esophageal stricture.

CLINICAL RELEVANCE/APPLICATION

This new flexible 3D nanonetworked silica film may serve as a promising polymer-free drug delivery platform for suppressing stent-induced tissue hyperplasia in the esophagus and other luminal organs.

Radiomics-based Prediction Model for Outcomes of Radioembolization in Metastatic Colorectal Cancer

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - IR DPS

Participants
Philipp Schindler, MD, Muenster, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the benefit of a radiomics-based model for predicting response and survival of patients with colorectal liver metastases treated with Yttrium-90 transarterial radioembolization (TARE).

METHODS AND MATERIALS

In this single center retrospective study fifty-one patients undergoing TARE were included. Treatment response was assessed by the Response Evaluation Criteria in Solid Tumors (RECIST) at follow-up after 3 months. Patients were stratified into responder (complete/partial response and disease control, n=24) and non-responder (progressive disease, n=27). Radiomic features (RF) were extracted from baseline CT after segmenting liver tumor volume. A radiomics-based model was built based on a radiomics signature consisting of reliable RFs that allow classification of response using multivariate logistic regression. Decision curve analysis was performed to evaluate the clinical benefit of the prediction model. According to a cutoff determined in the model, patients were assigned to either high- or low-risk groups for disease progression. Kaplan-Meier analysis was performed to analyze survival between high- and low-risk groups.

RESULTS

Two independent radiomic features differentiated well between responders and non-responders. For predicting treatment response, the area under the receiver operating characteristic curve of the radiomics-based model was 0.75 (95% CI, 0.48-1), providing larger net benefit than without radiomics-based model as determined by decision curve analysis. The high-risk group revealed shorter overall survival than the low-risk group (3.4 vs. 6.4 months, $p<0.001$).

CONCLUSION

s The radiomics-based model may predict the response and survival outcome in patients treated with TARE for colorectal liver metastases.

CLINICAL RELEVANCE/APPLICATION

This radiomics-based approach may provide an important decision tool for planning TARE and hereby optimize patient selection.

A Machine Learning Approach to Procedure-Related Mortality Prediction in Patients Undergoing Lower Extremity Endovascular Interventions

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - IR DPS

Participants
Meredith Cox, Durham, NC (*Presenter*) Nothing to Disclose

PURPOSE

A risk assessment for procedure-related mortality following lower extremity endovascular procedures can help clinicians identify optimal treatment plans and set realistic patient expectations. We develop a machine learning model using multi-hospital data to predict risk of death in patients with peripheral artery disease (PAD) undergoing lower extremity endovascular interventions and interpret the model to identify predictive factors for procedure-related mortality.

METHODS AND MATERIALS

Our study included 14,444 patients who underwent lower extremity endovascular procedures for PAD between 2011 and 2018 extracted from the American College of Surgeons National Surgical Quality Improvement Program (ACS NSQIP) database. Missing values were imputed using Optimal Imputation, and we selected an optimal feature set using Minimum Redundancy Maximum Relevance (mRMR). We trained a random forest model to predict 30-day mortality using 9,407 cases from 2011-2016 balanced with random oversampling of the minority class, and the model was tested using 5,037 independent cases from 2017-2018. We used Gini Importance and SHapley Additive exPlanations (SHAP) to understand the features that most significantly influenced model output. We tested for algorithmic fairness by calculating performance metrics across different races, sexes, and age groups.

RESULTS

The 20 predictive variables selected using mRMR were physiologic high-risk factors, elective surgery, functional status, creatinine, INR, BUN, diabetes, claudication, HCT, renal failure, albumin, dyspnea, pulmonary comorbidities, WBC, asymptomatic status, alkaline phosphatase, platelet count, SGOT, PTT, and bilirubin. Using these features, the random forest model achieved an AUC of 0.75 and an accuracy of 0.87 on the testing set. The model performed equally well on white and nonwhite patients (Delong p-value = 0.295), male and female patients (Delong p-value = 0.960), and patients under age 65 and patients age 65 and older (Delong p-value = 0.650).

CONCLUSION

s We present a machine learning model that predicts 30-day mortality outcomes in PAD patients undergoing lower extremity endovascular procedures that is both interpretable and fair. This model may aid in clinical decision-making to reduce procedure-related mortality in patients with PAD.

CLINICAL RELEVANCE/APPLICATION

Our machine learning model performs well for risk stratification in patients undergoing lower-extremity endovascular interventions, which may aid in optimizing patient outcomes.

Holden Archer, Dallas, TX (*Presenter*) Nothing to Disclose

PURPOSE

Hip dysplasia (HD) with under-coverage of the acetabulum can lead to hip osteoarthritis. There are several radiographic measurements used for the diagnosis of HD, the most common being the Lateral Center Edge Angle (LCEA) followed by the Tönnis angle and the extrusion index. Artificial intelligence (AI)-based software (HIPPO) using a deep learning algorithm produces such radiographic measurements consistently and reproducibly. Importantly, patient reported outcome measures (PROMs) inform treating physicians regarding the patient's subjective perceptions about their health. The aim of this study was to correlate AI-derived and manual measurements to PROMs with the hypothesis that less worse HD measurements linearly correlate with better PROMs.

METHODS AND MATERIALS

Using an electronic database of patients from institutional hip preservation clinic, 256 hips from 130 patients with a diagnosis of HD, AI output and PROMs were included. PROMS obtained at initial office visit included HHS, iHOT-12, SF-12, and Eq-VAS scores. Spearman's rank-order correlation was used. Three manual readers'(M) and their correlations were used as a control for AI.

RESULTS

With M-derived measurements, ipsilateral HHS weakly correlated with an increasing LCEA at 0.18, decreasing extrusion index at -0.14 (p=0.183) and decreasing Tonnis angle at -0.24, respectively. Similarly, AI-derived measurements also weakly correlated with HHS, e.g. Tonnis Angle at -0.20 (p=0.509), LCEA at 0.13, extrusion index at -0.15, and Tonnis angle with Eq Vas at -0.11, respectively. Statistical significance was only reached with respect to AI-derived measurement correlations between iHOT12 and SF12 with CCD (p=0.042 and 0.048).

CONCLUSION

s AI-derived radiographic measurements showed weak and fewer than expected correlations with PROM parameters in the setting of HD and while most being non-significant, they suggest a possible future role of AI to predict patient reported clinical outcome measures. Key Points: AI- and manually-derived measurements of LCEA, extrusion index and Tonnis angles showed weak correlations with PROMs. Significant correlations were seen with CCD and PROMs assessing patient's perceptions of own health and quality of life (p<0.05). The strength of AI predictability of PROMs is likely limited likely due to the complex disease process of HD.

CLINICAL RELEVANCE/APPLICATION

This study suggests a possible future role for AI-determined radiographic measurements for prediction of PROMs.

M5B-SPMK-2 How Does an AI Software for Detection of Bone Fractures Influence Radiologists in the Emergency Department?

Participants
Gianluca Folco, MD, Milano, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To assess the influence of an AI software for bone fracture diagnosis on an Emergency Department (ED) workload.

METHODS AND MATERIALS

An AI software for bone fracture diagnosis (BoneView, Gleamer, France) was added to our PACS on January 11; it processes bone X-rays of upper and lower limbs, lumbosacral spine, ribs, pelvis, hips and displays its diagnostic outcome: "fracture", "doubt fracture", or "no fracture". Furthermore, it adds regions of interest to X-ray images, indicating the AI software-detected fractures. Radiologists performed a prospective evaluation, both before and after the display of the AI software outcome, recording the diagnosis of "fracture", "doubt fracture", or "no fracture" and the number of fracture sites. The software's influence on the total X-ray workload of radiologists was also calculated, factoring in the AI outcome "not available" displayed due to incompatible anatomical districts. Concordance between radiological diagnosis without and with the aid of the AI software was compared using Wilcoxon signed-rank test, with significant P<0.05.

RESULTS

A total of 195 exams were evaluated by radiologists, with a diagnosis rate of no fracture, doubt fracture, and fracture of 121 (62%,

95%CI 55-69%), 8 (4%, 95%CI 2-8%), and 66 (34%, 95%CI 27-41%), respectively; AI software evaluation led to a change in diagnosis in 4 cases (2%, 95%CI 1-5%, P=0.256), involving 2 "fracture", 1 "doubt fracture" (initially deemed "no fracture"), and 1 "no fracture" (initially deemed "fracture"). The AI software was applicable in 34% of the ED examinations and could perform a diagnostic evaluation for 28% of them, having a decisive impact on 0.7% of the total X-rays.

CONCLUSION

s In our Emergency Department, the AI software influenced 2% of diagnoses (not statistically significant), with less than 1% impact on the radiological workload.

CLINICAL RELEVANCE/APPLICATION

We evaluated the impact of an AI software for the detection of bone fractures in our Emergency Department to assess whether its impact on the radiological workload would prove statistically significant. Results showed that the AI software has a relatively small impact on the total ED X-ray workload, making it not particularly cost-effective. However, further studies may show that AI-based detection of fractures improves the overall diagnostic accuracy in the ED, and that it provides a significant impact when only musculoskeletal radiological exams are taken into account.

M5B-SPMK-3 Noise Reduction and Image Quality Improvement in Ultra-low-dose Whole-body CT Scans Using Deep Learning-based CT Reconstruction Program in Patients with Multiple Myeloma

Participants
Jiseon Oh, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of our study was to evaluate the effect of a commercial deep learning-based CT reconstruction program (ClariCT.AI; ClariPI) on the image quality of ultra-low-dose whole-body CT scans.

METHODS AND MATERIALS

Sixteen patients with multiple myeloma who underwent low-dose whole-body CT using dual-source CT scanners (Somatom Force; Siemens Healthineers) were enrolled. All CT scans were taken with a dual tube system, and the radiation dose ratio of A and B tubes was set to be 3 to 1. As a result, three image sets were collected: ultra-low-dose CT using B tube data with iterative reconstruction (ULD-IR), low-dose CT using merged data from A and B tubes with iterative reconstruction (LD-IR), and ultra-low-dose CT using B tube data with deep learning algorithm (ULD-DL). Afterwards, image noise, the signal-to-noise ratio (SNR), and the contrast-to-noise ratio (CNR) were measured for each scan. For subjective evaluation, subjective noise, spatial resolution for bone and soft tissue, and overall image quality were assessed.

RESULTS

The mean effective dose for the sixteen CT scans was 6.03 ± 1.69 mSv (range, 4.18-9.53 mSv) and estimated mean effective dose of B tube was 1.56 ± 0.44 mSv (range, 1.03-2.49 mSv). The average measured noise for ULD-IR, LD-IR, and ULD-DL was 27.26 ± 30.99, 15.98 ± 14.13, and 13.72 ± 13.40, respectively ($p < .05$). Deep learning-based image reconstruction significantly improved the SNR and CNR of ULD whole-body CT ($p = .001$), and there was no significant difference in the SNR and CNR between LD-IR and ULD-DL ($p= .10$). In the subjective analysis, LD-IR showed less subjective noise and better overall image quality than ULD-DL ($p < .05$), but there was no significant difference in the spatial resolution for bone and soft tissue between LD-IR and ULD-DL ($p= .07$).

CONCLUSION

s With 25% of the radiation dose, ULD whole-body CT with deep learning-based algorithm showed comparable image quality to that of LD whole-body CT.

CLINICAL RELEVANCE/APPLICATION

Deep learning-based algorithm can effectively reduce radiation dose with acceptable image quality, hence enabling the use of ULD whole body CT as an initial examination in multiple myeloma patients.

M5B-SPMK-4 Value-added Opportunistic Screening: Prediction Model of Osteoporosis Based on Attenuation Value of Thoracic Vertebrae and Clinical Risk Factors

Participants
Jinrong Yang, (*Presenter*) Nothing to Disclose

PURPOSE

This study is to establish and verify a nomogram model based on attenuation value of thoracic vertebrae and clinical risk factors for predicting the risk of osteoporosis.

METHODS AND MATERIALS

This is a cross-sectional study. A total of 1046 patients were enrolled and the baseline clinical data, biochemical indicators, concomitant diseases were collected. The volume attenuation values of thoracic vertebrae were automatically measured by artificial intelligence. The whole patients were randomly divided into the training set of 732 cases (70%) and the validation set of 314 cases (30%). Both two sets, the diagnostic criteria established by the World Health Organization (WHO) in 1994 based on dual-energy X-ray absorptiometry (DXA) were adopted for the diagnosis of osteoporosis. In the training set, variance, t-test (for normal distribution) /Mann-Whitney U-test (for non-normal distribution), least absolute shrinkage and selection operator (LASSO) were used for selecting the thoracic vertebrae CT values to construct AI measurement score and multivariate logistic backward stepwise regression were used to analyze the influencing factors of osteoporosis. According to the clinical application for different data conditions, five nomogram prediction models were constructed, named AIMeasure model, BasicClinical model, TotalClinical model, AIBasicClinical model, AITotalClinical model. Moreover, receiver operating characteristic (ROC) curve, calibration curve and decision curve analyses (DCA) were used to test the distinction, accuracy and clinical applicability of the model both in training set and validation set.

RESULTS

The results showed age, sex, weight, BMI, smoking, high density lipoprotein cholesterol (HDL_C), low density lipoprotein cholesterol

(LDL_C), serum calcium and low CT attenuation value were all related to the occurrence of osteoporosis. The area under the ROC curve of the above five models was 0.878, 0.712, 0.738, 0.897, 0.898 in the training set and was 0.887, 0.773, 0.777, 0.900, 0.902 in the verification set, respectively. Moreover, the calibration curves and DCAs of the models containing attenuation values performed well on accuracy and clinical practicality both two sets.

CONCLUSION

s The risk prediction nomogram models containing attenuation values have good predictive ability and clinical value, which could be used as an effective tool for the risk prediction of osteoporosis. Furthermore, they would facilitate earlier intervention to prevent the future development of osteoporosis and occurrence of osteoporotic fractures.

CLINICAL RELEVANCE/APPLICATION

This study showed the attenuation values of thoracic vertebrae on chest CT could be used for opportunistic screening of osteoporosis.

M5B-SPMS-1 Deep Learning Automation of Kidney, Liver and Spleen Segmentation for Organ Volume Measurements in Autosomal Dominant Polycystic Kidney Disease

Awards
Trainee Research Prize - Medical Student

Participants
Arman Sharbatdaran, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited renal disease and it affects other organs including liver, spleen, pancreas, seminal vesicles, arachnoid, lymphatics and the cardiovascular system. Organ volume measurements are a critical clinical metric in managing ADPKD patients. But manually contouring each organ on every image slice is tedious and prone to error/bias. Here we expand a deep learning model optimized for kidney segmentations to also segment liver and spleen in ADPKD.

METHODS AND MATERIALS

A 2D U-net deep learning approach to segment kidneys was optimized to also segment liver and spleen volume. This required optimization of image cropping for each organ and an effective algorithm to determine the identity of overlap voxels, which are labeled as more than one organ. Radiologists manually labeled T2-weighted images from 213 ADPKD subjects as ground truth to train the model, which was then validated by 30 additional prospective and 30 external subjects for a total of 319 ADPKD subjects. The mean time and interobserver variability for manual organ segmentation and model-assisted segmentation for the 1st 10 prospective cases were evaluated by 3 trained observers to assess the efficiency of the model.

RESULTS

Kidney, liver, and spleen volumes had average percent error of 5%, 4%, and 7%, respectively, on external validation and 9%, 3%, and 5%, respectively on prospective validation. The Dice score associated with left kidney, right kidney, liver, and spleen were 0.96, 0.99, 0.97, 0.96, respectively on external validation and 0.96, 0.96, 0.97, 0.95, respectively on prospective validation. Time required for manual correction of deep learning segmentation errors was only 12:41 minutes compared to 19:19 minutes for completely manual segmentation, a 39% time saving ($p=0.001$). Interobserver variability of model segmentations was reduced 3-fold compared to manual segmentation.

CONCLUSION

s Deep learning reduces radiologists' time required to perform multi-organ segmentation in ADPKD and reduces measurement variability.

CLINICAL RELEVANCE/APPLICATION

Automating organ volume measurements and improving reproducibility will allow for more accurate assessment of disease progressing and response to treatments as well as potentially titration of treatments for improving ADPKD patient care.

M5B-SPNMMI-1 MRI Dynamic Tracing Study of the Effect of PLL-USPIONS-PMSCc Molecular Probe on Colorectal Cancer Xenografts in Nude Mice

Participants
Hua He, MMedSc, MMedSc, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

Human placental mesenchymal stem cells (PMSCs) labeled with polylysine-ultramicro and superparamagnetic oxide nano-iron particle protein complexes and transplanted into colorectal cancer (CRC) animal models , to explore the feasibility of molecular imaging of PLL-USPIONS-PMSCc targeting CRC tumor-bearing mice and the effect of PMSCs on CRC.

METHODS AND MATERIALS

PMSCs were cultured, transfected with polylysine (PLL), and PMSCs-PLL were magnetically labeled with USPION, the PLL-USPIONS-PMSCc molecular probe was transplanted into the experimental group colorectal cancer animal model through the tail vein of the rat, in the same way, 200 μl of PBS without cells was injected into the tumor of the tumor-bearing mice as a blank control,T2WI, T2mapping, T2*mapping sequences were used to observe the signal distribution and change characteristics of transplanted tumor and PMSCc, observation of the signal distribution and change characteristics in the two groups of transplanted tumors measured the size, T2, T2* value of tumor, calculated inhibition rate.

RESULTS

? In the experimental group, the low signal of PMSCc could be detected in the transplanted tumor, and the signal and parameter values of PMSCc and tumor changed dynamically over time, Labeling of human placental mesenchymal stem cells with ultra-micro and superparamagnetic iron oxide nanoparticles, the T2 and T2* values of the transplanted tumors in the experimental group and the control group were 73.004±1.529 , 80.357±4.347($P<0.05$). ? The growth curves of transplanted tumors in the two groups are similar and there were statistical differences in volume change($P<0.05$), inhibitory rate is positive.

CONCLUSION

s 3.0T MRI can safely and effectively track PMSCs in vivo. PMSCs have directional chemotaxis to CRC, can accumulate into tumors, and finally inhibit tumor growth through the interaction of promotion and inhibition of tumor growth at different stages.

CLINICAL RELEVANCE/APPLICATION

Provide basic research data for the targeted therapy of placental mesenchymal stem cells in colorectal cancer.

M5B-SPNMMI-2 Reliability of Deauville Scale for Lymphoma PET Assessment in FIL, IELSG and SAKK Multi-center Clinical Trials

Participants
Fabrizio Bergesio, (*Presenter*) Nothing to Disclose

PURPOSE

Deauville scale (DS) is the recommended scoring system for reporting Positron Emission Tomography (PET/CT) in FDG-avid lymphoma.In this work we evaluated the reliability of the DS used in multi-center trials of Italian Foundation Lymphoma (FIL), International Extranodal Lymphoma Study Group (IELSG) and Swiss Group for Clinical Cancer Research (SAKK).

METHODS AND MATERIALS

Six trials were included in this analysis: FOLL12 (Follicular Lymphoma, ePET), DLCL10 (Diffuse Large B-Cell Lymphoma, ePET),ROUGE (Advanced-stage classical Hodgkin Lymphoma, iPET and ePET),ELDHL (Classical Hodgkin Lymphoma, iPET)IELSG37 (Primary Mediastinal Large B-Cell Lymphoma, ePET).SAKK3819 (Diffuse Large B-Cell Lymphoma, training dataset (tPET) of 40pts).PET/CT images were independently reviewed by a group of nuclear medicine physicians blinded to patient history, clinical data and treatment outcome. The reference lesion was visually scored according to DS. For each study we evaluated the reliability among all

reviewers using: the Krippendorff Alpha (KA) calculated on the discrete (d) 5-point scale and the Cohen Kappa (CK) calculated on the binary PET positive/negative scale using different trial-related threshold of positivity and the percentage overall agreement (OA), the positive agreement (PA), the negative agreement (NA) as the ratio of number of concordant cases plus half of the number of discordant cases respect to the number of cases.

RESULTS

729ePET (641PET-/88PET+) included in the FIL-FOLL12 trial were reviewed by 6 expertise; the KA, CK,OA, PA, NA values were 0.30, 0.62, 0.92, 0.77, 0.94 respectively. 108ePET (86PET-/22PET+) included in the FIL-DLCL10 trial were reviewed by 5 expertise; the KA, CK, OA, PA, NA values were 0.37, 0.65, 0.88, 0.75, 0.91 respectively.455ePET (239PET-/216PET+) included in the IELSG37 trial were reviewed by 6 expertise; the KA, CK, OA, PA, NA values were 0.49, 0.75, 0.86, 0.86, 0.87 respectively.465 iPET (391PET-/74PET+) and 428ePET (374PET-/54PET+) included in the FIL-ROUGE trial were reviewed by 5 expertise. For iPET the KA, CK, OA, PA, NA values were 0.36, 0.75, 0.94, 0.95, 0.93 respectively. For ePET the KA, CK, OA, PA, NA values were 0.30, 0.75, 0.95, 0.95, 0.94 respectively. 69iPET (50PET-/19PET+) included in the FIL-ELDHL trial were reviewed by 3 expertise; the KA, CK, OA, PA, NA values were 0.40, 0.65, 0.95, 0.95, 0.94 respectively.40 tPET (22PET-/18PET+) included in the training set of SAKK3819 trial were reviewed by 5 expertise; the KA, CK, OA, PA, NA values were 0.48, 0.85, 0.93, 0.94, 0.91 respectively.

CONCLUSION

s The results show that the Deauville Score is a reproducible technique in clinical trials using FDG-PET/CT for response assessment in several lymphomas diseases

CLINICAL RELEVANCE/APPLICATION

Clinical Trial

M5B-SPNMMI-3 68Ga-DOTATATE PET/MRI for Detection of Liver Metastases from Gastro-entero-pancreatic (GEP) Neuroendocrine Tumors (NETs): A Multi-reader Study

Participants
Aparna Singh, MBBS, Rochester, MN (*Presenter*) Nothing to Disclose

PURPOSE

To determine if additional list-mode liver PET during 68Ga-DOTATATE PET/MRI increases the diagnostic performance for liver metastases detection vis-à-vis whole-body (WB) PET/MR and liver MR in patients with GEP NETs.

METHODS AND MATERIALS

In this IRB-approved, HIPAA-compliant retrospective study, 50 patients with GEP NETs underwent a 68Ga-DOTATATE PET/MRI, which included WB PET/MRI followed by focused list-mode respiratory-compensated liver PET and simultaneous co-acquisition of gadoxetate-enhanced liver MR sequences. Liver lesions on WB PET, focused PET, and MR image-sets were independently evaluated by three blinded fellowship-trained radiologists in separate sessions spaced at least 2-weeks apart for number, localization, etiology (benign, metastases, indeterminate), and conspicuity (definitely present, equivocal, definitely absent). Reference standard was histopathology or clinico-radiological follow-up.

RESULTS

There were 127 liver metastases (98 DOTATATE-avid, 29 non-DOTATATE-avid) in 34 patients whereas 16 patients had benign lesions or no metastases. Lesion-based analyses showed highest sensitivity (95% CI) for focused PET [76.6% (72.1-80.8%)] followed by MRI [74.8% (70.1-79.1%)] and WB PET [70.1% (65.2-74.6%)]. Accuracy was also highest for focused PET [73.3% (68.9-77.2%)] followed by WB PET [68.4% (63.9-72.6%)] and MRI [64.8% (60.7-68.7%)]. Interrater agreement was good for all three image-sets but was highest for focused PET (Fleiss' kappa 0.82) followed by WB PET (0.78) and MRI (0.61), p=0.03.

CONCLUSION

s List-mode liver PET during 68Ga-DOTATATE PET/MRI increases the diagnostic performance for liver metastases vis-à-vis WB PET/MR and gadoxetate-enhanced liver MR in patients with GEP NETs.

CLINICAL RELEVANCE/APPLICATION

A 68Ga-DOTATATE PET/MRI protocol, which includes list-mode respiratory-compensated liver PET with co-acquisition of gadoxetate-enhanced liver MR, can be a one-stop-shop staging exam for patients with GEP NETs.

MRI Dynamic Tracing Study of the Effect of PLL-USPIONS-PMSCc Molecular Probe on Colorectal Cancer Xenografts in Nude Mice

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NMMI DPS

Participants
Hua He, MMedSc, MMedSc, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

Human placental mesenchymal stem cells (PMSCs) labeled with polylysine-ultramicro and superparamagnetic oxide nano-iron particle protein complexes and transplanted into colorectal cancer (CRC) animal models , to explore the feasibility of molecular imaging of PLL-USPIONS-PMSCc targeting CRC tumor-bearing mice and the effect of PMSCs on CRC.

METHODS AND MATERIALS

PMSCs were cultured, transfected with polylysine (PLL), and PMSCs-PLL were magnetically labeled with USPION, the PLL-USPIONS-PMSCc molecular probe was transplanted into the experimental group colorectal cancer animal model through the tail vein of the rat, in the same way, 200 μl of PBS without cells was injected into the tumor of the tumor-bearing mice as a blank control,T2WI, T2mapping, T2*mapping sequences were used to observe the signal distribution and change characteristics of transplanted tumor and PMSCc, observation of the signal distribution and change characteristics in the two groups of transplanted tumors measured the size, T2, T2* value of tumor, calculated inhibition rate.

RESULTS

? In the experimental group, the low signal of PMSCc could be detected in the transplanted tumor, and the signal and parameter values of PMSCc and tumor changed dynamically over time, Labeling of human placental mesenchymal stem cells with ultra-micro and superparamagnetic iron oxide nanoparticles, the T2 and T2* values of the transplanted tumors in the experimental group and the control group were 73.004±1.529 , 80.357±4.347($P<0.05$). ? The growth curves of transplanted tumors in the two groups are similar and there were statistical differences in volume change($P<0.05$), inhibitory rate is positive.

CONCLUSION

s 3.0T MRI can safely and effectively track PMSCs in vivo. PMSCs have directional chemotaxis to CRC, can accumulate into tumors, and finally inhibit tumor growth through the interaction of promotion and inhibition of tumor growth at different stages.

CLINICAL RELEVANCE/APPLICATION

Provide basic research data for the targeted therapy of placental mesenchymal stem cells in colorectal cancer.

M5B-SPNMMI-2

Reliability of Deauville Scale for Lymphoma PET Assessment in FIL, IELSG and SAKK Multi-center Clinical Trials

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NMMI DPS

Participants
Fabrizio Bergesio, (*Presenter*) Nothing to Disclose

PURPOSE

Deauville scale (DS) is the recommended scoring system for reporting Positron Emission Tomography (PET/CT) in FDG-avid lymphoma.In this work we evaluated the reliability of the DS used in multi-center trials of Italian Foundation Lymphoma (FIL), International Extranodal Lymphoma Study Group (IELSG) and Swiss Group for Clinical Cancer Research (SAKK).

METHODS AND MATERIALS

Six trials were included in this analysis: FOLL12 (Follicular Lymphoma, ePET), DLCL10 (Diffuse Large B-Cell Lymphoma, ePET),ROUGE (Advanced-stage classical Hodgkin Lymphoma, iPET and ePET),ELDHL (Classical Hodgkin Lymphoma, iPET)IELSG37 (Primary Mediastinal Large B-Cell Lymphoma, ePET).SAKK3819 (Diffuse Large B-Cell Lymphoma, training dataset (tPET) of 40pts).PET/CT images were independently reviewed by a group of nuclear medicine physicians blinded to patient history, clinical data and treatment outcome. The reference lesion was visually scored according to DS. For each study we evaluated the reliability among all reviewers using: the Krippendorff Alpha (KA) calculated on the discrete (d) 5-point scale and the Cohen Kappa (CK) calculated on the binary PET positive/negative scale using different trial-related threshold of positivity and the percentage overall agreement (OA), the positive agreement (PA), the negative agreement (NA) as the ratio of number of concordant cases plus half of the number of discordant cases respect to the number of cases.

RESULTS

729ePET (641PET-/88PET+) included in the FIL-FOLL12 trial were reviewed by 6 expertise; the KA, CK,OA, PA, NA values were 0.30, 0.62, 0.92, 0.77, 0.94 respectively. 108ePET (86PET-/22PET+) included in the FIL-DLCL10 trial were reviewed by 5 expertise; the KA, CK, OA, PA, NA values were 0.37, 0.65, 0.88, 0.75, 0.91 respectively.455ePET (239PET-/216PET+) included in the IELSG37 trial were reviewed by 6 expertise; the KA, CK, OA, PA, NA values were 0.49, 0.75, 0.86, 0.86, 0.87 respectively.465 iPET (391PET-/74PET+) and 428ePET (374PET-/54PET+) included in the FIL-ROUGE trial were reviewed by 5 expertise. For iPET the KA, CK, OA, PA, NA values were 0.36, 0.75, 0.94, 0.95, 0.93 respectively. For ePET the KA, CK, OA, PA, NA values were 0.30, 0.75, 0.95, 0.95, 0.94 respectively. 69iPET (50PET-/19PET+) included in the FIL-ELDHL trial were reviewed by 3 expertise; the KA, CK, OA, PA, NA values were 0.40, 0.65, 0.95, 0.95, 0.94 respectively.40 tPET (22PET-/18PET+) included in the training set of SAKK3819 trial were reviewed by 5 expertise; the KA, CK, OA, PA, NA values were 0.48, 0.85, 0.93, 0.94, 0.91 respectively.

CONCLUSION

s The results show that the Deauville Score is a reproducible technique in clinical trials using FDG-PET/CT for response assessment in several lymphomas diseases

68Ga-DOTATATE PET/MRI for Detection of Liver Metastases from Gastro-entero-pancreatic (GEP) Neuroendocrine Tumors (NETs): A Multi-reader Study

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NMMI DPS

Participants
Aparna Singh, MBBS, Rochester, MN (*Presenter*) Nothing to Disclose

PURPOSE

To determine if additional list-mode liver PET during 68Ga-DOTATATE PET/MRI increases the diagnostic performance for liver metastases detection vis-à-vis whole-body (WB) PET/MR and liver MR in patients with GEP NETs.

METHODS AND MATERIALS

In this IRB-approved, HIPAA-compliant retrospective study, 50 patients with GEP NETs underwent a 68Ga-DOTATATE PET/MRI, which included WB PET/MRI followed by focused list-mode respiratory-compensated liver PET and simultaneous co-acquisition of gadoxetate-enhanced liver MR sequences. Liver lesions on WB PET, focused PET, and MR image-sets were independently evaluated by three blinded fellowship-trained radiologists in separate sessions spaced at least 2-weeks apart for number, localization, etiology (benign, metastases, indeterminate), and conspicuity (definitely present, equivocal, definitely absent). Reference standard was histopathology or clinico-radiological follow-up.

RESULTS

There were 127 liver metastases (98 DOTATATE-avid, 29 non-DOTATATE-avid) in 34 patients whereas 16 patients had benign lesions or no metastases. Lesion-based analyses showed highest sensitivity (95% CI) for focused PET [76.6% (72.1-80.8%)] followed by MRI [74.8% (70.1-79.1%)] and WB PET [70.1% (65.2-74.6%)]. Accuracy was also highest for focused PET [73.3% (68.9-77.2%)] followed by WB PET [68.4% (63.9-72.6%)] and MRI [64.8% (60.7-68.7%)]. Interrater agreement was good for all three image-sets but was highest for focused PET (Fleiss' kappa 0.82) followed by WB PET (0.78) and MRI (0.61), p=0.03.

CONCLUSION

s List-mode liver PET during 68Ga-DOTATATE PET/MRI increases the diagnostic performance for liver metastases vis-à-vis WB PET/MR and gadoxetate-enhanced liver MR in patients with GEP NETs.

CLINICAL RELEVANCE/APPLICATION

A 68Ga-DOTATATE PET/MRI protocol, which includes list-mode respiratory-compensated liver PET with co-acquisition of gadoxetate-enhanced liver MR, can be a one-stop-shop staging exam for patients with GEP NETs.

M5B-SPNPM-1 Current Status and Trends in Diversity by Race, Ethnicity, and Sex among US Diagnostic Radiology Trainees

Participants
Kamil Abu-Shaban, BEng, (*Presenter*) Nothing to Disclose

PURPOSE

To assess the current status and trends in the diversity of the U.S. diagnostic radiology resident workforce by race, ethnicity, and sex from 2011 to 2020.

METHODS AND MATERIALS

Publicly available data was obtained from the Accreditation Council for Graduate Medical Education (ACGME) website regarding US radiology trainees between 2011 and 2020. The most recent demographic data for US medical students was derived from the American Association of Medical Colleges (AAMC) in 2019. Chi-square was used to compare 2011 vs. 2020 URM data, 2020 URM vs. 2020 US Census data, and 2020 URM data vs. 2019 AAMC data. Least-squares linear regression was used to quantify trends in URM representation from 2011-2020.

RESULTS

In 2011, 53.7% of trainees were White, 16.7% Asian or Pacific Islander, 2.4% Hispanic, 2.2% Black or African American, 0.28% Native American/Alaskan and 24.78% Other/Unknown. In 2020, 51.27% of trainees were White, 22.7% Asian or Pacific Islander, 4.8% Hispanic, 3.8% Black or African American, 0.30% Native American/Alaskan and 17.1% Other/Unknown. Comparing overall URM percentage from 2011-2020, racial and ethnic URM representation increased for all radiology trainees (4.9% to 9.2%, $p<.001$). Analysis of all other ACGME specialties on average did not show a significant increase in URM percentage (9.6% to 11.5%, $p=.06$). URM percentage in radiology is still less than that of all other ACGME specialties on average in 2020 (9.2% vs. 11.5%, $p<.001$) and 2019 AAMC medical student URM data (9.2% vs 11.1%, $p<.001$). In 2020, the percentage of female radiology trainees was 25.8% compared to 26.7% in 2011, a statistically significant decrease on Chi-square analysis ($p<.05$). Female percentage in radiology trainees was also less than all other specialties in 2020 (25.8% vs. 45.1%, $p<.001$). Comparing the 2020 US census to our results, we found that radiology trainees have less URM in terms of race/ethnicity (31.5% vs. 9.2%, $p<.001$) and female representation (50.8% vs. 25.8%, $p<.001$).

CONCLUSION

s Though there have been significant increases in URM representation in radiology since 2011, URM trainees remain underrepresented in diagnostic radiology programs. Finally, females remain under-represented, a figure that has statistically worsened since 2011.

CLINICAL RELEVANCE/APPLICATION

To recruit the best and brightest, program directors should increase efforts to increase the diversity of radiology programs.

M5B-SPNPM-2 Demographics and Life Experiences of International Medical Graduates: Survey Results from IMG Applicants for Radiology Residency

Participants
Fernando Rivera-Melendez, Catano, PR (*Presenter*) Nothing to Disclose

PURPOSE

International Medical Graduates (IMGs) comprise approximately 25% of the US physician workforce and bring a plethora of diverse life experiences to residency programs. Our purpose was to characterize the demographic characteristics and life experiences of IMG applicants to radiology residency programs using survey data.

METHODS AND MATERIALS

Survey questions were modified from the validated AAMC Matriculating Student Questionnaire. Survey participants were derived from a virtual multi-institution Radiology Bootcamp session focused on pathways for success for IMGs interested in Radiology. The survey was emailed in advance to participants. IRB deemed that this anonymous voluntary survey met criteria for exemption.

RESULTS

84 respondents met criteria for study inclusion among 92 participants (response rate 91%). Of eligible respondents, 80% were Non-US IMGs and 20% were US IMGs. 19% were Black/African American, 41% were Asian, and 22% were Hispanic/Latinx, a statistically significantly higher proportion of URM trainees compared with US radiology residents ($p < 0.001$). 42% were women; a statistically significantly higher proportion of female trainees compared with US radiology residents ($p = 0.03$). 2% of participants reported a disability. 39% stated that English was their primary language and were fluent in an average of 2.2 languages (range 1-5). 62% of participants reported that they have used an Electronic Health Records system. Before applying to radiology residency, 37% reported practicing independently as physicians, 56% published peer-reviewed papers, 49% presented research findings at conferences/meetings, and 44% participated in leadership positions at local or national societies. Regarding practice plans, 43% plan to practice in underserved areas, 80% were interested in participating in patient care, 79% expressed interest in participating in research, and 75% expressed interested in teaching.

CONCLUSION

sIn comparison with the demographics of current radiology residents, international medical graduate applicants to radiology residency programs represent a more diverse applicant pool with an array of professional skills and life experiences.

CLINICAL RELEVANCE/APPLICATION

Radiology residency programs should consider applications from international medical graduates as a vehicle to enrich training programs with diverse trainees with rich life experiences.

M5B-SPNPM-3 Finding the Bamboo Ceiling: AAPI Faculty Composition in Academic Radiology

Participants
Dylan Sadowsky, Lakeland, FL (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study is to examine the current distribution of Asian American and Pacific Islander (AAPI) Radiology faculty in medical schools with respect to rank in relation to other demographics.

METHODS AND MATERIALS

A cross sectional study was performed using the AAMC's 2020 U.S. Medical School Faculty website via Table 19: U.S. Medical School Faculty by Sex, Race/Ethnicity, Rank, and Department, 2020.1 The total number of full-time faculty at all US medical school's radiology departments in each rank (Professor, Associate Professor, Assistant Professor, and Instructor) and the total number of Asian and Native Hawaiian or other Pacific Islander in each of these ranks in 2020 were identified and included. Chi-square analysis was performed to compare the groups at each rank.

RESULTS

4,395 Radiologists were included in the data with 997 (22.7%) reported to be of AAPI origin. Chi-square analysis of AAPI vs non-AAPI faculty at the Full Professor (12.6% vs 19%), Associate Professor (16.8% vs 20.0%), Assistant Professor (58.1% vs 52.3%), and instructor (12.5% vs 8.8%) ranks were performed demonstrating statistically significant differences in observed versus expected composition ($p<0.00001$). Of the Asian or Pacific Islanders included, 126 (12.6%), 167 (16.8%), 579 (58.1%), and 125 (12.5%) held the title of professor, associate professor, assistant professor, or instructor, respectively. As opposed to all other races who had 646 (19%), 678 (20.0%), 1776 (52.3%), and 298 (8.8%) professors, associate professors, assistant professors, or instructors, respectively. The chi squared statistic was found to be 39.65 and $p < 0.01$. Faculty rank composition when normalized (% at Rank/% AAPI) was 0.72, 0.87, 1.08, 1.30 for Full professor, Associate professor, Assistant professor and instructor levels, respectively.

CONCLUSION

s This study suggests that there are relatively fewer upper level AAPI faculty and more junior AAPI faculty within academic radiology. Nationally, organizations in multidisciplinary fields such as medicine and law have strengthened their commitment to fighting racism and racial inequity.

CLINICAL RELEVANCE/APPLICATION

Further studies and interventions to address this disparity are warranted to investigate potential racial imbalances in medicine.

Further studies and interventions to address this disparity are warranted to investigate potential racial imbalances in medicine.

M5B-SPNR-1 Occlusion Type, Number of Recanalization Passages and Dose Program Determine Radiation Dose in Endovascular Stroke Thrombectomy

Participants
Gregor Peter, (*Presenter*) Nothing to Disclose

PURPOSE

Identification of independent treatment factors associated with high radiation exposure during endovascular mechanical thrombectomy (EMT) in acute ischemic stroke.

METHODS AND MATERIALS

This retrospective analysis included all patients treated by means of EMT during the 2-year-period 2017-2018 in a comprehensive stroke center. EMT were performed by four internal and three external certified neuroradiologists in a clinic overlapping on call system. Radiation exposure as the dependent variable (dose area product DAP, Gy x cm2) was dichotomized in <100 Gy x cm2 and =100 Gy x cm2. Independent variables were age (<75 vs. =75 y), time of intervention (during vs. beyond workday), treating neuroradiologist (internal vs. external), occlusion type (mono vs. tandem), repercussion success (TICI 0 -2A vs. TICI 2B/3), recanalization attempts (=2 vs. >2) and dose protocol (normal dose in 2017 vs. low dose (LD) in 2018).

RESULTS

EMT treatments of 208 patients (111 female, 97 male, mean age 71.6 y) were analyzed. Median DAP was 86.6 Gy x cm2 and could be reduced from 104.8 Gy x cm2 (N=105 in 2017) to 73.3 Gy x cm2 (N=103 in 2018) with LD program. Multivariable binary logistic regression analysis revealed a significantly increased radiation exposure (= 100 Gy x cm2)in tandem occlusion type (P<.001), >2 recanalization attempts (P<.001) and normal dose protocol (P=.002).

CONCLUSION

s Tandem occlusion type and number of recanalization attempts are the dominant treatment factors for the amount of radiation exposure in stroke EMT. Modern dose reduction programs can significantly reduce the radiation exposure in EMT for patients and for the medical staff and should be implemented routinely.

CLINICAL RELEVANCE/APPLICATION

Future reference discussion or extensive radiation doses in specific patients should consider the aspects of this study.

M5B-SPNR-11 Optimization For the Contrast Enhancement at Head Computed Tomography Angiography by Using the Patient Body Size Indexes

Participants
Hiroyasu Sanai, RT, Kurashiki, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Head computed tomography angiography (CTA) is noninvasive, easy to acquire, and offers excellent detail in identifying site and nature of the lesion. Even if head CTA is performed with the same protocol, the contrast enhancement (CE) differs depending on the patient body size. The purpose of this study was to investigate whether body size indexes (BSI) such as the height, body weight, body mass index, body surface area, lean body weight, and blood volume that calculated by height and body weight estimated middle cerebral artery CE on head CTA scans.

METHODS AND MATERIALS

This retrospective study was approved by our institutional review board; informed patient consent was waived. Between April 2020 and October 2021, 99 patients with vascular disease underwent head CTA. The CT number (in Hounsfield units, HU) of the middle cerebral artery at proximal (M1) on unenhanced scans and arterial phase scans was recorded. We calculated changes in the contrast enhancement per iodine dose (HU / gI) (CEID) to evaluate the correlation with BSI. We performed linear regression analyses between CEID and BSI.

RESULTS

The CEID of the middle cerebral artery during arterial phase was 15.8 ± 4.1 HU / gI. CEID and BSA showed the strongest inverse

correlation (r = 0.779). Among the BSI used in our study, BSA was the most important estimated factor the CEDI of the middle cerebral artery on head CTA acquired during the arterial phase.

CONCLUSION

s The BSA exhibited the strongest correlation with middle cerebral artery contrast enhancement during the arterial phase.

CLINICAL RELEVANCE/APPLICATION

BSA tailor contrast injection methods was superior other BSI parameters during the head CTA.

M5B-SPNR-12 Precise Assessment of Penumbra in Patients with Acute Anterior Circulation Ischemic Stroke by the Multiphase MR Angiography Collateral Map

Participants
Hyun Jeong Kim, MD, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

Precise collateral and penumbra assessment can identify individual diversity of infarct progression and assist appropriate treatment decision making in patient with acute ischemic stroke. This study is to verify the ability of the multiphase MR angiography collateral map (Cmap) to estimate penumbra in patients with acute ischemic stroke due to large vessel steno-occlusion in the anterior circulation.

METHODS AND MATERIALS

The secondary analysis of an ongoing prospective observational study included data from participants with acute ischemic stroke due to occlusion or stenosis of the internal carotid artery and/or the middle cerebral artery (M1 or M2 segment) within 8 hours of onset to MR acquisition time and without change in baseline steno-occlusive lesion on follow-up angiography. We measured the volume ratios of follow-up and baseline DWI lesions (lesion growth ratio), Tmax > 6 seconds lesion and baseline DWI lesion (Tmax/DWI mismatch ratio), and, of the Cmap at admission, hypoperfused lesions on immediately preceded phase of the baseline DWI lesion phase and on baseline DWI lesion phase which has the coincided hypoperfused area with the baseline DWI lesion (Cmap mismatch ratio). We compared sensitivity, specificity, accuracy, and AUC of Cmap mismatch ratio and Tmax/DWI mismatch ratio in lesion growth and evaluated concordance correlation of Tmax/DWI mismatch ratio and Cmap mismatch ratio with lesion growth ratio.

RESULTS

From March 2016 to March 2021, among 566 participants, 48 participants (27 males, mean age 75) were included. The sensitivities of Cmap and Tmax in lesion growth were 97% and 93.9% (P=0.56), the specificities were 100% and 80.0% (P=0.08), the accuracies were 97.9% and 89.6% (P=0.10), and the AUC were 1.0 and 0.84 (P=0.04), respectively. The concordance correlation coefficients of Cmap mismatch ratio and Tmax/DWI mismatch ratio with lesion growth ratio were 0.95 (95% CI, 0.92-0.97) and 0.28 (95% CI 0.17-0.39), respectively. The difference of concordance correlation coefficients of Cmap mismatch ratio and Tmax/DWI mismatch ratio with lesion growth ratio was 0.66 (95% CI 0.34-0.96). Cmap was superior to Tmax in prediction of lesion growth and Cmap mismatch ratio was better correlated with infarct growth ratio than Tmax/DWI mismatch ratio, significantly.

CONCLUSION

s Individual-based assessment of penumbra of patients with acute ischemic stroke due to large vessel steno-occlusion in anterior circulation is possible with Cmap.

CLINICAL RELEVANCE/APPLICATION

Cmap was derived from dynamic contrast-enhanced MR angiography (DCE-MRA). Therefore, within 3 minutes of imaging time for DWI and DCE-MRA, we can estimate baseline infarct volume, causative vessel location, collateral-perfusion status, and penumbra precisely.

M5B-SPNR-13 Cortical Venous Blood Velocity Changes and Its Value in Predicting Prognosis in Acute Ischemic Stroke Patients with Large Vessel Occlusion

Participants
Jingjie Wang, (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to explore the cortical venous blood velocity changes in acute ischemic stroke patients with large vessel occlusion (LVO-AIS) and to explore its value in predicting prognosis.

METHODS AND MATERIALS

The whole-brain 4D-CTA/CTP data and clinical data of LVO-AIS were collected from June 2020 to October 2021. A group of normal 4D-CTA/CTP data was gathered as a control group. The venous inflow time (VIT), the venous peak time (VPT), and the venous outflow time (VOT) of the cerebral cortex on both sides of the patients and the healthy control group were recorded and analyzed. Statistical description and comparison among VIT/VPT/VOT of both sides of patients and the healthy control groups were performed. Then, VIT, VPT, and VOT of patients with different prognoses were then statistically described and compared between groups. Third, logistic regression analysis was used to explore the relationship between the three venous times and prognosis. Finally, ROC curves were drawn to assess the value of the altered cortical vein imaging in predicting prognosis.

RESULTS

149 LVO-AIS patients and 73 healthy controls were collected. VIT, VPT, and VOT on the patients' both sides showed a significant delay ($p < 0.05$). There were significant differences in VIT and VPT on both sides between the patients with good and poor prognoses ($p < 0.05$). Logistic regression for all the patients showed that VPT on the affected side, arterial collateral score, and NIHSS were independent predictors of poor prognosis, with a correct percentage of 79.6%, AUC of NIHSS was larger (0.786), the AUC of VPT (0.697) on the affected side were smaller. Logistic regression for patients onset within 24 hours showed that VPT on the affected side and NIHSS were independent predictors of poor prognosis, with a correct percentage of 91.5%. the AUC of the NIHSS remains larger (0.753) but declined, while the AUC of VPT (0.711) on the affected side rose.

CONCLUSION

s Cortical venous blood velocity significantly altered on both the affected and healthy side of LVO-AIS patients. The delayed ipsilateral VPT in LVO-AIS patients can be used as a new imaging indicator to predict poor prognosis.

CLINICAL RELEVANCE/APPLICATION

The slow venous flow may provide marked information about collateral circulation. The 4D-CTA imaging offers specific blood velocity information to assess the relationship between poor cortical venous visualization and clinical outcomes of LVO-AIS in the early stage. Therefore, we propose quantifying the speed of cortical vein development on the affected side of LVO-AIS using a whole-brain 4D-CTA/CTP technique and exploring the time markers and values of cortical vein development.

M5B-SPNR-14 Sex Differences in Intracranial Atherosclerotic Plaques Among Patients with Ischemic Stroke

Participants
Xuejiao Yan, (*Presenter*) Nothing to Disclose

PURPOSE

High-risk intracranial arterial plaques are the most common cause of ischemic stroke and their characteristics vary between male and female patients. However, sex differences in intracranial plaques among symptomatic patients have rarely been discussed. This study aimed to evaluate sex differences in intracranial atherosclerotic plaques among Chinese patients with cerebral ischemia.

METHODS AND MATERIALS

One hundred and ten patients who experienced ischemic events underwent 3T cardiovascular magnetic resonance vessel wall scanning for the evaluation of intracranial atherosclerotic disease. Each plaque was classified according to its likelihood of causing a stroke (as culprit, uncertain, or non-culprit). The outer wall area (OWA) and lumen area of the lesion and reference sites were measured, and the wall and plaque areas, remodeling ratio, and plaque burden (characterized by a normalized wall index) were further calculated. The composition (T1 hyperintensity, enhancement) and morphology (surface irregularity) of each plaque were analyzed. Sex differences in intracranial plaque characteristics were compared between male and female patient groups.

RESULTS

Overall, 311 plaques were detected in 110 patients with ischemic stroke (81 and 29 male and female patients, respectively). The OWA ($P < 0.001$) and wall area ($P < 0.001$) of intracranial arterial lesions were significantly larger in male patients. Regarding culprit plaques, the plaque burden in male patients was similar to that in female patients ($P = 0.178$, odds ratio [OR]: 0.168, 95% confidence interval [CI]: -0.020 to 0.107). However, the prevalence of plaque T1 hyperintensity was significantly higher than that in female patients ($P = 0.005$, OR: 15.362, 95% CI: 2.280 to 103.49). In the overall ischemic stroke sample, intracranial T1 hyperintensity was associated with male sex (OR: 13.480, 95% CI: 2.444-74.354, $P = 0.003$), systolic blood pressure (OR: 1.019, 95% CI: 1.002-1.036, $P = 0.031$), and current smoker (OR: 3.245, 95% CI: 1.097-9.598, $P = 0.033$).

CONCLUSION

s For patients with ischemic stroke, the intracranial plaque burden in male patients was similar to that in female patients; however, the plaque characteristics in male patients are associated with higher risk, especially in culprit plaques.

CLINICAL RELEVANCE/APPLICATION

Our findings highlight the sex-specific characteristics of intracranial atherosclerotic plaques. The results suggest that men with ischemic stroke, while having a similar intracranial plaque burden to women, have a higher plaque risk profile, especially for culprit plaques. multi-contrast CMR vessel wall imaging can help stroke patients of different sexes better understand their atherosclerosis risk and further optimize their clinical management.

M5B-SPNR-15 Assessing Management of Acute Ischemic Stroke Using DICOM-Timestamps

Participants
Alexander Rau, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Since the management of acute stroke is time crucial, time data are relevant for both research and quality management. In routine clinical practice, these time data are often not reliably captured and documented. We investigated the value of image-based time data as captured automatically in the DICOM format.

METHODS AND MATERIALS

We enrolled data from two independent stroke centres (n=3.151 and n=2.092). Data from the first centre was assessed whether cases with large-vessel-occlusion (LVO, n=1.095), small-vessel-occlusions (SVO, n=422) and no occlusion (n=1634) show different arrival times at the hospital. The DICOM-tag StudyTime was used to analyse the distribution of scan times throughout the day. A convolutional probabilistic model for the distribution was generated with the following assumptions: (A) probability of stroke is uniform throughout the day, (B) people go to sleep at 21:00+/-3h and wake up at 7:00+/-3h, (C) ambulance transport follows combined gaussian and exponential distribution (Fig. 1).

RESULTS

The temporal distribution at both centres was exceptionally consistent with a peak around 10:00 AM. No relevant difference was found between vascular occlusion groups (large, small, and no occlusions) regarding their arrival time at the hospital. The real-world data and the simulation using a probabilistic model showed very good agreement.

CONCLUSION

s DICOM-timestamps can be used to assess the time course of management of acute ischemic stroke. Using this data we observed a peak of scans at 10.00 AM which can be explained with a probabilistic model describing a patient waking up, realising new symptoms, calling an ambulance and being transported to hospital. Furthermore, patients with large vessel occlusion do not seem to wake up earlier due to their stroke.

CLINICAL RELEVANCE/APPLICATION

DICOM-timestamp analysis has the potential to serve as a tool for quality control, optimised resource management, and stroke research in general since they are always automatically captured by the imaging devices as opposed to manual data collection in routine clinical practice.

M5B-SPNR-16 Assessment of Intracranial Atherosclerotic Disease Using PETRA-MRA: Comparison of 3D-TOF and CTA with DSA

Participants
Junxia Niu, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Noninvasive assessment of intracranial atherosclerotic disease is important to manage ischemic stroke patients. 3D pointwise encoding time reduction magnetic resonance angiography (PETRA-MRA) is a promising non-contrast magnetic resonance angiography (MRA) technique for intracranial stenosis assessment. However, few previous studies have compared the diagnostic performance of PETRA-MRA with digital subtraction angiography (DSA) for intracranial atherosclerotic assessment relative to 3D time-of-flight (TOF), magnetic resonance angiography (MRA) and computed tomography angiography (CTA). The study's aim was to evaluate the diagnostic performance of PETRA-MRA, TOF-MRA and CTA, using DSA as a reference standard in patients with intracranial arterial stenosis.

METHODS AND MATERIALS

Thirty-eight patients with 66 intracranial arterial plaques (age 56 ± 10 years, 25males) underwent PETRA-MRA, TOF-MRA, CTA and DSA within 1 month. The image quality of MRAs and CTA were graded on a 1-4 scale (1= poor, 4 = excellent) independently by three radiologists. The degree of stenosis and lesion length were measured by two radiologists independently on all imaging modalities.

RESULTS

There was an excellent interreader agreement for the stenosis and lesion length assessment on PETRA-MRA, TOF-MRA, CTA and DSA (ICCs > 0.95). PETRA-MRA, TOF-MRA and CTA had excellent image quality (3.98 ± 0.12, 3.95 ± 0.21,3.94 ± 0.24, P=0.249). PETRA-MRA had better agreement with DSA for stenosis measurements comparing with TOF-MRA and CTA (ICC = 0.92 vs. 0.88, 0.81). PETRA-MRA had higher sensitivity and specificity for detecting stenosis >50% than TOF-MRA and CTA;TOF-MRA had higher sensitivity and specificity for detecting stenosis >75% than PETRA-MRA and CTA, using DSA as the standard. CTA overestimated the degree of stenosis compared to DSA (64.3 ±20.0 vs. 53.3 ±18.9%, p = 0.001), while PETRA-MRA and TOF-MRA didn't (54.9 ± 18.1 vs. 53.3 ±18.9%, p = 0.41; 55.9 ± 17.7 vs. 53.3 ±18.9%, p = 0.68). PETRA-MRA and TOF-MRA had better agreement with DSA for lesion length measurements compared with CTA (ICC = 0.98 ,0.97 vs. 0.74).

CONCLUSION

s PETRA-MRA is accurate for quantifying intracranial arterial stenosis compared with DSA and performs better than TOF-MRA and CTA in stenosis >50%.TOF-MRA performs better than PETRA-MRA and CTA in stenosis >70%. CTA overestimated the degree of stenosis compared to DSA. In lesion length, all 3 images perform well with DSA.

CLINICAL RELEVANCE/APPLICATION

Comparing with TOF-MRA and CTA, PETRA-MRA is less sensitive to motion effects , can improve flow dephasing to better demonstrate the artery lumina and has the acoustic noise attenuation which is beneficial to the child, the pregnant and the manic patient vulnerable to the noise.

M5B-SPNR-17 Optimal Scan Number of Whole-brain CT Perfusion in Patients with Acute Ischemic Stroke

Participants
Sentaro Takada, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Computed tomographic perfusion (CTP) imaging is useful for determining the treatment strategy of acute ischemic stroke. The optimal scanning protocol of CTP to obtain reliable lesion volumes with CTP has not been fully established. We aimed to investigate the optimal scanning protocol of CTP in patients with acute ischemic stroke.

METHODS AND MATERIALS

This study included 29 consecutive patients with acute ischemic stroke (13 men, 26 women; mean age 77.5 years) who underwent whole-brain CTP on a 320-slice multidetector CT scanner. The data acquisition parameters for dynamic volume scanning were 320 × 0.5-mm detector collimation, 1.0-s tube rotation time, 100-mA tube current, and 80-kVp tube voltage. Twenty-three sampling scans were performed at the following varied intervals: 2 passes every 3 seconds intended for the prearrival baseline, 16 passes every 1.5 seconds targeting the rise and fall of enhancement, and 5 passes at 5-second intervals to complete and extend the temporal sampling window for 70.5 seconds. The penumbra and core volumes obtained from full imaging data were compared to those obtained from 3/4 and 1/2 imaging data. RAPID was used for penumbra and core quantification; their thresholds were 6-second increase in Tmax compared to healthy side for penumbra and 30% reduction in cerebral blood flow compared to healthy side for core. Spearmon correlation coefficient and Bland-Altman analysis were used for the statistical analysis.

RESULTS

The penumbra and core volumes obtained from the full, the 3/4, and 1/2 data were 103.9 ± 69.7 ml and 13.3 ± 24.0 ml, 102.2 ± 72.0 ml and 13.7 ± 24.2 ml, and 102.3 ± 69.9 ml and 13.3 ± 24.9 ml, respectively. There was no significant difference between the three groups in penumbra and core volume (penumbra, P = 0.99 and core, P = 0.097). Spearmon correlation coefficient showed a good agreement between the penumbra and core volumes generated from full and 1/2 data (penumbra, R = 0.991 and core, R = 0.999). Bland-Altman analysis showed the mean difference (± 2SD) for 1/2 data of penumbra and ischemic core volume against full data was 1.6 ml (± 18.7) and 0.1 ml (± 2.6).

CONCLUSION

s In patients with acute ischemic stroke, whole-brain CTP images with half scan data may provide equivalent diagnostic value

compared with full scan data.

CLINICAL RELEVANCE/APPLICATION

Whole-brain CTP can reduce scan data by half and may reduce radiation exposure.

M5B-SPNR-18 Anterior Ischemic Stroke: Analysis of the Multivariable CT-Based Models for Prediction of Clinical Outcome

Participants
Aleksandr Drozdov, MD, El Paso, TX (*Presenter*) Nothing to Disclose

PURPOSE

To determine the predictive value of multiple CT- based measurements, individually and collectively, including arterial collateral filling (AC), tissue perfusion parameters, as well as cortical (CV) and medullary venous (MV) outflow, in patients with acute ischemic stroke (AIS).

METHODS AND MATERIALS

We retrospectively reviewed a database of patients with AIS in the middle cerebral artery distribution, who were evaluated by multiphase CT-angiography and perfusion. AC pial filling was evaluated using a scoring system described by Menon et al. The CV system was scored by the adopted PRECISE system as described by Parthasarathy et al. The MV status was evaluated using a method described by Drozdov et al. The perfusion parameters were calculated using the FDA-approved automated software. A good clinical outcome was defined as a Modified Rankin Scale of 0-2 at 90 days.

RESULTS

A total of 64 patients were included. Each of the CT-based measurements were able to predict clinical outcome independently ($P<0.05$). AC pial filling model did slightly better compared to other measurement models (AUC = 0.659, OR 4.11 (1.35-12.54)) vs CV (AUC=0.644, OR 3.29 (1.16 - 9.3)) vs MV (AUC=0.609 OR 6.17 (1.76 - 21.64)). Among perfusion parameters, the best prediction model was core size <30 ml vs =30 ml (AUC=0.629 OR 4.64 (1.13 - 17.7)). In multivariable modeling with two variables, AC combined with MV had the highest predictive value (AUC=0.721) followed by MV and CV (AUC=0.711). For other combinations, the AUC ranged from 0.684 to 0.698. Multivariable modeling with all 4 variables resulted in the highest predictive value AUC=0.763.

CONCLUSION

s A model using the combination of multiple CT- based measurements is highly predictive of clinical outcomes in acute ischemic stroke and does better compared to the individual measurements alone

CLINICAL RELEVANCE/APPLICATION

The combination of arterial collateral flow, tissue perfusion, and venous outflow provides a more accurate prediction of clinical outcomes in AIS and performs better than each variable on its own. This additive effect of these techniques suggests that the information collected by each of these methods is only partially overlapping.

M5B-SPNR-19 Recurrent IDH-wild-type Glioblastoma: Association of Baseline Restricted Diffusion Pattern and Tumor Enhancement Volume with Repeat Resection Free Survival

Participants
David Timaran Montenegro, MD, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

Despite advances in therapeutical options for glioblastoma, the overall prognosis remains poor with only 5.1% of patients surviving 5 years. Standard regimens include surgery and chemoradiation therapy. Repeat resection is a potential treatment option for recurrence aimed to control neurological symptoms and extend overall survival (OS). Recent studies, however, have reported that repeat resection may increase complications and may not benefit OS. Therefore, we aim to evaluate if baseline MRI may predict repeat resection free survival among patients with recurrent IDH-wild-type glioblastoma

METHODS AND MATERIALS

A single center, retrospective study of a prospectively maintained database of 161 patients with glioblastomas was performed. Fifteen (9.3%) subjects with IDH mutant glioblastomas were excluded. Overall, 146 patients, 86 men (59%) and 60 women (41%), with a median age of 61 years (interquartile range [IQR], 52-68 years) treated with surgical resection were enrolled. Baseline brain MRIs were assessed using the VASARI criteria and semiautomated tumoral segmentation. Linear regression analysis was used to assess associations between tumor volumes and time to repeat resection. Kaplan Meir curve and Long Rank test were used for survival analysis

RESULTS

In total, 37 patients (25%) required repeat resection at a median time of 6.4 months (IQR,3.9-10.9 months) due to tumor recurrence. Out of the 25 VASARI criteria, only restricted diffusion was found to affect repeat resection free survival. At 3, 6, 12 and 24 months, overall repeat resection free survival for patients with restricted diffusion was 94%, 29%, 0% and 0% versus 86%, 42%,28% and 14% for patients with mixed restricted/facilitated diffusion and 92%, 77%, 38% and 7% in patients with facilitated diffusion, respectively (Log-rank/Mantel-Cox estimate, 9.09) ($p=0.01$). In addition, regression analysis revealed that tumor enhancement volumes were associated with repeat resection free survival ($p=0.04$). Patients with tumor enhancement volumes equal or greater than 32 ml had resection free survival rates of 100%, 75%, 50% and 37% at 3, 6, 12 and 24 months, respectively, versus patients with lower tumor enhancement volumes with survival rates of 93%, 44%, 10% and 0%

CONCLUSION

s Patients with IDH-wild-type glioblastomas that had intralesional restricted diffusion and lower enhancing volumes were associated with lower repeat resection rates at 3, 6, 12 and 24 months compared to patients with tumoral facilitated diffusion and larger tumor enhancement volumes

CLINICAL RELEVANCE/APPLICATION

Our results provide information that will help to determine prognosis of patients with wild type glioblastomas.

M5B-SPNR-20 The Statin Medication Efficacy on Intracranial Atherosclerotic Plaque and Its Influencing Factors: A Magnetic Resonance Vessel Wall Imaging Study

Participants
Cong Liu, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the value of magnetic resonance vessel wall imaging (VWI) in evaluating the efficacy of statins on intracranial atherosclerotic plaque, and analyze the clinical and plaque characteristics that may be related with the treatment efficacy.

METHODS AND MATERIALS

A total of 53 patients with intracranial atherosclerotic disease and treated with statins were enrolled in this study. All patients underwent VWI scans during the baseline and follow-up period. The plaque characteristics, including plaque length, plaque thickness, plaque burden, the degree of vascular stenosis, the degree of plaque enhancement, vascular remodeling and plaque location were measured. The patient's clinical information at baseline was also collected. The patients were divided into two groups according to the tri-sectional quantiles of rate change of every plaque characteristic (good responder and poor responder). The difference of patient's clinical and plaque characteristics at baseline between the two groups was analyzed with t test, rank sum test or Chi-square test, and the relationship between patient's clinical and plaque characteristics and medication efficacy was assessed with multiple linear regression.

RESULTS

Compared with the baseline, the plaque thickness (1.30[1.05-1.50]mm vs. 1.30[1.20-1.50]mm, p=0.016), plaque burden (51.42[33.47-76.98]% vs. 61.39[38.81-83.74]%, p=0.001), vessel stenosis (30.00[18.00-54.50]% vs. 39.39[21.00-63.04]%, p=0.001) and plaque enhancement (122.3±49.7% vs. 148.8±43.1%, p<0.001) were significantly reduced in patients after treated with statins, especially in patients treated with statins for more than 6 months. The history of hypertension (B=0.188, SE=0.086, P=0.034) and baseline BMI (kg/m2, B=0.043, SE=0.013, P=0.002) were negatively correlated with the reduction of plaque enhancement, while the medication period (month, B=-0.03, SE=0.011, P=0.008) and baseline plaque enhancement (B=-0.215, SE=0.103, P=0.043) were positively correlated with the reduction of plaque enhancement.

CONCLUSION

s In this study, we confirmed with VWI that statins can stabilize intracranial atherosclerotic plaques, and the therapeutic effects of statins on intracranial atherosclerotic plaques may have relationship with some of the patient's clinical and plaque characteristics at baseline.

CLINICAL RELEVANCE/APPLICATION

Compared with conventional luminal imaging techniques, VWI can directly provide more detailed plaque morphological information and help assess the statin medication efficacy on intracranial atherosclerotic plaque.

M5B-SPNR-4 Comparison of High-Resolution Vessel Wall Magnetic Resonance Imaging with Time of Flight Angiography to Detect Luminal Stenosis in Ischemic Stroke

Participants
Joel Samuel, MBBS, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Ischemic stroke inflicts a major disease burden worldwide. Assessment of the lumen of intracranial vasculature using magnetic resonance angiography or CT angiography is the conventional method for evaluating pathology in the culprit vessel. High-resolution vessel wall magnetic resonance imaging is an emerging method which allows direct visualization of the vessel wall pathology. In addition, vessel wall imaging sequences can also be used to detect the extent of luminal stenosis.We compare the diagnostic performance of time-of-flight magnetic resonance angiography against vessel wall imaging sequences for detecting luminal stenosis in patients presenting with ischemic stroke. Vessel wall imaging was taken as the reference test. We further determine the correlation between the degree of stenosis in time-of-flight MR angiography and vessel wall imaging sequences.

METHODS AND MATERIALS

A prospective observational study conducted from 2019 - 2020, with a sample size of 150. The study group was patients with a clinical diagnosis of stroke, without hemorrhage on computed tomography, within the age of 18 - 70. Time of flight magnetic resonance angiography and vessel wall images were obtained using a 1.5T MRI system. The images were analyzed by a single observer. The presence of stenosis in the vascular territory of the infarcted region was determined, and the most stenotic lesion was taken as the culprit plaque. The percentage of stenosis was calculated by WASID criteria.

RESULTS

Time of flight magnetic resonance angiography had acceptable performance (AUC 0.896, sensitivity 85.9% and specificity 93.3%) but poor negative predictive value (42.1%) for detection of stenosis with vessel wall imaging as the reference standard. Spearman rank order correlation between degree of stenosis on vessel wall imaging and time-of-flight angiography showed statistically significant but moderate correlation (r = 0.715).

CONCLUSION

s Vessel wall imaging has superior diagnostic power to detect and quantify luminal stenosis compared to time-of-flight magnetic resonance angiography. Vessel wall imaging has a unique ability to detect non stenotic vulnerable plaques.

CLINICAL RELEVANCE/APPLICATION

The conventional time-of-flight angiography sequence in MR stroke protocols can be replaced by a vessel wall imaging sequence, yielding greater diagnostic information without significant increase in acquisition times.

M5B-SPNR-5 The Clinical Significance of the Hyperintense Acute Reperfusion Marker Sign in Subacute Stroke

Participants
Ji Young Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The hyperintense acute reperfusion marker (HARM) is characterized by the delayed enhancement of the subarachnoid or subpial space observed on postcontrast fluid-attenuated inversion recovery (FLAIR) images, and is considered a cerebral reperfusion marker for various brain disorders, including infarction. In this study, we evaluated the cerebral distribution patterns of HARM for discriminating between an enhancing subacute infarction and an enhancing mass located in the cortex and subcortical white matter.

METHODS AND MATERIALS

We analyzed consecutive patients who experienced a subacute ischemic stroke, were hospitalized, and underwent conventional brain magnetic resonance imaging including postcontrast FLAIR within 14 days from symptom onset, as well as those who had lesions corresponding to a clinical sign detected by diffusion-weighted imaging and postcontrast T1-weighted imaging between May 2019 and May 2021. A total of 199 patients were included in the study. Of them, 94 were finally included in the subacute infarction group. During the same period, 76 enhancing masses located in the cortex or subcortical white matter, which were subcategorized as metastasis, malignant glioma, and lymphoma, were analyzed. We analyzed the overall incidence of HARM in subacute ischemic stroke cases, and compared the enhancement patterns between cortical infarctions and cortical masses.

RESULTS

Among 94 patients with subacute stroke, 78 patients (83%) presented HARM, and among 76 patients with subcortical masses, 48 patients (63%) presented peripheral rim enhancement. Of 170 subcortical enhancing lesions, 88 (51.8%) showed HARM, and 78 (88.6%) were determined to be subacute infarction. Among 94 patients with subacute stroke, 48 patients (51%) had diffusion restrictions, and HARM was found in 39 patients (81.2%). Of the 46 patients (49%) without diffusion restriction, 39 patients (84.8%) showed HARM.

CONCLUSION

s The presence of HARM was significantly associated with subacute infarctions. For the masses, a peripheral rim enhancement pattern was observed around the mass rather than the cerebral sulci on postcontrast FLAIR.

CLINICAL RELEVANCE/APPLICATION

We found that HARM with enhancing subcortical nodules was highly suggestive of subacute infarctions, and recommended a postcontrast FLAIR sequence for differentiating the ischemic subcortical infarctions from malignant lesions such as small metastasis.

M5B-SPNR-7 Towards Personalized Radiotherapy: Tumor Growth Modeling May Supplement Traditional Radiotherapy Planning in Glioblastoma

Participants
Marie-Christin Metz, MD, (*Presenter*) Nothing to Disclose

PURPOSE

One of the main challenges in the treatment of glioblastoma is the prediction of their individual growth behavior to guide more accurate radiotherapy after resection. Here, we introduce a new, deep learning - based tumor growth model which partially exceeds standard radiotherapy plans in covering the recurrence area.

METHODS AND MATERIALS

Our recently developed tumor growth model is based on a novel deep learning solver of the inverse problem in a Fisher-Kolmogorov growth model. We applied it to 30 cases of our prospective glioma cohort by utilizing FLAIR-, T2-, T1-, and T1-CE-data and compared volume and recurrence coverage with standard radiotherapy plans that were registered to the recurrence image. Statistical analysis was performed by applying Wilcoxon Signed Rank Test.

RESULTS

Depending on the chosen cut-off value of the predicted tumor cell density we saw a comparable target volume ($p = 0.769$) with slight improvement of the covered recurrence area (mean improvement was 0.8% for a cut-off value of 50% for predicted tumor cell density with no significant difference due to the small sample size, $p = 0.797$). The growth maps especially performed better in tumors with a highly diffuse growth pattern which exceed the traditional radiotherapy margins but are well captured in the estimated tumor spread from the growth model.

CONCLUSION

s Here, we showed that utilizing a novel, deep learning - based tumor growth model for glioblastoma performed at least equally well to traditional radiotherapy plans in terms of recurrence coverage in our cohort, showing promise to improve in particular the planning of radiotherapy for highly infiltrative tumors. In a next step, we aim to correlate the calculated values with biological markers of proliferation and infiltration and validate our assumptions on larger data sets.

CLINICAL RELEVANCE/APPLICATION

Deep learning- based tumor growth modeling in glioblastoma carries potential to inform more personalized radiotherapy plans by predicting individual tumor spread. This may improve patient outcome in the future.

M5B-SPNR-9 Evaluation of A Deep Learning Model For The Detection Of Ischemic Acute Stroke Lesions And Assessment Of ASPECTS On Non-contrast CT Scans: A Multicenter Study

Participants
Weidao Chen, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Early detection of ischemia and assessing Alberta Stroke Project Early CT Score (ASPECTS) on non-contrast computed tomography

Early detection of ischemia and assessing Alberta Stroke Project Early CT Score (ASPECTS) on non-contrast computed tomography (NCCT) plays a crucial role in the treatment of acute ischemic stroke (AIS). We aim to develop a robust deep learning (DL) model for automated detection of AIS lesions and assessment of ASPECTS based on NCCT images

METHODS AND MATERIALS

From January 2013 to December 2017, NCCT images of 1391 AIS patients (<6h from symptom onset to CT) from 5 hospitals were retrospectively collected and divided in to the training dataset (n=1179) and internal validation dataset (n=212). Another 85 AIS patients from other three stroke centers were used as external validation dataset. All patients underwent follow-up diffusion-weighted (DW) MRI (within 24h after AIS), and the infarction regions on NCCT were manually contoured on DW MRI scans. A DL model was proposed for assessing ASPECTS, and model performance was evaluated with receiver operating characteristic (ROC) curve. The diagnostic performance of DL model was also compared with that of four experienced radiologists in the external validation dataset

RESULTS

In total 4240 (212 patients × 20 regions) and 1700 (85 patients × 20 regions) ASPECT regions in the internal and external validation datasets were scored. The AUC of the DL model was 0.876 (95% CI, 0.846-0.907) in the internal validation dataset. The DL model exhibited good performance in the external dataset with AUC achieving 0.729 (95% CI, 0.679-0.779), and the performance was non-inferior to that of four experienced radiologists (all p values > 0.05). The diagnostic accuracy of four radiologists was improved after DL model assistance with average sensitivity and specificity increased from 25.4% and 89.6%, to 33.3% and 91.5%, while the average diagnostic time per-case was reduced from 219.0 sec to 175.7 sec ($p < 0.01$), respectively

CONCLUSION

s The NCCT-based DL model shows favorable performance and good robustness in multi-center validation datasets and can assist radiologists to achieve better performance for the early diagnosis of AIS

CLINICAL RELEVANCE/APPLICATION

This multicenter study demonstrated the deep learning model for detection of infarction and assessment of ASPECTS score on non-contrast CT had good feasibility and reliability for AIS patients

Occlusion Type, Number of Recanalization Passages and Dose Program Determine Radiation Dose in Endovascular Stroke Thrombectomy

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Gregor Peter, (*Presenter*) Nothing to Disclose

PURPOSE

Identification of independent treatment factors associated with high radiation exposure during endovascular mechanical thrombectomy (EMT) in acute ischemic stroke.

METHODS AND MATERIALS

This retrospective analysis included all patients treated by means of EMT during the 2-year-period 2017-2018 in a comprehensive stroke center. EMT were performed by four internal and three external certified neuroradiologists in a clinic overlapping on call system. Radiation exposure as the dependent variable (dose area product DAP, Gy x cm2) was dichotomized in <100 Gy x cm2 and =100 Gy x cm2. Independent variables were age (<75 vs. =75 y), time of intervention (during vs. beyond workday), treating neuroradiologist (internal vs. external), occlusion type (mono vs. tandem), repercussion success (TICI 0 -2A vs. TICI 2B/3), recanalization attempts (=2 vs. >2) and dose protocol (normal dose in 2017 vs. low dose (LD) in 2018).

RESULTS

EMT treatments of 208 patients (111 female, 97 male, mean age 71.6 y) were analyzed. Median DAP was 86.6 Gy x cm2 and could be reduced from 104.8 Gy x cm2 (N=105 in 2017) to 73.3 Gy x cm2 (N=103 in 2018) with LD program. Multivariable binary logistic regression analysis revealed a significantly increased radiation exposure (= 100 Gy x cm2)in tandem occlusion type (P<.001), >2 recanalization attempts (P<.001) and normal dose protocol (P=.002).

CONCLUSION

s Tandem occlusion type and number of recanalization attempts are the dominant treatment factors for the amount of radiation exposure in stroke EMT. Modern dose reduction programs can significantly reduce the radiation exposure in EMT for patients and for the medical staff and should be implemented routinely.

CLINICAL RELEVANCE/APPLICATION

Future reference discussion or extensive radiation doses in specific patients should consider the aspects of this study.

Optimization For the Contrast Enhancement at Head Computed Tomography Angiography by Using the Patient Body Size Indexes

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Hiroyasu Sanai, RT, Kurashiki, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Head computed tomography angiography (CTA) is noninvasive, easy to acquire, and offers excellent detail in identifying site and nature of the lesion. Even if head CTA is performed with the same protocol, the contrast enhancement (CE) differs depending on the patient body size. The purpose of this study was to investigate whether body size indexes (BSI) such as the height, body weight, body mass index, body surface area, lean body weight, and blood volume that calculated by height and body weight estimated middle cerebral artery CE on head CTA scans.

METHODS AND MATERIALS

This retrospective study was approved by our institutional review board; informed patient consent was waived. Between April 2020 and October 2021, 99 patients with vascular disease underwent head CTA. The CT number (in Hounsfield units, HU) of the middle cerebral artery at proximal (M1) on unenhanced scans and arterial phase scans was recorded. We calculated changes in the contrast enhancement per iodine dose (HU / gI) (CEID) to evaluate the correlation with BSI. We performed linear regression analyses between CEID and BSI.

RESULTS

The CEID of the middle cerebral artery during arterial phase was 15.8 ± 4.1 HU / gI. CEID and BSA showed the strongest inverse correlation (r = 0.779). Among the BSI used in our study, BSA was the most important estimated factor the CEDI of the middle cerebral artery on head CTA acquired during the arterial phase.

CONCLUSION

s The BSA exhibited the strongest correlation with middle cerebral artery contrast enhancement during the arterial phase.

CLINICAL RELEVANCE/APPLICATION

BSA tailor contrast injection methods was superior other BSI parameters during the head CTA.

Precise Assessment of Penumbra in Patients with Acute Anterior Circulation Ischemic Stroke by the Multiphase MR Angiography Collateral Map

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Hyun Jeong Kim, MD, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

Precise collateral and penumbra assessment can identify individual diversity of infarct progression and assist appropriate treatment decision making in patient with acute ischemic stroke. This study is to verify the ability of the multiphase MR angiography collateral map (Cmap) to estimate penumbra in patients with acute ischemic stroke due to large vessel steno-occlusion in the anterior circulation.

METHODS AND MATERIALS

The secondary analysis of an ongoing prospective observational study included data from participants with acute ischemic stroke due to occlusion or stenosis of the internal carotid artery and/or the middle cerebral artery (M1 or M2 segment) within 8 hours of onset to MR acquisition time and without change in baseline steno-occlusive lesion on follow-up angiography. We measured the volume ratios of follow-up and baseline DWI lesions (lesion growth ratio), Tmax > 6 seconds lesion and baseline DWI lesion (Tmax/DWI mismatch ratio), and, of the Cmap at admission, hypoperfused lesions on immediately preceded phase of the baseline DWI lesion phase and on baseline DWI lesion phase which has the coincided hypoperfused area with the baseline DWI lesion (Cmap mismatch ratio). We compared sensitivity, specificity, accuracy, and AUC of Cmap mismatch ratio and Tmax/DWI mismatch ratio in lesion growth and evaluated concordance correlation of Tmax/DWI mismatch ratio and Cmap mismatch ratio with lesion growth ratio.

RESULTS

From March 2016 to March 2021, among 566 participants, 48 participants (27 males, mean age 75) were included. The sensitivities of Cmap and Tmax in lesion growth were 97% and 93.9% (P=0.56), the specificities were 100% and 80.0% (P=0.08), the accuracies were 97.9% and 89.6% (P=0.10), and the AUC were 1.0 and 0.84 (P=0.04), respectively. The concordance correlation coefficients of Cmap mismatch ratio and Tmax/DWI mismatch ratio with lesion growth ratio were 0.95 (95% CI, 0.92-0.97) and 0.28 (95% CI 0.17-0.39), respectively. The difference of concordance correlation coefficients of Cmap mismatch ratio and Tmax/DWI mismatch ratio with lesion growth ratio was 0.66 (95% CI 0.34-0.96). Cmap was superior to Tmax in prediction of lesion growth and Cmap mismatch ratio was better correlated with infarct growth ratio than Tmax/DWI mismatch ratio, significantly.

CONCLUSION

s Individual-based assessment of penumbra of patients with acute ischemic stroke due to large vessel steno-occlusion in anterior circulation is possible with Cmap.

CLINICAL RELEVANCE/APPLICATION

Cmap was derived from dynamic contrast-enhanced MR angiography (DCE-MRA). Therefore, within 3 minutes of imaging time for DWI and DCE-MRA, we can estimate baseline infarct volume, causative vessel location, collateral-perfusion status, and penumbra precisely.

M5B-SPNR-13

Cortical Venous Blood Velocity Changes and Its Value in Predicting Prognosis in Acute Ischemic Stroke Patients with Large Vessel Occlusion

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Jingjie Wang, (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to explore the cortical venous blood velocity changes in acute ischemic stroke patients with large vessel occlusion (LVO-AIS) and to explore its value in predicting prognosis.

METHODS AND MATERIALS

The whole-brain 4D-CTA/CTP data and clinical data of LVO-AIS were collected from June 2020 to October 2021. A group of normal 4D-CTA/CTP data was gathered as a control group. The venous inflow time (VIT), the venous peak time (VPT), and the venous outflow time (VOT) of the cerebral cortex on both sides of the patients and the healthy control group were recorded and analyzed. Statistical description and comparison among VIT/VPT/VOT of both sides of patients and the healthy control groups were performed. Then, VIT, VPT, and VOT of patients with different prognoses were then statistically described and compared between groups. Third, logistic regression analysis was used to explore the relationship between the three venous times and prognosis. Finally, ROC curves were drawn to assess the value of the altered cortical vein imaging in predicting prognosis.

RESULTS

149 LVO-AIS patients and 73 healthy controls were collected. VIT, VPT, and VOT on the patients' both sides showed a significant delay ($p < 0.05$). There were significant differences in VIT and VPT on both sides between the patients with good and poor prognoses ($p < 0.05$). Logistic regression for all the patients showed that VPT on the affected side, arterial collateral score, and NIHSS were independent predictors of poor prognosis, with a correct percentage of 79.6%, AUC of NIHSS was larger (0.786), the AUC of VPT (0.697) on the affected side were smaller. Logistic regression for patients onset within 24 hours showed that VPT on the affected side and NIHSS were independent predictors of poor prognosis, with a correct percentage of 91.5%. the AUC of the NIHSS remains larger (0.753) but declined, while the AUC of VPT (0.711) on the affected side rose.

CONCLUSION

s Cortical venous blood velocity significantly altered on both the affected and healthy side of LVO-AIS patients. The delayed ipsilateral VPT in LVO-AIS patients can be used as a new imaging indicator to predict poor prognosis.

CLINICAL RELEVANCE/APPLICATION

The slow venous flow may provide marked information about collateral circulation. The 4D-CTA imaging offers specific blood velocity information to assess the relationship between poor cortical venous visualization and clinical outcomes of LVO-AIS in the early stage. Therefore, we propose quantifying the speed of cortical vein development on the affected side of LVO-AIS using a whole-brain 4D-CTA/CTP technique and exploring the time markers and values of cortical vein development.

Sex Differences in Intracranial Atherosclerotic Plaques Among Patients with Ischemic Stroke

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Xuejiao Yan, (*Presenter*) Nothing to Disclose

PURPOSE

High-risk intracranial arterial plaques are the most common cause of ischemic stroke and their characteristics vary between male and female patients. However, sex differences in intracranial plaques among symptomatic patients have rarely been discussed. This study aimed to evaluate sex differences in intracranial atherosclerotic plaques among Chinese patients with cerebral ischemia.

METHODS AND MATERIALS

One hundred and ten patients who experienced ischemic events underwent 3T cardiovascular magnetic resonance vessel wall scanning for the evaluation of intracranial atherosclerotic disease. Each plaque was classified according to its likelihood of causing a stroke (as culprit, uncertain, or non-culprit). The outer wall area (OWA) and lumen area of the lesion and reference sites were measured, and the wall and plaque areas, remodeling ratio, and plaque burden (characterized by a normalized wall index) were further calculated. The composition (T1 hyperintensity, enhancement) and morphology (surface irregularity) of each plaque were analyzed. Sex differences in intracranial plaque characteristics were compared between male and female patient groups.

RESULTS

Overall, 311 plaques were detected in 110 patients with ischemic stroke (81 and 29 male and female patients, respectively). The OWA ($P < 0.001$) and wall area ($P < 0.001$) of intracranial arterial lesions were significantly larger in male patients. Regarding culprit plaques, the plaque burden in male patients was similar to that in female patients ($P = 0.178$, odds ratio [OR]: 0.168, 95% confidence interval [CI]: -0.020 to 0.107). However, the prevalence of plaque T1 hyperintensity was significantly higher than that in female patients ($P = 0.005$, OR: 15.362, 95% CI: 2.280 to 103.49). In the overall ischemic stroke sample, intracranial T1 hyperintensity was associated with male sex (OR: 13.480, 95% CI: 2.444-74.354, $P = 0.003$), systolic blood pressure (OR: 1.019, 95% CI: 1.002-1.036, $P = 0.031$), and current smoker (OR: 3.245, 95% CI: 1.097-9.598, $P = 0.033$).

CONCLUSION

s For patients with ischemic stroke, the intracranial plaque burden in male patients was similar to that in female patients; however, the plaque characteristics in male patients are associated with higher risk, especially in culprit plaques.

CLINICAL RELEVANCE/APPLICATION

Our findings highlight the sex-specific characteristics of intracranial atherosclerotic plaques. The results suggest that men with ischemic stroke, while having a similar intracranial plaque burden to women, have a higher plaque risk profile, especially for culprit plaques. multi-contrast CMR vessel wall imaging can help stroke patients of different sexes better understand their atherosclerosis risk and further optimize their clinical management.

M5B-SPNR-15

Assessing Management of Acute Ischemic Stroke Using DICOM-Timestamps

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Alexander Rau, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Since the management of acute stroke is time crucial, time data are relevant for both research and quality management. In routine clinical practice, these time data are often not reliably captured and documented. We investigated the value of image-based time data as captured automatically in the DICOM format.

METHODS AND MATERIALS

We enrolled data from two independent stroke centres (n=3.151 and n=2.092). Data from the first centre was assessed whether cases with large-vessel-occlusion (LVO, n=1.095), small-vessel-occlusions (SVO, n=422) and no occlusion (n=1634) show different arrival times at the hospital. The DICOM-tag StudyTime was used to analyse the distribution of scan times throughout the day. A convolutional probabilistic model for the distribution was generated with the following assumptions: (A) probability of stroke is uniform throughout the day, (B) people go to sleep at 21:00+/-3h and wake up at 7:00+/-3h, (C) ambulance transport follows combined gaussian and exponential distribution (Fig. 1).

RESULTS

The temporal distribution at both centres was exceptionally consistent with a peak around 10:00 AM. No relevant difference was found between vascular occlusion groups (large, small, and no occlusions) regarding their arrival time at the hospital. The real-world data and the simulation using a probabilistic model showed very good agreement.

CONCLUSION

s DICOM-timestamps can be used to assess the time course of management of acute ischemic stroke. Using this data we observed a peak of scans at 10.00 AM which can be explained with a probabilistic model describing a patient waking up, realising new symptoms, calling an ambulance and being transported to hospital. Furthermore, patients with large vessel occlusion do not seem to wake up earlier due to their stroke.

CLINICAL RELEVANCE/APPLICATION

DICOM-timestamp analysis has the potential to serve as a tool for quality control, optimised resource management, and stroke research in general since they are always automatically captured by the imaging devices as opposed to manual data collection in routine clinical practice.

M5B-SPNR-16

Assessment of Intracranial Atherosclerotic Disease Using PETRA-MRA: Comparison of 3D-TOF and CTA with DSA

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Junxia Niu, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Noninvasive assessment of intracranial atherosclerotic disease is important to manage ischemic stroke patients. 3D pointwise encoding time reduction magnetic resonance angiography (PETRA-MRA) is a promising non-contrast magnetic resonance angiography (MRA) technique for intracranial stenosis assessment. However, few previous studies have compared the diagnostic performance of PETRA-MRA with digital subtraction angiography (DSA) for intracranial atherosclerotic assessment relative to 3D time-of-flight (TOF), magnetic resonance angiography (MRA) and computed tomography angiography (CTA). The study's aim was to evaluate the diagnostic performance of PETRA-MRA, TOF-MRA and CTA, using DSA as a reference standard in patients with intracranial arterial stenosis.

METHODS AND MATERIALS

Thirty-eight patients with 66 intracranial arterial plaques (age 56 ± 10 years, 25males) underwent PETRA-MRA, TOF-MRA, CTA and DSA within 1 month. The image quality of MRAs and CTA were graded on a 1-4 scale (1= poor, 4 = excellent) independently by three radiologists. The degree of stenosis and lesion length were measured by two radiologists independently on all imaging modalities.

RESULTS

There was an excellent interreader agreement for the stenosis and lesion length assessment on PETRA-MRA, TOF-MRA, CTA and DSA (ICCs > 0.95). PETRA-MRA, TOF-MRA and CTA had excellent image quality (3.98 ± 0.12, 3.95 ± 0.21,3.94 ± 0.24, P=0.249). PETRA-MRA had better agreement with DSA for stenosis measurements comparing with TOF-MRA and CTA (ICC = 0.92 vs. 0.88, 0.81). PETRA-MRA had higher sensitivity and specificity for detecting stenosis >50% than TOF-MRA and CTA;TOF-MRA had higher sensitivity and specificity for detecting stenosis >75% than PETRA-MRA and CTA, using DSA as the standard. CTA overestimated the degree of stenosis compared to DSA (64.3 ±20.0 vs. 53.3 ±18.9%, p = 0.001), while PETRA-MRA and TOF-MRA didn't (54.9 ± 18.1 vs. 53.3 ±18.9%, p = 0.41; 55.9 ± 17.7 vs. 53.3 ±18.9%, p = 0.68). PETRA-MRA and TOF-MRA had better agreement with DSA for lesion length measurements compared with CTA (ICC = 0.98 ,0.97 vs. 0.74).

CONCLUSION

s PETRA-MRA is accurate for quantifying intracranial arterial stenosis compared with DSA and performs better than TOF-MRA and CTA in stenosis >50%.TOF-MRA performs better than PETRA-MRA and CTA in stenosis >70%. CTA overestimated the degree of stenosis compared to DSA. In lesion length, all 3 images perform well with DSA.

CLINICAL RELEVANCE/APPLICATION

Comparing with TOF-MRA and CTA, PETRA-MRA is less sensitive to motion effects , can improve flow dephasing to better demonstrate the artery lumina and has the acoustic noise attenuation which is beneficial to the child, the pregnant and the manic patient vulnerable to the noise.

M5B-SPNR-17

Optimal Scan Number of Whole-brain CT Perfusion in Patients with Acute Ischemic Stroke

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Sentaro Takada, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Computed tomographic perfusion (CTP) imaging is useful for determining the treatment strategy of acute ischemic stroke. The optimal scanning protocol of CTP to obtain reliable lesion volumes with CTP has not been fully established. We aimed to investigate the optimal scanning protocol of CTP in patients with acute ischemic stroke.

METHODS AND MATERIALS

This study included 29 consecutive patients with acute ischemic stroke (13 men, 26 women; mean age 77.5 years) who underwent whole-brain CTP on a 320-slice multidetector CT scanner. The data acquisition parameters for dynamic volume scanning were 320 × 0.5-mm detector collimation, 1.0-s tube rotation time, 100-mA tube current, and 80-kVp tube voltage. Twenty-three sampling scans were performed at the following varied intervals: 2 passes every 3 seconds intended for the prearrival baseline, 16 passes every 1.5 seconds targeting the rise and fall of enhancement, and 5 passes at 5-second intervals to complete and extend the temporal sampling window for 70.5 seconds. The penumbra and core volumes obtained from full imaging data were compared to those obtained from 3/4 and 1/2 imaging data. RAPID was used for penumbra and core quantification; their thresholds were 6-second increase in Tmax compared to healthy side for penumbra and 30% reduction in cerebral blood flow compared to healthy side for core. Spearmon correlation coefficient and Bland-Altman analysis were used for the statistical analysis.

RESULTS

The penumbra and core volumes obtained from the full, the 3/4, and 1/2 data were 103.9 ± 69.7 ml and 13.3 ± 24.0 ml, 102.2 ± 72.0 ml and 13.7 ± 24.2 ml, and 102.3 ± 69.9 ml and 13.3 ± 24.9 ml, respectively. There was no significant difference between the three groups in penumbra and core volume (penumbra, P = 0.99 and core, P = 0.097). Spearmon correlation coefficient showed a good agreement between the penumbra and core volumes generated from full and 1/2 data (penumbra, R = 0.991 and core, R = 0.999). Bland-Altman analysis showed the mean difference (± 2SD) for 1/2 data of penumbra and ischemic core volume against full data was 1.6 ml (± 18.7) and 0.1 ml (± 2.6).

CONCLUSION

s In patients with acute ischemic stroke, whole-brain CTP images with half scan data may provide equivalent diagnostic value compared with full scan data.

CLINICAL RELEVANCE/APPLICATION

Whole-brain CTP can reduce scan data by half and may reduce radiation exposure.

Anterior Ischemic Stroke: Analysis of the Multivariable CT-Based Models for Prediction of Clinical Outcome

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Aleksandr Drozdov, MD, El Paso, TX (*Presenter*) Nothing to Disclose

PURPOSE

To determine the predictive value of multiple CT- based measurements, individually and collectively, including arterial collateral filling (AC), tissue perfusion parameters, as well as cortical (CV) and medullary venous (MV) outflow, in patients with acute ischemic stroke (AIS).

METHODS AND MATERIALS

We retrospectively reviewed a database of patients with AIS in the middle cerebral artery distribution, who were evaluated by multiphase CT-angiography and perfusion. AC pial filling was evaluated using a scoring system described by Menon et al. The CV system was scored by the adopted PRECISE system as described by Parthasarathy et al. The MV status was evaluated using a method described by Drozdov et al. The perfusion parameters were calculated using the FDA-approved automated software. A good clinical outcome was defined as a Modified Rankin Scale of 0-2 at 90 days.

RESULTS

A total of 64 patients were included. Each of the CT-based measurements were able to predict clinical outcome independently (P<0.05). AC pial filling model did slightly better compared to other measurement models (AUC = 0.659, OR 4.11 (1.35-12.54)) vs CV (AUC=0.644, OR 3.29 (1.16 - 9.3)) vs MV (AUC=0.609 OR 6.17 (1.76 - 21.64)). Among perfusion parameters, the best prediction model was core size <30 ml vs =30 ml (AUC=0.629 OR 4.64 (1.13 - 17.7)). In multivariable modeling with two variables, AC combined with MV had the highest predictive value (AUC=0.721) followed by MV and CV (AUC=0.711). For other combinations, the AUC ranged from 0.684 to 0.698. Multivariable modeling with all 4 variables resulted in the highest predictive value AUC=0.763.

CONCLUSION

s A model using the combination of multiple CT- based measurements is highly predictive of clinical outcomes in acute ischemic stroke and does better compared to the individual measurements alone

CLINICAL RELEVANCE/APPLICATION

The combination of arterial collateral flow, tissue perfusion, and venous outflow provides a more accurate prediction of clinical outcomes in AIS and performs better than each variable on its own. This additive effect of these techniques suggests that the information collected by each of these methods is only partially overlapping.

Recurrent IDH-wild-type Glioblastoma: Association of Baseline Restricted Diffusion Pattern and Tumor Enhancement Volume with Repeat Resection Free Survival

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
David Timaran Montenegro, MD, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

Despite advances in therapeutical options for glioblastoma, the overall prognosis remains poor with only 5.1% of patients surviving 5 years. Standard regimens include surgery and chemoradiation therapy. Repeat resection is a potential treatment option for recurrence aimed to control neurological symptoms and extend overall survival (OS). Recent studies, however, have reported that repeat resection may increase complications and may not benefit OS. Therefore, we aim to evaluate if baseline MRI may predict repeat resection free survival among patients with recurrent IDH-wild-type glioblastoma

METHODS AND MATERIALS

A single center, retrospective study of a prospectively maintained database of 161 patients with glioblastomas was performed. Fifteen (9.3%) subjects with IDH mutant glioblastomas were excluded. Overall, 146 patients, 86 men (59%) and 60 women (41%), with a median age of 61 years (interquartile range [IQR], 52-68 years) treated with surgical resection were enrolled. Baseline brain MRIs were assessed using the VASARI criteria and semiautomated tumoral segmentation. Linear regression analysis was used to assess associations between tumor volumes and time to repeat resection. Kaplan Meir curve and Long Rank test were used for survival analysis

RESULTS

In total, 37 patients (25%) required repeat resection at a median time of 6.4 months (IQR,3.9-10.9 months) due to tumor recurrence. Out of the 25 VASARI criteria, only restricted diffusion was found to affect repeat resection free survival. At 3, 6, 12 and 24 months, overall repeat resection free survival for patients with restricted diffusion was 94%, 29%, 0% and 0% versus 86%, 42%,28% and 14% for patients with mixed restricted/facilitated diffusion and 92%, 77%, 38% and 7% in patients with facilitated diffusion, respectively (Log-rank/Mantel-Cox estimate, 9.09) (p=0.01). In addition, regression analysis revealed that tumor enhancement volumes were associated with repeat resection free survival (p=0.04). Patients with tumor enhancement volumes equal or greater than 32 ml had resection free survival rates of 100%, 75%, 50% and 37% at 3, 6, 12 and 24 months, respectively, versus patients with lower tumor enhancement volumes with survival rates of 93%, 44%, 10% and 0%

CONCLUSION

s Patients with IDH-wild-type glioblastomas that had intralesional restricted diffusion and lower enhancing volumes were associated with lower repeat resection rates at 3, 6, 12 and 24 months compared to patients with tumoral facilitated diffusion and larger tumor enhancement volumes

CLINICAL RELEVANCE/APPLICATION

Our results provide information that will help to determine prognosis of patients with wild type glioblastomas.

M5B-SPNR-20

The Statin Medication Efficacy on Intracranial Atherosclerotic Plaque and Its Influencing Factors: A Magnetic Resonance Vessel Wall Imaging Study

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Cong Liu, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the value of magnetic resonance vessel wall imaging (VWI) in evaluating the efficacy of statins on intracranial atherosclerotic plaque, and analyze the clinical and plaque characteristics that may be related with the treatment efficacy.

METHODS AND MATERIALS

A total of 53 patients with intracranial atherosclerotic disease and treated with statins were enrolled in this study. All patients underwent VWI scans during the baseline and follow-up period. The plaque characteristics, including plaque length, plaque thickness, plaque burden, the degree of vascular stenosis, the degree of plaque enhancement, vascular remodeling and plaque location were measured. The patient's clinical information at baseline was also collected. The patients were divided into two groups according to the tri-sectional quantiles of rate change of every plaque characteristic (good responder and poor responder). The difference of patient's clinical and plaque characteristics at baseline between the two groups was analyzed with t test, rank sum test or Chi-square test, and the relationship between patient's clinical and plaque characteristics and medication efficacy was assessed with multiple linear regression.

RESULTS

Compared with the baseline, the plaque thickness (1.30[1.05-1.50]mm vs. 1.30[1.20-1.50]mm, p=0.016), plaque burden (51.42[33.47-76.98]% vs. 61.39[38.81-83.74]%, p=0.001), vessel stenosis (30.00[18.00-54.50]% vs. 39.39[21.00-63.04]%, p=0.001) and plaque enhancement (122.3±49.7% vs. 148.8±43.1%, p<0.001) were significantly reduced in patients after treated with statins, especially in patients treated with statins for more than 6 months. The history of hypertension (B=0.188, SE=0.086, P=0.034) and baseline BMI (kg/m2, B=0.043, SE=0.013, P=0.002) were negatively correlated with the reduction of plaque enhancement, while the medication period (month, B=-0.03, SE=0.011, P=0.008) and baseline plaque enhancement (B=-0.215, SE=0.103, P=0.043) were positively correlated with the reduction of plaque enhancement.

CONCLUSION

s In this study, we confirmed with VWI that statins can stabilize intracranial atherosclerotic plaques, and the therapeutic effects of statins on intracranial atherosclerotic plaques may have relationship with some of the patient's clinical and plaque characteristics at baseline.

CLINICAL RELEVANCE/APPLICATION

Compared with conventional luminal imaging techniques, VWI can directly provide more detailed plaque morphological information and help assess the statin medication efficacy on intracranial atherosclerotic plaque.

M5B-SPNR-4

Comparison of High-Resolution Vessel Wall Magnetic Resonance Imaging with Time of Flight Angiography to Detect Luminal Stenosis in Ischemic Stroke

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Joel Samuel, MBBS, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Ischemic stroke inflicts a major disease burden worldwide. Assessment of the lumen of intracranial vasculature using magnetic resonance angiography or CT angiography is the conventional method for evaluating pathology in the culprit vessel. High-resolution vessel wall magnetic resonance imaging is an emerging method which allows direct visualization of the vessel wall pathology. In addition, vessel wall imaging sequences can also be used to detect the extent of luminal stenosis.We compare the diagnostic performance of time-of-flight magnetic resonance angiography against vessel wall imaging sequences for detecting luminal stenosis in patients presenting with ischemic stroke. Vessel wall imaging was taken as the reference test. We further determine the correlation between the degree of stenosis in time-of-flight MR angiography and vessel wall imaging sequences.

METHODS AND MATERIALS

A prospective observational study conducted from 2019 - 2020, with a sample size of 150. The study group was patients with a clinical diagnosis of stroke, without hemorrhage on computed tomography, within the age of 18 - 70. Time of flight magnetic resonance angiography and vessel wall images were obtained using a 1.5T MRI system. The images were analyzed by a single observer. The presence of stenosis in the vascular territory of the infarcted region was determined, and the most stenotic lesion was taken as the culprit plaque. The percentage of stenosis was calculated by WASID criteria.

RESULTS

Time of flight magnetic resonance angiography had acceptable performance (AUC 0.896, sensitivity 85.9% and specificity 93.3%) but poor negative predictive value (42.1%) for detection of stenosis with vessel wall imaging as the reference standard. Spearman rank order correlation between degree of stenosis on vessel wall imaging and time-of-flight angiography showed statistically significant but moderate correlation (r = 0.715).

CONCLUSION

s Vessel wall imaging has superior diagnostic power to detect and quantify luminal stenosis compared to time-of-flight magnetic resonance angiography. Vessel wall imaging has a unique ability to detect non stenotic vulnerable plaques.

CLINICAL RELEVANCE/APPLICATION

The conventional time-of-flight angiography sequence in MR stroke protocols can be replaced by a vessel wall imaging sequence, yielding greater diagnostic information without significant increase in acquisition times.

M5B-SPNR-5

The Clinical Significance of the Hyperintense Acute Reperfusion Marker Sign in Subacute Stroke

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Ji Young Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The hyperintense acute reperfusion marker (HARM) is characterized by the delayed enhancement of the subarachnoid or subpial space observed on postcontrast fluid-attenuated inversion recovery (FLAIR) images, and is considered a cerebral reperfusion marker for various brain disorders, including infarction. In this study, we evaluated the cerebral distribution patterns of HARM for discriminating between an enhancing subacute infarction and an enhancing mass located in the cortex and subcortical white matter.

METHODS AND MATERIALS

We analyzed consecutive patients who experienced a subacute ischemic stroke, were hospitalized, and underwent conventional brain magnetic resonance imaging including postcontrast FLAIR within 14 days from symptom onset, as well as those who had lesions corresponding to a clinical sign detected by diffusion-weighted imaging and postcontrast T1-weighted imaging between May 2019 and May 2021. A total of 199 patients were included in the study. Of them, 94 were finally included in the subacute infarction group. During the same period, 76 enhancing masses located in the cortex or subcortical white matter, which were subcategorized as metastasis, malignant glioma, and lymphoma, were analyzed. We analyzed the overall incidence of HARM in subacute ischemic stroke cases, and compared the enhancement patterns between cortical infarctions and cortical masses.

RESULTS

Among 94 patients with subacute stroke, 78 patients (83%) presented HARM, and among 76 patients with subcortical masses, 48 patients (63%) presented peripheral rim enhancement. Of 170 subcortical enhancing lesions, 88 (51.8%) showed HARM, and 78 (88.6%) were determined to be subacute infarction. Among 94 patients with subacute stroke, 48 patients (51%) had diffusion restrictions, and HARM was found in 39 patients (81.2%). Of the 46 patients (49%) without diffusion restriction, 39 patients (84.8%) showed HARM.

CONCLUSION

s The presence of HARM was significantly associated with subacute infarctions. For the masses, a peripheral rim enhancement pattern was observed around the mass rather than the cerebral sulci on postcontrast FLAIR.

CLINICAL RELEVANCE/APPLICATION

We found that HARM with enhancing subcortical nodules was highly suggestive of subacute infarctions, and recommended a postcontrast FLAIR sequence for differentiating the ischemic subcortical infarctions from malignant lesions such as small metastasis.

M5B-SPNR-7

Towards Personalized Radiotherapy: Tumor Growth Modeling May Supplement Traditional Radiotherapy Planning in Glioblastoma

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Marie-Christin Metz, MD, (*Presenter*) Nothing to Disclose

PURPOSE

One of the main challenges in the treatment of glioblastoma is the prediction of their individual growth behavior to guide more accurate radiotherapy after resection. Here, we introduce a new, deep learning - based tumor growth model which partially exceeds standard radiotherapy plans in covering the recurrence area.

METHODS AND MATERIALS

Our recently developed tumor growth model is based on a novel deep learning solver of the inverse problem in a Fisher-Kolmogorov growth model. We applied it to 30 cases of our prospective glioma cohort by utilizing FLAIR-, T2-, T1-, and T1-CE-data and compared volume and recurrence coverage with standard radiotherapy plans that were registered to the recurrence image. Statistical analysis was performed by applying Wilcoxon Signed Rank Test.

RESULTS

Depending on the chosen cut-off value of the predicted tumor cell density we saw a comparable target volume ($p = 0.769$) with slight improvement of the covered recurrence area (mean improvement was 0.8% for a cut-off value of 50% for predicted tumor cell density with no significant difference due to the small sample size, $p = 0.797$). The growth maps especially performed better in tumors with a highly diffuse growth pattern which exceed the traditional radiotherapy margins but are well captured in the estimated tumor spread from the growth model.

CONCLUSION

s Here, we showed that utilizing a novel, deep learning - based tumor growth model for glioblastoma performed at least equally well to traditional radiotherapy plans in terms of recurrence coverage in our cohort, showing promise to improve in particular the planning of radiotherapy for highly infiltrative tumors. In a next step, we aim to correlate the calculated values with biological markers of proliferation and infiltration and validate our assumptions on larger data sets.

CLINICAL RELEVANCE/APPLICATION

Deep learning- based tumor growth modeling in glioblastoma carries potential to inform more personalized radiotherapy plans by predicting individual tumor spread. This may improve patient outcome in the future.

M5B-SPNR-9

Evaluation of A Deep Learning Model For The Detection Of Ischemic Acute Stroke Lesions And Assessment Of ASPECTS On Non-contrast CT Scans: A Multicenter Study

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - NR DPS

Participants
Weidao Chen, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Early detection of ischemia and assessing Alberta Stroke Project Early CT Score (ASPECTS) on non-contrast computed tomography (NCCT) plays a crucial role in the treatment of acute ischemic stroke (AIS). We aim to develop a robust deep learning (DL) model for automated detection of AIS lesions and assessment of ASPECTS based on NCCT images

METHODS AND MATERIALS

From January 2013 to December 2017, NCCT images of 1391 AIS patients (<6h from symptom onset to CT) from 5 hospitals were retrospectively collected and divided in to the training dataset (n=1179) and internal validation dataset (n=212). Another 85 AIS patients from other three stroke centers were used as external validation dataset. All patients underwent follow-up diffusion-weighted (DW) MRI (within 24h after AIS), and the infarction regions on NCCT were manually contoured on DW MRI scans. A DL model was proposed for assessing ASPECTS, and model performance was evaluated with receiver operating characteristic (ROC) curve. The diagnostic performance of DL model was also compared with that of four experienced radiologists in the external validation dataset

RESULTS

In total 4240 (212 patients × 20 regions) and 1700 (85 patients × 20 regions) ASPECT regions in the internal and external validation datasets were scored. The AUC of the DL model was 0.876 (95% CI, 0.846-0.907) in the internal validation dataset. The DL model exhibited good performance in the external dataset with AUC achieving 0.729 (95% CI, 0.679-0.779), and the performance was non-inferior to that of four experienced radiologists (all p values > 0.05). The diagnostic accuracy of four radiologists was improved after DL model assistance with average sensitivity and specificity increased from 25.4% and 89.6%, to 33.3% and 91.5%, while the average diagnostic time per-case was reduced from 219.0 sec to 175.7 sec ($p < 0.01$), respectively

CONCLUSION

s The NCCT-based DL model shows favorable performance and good robustness in multi-center validation datasets and can assist radiologists to achieve better performance for the early diagnosis of AIS

CLINICAL RELEVANCE/APPLICATION

This multicenter study demonstrated the deep learning model for detection of infarction and assessment of ASPECTS score on non-contrast CT had good feasibility and reliability for AIS patients

M5B-SPOB-1 Whole-Volume MRI Radiomic Tumor Profiles Predict Survival in Uterine Cervical Cancer

Participants
Kari Wagner-Larsen, Bergen, Norway (*Presenter*) Nothing to Disclose

PURPOSE

To investigate whether pretreatment MRI-based radiomic tumor features predict disease-specific survival (DSS) in uterine cervical cancer (CC).

METHODS AND MATERIALS

This retrospective study included 135 (training set: n=90; validation set: n=45) histologically confirmed CC patients diagnosed in 2009-2017 who had pretreatment pelvic MRI depicting visible CC tumor. MRI included axial (oblique) T2-weighted MRI (T2WI) and axial (oblique) diffusion-weighted imaging (DWI). The primary tumors were manually segmented on T2WI, and the tumor masks were used to extract radiomic features from T2WI, high b-value DWI, and apparent diffusion coefficient (ADC) maps.LASSO Cox analysis was used to select significant features from T2WI only and from both T2WI and DWI (with ADC) to construct prediction models for DSS. The radiomic signature from T2WI only (T2rad) included tumor volume, gray level size zone matrix (GLSZM) feature (n=1), and shape-based features (n=3). The radiomic signature from both T2WI and DWI (T2+DWIrad) included tumor volume, GLSZM (n=2)-, neighboring gray tone difference matrix (NGTDM) (n=1)-, and gray level co-occurence matrix (GLCM) (n=1) features.Prognostic performance of the radiomic signatures and MRI-measured maximum tumor diameter (tumormax) was evaluated by area under time-dependent receiver operating characteristics (tdROC) curves (AUC) in the training- (AUCT) and validation (AUCV) set. Survival was analyzed using Kaplan-Meier with log-rank test and Cox proportional hazard model.

RESULTS

The tdROC curves for predicting DSS at 5 years yielded AUCT/AUCV for tumormax, T2rad, and T2+DWIrad of 0.69/0.66, 0.75/0.71, and 0.82/0.72, respectively. High radiomic score for T2rad and T2+DWIrad was associated with reduced DSS in the training- ($P < 0.001$ for both) and validation ($P = 0.09$ and $P = 0.03$, respectively) set. Both radiomic signatures significantly predicted DSS with hazard ratios (HR) of 1.8-2.0 in the validation set ($P = 0.006$). After adjusting for 2018 FIGO stage (I-II vs. III-IV), T2rad independently predicted DSS (HR 1.6, $P = 0.03$), whereas T2+DWIrad only tended to the same (HR 1.7, $P = 0.06$).

CONCLUSION

s The MRI-based whole-volume radiomic signatures, T2rad and T2+DWIrad, both yield high AUCs for predicting DSS in CC in the training- and validation set. Both radiomic signatures yield higher AUCs than tumormax and independently predict DSS after adjusting for 2018 FIGO stage.

CLINICAL RELEVANCE/APPLICATION

Whole-volume MRI radiomic tumor profiles may aid in pretreatment prognostication in CC patients.

M5B-SPOB-2 Deep Myometrial Invasion of Endometrial Cancer - Sensitivity and Specificity of Fused T2 - Diffusion Weighted, Dynamic Contrast-Enhanced and T2 Weighed Magnetic Resonance Imaging

Participants
Jaromir Kargol, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate and compare the sensitivity and specificity of fused T2 weighted - diffusion weighted magnetic resonance images, dynamic contrast enhanced (DCE) images and standard T2 weighted (T2WI) images in the diagnosis of deep myometrial invasion in patients with endometrial cancer.

METHODS AND MATERIALS

This is a single-center prospective study in a group of 83 consecutive patients (aged 36-86, median age 65), diagnosed with primary endometrial cancer after dilatation and curettage procedure. All patients underwent preoperative staging using the 1.5T magnetic resonance system. The images were evaluated by experienced radiologists blinded to histopathological and clinical data, using T2WI images, fused T2WI-DWI images and DCE images, to detect the depth of myometrial invasion of more than 50%. The findings were compared with the data from the histopathological analysis of surgical specimens.

RESULTS

Deep myometrial invasions were confirmed in 41 of the 83 (49.4%) cases. The fused T2WI-DWI images provided better sensitivity (85.4% vs. 73.2%) and specificity (88.1% vs. 85.7%) in the detection of deep myometrial invasion than morphological T2WI alone. Contrast administration provided better diagnostic performance compared to T2WI images (78.0% vs. 73.2% for sensitivity and 90.5% vs. 85.7% for specificity). Fused imaging had higher sensitivity than DCE imaging (85.4% vs. 78.0%), although it had lower specificity (88.1% vs. 90.5%).

CONCLUSION

s Magnetic resonance imaging has a high diagnostic performance for preoperative staging of endometrial cancer. Both fused T2WI-DWI and DCE magnetic resonance images have better sensitivity and specificity in the diagnosis of deep myometrial invasion than T2WI images. Utilizing fused T2WI-DWI may be a way to avoid the need for use of contrast medium.

CLINICAL RELEVANCE/APPLICATION

Adherence of fused T2WI-DWI images to the preoperative MRI protocol improves the percentage of correctly diagnosed deep myometrial invasion cases among patients with endometrial cancer.

M5B-SPPH-1 Newly Developed Deep Learning Reconstruction (DLR) for Dynamic Contrast-Enhanced CT Angiography: Comparison of Capability for Image Quality Improvements and Abdominal Arteries Assessments among DLR, Hybrid-Type and Model-Based Iterative Reconstructions (IRs) in Patients with Hepatic and Pancreatic Malignant Tumors

Participants
Yoshiharu Ohno, MD, PhD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research Grant, Daiichi Sankyo Co, Ltd;Research Grant, Ministry of Education, Culture, Sports, Science and Technology

PURPOSE

To determine the capability of newly developed deep learning reconstruction (nDLR) for dynamic contrast-enhanced CT angiography (CE-CTA) for image quality improvement and vascular assessment as compared with conventional deep learning reconstruction for abdomen (cDLR), hybrid-type and model-based iterative reconstruction (IRs).

METHODS AND MATERIALS

Forty patients suspected of hepatic and pancreatic malignant tumors underwent dynamic CE-CTA at 320-detector row CTs. To compare quantitative image quality improvement among all methods, region of interests (ROIs) were placed over liver, aorta, celiac artery, proper, right and left hepatic arteries, cystic artery, dorsal pancreatic artery and fat for determination of CT values, signal-to-noise ratios (SNRs) and contrast-to-noise ratios (CNRs) of on all CT data. To compare qualitative image quality among all methods, two board-certified abdominal radiologists assessed overall image quality and depiction of all above-mentioned arteries on each CT data by means of 5-point scale, and final value of each quantitative index were determined by consensus of two readers on each CT data set. For comparison of quantitative image quality, all indexes were compared among all methods by Tukey's HSD test. To evaluate inter-observer agreements of overall image quality and all above-mentioned arteries, kappa statistics with ?2 tests were performed. On comparison of qualitative indexes, each index was also compared among all methods by Wilcoxon signed-rank test.

RESULTS

On quantitative image quality comparisons, SNR and CNR of nDLR at all arteries except cystic artery were significantly higher than those of hybrid-type IR ($p<0.05$). In addition, SNRs and CNRs of nDLR at aorta and celiac artery were significantly higher than those of mode-based IR ($p<0.05$) or cDLR ($p<0.05$). Inter-observer agreement of overall image quality and all arteries on all methods were determined as significantly substantial or almost perfect ($0.73=?=1.0$, $p<0.0001$). On qualitative image quality comparisons, overall image qualities of nDLR, cDLR and MBIR were significantly higher than that of hybrid-type IR ($p<0.05$). Depictions of bilateral hepatic arteries and cystic artery of nDLR, cDLR and MBIR were significantly higher than those of hybrid-type IR ($p<0.05$).

CONCLUSION

s Newly developed DLR for dynamic CE-CTA has equal or superior capability to other methods, especially hybrid-type IR, for improving image quality and vasculature assessment in routine clinical practice.

CLINICAL RELEVANCE/APPLICATION

Newly developed DLR for dynamic CE-CTA has equal or superior capability to other methods, especially hybrid-type IR, for improving image quality and vasculature assessment in routine clinical practice.

M5B-SPPH-2 3D Context-Aware Deep Learning Network in Detection of Pulmonary Mass-Like Lesions: A Preliminary Study

Participants
Yan Zhang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the feasibility and reliability of 3D context-aware deep learning method in detection of pulmonary mass-like lesions by comparisons with radiologists.

METHODS AND MATERIALS

We built Context-aware DL network for detection of slice-level mass-like lesion based on deep learning 2722 CT scanning dataset,

with 2601 slice-level annotations confirmed by experienced pathologists. For the modeling of 3D context, this network took three consecutive slices from axial view as input. For the modeling of 2D context, we implemented an Atrous Spatial Pyramid Pooling (ASPP) module. During inference, the detected slice-level 2D lesion region were aggregated to 3D detection results based on their spatial continuity. Then, all the chest CT examinations were analyzed by Context-aware automatic mass detection (CAMD) from January of 2018 to March of 2019 as group A, and the results were compared with two experienced radiologists (group B). Statistical analysis were made with P<0.05.

RESULTS

A total of 563 CT scans were tested, with 176 mass-like lesions detected in group A and 159 in group B. Compared with radiologists, CAMD demonstrates 19 missed lesions, with 12 of which located at lung hilum. Besides, 36 cases were misdiagnosed, including 18 cases of pulmonary patchy infiltrates and consolidations, 7 cases of atelectasis, 6 cases of encapsulated effusion, 5 cases of hilar lymph nodes or pulmonary arteries and/or veins. The detection rate of CAMD in mass-like lesions was 76.2%, with 20.5% false rate and 8.2% missed rate.

CONCLUSION

s Compared with experienced radiologists, context-aware automatic mass detection (CAMD) demonstrates potential feasibility in detection of pulmonary mass-like lesions.

CLINICAL RELEVANCE/APPLICATION

with the further development of artificial intelligence, CAMD will help radiologists quickly locate lesions for diagnosis and generate structured reports.

M5B-SPPH-4 Photon-Counting Computed Tomography: Influence of Focal Spot Size on High Spatial Resolution Imaging

Participants
Trevor Vent, (*Presenter*) Nothing to Disclose

PURPOSE

Photon-Counting Computed Tomography (PCCT) has potential to provide significant benefits in diagnostic imaging, including high spatial resolution imaging. A limited x-ray flux at small focal spot sizes imposes limitations on attainable spatial resolution. This study examines the effects of the focal spot size of the x-ray tube on high spatial resolution imaging of a first-generation clinical dual source PCCT.

METHODS AND MATERIALS

To evaluate the spatial resolution of a clinical PCCT scanner (Naeotom Alpha, Siemens Healthineers), a high-contrast lead foil Siemens Star (Type 9/10/360-003, Supertech) was placed with a 3D-printed adapter into a technical CT phantom (Multi-Energy CT Phantom, Sun Nuclear) to simulate realistic patient sizes. The phantom was scanned with a high-resolution protocol at two radiation dose levels (10, 16 mGy) that corresponded to two focal spot sizes (small: 0.4 x 0.4 mm2, large: 0.6 x 0.7 mm2). Scans were repeated three times, and slices were reconstructed with 0.2 mm slice thickness, 0.1 mm slice spacing, and three different reconstruction kernels (Hr72, Hr84, Hr98). Images were evaluated using a contrast transfer function (CTF) analysis. Limiting spatial resolution (LSR) was measured at 50% and 10% modulation.

RESULTS

LSR varied with focal spot size and reconstruction kernel. LSR increased with increasing reconstruction kernel for the small focal spot size: 25, 31.5, and 93 lp/cm (10% modulation), respectively. LSR was limited by the larger focal spot size at higher reconstruction kernels: 25, 30.5, and 30.5 lp/cm, respectively. There are no discernible differences between the Hr84 and Hr98 reconstruction kernels suggesting that the larger focal spot size was the limiting factor of resolution.

CONCLUSION

s In this study, the resolution capabilities of a clinical PCCT system were evaluated based on reconstruction mode and focal spot size. The X-ray tube flux constraints must be overcome to fully unfold the high-resolution capabilities to all anatomical regions and patient sizes. In all modes, the PCCT system outperforms existing conventional CT technology in terms of spatial resolution achievable.

CLINICAL RELEVANCE/APPLICATION

In clinical practice, high-resolution PCCT has the potential to aid in the diagnosis of diseases by providing visualization of small structures that may be difficult to identify on conventional CT.

M5B-SPPH-5 Differences in Noise Reduction Performance Between Two Deep-Learning CT Image Reconstruction Techniques: A Novel Textured Phantom Approach

Participants
Hiroki Kawashima, PhD, RT, Kanazawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To characterize the noise reduction performance between two deep-learning image reconstruction (DLIR) techniques, using a phantom containing a simple uniform region and a complex non-uniform region.

METHODS AND MATERIALS

A water-bath phantom with a diameter of 300 mm was used as a base phantom. A textured phantom with a diameter of 128 mm, which was made of two materials, one equivalent to water and the other being 12 mg/mL diluted iodine, irregularly mixed to create a complex texture (non-uniform region), was placed in the base phantom. Thirty repeated phantom scans were performed using two CT scanners (GE, Revolution CT with Apex Edition; Canon, Aquilion One PRISM Edition) at two dose levels (CTDI: 5 and 15 mGy). Images were reconstructed with each CT system's filtered back projection (FBP) and DLIR [GE, TrueFidelity (TF); Canon, Advanced intelligent Clear-IQ Engine Body Sharp (AC)] for three process strengths. For basic characteristics of noise, the standard deviation (SD) and noise power spectrum (NPS) were measured for the uniform (water) region. A noise magnitude map was generated by

calculating the inter-image SD at each pixel position across the 30 images. Then, a noise reduction map (NRM), which visualizes the relative differences in noise magnitude between FBP and DLIR, was calculated. The NRM values ranged from 0.0 to 1.0. A low NRM value represents a less aggressive noise reduction. The histograms of the NRM value were analyzed for the uniform and non-uniform regions.

RESULTS

The reduction in noise magnitude compared with FBP tended to be greater with AC (45%-85%) than with TF (32%-65%). The average NPS frequencies of TF and AC were almost comparable to those of FBP, except for the low-dose condition and the high noise reduction strength for AC. The NRM values of TF and AC were higher in the uniform region than in the non-uniform region. In the non-uniform region, TF's average NRM values (0.21-0.48) tended to be lower than AC's (0.39-0.78). The histograms for TF showed a small overlap between the uniform and the non-uniform regions; in contrast, those for AC showed a greater overlap. This difference seems to indicate that TF processes the uniform and non-uniform regions more differently than AC does.

CONCLUSION

s This study has revealed a distinct difference in characteristics between the two DLIR techniques: TF tends to offer less aggressive noise reduction in non-uniform regions and preserve the original signals, whereas AC tends to prioritize noise filtering over edge-preservation, especially at the low-dose condition and with the high noise reduction strength.

CLINICAL RELEVANCE/APPLICATION

An appropriate combination of strength and dose level should be selected for clinical use of each DLIR technique.

M5B-SPPH-6 Discriminability of Frequency-Dependent Non-Gaussian Noise Properties in CT and the Limitation of the Noise Power Spectrum to Describe Noise Texture with Non-Linear Reconstruction Algorithms.

Participants
Daniel Shin, MS, Los Angeles, CA (*Presenter*) Employee, Canon Medical Systems Corporation

PURPOSE

To demonstrate the impact of frequency-dependent higher order, non-Gaussian noise properties on perceived noise texture via a human observer study using abdominal CT reconstruction algorithms as a use case.

METHODS AND MATERIALS

A 32 cm water phantom was scanned at two tube current levels on an Aquilion ONE Genesis CT system (Canon Medical Systems, Otawara, Japan). The raw data was reconstructed with three abdominal reconstruction algorithms: a model-based iterative reconstruction (MBIR) algorithm (FIRST), a deep-learning reconstruction (DLR) algorithm (AiCE), and, for one tube current, filtered backprojection (FBP) as a control. First, quantitative analysis of the noise in the resulting reconstructions was performed by extracting regions of interest (ROIs) (100x100 pixels) from the image data and assessing the 4th order statistics of each ROI via a global and frequency-binned excess kurtosis measurement. To evaluate the detectability of the non-Gaussian characteristics of these noise images, pure Gaussian noise counterpart image datasets with the same mean, standard deviation (SD), and Noise Power Spectrum (NPS) as each acquired data condition were also generated by convolving random white noise with the root-NPS of the acquired data. Then, using a two-alternative forced choice experiment, nine naïve observers were tasked with distinguishing the acquired noise image from its pure Gaussian counterpart.

RESULTS

Excess kurtosis in the image ROIs was 0.01 for FBP, 0.74-0.85 for FIRST, and -0.13-0.21 for AiCE. Excess kurtosis trends differ with frequency band. From the observer study, it was found that FBP images appear indistinguishable from their pure Gaussian counterparts (AUC=.54), while MBIR images were readily distinguishable from Gaussian ones (AUC=.98-1). DLR images are more difficult to distinguish from their pure Gaussian counterparts (AUC 0.56-.85), which indicates that perceived noise texture is more similar to Gaussian noise.

CONCLUSION

s This work demonstrates that the appearance of CT noise texture may be dependent on frequency-dependent higher-order statistics not captured by the NPS. In some cases, noise textures with identical NPS and SD can be distinguished based on non-Gaussian properties. Deep-learning reconstruction has lower levels of excess kurtosis and is less readily discriminable from Gaussian noise, despite having a similar NPS to MBIR.

CLINICAL RELEVANCE/APPLICATION

Noise texture can influence the acceptability of a reconstruction algorithm to the radiologist and thus full characterization of the noise is key to understanding and describing reconstruction algorithm performance.

M5B-SPPH-7 A Multi Decade Study of CT Protocol Optimization underneath the Influence of Physicists, Radiologists and Improving Scanner Technologies

Participants
Joseph Meier, PhD, Madison, WI (*Presenter*) Nothing to Disclose

PURPOSE

Adjusting CT protocols for optimization of image quality across a large site requires a multidisciplinary effort. Optimizing the performance of Automatic Tube Current Control (AEC) avoids acquiring images with high amounts of noise or with too low noise when the tube current(mA) is maxxing or minning out respectively. This study investigates the longitudinal impact that protocol optimization by a team of medical physicists and radiologists and improvements in scanner technology have on the performance of the site's AEC.

METHODS AND MATERIALS

We analyzed 536 exams from either routine chest or routine abdomen from early protocol optimization(2007-2008) and 739 from current protocol optimization(2021-2022). Proper AEC function was measured for each examination by calculating the percentage of images at the maximum mA (%imgmax_mA)and minimum(%imgmin_mA). Examinations were classified as suboptimal if the

%imgmax_mA or %imgmin_mA was greater than 20%.

RESULTS

For the chest exams, the mean %imgmax_mA decreased from 31.9 ± 32.6% to 10.3 ± 8.5%($p<0.001$) from the early to current protocol periods. Similarly, for the abdominal exams the mean %imgmax_mA decreased from 35.4 ± 35.5% to 14.3 ± 16.6% ($p<0.001$). For the chest exams, the mean %imgmin_mA decreased from 19.0 ± 32.1% to 3.6 ± 4.2%($p<0.001$). Similarly, for the abdominal exams, the mean %imgmin_mA decreased from 21.8 ± 35.1% to 3.6 ± 13.4%($p<0.001$). The percent of suboptimal chest exams for %imgmax_mA(%imgmin_mA) decreased from 46.4(21.6)% to 8.2(1.1)%. Similarly, the percent of suboptimal abdominal exams for %imgmax_mA(%imgmin_mA), decreased from 44.3(27.4)% to 12.0(3.0)%.

CONCLUSION

s This work shows that the incidence of suboptimal routine chest and abdominal examinations as measured by the percentage of images at the maximum or minimum mA, was greatly reduced through protocol optimization by medical physicists and radiologists as well as emerging scanner technology.

CLINICAL RELEVANCE/APPLICATION

A multidecade analysis of CT tube current modulation data shows that the efforts of medical physicists and radiologists combined with evolving scanner technology has greatly reduced the number of suboptimal CT exams.

M5B-SPPH-8 Clinical Thorax CT Image Quality Assessment Using Spectral and Spatial Features

Participants
Zahra Passand, MSc, (*Presenter*) Nothing to Disclose

PURPOSE

The quality of computed tomography (CT) images is affected by different parameters such as patient motion and anatomy, detector design, scatter, the reconstruction algorithm and others. Patient CT images are not automatically analyzed by the scanner software during clinical routine. Introducing continuous monitoring of CT image quality would be beneficial for diagnostic purposes. As a consequence of such a broader analysis, the applied dose could be reduced while maintaining sufficient image quality level. Since most of the existing image quality analysis approaches are based on dedicated phantoms, we propose a method which combines the modulation transfer function (MTF), the frequency spectrum and the noise power spectrum (NPS) in a predefined regions of interest (ROI) to compute various image quality features. A classifier was trained using these features to distinguish different level of image quality.

METHODS AND MATERIALS

The thorax CT images which were acquired from 30 patients were annotated by different radiologists. In this initial study, two quality levels (either "low" or "high") were used. For each CT image, an ROI containing the major fissure of the left lung was manually selected and was used to estimate the image quality. The outer edges of the major fissure were automatically detected using an active contour algorithm. The MTF was computed using the edge and line scan functions of the major fissure within the selected ROI. In addition to the MTF, the frequency power spectrum was estimated in the same ROI. The NPS was estimated from a homogenous area close to the ROI of the major fissure. Based on the parameters, several other frequency domain features were derived to determine the image quality. A classifier was trained using these features.

RESULTS

Using the estimated features, a classification accuracy of 89% was achieved using the validation data set.

CONCLUSION

s Using the image quality features which were defined for this work, CT images were classified in one of the two image quality categories. The classification results were in high agreement with the manual annotation performed by radiologists. Future work will include additional features and CT images to further improve and validate this approach.

CLINICAL RELEVANCE/APPLICATION

The developed method has the potential to be used during clinical routine for image quality analysis and documentation. Long term studies would be required to analyze the quality over a larger population to investigate potential dose reduction strategies.

M5B-SPPH-9 Deep Scatter Estimation (DSE) for High Scatter Frequencies caused by Coarse Anti Scatter Grids in Clinical CT

Participants
Julien Erath, Forchheim, Germany (*Presenter*) Employee, Siemens AG

PURPOSE

To estimate and correct for high frequencies in scatter signals transmitted through coarse anti scatter grids (ASGs) as used in photon counting CT.

METHODS AND MATERIALS

CT detectors with very small pixels, such as in photon-counting CT, may have anti scatter grids with a grid spacing being an integer multiple of the detector pixel size. For example, an ASG field may comprise a 2x3 matrix of detector pixels. The shading of the scattered radiation caused by the grid affects each of the six pixels within a grid field differently. Although scatter is a low frequency effect, this pixel-dependent shading results in high frequencies in the scatter signal transmitted through the ASG. These may cause moiré artifacts in the reconstructed images. We trained a deep learning-based scatter estimation (DSE) network to estimate that scatter signal, which can then be used to correct the measured data (e.g. by subtraction). To train DSE, scatter signals were obtained by Monte Carlo simulation of patient CT data. The geometry of the CT and of the coarse ASG matches the one of a clinical photon-counting CT (Naeotom Alpha, Siemens Healthineers). To adapt the network architecture to the coarse ASG, the network receives the six different pixel locations as separate input channels and is trained to predict six different output channels of the pixel locations, which can then be merged to obtain the scatter estimation for the whole detector. The DSE-corrected data are then reconstructed and evaluated in image domain.

RESULTS

With the proposed neural network, the high frequency components of the scatter signal can be estimated and corrected very efficiently. DSE reduces scatter artifacts across all patients from a mean absolute error of about 10 HU to below 1 HU. DSE reduces scatter artifacts across all patients from a mean absolute error of about 10 HU to below 1 HU. The amplitude of the moiré artifacts can be reduced from about 15 HU to below 2 HU. With the proposed algorithm the moiré artifacts can be significantly reduced and the diagnostic image quality improved.

CONCLUSION

s DSE can estimate ASG-modulated scatter frequencies in CT data and correct both for the scatter artifacts and for the moiré artifacts caused by the coarse ASG.

CLINICAL RELEVANCE/APPLICATION

DSE leads to an accurate scatter correction of the moiré artifacts and can be crucial for accurate diagnostic CT image quality.

Newly Developed Deep Learning Reconstruction (DLR) for Dynamic Contrast-Enhanced CT Angiography: Comparison of Capability for Image Quality Improvements and Abdominal Arteries Assessments among DLR, Hybrid-Type and Model-Based Iterative Reconstructions (IRs) in Patients with Hepatic and Pancreatic Malignant Tumors

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - PH DPS

Participants
Yoshiharu Ohno, MD, PhD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research Grant, Daiichi Sankyo Co, Ltd;Research Grant, Ministry of Education, Culture, Sports, Science and Technology

PURPOSE

To determine the capability of newly developed deep learning reconstruction (nDLR) for dynamic contrast-enhanced CT angiography (CE-CTA) for image quality improvement and vascular assessment as compared with conventional deep learning reconstruction for abdomen (cDLR), hybrid-type and model-based iterative reconstruction (IRs).

METHODS AND MATERIALS

Forty patients suspected of hepatic and pancreatic malignant tumors underwent dynamic CE-CTA at 320-detector row CTs. To compare quantitative image quality improvement among all methods, region of interests (ROIs) were placed over liver, aorta, celiac artery, proper, right and left hepatic arteries, cystic artery, dorsal pancreatic artery and fat for determination of CT values, signal-to-noise ratios (SNRs) and contrast-to-noise ratios (CNRs) of on all CT data. To compare qualitative image quality among all methods, two board-certified abdominal radiologists assessed overall image quality and depiction of all above-mentioned arteries on each CT data by means of 5-point scale, and final value of each quantitative index were determined by consensus of two readers on each CT data set. For comparison of quantitative image quality, all indexes were compared among all methods by Tukey's HSD test. To evaluate inter-observer agreements of overall image quality and all above-mentioned arteries, kappa statistics with ?2 tests were performed. On comparison of qualitative indexes, each index was also compared among all methods by Wilcoxon signed-rank test.

RESULTS

On quantitative image quality comparisons, SNR and CNR of nDLR at all arteries except cystic artery were significantly higher than those of hybrid-type IR ($p<0.05$). In addition, SNRs and CNRs of nDLR at aorta and celiac artery were significantly higher than those of mode-based IR ($p<0.05$) or cDLR ($p<0.05$). Inter-observer agreement of overall image quality and all arteries on all methods were determined as significantly substantial or almost perfect ($0.73=?=1.0$, $p<0.0001$). On qualitative image quality comparisons, overall image qualities of nDLR, cDLR and MBIR were significantly higher than that of hybrid-type IR ($p<0.05$). Depictions of bilateral hepatic arteries and cystic artery of nDLR, cDLR and MBIR were significantly higher than those of hybrid-type IR ($p<0.05$).

CONCLUSION

s Newly developed DLR for dynamic CE-CTA has equal or superior capability to other methods, especially hybrid-type IR, for improving image quality and vasculature assessment in routine clinical practice.

CLINICAL RELEVANCE/APPLICATION

Newly developed DLR for dynamic CE-CTA has equal or superior capability to other methods, especially hybrid-type IR, for improving image quality and vasculature assessment in routine clinical practice.

Photon-Counting Computed Tomography: Influence of Focal Spot Size on High Spatial Resolution Imaging

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - PH DPS

Participants
Trevor Vent, (*Presenter*) Nothing to Disclose

PURPOSE

Photon-Counting Computed Tomography (PCCT) has potential to provide significant benefits in diagnostic imaging, including high spatial resolution imaging. A limited x-ray flux at small focal spot sizes imposes limitations on attainable spatial resolution. This study examines the effects of the focal spot size of the x-ray tube on high spatial resolution imaging of a first-generation clinical dual source PCCT.

METHODS AND MATERIALS

To evaluate the spatial resolution of a clinical PCCT scanner (Naeotom Alpha, Siemens Healthineers), a high-contrast lead foil Siemens Star (Type 9/10/360-003, Supertech) was placed with a 3D-printed adapter into a technical CT phantom (Multi-Energy CT Phantom, Sun Nuclear) to simulate realistic patient sizes. The phantom was scanned with a high-resolution protocol at two radiation dose levels (10, 16 mGy) that corresponded to two focal spot sizes (small: 0.4 x 0.4 mm2, large: 0.6 x 0.7 mm2). Scans were repeated three times, and slices were reconstructed with 0.2 mm slice thickness, 0.1 mm slice spacing, and three different reconstruction kernels (Hr72, Hr84, Hr98). Images were evaluated using a contrast transfer function (CTF) analysis. Limiting spatial resolution (LSR) was measured at 50% and 10% modulation.

RESULTS

LSR varied with focal spot size and reconstruction kernel. LSR increased with increasing reconstruction kernel for the small focal spot size: 25, 31.5, and 93 lp/cm (10% modulation), respectively. LSR was limited by the larger focal spot size at higher reconstruction kernels: 25, 30.5, and 30.5 lp/cm, respectively. There are no discernible differences between the Hr84 and Hr98 reconstruction kernels suggesting that the larger focal spot size was the limiting factor of resolution.

CONCLUSION

s In this study, the resolution capabilities of a clinical PCCT system were evaluated based on reconstruction mode and focal spot size. The X-ray tube flux constraints must be overcome to fully unfold the high-resolution capabilities to all anatomical regions and patient sizes. In all modes, the PCCT system outperforms existing conventional CT technology in terms of spatial resolution achievable.

CLINICAL RELEVANCE/APPLICATION

In clinical practice, high-resolution PCCT has the potential to aid in the diagnosis of diseases by providing visualization of small structures that may be difficult to identify on conventional CT.

Differences in Noise Reduction Performance Between Two Deep-Learning CT Image Reconstruction Techniques: A Novel Textured Phantom Approach

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - PH DPS

Participants
Hiroki Kawashima, PhD, RT, Kanazawa, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To characterize the noise reduction performance between two deep-learning image reconstruction (DLIR) techniques, using a phantom containing a simple uniform region and a complex non-uniform region.

METHODS AND MATERIALS

A water-bath phantom with a diameter of 300 mm was used as a base phantom. A textured phantom with a diameter of 128 mm, which was made of two materials, one equivalent to water and the other being 12 mg/mL diluted iodine, irregularly mixed to create a complex texture (non-uniform region), was placed in the base phantom. Thirty repeated phantom scans were performed using two CT scanners (GE, Revolution CT with Apex Edition; Canon, Aquilion One PRISM Edition) at two dose levels (CTDI: 5 and 15 mGy). Images were reconstructed with each CT system's filtered back projection (FBP) and DLIR [GE, TrueFidelity (TF); Canon, Advanced intelligent Clear-IQ Engine Body Sharp (AC)] for three process strengths. For basic characteristics of noise, the standard deviation (SD) and noise power spectrum (NPS) were measured for the uniform (water) region. A noise magnitude map was generated by calculating the inter-image SD at each pixel position across the 30 images. Then, a noise reduction map (NRM), which visualizes the relative differences in noise magnitude between FBP and DLIR, was calculated. The NRM values ranged from 0.0 to 1.0. A low NRM value represents a less aggressive noise reduction. The histograms of the NRM value were analyzed for the uniform and non-uniform regions.

RESULTS

The reduction in noise magnitude compared with FBP tended to be greater with AC (45%-85%) than with TF (32%-65%). The average NPS frequencies of TF and AC were almost comparable to those of FBP, except for the low-dose condition and the high noise reduction strength for AC. The NRM values of TF and AC were higher in the uniform region than in the non-uniform region. In the non-uniform region, TF's average NRM values (0.21-0.48) tended to be lower than AC's (0.39-0.78). The histograms for TF showed a small overlap between the uniform and the non-uniform regions; in contrast, those for AC showed a greater overlap. This difference seems to indicate that TF processes the uniform and non-uniform regions more differently than AC does.

CONCLUSION

s This study has revealed a distinct difference in characteristics between the two DLIR techniques: TF tends to offer less aggressive noise reduction in non-uniform regions and preserve the original signals, whereas AC tends to prioritize noise filtering over edge-preservation, especially at the low-dose condition and with the high noise reduction strength.

CLINICAL RELEVANCE/APPLICATION

An appropriate combination of strength and dose level should be selected for clinical use of each DLIR technique.

M5B-SPPH-6

Discriminability of Frequency-Dependent Non-Gaussian Noise Properties in CT and the Limitation of the Noise Power Spectrum to Describe Noise Texture with Non-Linear Reconstruction Algorithms.

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - PH DPS

Participants
Daniel Shin, MS, Los Angeles, CA (*Presenter*) Employee, Canon Medical Systems Corporation

PURPOSE

To demonstrate the impact of frequency-dependent higher order, non-Gaussian noise properties on perceived noise texture via a human observer study using abdominal CT reconstruction algorithms as a use case.

METHODS AND MATERIALS

A 32 cm water phantom was scanned at two tube current levels on an Aquilion ONE Genesis CT system (Canon Medical Systems, Otawara, Japan). The raw data was reconstructed with three abdominal reconstruction algorithms: a model-based iterative reconstruction (MBIR) algorithm (FIRST), a deep-learning reconstruction (DLR) algorithm (AiCE), and, for one tube current, filtered backprojection (FBP) as a control. First, quantitative analysis of the noise in the resulting reconstructions was performed by extracting regions of interest (ROIs) (100x100 pixels) from the image data and assessing the 4th order statistics of each ROI via a global and frequency-binned excess kurtosis measurement. To evaluate the detectability of the non-Gaussian characteristics of these noise images, pure Gaussian noise counterpart image datasets with the same mean, standard deviation (SD), and Noise Power Spectrum (NPS) as each acquired data condition were also generated by convolving random white noise with the root-NPS of the acquired data. Then, using a two-alternative forced choice experiment, nine naïve observers were tasked with distinguishing the acquired noise image from its pure Gaussian counterpart.

RESULTS

Excess kurtosis in the image ROIs was 0.01 for FBP, 0.74-0.85 for FIRST, and -0.13-0.21 for AiCE. Excess kurtosis trends differ with frequency band. From the observer study, it was found that FBP images appear indistinguishable from their pure Gaussian counterparts (AUC=.54), while MBIR images were readily distinguishable from Gaussian ones (AUC=.98-1). DLR images are more difficult to distinguish from their pure Gaussian counterparts (AUC 0.56-.85), which indicates that perceived noise texture is more similar to Gaussian noise.

CONCLUSION

s This work demonstrates that the appearance of CT noise texture may be dependent on frequency-dependent higher-order statistics not captured by the NPS. In some cases, noise textures with identical NPS and SD can be distinguished based on non-Gaussian properties. Deep-learning reconstruction has lower levels of excess kurtosis and is less readily discriminable from Gaussian noise, despite having a similar NPS to MBIR.

CLINICAL RELEVANCE/APPLICATION

Noise texture can influence the acceptability of a reconstruction algorithm to the radiologist and thus full characterization of the noise is key to understanding and describing reconstruction algorithm performance.

A Multi Decade Study of CT Protocol Optimization underneath the Influence of Physicists, Radiologists and Improving Scanner Technologies

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - PH DPS

Participants
Joseph Meier, PhD, Madison, WI (*Presenter*) Nothing to Disclose

PURPOSE

Adjusting CT protocols for optimization of image quality across a large site requires a multidisciplinary effort. Optimizing the performance of Automatic Tube Current Control (AEC) avoids acquiring images with high amounts of noise or with too low noise when the tube current(mA) is maxxing or minning out respectively. This study investigates the longitudinal impact that protocol optimization by a team of medical physicists and radiologists and improvements in scanner technology have on the performance of the site's AEC.

METHODS AND MATERIALS

We analyzed 536 exams from either routine chest or routine abdomen from early protocol optimization(2007-2008) and 739 from current protocol optimization(2021-2022). Proper AEC function was measured for each examination by calculating the percentage of images at the maximum mA (%imgmax_mA)and minimum(%imgmin_mA). Examinations were classified as suboptimal if the %imgmax_mA or %imgmin_mA was greater than 20%.

RESULTS

For the chest exams, the mean %imgmax_mA decreased from 31.9 ± 32.6% to 10.3 ± 8.5%($p<0.001$) from the early to current protocol periods. Similarly, for the abdominal exams the mean %imgmax_mA decreased from 35.4 ± 35.5% to 14.3 ± 16.6% ($p<0.001$). For the chest exams, the mean %imgmin_mA decreased from 19.0 ± 32.1% to 3.6 ± 4.2%($p<0.001$). Similarly, for the abdominal exams, the mean %imgmin_mA decreased from 21.8 ± 35.1% to 3.6 ± 13.4%($p<0.001$). The percent of suboptimal chest exams for %imgmax_mA(%imgmin_mA) decreased from 46.4(21.6)% to 8.2(1.1)%. Similarly, the percent of suboptimal abdominal exams for %imgmax_mA(%imgmin_mA), decreased from 44.3(27.4)% to 12.0(3.0)%.

CONCLUSION

s This work shows that the incidence of suboptimal routine chest and abdominal examinations as measured by the percentage of images at the maximum or minimum mA, was greatly reduced through protocol optimization by medical physicists and radiologists as well as emerging scanner technology.

CLINICAL RELEVANCE/APPLICATION

A multidecade analysis of CT tube current modulation data shows that the efforts of medical physicists and radiologists combined with evolving scanner technology has greatly reduced the number of suboptimal CT exams.

Clinical Thorax CT Image Quality Assessment Using Spectral and Spatial Features

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - PH DPS

Participants
Zahra Passand, MSc, (*Presenter*) Nothing to Disclose

PURPOSE

The quality of computed tomography (CT) images is affected by different parameters such as patient motion and anatomy, detector design, scatter, the reconstruction algorithm and others. Patient CT images are not automatically analyzed by the scanner software during clinical routine. Introducing continuous monitoring of CT image quality would be beneficial for diagnostic purposes. As a consequence of such a broader analysis, the applied dose could be reduced while maintaining sufficient image quality level. Since most of the existing image quality analysis approaches are based on dedicated phantoms, we propose a method which combines the modulation transfer function (MTF), the frequency spectrum and the noise power spectrum (NPS) in a predefined regions of interest (ROI) to compute various image quality features. A classifier was trained using these features to distinguish different level of image quality.

METHODS AND MATERIALS

The thorax CT images which were acquired from 30 patients were annotated by different radiologists. In this initial study, two quality levels (either "low" or "high") were used. For each CT image, an ROI containing the major fissure of the left lung was manually selected and was used to estimate the image quality. The outer edges of the major fissure were automatically detected using an active contour algorithm. The MTF was computed using the edge and line scan functions of the major fissure within the selected ROI. In addition to the MTF, the frequency power spectrum was estimated in the same ROI. The NPS was estimated from a homogenous area close to the ROI of the major fissure. Based on the parameters, several other frequency domain features were derived to determine the image quality. A classifier was trained using these features.

RESULTS

Using the estimated features, a classification accuracy of 89% was achieved using the validation data set.

CONCLUSION

s Using the image quality features which were defined for this work, CT images were classified in one of the two image quality categories. The classification results were in high agreement with the manual annotation performed by radiologists. Future work will include additional features and CT images to further improve and validate this approach.

CLINICAL RELEVANCE/APPLICATION

The developed method has the potential to be used during clinical routine for image quality analysis and documentation. Long term studies would be required to analyze the quality over a larger population to investigate potential dose reduction strategies.

Deep Scatter Estimation (DSE) for High Scatter Frequencies caused by Coarse Anti Scatter Grids in Clinical CT

Monday, Nov. 28 12:45PM - 1:15PM Room: Learning Center - PH DPS

Participants
Julien Erath, Forchheim, Germany (*Presenter*) Employee, Siemens AG

PURPOSE

To estimate and correct for high frequencies in scatter signals transmitted through coarse anti scatter grids (ASGs) as used in photon counting CT.

METHODS AND MATERIALS

CT detectors with very small pixels, such as in photon-counting CT, may have anti scatter grids with a grid spacing being an integer multiple of the detector pixel size. For example, an ASG field may comprise a 2x3 matrix of detector pixels. The shading of the scattered radiation caused by the grid affects each of the six pixels within a grid field differently. Although scatter is a low frequency effect, this pixel-dependent shading results in high frequencies in the scatter signal transmitted through the ASG. These may cause moiré artifacts in the reconstructed images. We trained a deep learning-based scatter estimation (DSE) network to estimate that scatter signal, which can then be used to correct the measured data (e.g. by subtraction). To train DSE, scatter signals were obtained by Monte Carlo simulation of patient CT data. The geometry of the CT and of the coarse ASG matches the one of a clinical photon-counting CT (Naeotom Alpha, Siemens Healthineers). To adapt the network architecture to the coarse ASG, the network receives the six different pixel locations as separate input channels and is trained to predict six different output channels of the pixel locations, which can then be merged to obtain the scatter estimation for the whole detector. The DSE-corrected data are then reconstructed and evaluated in image domain.

RESULTS

With the proposed neural network, the high frequency components of the scatter signal can be estimated and corrected very efficiently. DSE reduces scatter artifacts across all patients from a mean absolute error of about 10 HU to below 1 HU. DSE reduces scatter artifacts across all patients from a mean absolute error of about 10 HU to below 1 HU. The amplitude of the moiré artifacts can be reduced from about 15 HU to below 2 HU. With the proposed algorithm the moiré artifacts can be significantly reduced and the diagnostic image quality improved.

CONCLUSION

s DSE can estimate ASG-modulated scatter frequencies in CT data and correct both for the scatter artifacts and for the moiré artifacts caused by the coarse ASG.

CLINICAL RELEVANCE/APPLICATION

DSE leads to an accurate scatter correction of the moiré artifacts and can be crucial for accurate diagnostic CT image quality.

M5B-SPVA-1 Noise-Optimized Virtual Monoenergetic Reconstruction Improves Diagnostic Accuracy and Image Quality of Dual-Energy CT Angiography in Peripheral Arterial Occlusive Disease

Participants
Philipp Gruschwitz, Wuerzburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to evaluate the influence of a noise optimized virtual monoenergetic reconstruction algorithm (VMI+) on the image quality and diagnostic accuracy of dual-energy (DE) computed tomography angiography (CTA) of the lower extremity runoff.

METHODS AND MATERIALS

A total of 118 lower extremity runoff CTA performed on a 3rd generation DE-CT scanner in 109 patients (54 females; 75.6 ± 9.5 years) were included in this IRB-approved, HIPAA-compliant retrospective study. Axial image stacks were reconstructed with standard 120 kV setting and VMI+ of different keV levels. Objective image quality criteria (contrast attenuation, signal-to-noise [SNR] and contrast-to-noise ratio [CNR]) were measured and subjective image quality was evaluated. Diagnostic accuracy for significant stenosis (>75%) and vessel occlusion was assessed for 120 kV and 50 keV VMI+ images. In all patients, a digital subtraction angiography (DSA) served as standard of reference.

RESULTS

Intraluminal attenuation was highest in 40/50 keV VMI+ while SNR were similar to 120 kV images. In subjective assessment, intraluminal contrast of 50 keV images was deemed superior compared to 120 kV despite higher image noise. Sensitivity, specificity and accuracy of the detection of a vessel occlusion were superior in 50 keV VMI+, especially for the lower leg runoff (70%/92%/84%; 70%/91%/83%; p<0.001). 13 of 118 (11%) lower leg runoffs were only assessable with 50 keV VMI+. Relevant stenosis (> 75%) was found with 100% accuracy on VMI+.

CONCLUSION

s VMI+ reconstructions improve objective and subjective image quality and diagnostic accuracy of DE-CTA, allowing also the evaluation of lower leg runoffs inassessable with standard images.

CLINICAL RELEVANCE/APPLICATION

We could show that virtual monoenergetic reconstructions facilitate superior diagnostic accuracy compared to conventional linear blended images for significant artery stenosis and also allows for correct assessment of lower leg runoffs with pronounced arteriosclerosis that are not assessable with standard reformatting, first with sufficient patient number (109) using digital subtraction angiography as reference standard. These results underline that 50 keV should be used for routine evaluation of DE-CTA.

Sub-Events

R2-SPBR-1 Assessing the necessity of implant included mammography in women with breast implants.

Participants
Hee Jeong Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the necessity of implant full (IF) views in mammography for women with breast implants.

METHODS AND MATERIALS

Screening and diagnostic augmentation mammography performed in 748 women (mean age ± standard deviation, 46.4 ± 8.9 years) with no prior history of breast cancer from January 2009 to December 2019 were retrospectively identified. Routine mammography included four IF views and four implant displaced (ID) views. Breast cancer detection rate, sensitivity, mean glandular dose per breast, and implant rupture detection rate were evaluated and compared between routine eight views, four IF views and four ID views. Between-group differences were evaluated statistically using the t-test or paired t-test for continuous variables and the chi-square test for categoric variables. Cancer detection rate and sensitivity were compared using McNemar's test. A p-value less than 0.05 was considered statistically significant.

RESULTS

Incidence of breast cancer was 17.6% (132/748) and 15% (20/132) were mammographically occult. Breast cancer detection rate of routine eight views (15%; 95% CI: 12.6%, 17.7%) was higher than that of IF views (8.8%; 95% CI: 7.0%, 11.1%; p<0.0001), while not different from that of ID views (15%; 95% CI: 12.5%, 17.6%; p>0.999). The sensitivity of routine eight views (84.8%; 95% CI: 77.8%, 90.0%) was significantly higher than that of IF views (50%; 95% CI: 41.6%, 58.4%; p<0.0001), while not different from that of ID views (84.8%; 95% CI: 77.8%, 90.0%; p>0.999). Mean glandular dose was 1.05 mGy in routine eight views and 0.99 mGy in ID views (p<0.0001). Implant rupture was found in 2.1%(16/748). Implant rupture detection rate was 81.3% (13/16) in routine eight views and IF views and 12.5% (2/16) in ID views.

CONCLUSION

s Routine eight-view mammography and four ID views showed similar performance for detecting breast cancer and the diagnostic gain of four IF views was low.

CLINICAL RELEVANCE/APPLICATION

Considering the low clinical impact and cumulative radiation, the necessity IF views in mammography need to be reconsidered in women with breast implants.

R2-SPBR-2 Comparing the Performance of Full-Field Digital Mammography (FFDM) and Digital Breast Tomosynthesis (DBT) in the Post-Treatment Surveillance of Patients with a History of Breast Cancer: A Retrospective Study

Participants
Emily Nia, MD, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

Guidelines for imaging follow-up in patients with a history of breast cancer vary among different medical societies. However, all recommend annual screening mammography. The purpose of our study was to compare the performance of full-field digital mammography (FFDM) alone against FFDM plus digital breast tomosynthesis (DBT) in the post-treatment surveillance of asymptomatic patients with a history of breast cancer.

METHODS AND MATERIALS

In this institutional review board (IRB) approved retrospective review study, a comprehensive list of women with a history of breast cancer who underwent screening with either FFDM or FFDM plus DBT at our institution from 5/2017 to 5/2020 was retrieved. A total of 20,211 exams were identified and screening performance metrics were compared.

RESULTS

There was no significant difference in cancer detection rate (CDR) (9.4/1000 vs. 8.2/1000, P=0.38), recall rate (RR) (7.5% vs.

6.9%, P=0.087), or positive predictive value (PPV) (12.5% vs. 11.9%, P=0.74) between FFDM alone vs. FFDM plus DBT. Stratification by breast tissue identified no significant difference in CDR (P=0.581 and P=0.428), RR (P=0.230 and P=0.205), or PPV (P=0.908 and P=0.721) between fatty/scattered and heterogeneous/extremely dense breast tissue when comparing FFDM alone vs. FFDM plus DBT. Stratification by age did not identify a significant difference in RR or PPV between the two groups. However, CDR was significantly increased with FFDM alone vs. FFDM plus DBT in the 60-69 years group (P=0.021). Stratification by race did not identify a significant difference in RR or PPV between the two groups. However, CDR was significantly increased with FFDM plus DBT vs. FFDM alone in white women (P=0.036). Stratification by laterality (bilateral vs. unilateral exams post mastectomy) did not identify a significant difference in RR or PPV between the two groups. However, CDR was significantly increased in FFDM alone vs. FFDM plus DBT in unilateral exams (P=0.009).

CONCLUSION

s In general, the addition of DBT to FFDM does not improve CDR, RR, or PPV for asymptomatic women with a history of breast cancer.

CLINICAL RELEVANCE/APPLICATION

Supplemental screening modalities are needed beyond DBT for patients with a history of breast cancer.

R2-SPBR-3 Mammographic compression and its association with lesion conspicuity for calcification-only lesions

Participants
Melissa L. Hill, PHD, (*Presenter*) Consultant, Volpara Health Technologies Limited

PURPOSE

To investigate associations between modifiable mammographic image factors and conspicuity for lesions detectable by calcification only.

METHODS AND MATERIALS

OPTIMAM database cases were selected among 2343 with raw images and lesion conspicuity scores. Expert readers at two sites where screening was originally performed retrospectively marked regions of interest (ROI) and classified conspicuity for biopsy-proven lesions. After exclusions (bilateral lesions, implants, missing data) and selection of cases with lesions whose only mammographic features were calcifications, 586 cases (37 benign, 547 malignant) were included with obvious (OC; n=349), subtle (SC; n=201), or very subtle (VSC; n=36) conspicuity.Volumetric breast density (VBD), breast volume, compression pressure, contact area, and breast positioning measures were derived using Volpara Imaging Software (v3.4). Other factors were extracted from DICOM metadata (compression force, breast thickness, paddle type). VBD was computed as the mean from contralateral breast views, with all other image parameters from the affected breast MLO view only.Lesion ROI size, image-based lesion features, and histopathological characteristics were collected.Univariate analysis was performed to test non-modifiable parameters for associations with conspicuity. A multinomial logistic regression model was fit to predict lesion conspicuity for calcification-only lesions using Akaike Information Criterion for predictor selection among modifiable image factors and the parameters identified in univariate testing.

RESULTS

After adjusting for confounders, the longest ROI side length, compression pressure and screening site were significantly associated with the risk of SC and VSC vs OC, with odds ratios (OR) and 95% confidence intervals (CI) of 0.96 (0.94-0.97), 0.85 (0.78-0.92) and 0.52 (0.36-0.77), respectively for SC vs OC, and 0.93 (0.90-0.97), 0.81 (0.67-0.97) and 0.21 (0.08-0.53), respectively for VSC vs OC. Compression force was significantly associated with only SC vs OC, with OR and 95% CI of 1.01 (1.00-1.02).

CONCLUSION

s Among modifiable mammographic image factors in the MLO view, multinomial modelling demonstrated compression pressure to be predictive of calcification-only lesion conspicuity, with greater pressure reducing the risk of lower conspicuity. These results suggest that pressure-based compression targets may be effective towards achieving good diagnostic performance.

CLINICAL RELEVANCE/APPLICATION

The conspicuity of lesions visible on mammography by calcification only are associated with mammographic compression pressure. Screening program performance may benefit from ensuring adequate compression pressure.

R2-SPBR-4 Artificial Intelligence (AI) Comparison of Synthetic Mammography (SM) and Full Field Digital Mammography (FFDM) in Malignancy Detection

Participants
Laura Heacock, MD, MS, New York, NY (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the strengths and weaknesses of AI systems trained separately on synthetic mammography (SM) and full field digital mammography (FFDM).

METHODS AND MATERIALS

This was a retrospective, IRB-approved study. We trained two identical AI systems separately on paired FFDM and SM images, respectively, on a dataset of 1,239,272 combination (FFDM + DBT) screening mammography exams consecutively acquired from patients between 2017-2020. These examinations were separated with a 60/10/30 training/validation/test set split. Ground truth was either pathology-proven diagnosis or stability on imaging over time. Additionally, the images were supplemented with radiologist-annotated segmentation labels and classification for these segmentations (malignant/benign, distortion/non-distortion). The model is trained to localize lesions by generating the location of suspicious areas in the exam with bounding boxes. These detections are then used to generate a final score of malignancy for each mammogram. Preset false-positive (FP) rates were chosen for analysis. Location of bounding boxes on false negatives (FN) and high-scoring (high discrepancy between SM and FFDM AI scores) FP exams were reviewed and compared for both SM and FFDM models. Area under the curve (AUC) and chi-squared tests were used for statistical analysis.

RESULTS

The AI system achieved an AUC of 0.933 on SM and 0.909 on FFDM for identifying exams with malignant lesions. At a preset FP rate of 20%, there was a SM FN rate of 0.007% (9/121858) and a FFDM rate of 0.009% (12/121858) On review of bounding boxes, 58.3% (7/12) FN findings on FFDM were detected by the model but did not meet AI score criteria for malignancy. 66.7% (6/9) of SM findings were detected by the model but did not meet AI score criteria (p=0.34). SM FN were more likely to be masses compared to FFDM FN (7/9 vs 0/12; p<0.001); FFDM FN were more likely to be distortion (50%; 6/12) or calcifications (25%; 3/12). There was no significant correlation between FN in either modality and breast density, size, presence/absence of distortion, or presence/absence of calcifications. High-scoring FFDM FP were more likely to be asymmetries or circumscribed masses. High-scoring SM FP were more likely to be pseudo-distortion or pseudo-calcifications on review of corresponding DBT.

CONCLUSION

s AI systems highlight different areas of concern on FFDM and SM images, but demonstrate better performance on SM images.

CLINICAL RELEVANCE/APPLICATION

Most AI systems are trained on FFDM images. Radiologists using AI systems as a second reader should be aware that the strengths and weaknesses of these systems may vary when used on DBT-generated SM views.

R2-SPBR-5 Evaluation of The Impact of Sociodemographic Status on Breast Screening Volumes During The COVID-19 Pandemic In a Provincial, Population-based Organized Breast Screening Program

Participants
Tracee Wee, MD, BSc, Vancouver, BC (*Presenter*) Nothing to Disclose

PURPOSE

We sought to assess the impact of sociodemographic status on breast screening volumes (BSVs) during the COVID-19 pandemic in a large, population-based breast screening program which exclusively serves a provincial population of over 5 million.

METHODS AND MATERIALS

The BC Cancer Breast Screening database, a population-based database, was the primary dataset accessed. All patients who completed breast screening between April 1st, 2017 and March 31st, 2021 were eligible to participate. An average of three annual periods between April 1st, 2017 and March 31st, 2020 was utilized as the pre-COVID period to limit the effect of annual variation while the period between April 1st, 2020 and March 31st, 2021 was utilized as the COVID-impacted period. Residential postal codes were utilized to impute sociodemographic variables. The Postal CodeOM Coversion File Plus was utilized to map residential postal codes to 2016 Census standard geographical areas, which provided information on community size, income quintile and dissemination areas. Dissemination areas were subsequently linked to the Canadian Index of Multiple Deprivation (CIMD), which assigns a level of deprivation for each dissemination area in four dimensions.

RESULTS

Overall BSV was reduced by 23.0% during the COVID-impacted period as compared to the pre-COVID period. Percent reduction in BSV was greatest among younger patients 40 to 49 years of age (-31.3%) and patients residing in communities with a population of less than 10 000 (-27.0%). Percent reduction in BSV was greatest among patients in the lowest income quintile (-28.1%). Percent reduction in BSV was greatest for patients in the most deprived quintiles across all four dimensions of the CIMD: ethnocultural composition (-28.1%), situational vulnerability (-26.7%), economic dependency (-24.5%), and residential instability (-23.7%).

CONCLUSION

s Disproportionate reductions in BSVs were observed among younger patients, patients residing in rural communities, patients in lower income quintiles, and patients in quintiles which were most deprived during the COVID-19 pandemic.

CLINICAL RELEVANCE/APPLICATION

Identification of the exacerbation of underlying inequities in access to breast screening during the COVID-19 pandemic provides the opportunity to improve equitable access to breast screening for vulnerable populations.

R2-SPBR-6 Racial Disparities in Proportion of Patients Returning for Annual Screening Mammograms

Participants
Mina Moussavi, BSc, PhD, (*Presenter*) Employee, RadNet, Inc

PURPOSE

Screening guidelines are increasingly being scrutinized for appropriateness for all racial groups, as evidence suggests that cancer incidence and mortality may differ by race. Any such changes might need to consider adherence to current guidelines among these racial groups to more realistically address cancer disparities. We sought to compare the percentage of patients returning for recommended annual screening by race/ethnicity in a large and diverse population across the USA.

METHODS AND MATERIALS

Screening mammography data was retrospectively collected from 186 clinical sites across the United States from 2017-2021. Screening exams from 1,391,248 patients above the age of 35 years (mean age 58.2+/- 11.0 years) were collected. We reviewed patients with an initial exam prior to June 2019 and a subsequent screening exam 9-30 months later. The interval between initial and subsequent screening mammograms was defined as annual if they were 9-18 months apart and biennial if they were 19-30 months apart. We then analyzed the proportion of returning patients who were screened at the recommended annual cadence broken down by self-reported race and ethnicity. Confidence intervals were calculated using the adjusted Wald method.

RESULTS

White patients (n=396,372) returned annually more often than Black (n=159,823) and Asian (n=81,276) patients at 75.8%, 71.4%, and 71.8%, respectively. The proportion of Hispanic/Latino (n=152,126), Native Hawaiian/Pacific Islander (n=6,066), and American Indian/Alaska Native patients (n=4,332) returning annually was the lowest of all ethnic groups at 69.6%, 69.1%, and 68.3%, respectively.

CONCLUSION

s Black, Asian, and women from other non-White populations return for screening at a meaningfully lower rate than White women. As revisions to guidelines are being considered, these data on real-world adherence to existing guidelines might better inform any changes.

CLINICAL RELEVANCE/APPLICATION

Racial disparities in breast cancer screening adherence continue to persist and should be considered when updating mammography screening guidelines.

R2-SPBR-7 Visibility Trends and Tumor Characteristics of Malignant Architectural Distortion on Synthesized 2D and Tomosynthesis Mammograms: Can We Move Away From Surgery For A Low Risk AD Subset?

Participants
Cedric Pluguez-Turull, MD, Miami, FL (*Presenter*) Consultant, INFOTECHSoft, Inc

PURPOSE

Explore visibility trends of tomography-detected (TOMO) architectural distortion (AD) on synthesized 2D (s2D) mammography (MMG) and digital breast tomosynthesis (DBT) as well as other imaging and clinical parameters that predict pathology.

METHODS AND MATERIALS

Clinical and imaging data was extracted from our EMR and PACS for 1.7 years of biopsied AD with both DBT and s2D at diagnosis yielding 297 cases. A retrospective review of clinical and imaging parameters on MMG, MRI and US was performed. Visibility analysis by consensus read was performed by three breast radiologists documenting AD on one view (CC or ML/MLO), two views or no views for s2D, and one view or two views on DBT. Other clinical and imaging parameters were also analyzed for statistical associations to pathologic outcomes. Tumor size, hormone receptor, Her2 and Ki67 for invasive breast cancer (iBC) were analyzed by consensus visibility.

RESULTS

297 biopsied AD detected by s2d + TOMO, 99 were malignant (33%), 89 were high-risk (30%), and 109 were benign (37%). PPV3 for malignancy was 33%. The most common outcome by sub-group is: IDC (54%) for malignancy, radial scar (88%) for high-risk, and stromal fibrosis (52%) for benign. The presence of an US correlate increases the likelihood of malignancy by 2.4x (PLR) with PPV=88%. A positive MRI increases malignancy likelihood by 4.2x (PLR) with PPV= 83% and the absence decreases the likelihood by 0.04x (NLR) with NPV=96%. Interreader agreement is fair (k=0.4) for tomo AD and fair (k=0.35) for s2D AD. Visibility analysis demonstrates more s2D-occult AD correspond to benign and high-risk subsets compared to s2D visible AD. There is a linear trend (p=0.03) for benign AD manifesting as s2D-occult or one view finding on TOMO. A loose trend of increasing malignant AD findings as s2D+TOMO visibility increases was not significant (p=0.93). The 2D-occult iBC size (median, IQR: 12,15) is smaller compared to 2D-visible iBC (median, IQR: 20,25) (p=0.04). No differences were found for tumor markers and molecular subtype.

CONCLUSION

s Interreader analysis shows there is poor agreement on AD detection for both s2D and TOMO AD. Negative MRI is suitable for downgrading AD to low suspicion for malignancy and perhaps defer biopsy. A higher proportion of benign and high-risk s2D-occult AD explains a decreased PPV for malignancy arising from AD in the DBT era. iBC arising from 2D-occult TOMO AD that were previously undetectable by 2D MMG are similar in tumor biology than their 2D-visible counterparts, but smaller in size.

CLINICAL RELEVANCE/APPLICATION

DBT finds identical, yet smaller, iBC than s2D mammography. Pertinent clinical and imaging factors could sway the breast imager to consider short-term follow-up or pre-biopsy Breast MRI for a particular subset of low-risk AD and patients.

R2-SPBR-1

Assessing the necessity of implant included mammography in women with breast implants.

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Hee Jeong Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the necessity of implant full (IF) views in mammography for women with breast implants.

METHODS AND MATERIALS

Screening and diagnostic augmentation mammography performed in 748 women (mean age ± standard deviation, 46.4 ± 8.9 years) with no prior history of breast cancer from January 2009 to December 2019 were retrospectively identified. Routine mammography included four IF views and four implant displaced (ID) views. Breast cancer detection rate, sensitivity, mean glandular dose per breast, and implant rupture detection rate were evaluated and compared between routine eight views, four IF views and four ID views. Between-group differences were evaluated statistically using the t-test or paired t-test for continuous variables and the chi-square test for categoric variables. Cancer detection rate and sensitivity were compared using McNemar's test. A p-value less than 0.05 was considered statistically significant.

RESULTS

Incidence of breast cancer was 17.6% (132/748) and 15% (20/132) were mammographically occult. Breast cancer detection rate of routine eight views (15%; 95% CI: 12.6%, 17.7%) was higher than that of IF views (8.8%; 95% CI: 7.0%, 11.1%; p<0.0001), while not different from that of ID views (15%; 95% CI: 12.5%, 17.6%; p>0.999). The sensitivity of routine eight views (84.8%; 95% CI: 77.8%, 90.0%) was significantly higher than that of IF views (50%; 95% CI: 41.6%, 58.4%; p<0.0001), while not different from that of ID views (84.8%; 95% CI: 77.8%, 90.0%; p>0.999). Mean glandular dose was 1.05 mGy in routine eight views and 0.99 mGy in ID views (p<0.0001). Implant rupture was found in 2.1%(16/748). Implant rupture detection rate was 81.3% (13/16) in routine eight views and IF views and 12.5% (2/16) in ID views.

CONCLUSION

s Routine eight-view mammography and four ID views showed similar performance for detecting breast cancer and the diagnostic gain of four IF views was low.

CLINICAL RELEVANCE/APPLICATION

Considering the low clinical impact and cumulative radiation, the necessity IF views in mammography need to be reconsidered in women with breast implants.

R2-SPBR-2

Comparing the Performance of Full-Field Digital Mammography (FFDM) and Digital Breast Tomosynthesis (DBT) in the Post-Treatment Surveillance of Patients with a History of Breast Cancer: A Retrospective Study

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Emily Nia, MD, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

Guidelines for imaging follow-up in patients with a history of breast cancer vary among different medical societies. However, all recommend annual screening mammography. The purpose of our study was to compare the performance of full-field digital mammography (FFDM) alone against FFDM plus digital breast tomosynthesis (DBT) in the post-treatment surveillance of asymptomatic patients with a history of breast cancer.

METHODS AND MATERIALS

In this institutional review board (IRB) approved retrospective review study, a comprehensive list of women with a history of breast cancer who underwent screening with either FFDM or FFDM plus DBT at our institution from 5/2017 to 5/2020 was retrieved. A total of 20,211 exams were identified and screening performance metrics were compared.

RESULTS

There was no significant difference in cancer detection rate (CDR) (9.4/1000 vs. 8.2/1000, P=0.38), recall rate (RR) (7.5% vs. 6.9%, P=0.087), or positive predictive value (PPV) (12.5% vs. 11.9%, P=0.74) between FFDM alone vs. FFDM plus DBT. Stratification by breast tissue identified no significant difference in CDR (P=0.581 and P=0.428), RR (P=0.230 and P=0.205), or PPV (P=0.908 and P=0.721) between fatty/scattered and heterogeneous/extremely dense breast tissue when comparing FFDM alone vs. FFDM plus DBT. Stratification by age did not identify a significant difference in RR or PPV between the two groups. However, CDR was significantly increased with FFDM alone vs. FFDM plus DBT in the 60-69 years group (P=0.021). Stratification by race did not identify a significant difference in RR or PPV between the two groups. However, CDR was significantly increased with FFDM plus DBT vs. FFDM alone in white women (P=0.036). Stratification by laterality (bilateral vs. unilateral exams post mastectomy) did not identify a significant difference in RR or PPV between the two groups. However, CDR was significantly increased in FFDM alone vs. FFDM plus DBT in unilateral exams (P=0.009).

CONCLUSION

s In general, the addition of DBT to FFDM does not improve CDR, RR, or PPV for asymptomatic women with a history of breast cancer.

CLINICAL RELEVANCE/APPLICATION

Supplemental screening modalities are needed beyond DBT for patients with a history of breast cancer.

R2-SPBR-3

Mammographic compression and its association with lesion conspicuity for calcification-only lesions

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Melissa L. Hill, PHD, (*Presenter*) Consultant, Volpara Health Technologies Limited

PURPOSE

To investigate associations between modifiable mammographic image factors and conspicuity for lesions detectable by calcification only.

METHODS AND MATERIALS

OPTIMAM database cases were selected among 2343 with raw images and lesion conspicuity scores. Expert readers at two sites where screening was originally performed retrospectively marked regions of interest (ROI) and classified conspicuity for biopsy-proven lesions. After exclusions (bilateral lesions, implants, missing data) and selection of cases with lesions whose only mammographic features were calcifications, 586 cases (37 benign, 547 malignant) were included with obvious (OC; n=349), subtle (SC; n=201), or very subtle (VSC; n=36) conspicuity.Volumetric breast density (VBD), breast volume, compression pressure, contact area, and breast positioning measures were derived using Volpara Imaging Software (v3.4). Other factors were extracted from DICOM metadata (compression force, breast thickness, paddle type). VBD was computed as the mean from contralateral breast views, with all other image parameters from the affected breast MLO view only.Lesion ROI size, image-based lesion features, and histopathological characteristics were collected.Univariate analysis was performed to test non-modifiable parameters for associations with conspicuity. A multinomial logistic regression model was fit to predict lesion conspicuity for calcification-only lesions using Akaike Information Criterion for predictor selection among modifiable image factors and the parameters identified in univariate testing.

RESULTS

After adjusting for confounders, the longest ROI side length, compression pressure and screening site were significantly associated with the risk of SC and VSC vs OC, with odds ratios (OR) and 95% confidence intervals (CI) of 0.96 (0.94-0.97), 0.85 (0.78-0.92) and 0.52 (0.36-0.77), respectively for SC vs OC, and 0.93 (0.90-0.97), 0.81 (0.67-0.97) and 0.21 (0.08-0.53), respectively for VSC vs OC. Compression force was significantly associated with only SC vs OC, with OR and 95% CI of 1.01 (1.00-1.02).

CONCLUSION

s Among modifiable mammographic image factors in the MLO view, multinomial modelling demonstrated compression pressure to be predictive of calcification-only lesion conspicuity, with greater pressure reducing the risk of lower conspicuity. These results suggest that pressure-based compression targets may be effective towards achieving good diagnostic performance.

CLINICAL RELEVANCE/APPLICATION

The conspicuity of lesions visible on mammography by calcification only are associated with mammographic compression pressure. Screening program performance may benefit from ensuring adequate compression pressure.

R2-SPBR-4

Artificial Intelligence (AI) Comparison of Synthetic Mammography (SM) and Full Field Digital Mammography (FFDM) in Malignancy Detection

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Laura Heacock, MD, MS, New York, NY (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the strengths and weaknesses of AI systems trained separately on synthetic mammography (SM) and full field digital mammography (FFDM).

METHODS AND MATERIALS

This was a retrospective, IRB-approved study. We trained two identical AI systems separately on paired FFDM and SM images, respectively, on a dataset of 1,239,272 combination (FFDM + DBT) screening mammography exams consecutively acquired from patients between 2017-2020. These examinations were separated with a 60/10/30 training/validation/test set split. Ground truth was either pathology-proven diagnosis or stability on imaging over time. Additionally, the images were supplemented with radiologist-annotated segmentation labels and classification for these segmentations (malignant/benign, distortion/non-distortion). The model is trained to localize lesions by generating the location of suspicious areas in the exam with bounding boxes. These detections are then used to generate a final score of malignancy for each mammogram. Preset false-positive (FP) rates were chosen for analysis. Location of bounding boxes on false negatives (FN) and high-scoring (high discrepancy between SM and FFDM AI scores) FP exams were reviewed and compared for both SM and FFDM models. Area under the curve (AUC) and chi-squared tests were used for statistical analysis.

RESULTS

The AI system achieved an AUC of 0.933 on SM and 0.909 on FFDM for identifying exams with malignant lesions. At a preset FP rate of 20%, there was a SM FN rate of 0.007% (9/121858) and a FFDM rate of 0.009% (12/121858) On review of bounding boxes, 58.3% (7/12) FN findings on FFDM were detected by the model but did not meet AI score criteria for malignancy. 66.7% (6/9) of SM findings were detected by the model but did not meet AI score criteria (p=0.34). SM FN were more likely to be masses compared to FFDM FN (7/9 vs 0/12; p<0.001); FFDM FN were more likely to be distortion (50%; 6/12) or calcifications (25%; 3/12). There was no significant correlation between FN in either modality and breast density, size, presence/absence of distortion, or presence/absence of calcifications. High-scoring FFDM FP were more likely to be asymmetries or circumscribed masses. High-scoring SM FP were more likely to be pseudo-distortion or pseudo-calcifications on review of corresponding DBT.

CONCLUSION

s AI systems highlight different areas of concern on FFDM and SM images, but demonstrate better performance on SM images.

CLINICAL RELEVANCE/APPLICATION

Most AI systems are trained on FFDM images. Radiologists using AI systems as a second reader should be aware that the strengths and weaknesses of these systems may vary when used on DBT-generated SM views.

R2-SPBR-5

Evaluation of The Impact of Sociodemographic Status on Breast Screening Volumes During The COVID-19 Pandemic In a Provincial, Population-based Organized Breast Screening Program

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Tracee Wee, MD, BSc, Vancouver, BC (*Presenter*) Nothing to Disclose

PURPOSE

We sought to assess the impact of sociodemographic status on breast screening volumes (BSVs) during the COVID-19 pandemic in a large, population-based breast screening program which exclusively serves a provincial population of over 5 million.

METHODS AND MATERIALS

The BC Cancer Breast Screening database, a population-based database, was the primary dataset accessed. All patients who completed breast screening between April 1st, 2017 and March 31st, 2021 were eligible to participate. An average of three annual periods between April 1st, 2017 and March 31st, 2020 was utilized as the pre-COVID period to limit the effect of annual variation while the period between April 1st, 2020 and March 31st, 2021 was utilized as the COVID-impacted period. Residential postal codes were utilized to impute sociodemographic variables. The Postal CodeOM Coversion File Plus was utilized to map residential postal codes to 2016 Census standard geographical areas, which provided information on community size, income quintile and dissemination areas. Dissemination areas were subsequently linked to the Canadian Index of Multiple Deprivation (CIMD), which assigns a level of deprivation for each dissemination area in four dimensions.

RESULTS

Overall BSV was reduced by 23.0% during the COVID-impacted period as compared to the pre-COVID period. Percent reduction in BSV was greatest among younger patients 40 to 49 years of age (-31.3%) and patients residing in communities with a population of less than 10 000 (-27.0%). Percent reduction in BSV was greatest among patients in the lowest income quintile (-28.1%). Percent reduction in BSV was greatest for patients in the most deprived quintiles across all four dimensions of the CIMD: ethnocultural composition (-28.1%), situational vulnerability (-26.7%), economic dependency (-24.5%), and residential instability (-23.7%).

CONCLUSION

s Disproportionate reductions in BSVs were observed among younger patients, patients residing in rural communities, patients in lower income quintiles, and patients in quintiles which were most deprived during the COVID-19 pandemic.

CLINICAL RELEVANCE/APPLICATION

Identification of the exacerbation of underlying inequities in access to breast screening during the COVID-19 pandemic provides the opportunity to improve equitable access to breast screening for vulnerable populations.

R2-SPBR-6

Racial Disparities in Proportion of Patients Returning for Annual Screening Mammograms

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Mina Moussavi, BSc, PhD, (*Presenter*) Employee, RadNet, Inc

PURPOSE

Screening guidelines are increasingly being scrutinized for appropriateness for all racial groups, as evidence suggests that cancer incidence and mortality may differ by race. Any such changes might need to consider adherence to current guidelines among these racial groups to more realistically address cancer disparities. We sought to compare the percentage of patients returning for recommended annual screening by race/ethnicity in a large and diverse population across the USA.

METHODS AND MATERIALS

Screening mammography data was retrospectively collected from 186 clinical sites across the United States from 2017-2021. Screening exams from 1,391,248 patients above the age of 35 years (mean age 58.2+/- 11.0 years) were collected. We reviewed patients with an initial exam prior to June 2019 and a subsequent screening exam 9-30 months later. The interval between initial and subsequent screening mammograms was defined as annual if they were 9-18 months apart and biennial if they were 19-30 months apart. We then analyzed the proportion of returning patients who were screened at the recommended annual cadence broken down by self-reported race and ethnicity. Confidence intervals were calculated using the adjusted Wald method.

RESULTS

White patients (n=396,372) returned annually more often than Black (n=159,823) and Asian (n=81,276) patients at 75.8%, 71.4%, and 71.8%, respectively. The proportion of Hispanic/Latino (n=152,126), Native Hawaiian/Pacific Islander (n=6,066), and American Indian/Alaska Native patients (n=4,332) returning annually was the lowest of all ethnic groups at 69.6%, 69.1%, and 68.3%, respectively.

CONCLUSION

s Black, Asian, and women from other non-White populations return for screening at a meaningfully lower rate than White women. As revisions to guidelines are being considered, these data on real-world adherence to existing guidelines might better inform any changes.

CLINICAL RELEVANCE/APPLICATION

Racial disparities in breast cancer screening adherence continue to persist and should be considered when updating mammography screening guidelines.

R2-SPBR-7

Visibility Trends and Tumor Characteristics of Malignant Architectural Distortion on Synthesized 2D and Tomosynthesis Mammograms: Can We Move Away From Surgery For A Low Risk AD Subset?

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - BR DPS

Participants
Cedric Pluguez-Turull, MD, Miami, FL (*Presenter*) Consultant, INFOTECHSoft, Inc

PURPOSE

Explore visibility trends of tomography-detected (TOMO) architectural distortion (AD) on synthesized 2D (s2D) mammography (MMG) and digital breast tomosynthesis (DBT) as well as other imaging and clinical parameters that predict pathology.

METHODS AND MATERIALS

Clinical and imaging data was extracted from our EMR and PACS for 1.7 years of biopsied AD with both DBT and s2D at diagnosis yielding 297 cases. A retrospective review of clinical and imaging parameters on MMG, MRI and US was performed. Visibility analysis by consensus read was performed by three breast radiologists documenting AD on one view (CC or ML/MLO), two views or no views for s2D, and one view or two views on DBT. Other clinical and imaging parameters were also analyzed for statistical associations to pathologic outcomes. Tumor size, hormone receptor, Her2 and Ki67 for invasive breast cancer (iBC) were analyzed by consensus visibility.

RESULTS

297 biopsied AD detected by s2d + TOMO, 99 were malignant (33%), 89 were high-risk (30%), and 109 were benign (37%). PPV3 for malignancy was 33%. The most common outcome by sub-group is: IDC (54%) for malignancy, radial scar (88%) for high-risk, and stromal fibrosis (52%) for benign. The presence of an US correlate increases the likelihood of malignancy by 2.4x (PLR) with PPV=88%. A positive MRI increases malignancy likelihood by 4.2x (PLR) with PPV= 83% and the absence decreases the likelihood by 0.04x (NLR) with NPV=96%. Interreader agreement is fair (k=0.4) for tomo AD and fair (k=0.35) for s2D AD. Visibility analysis demonstrates more s2D-occult AD correspond to benign and high-risk subsets compared to s2D visible AD. There is a linear trend (p=0.03) for benign AD manifesting as s2D-occult or one view finding on TOMO. A loose trend of increasing malignant AD findings as s2D+TOMO visibility increases was not significant (p=0.93). The 2D-occult iBC size (median, IQR: 12,15) is smaller compared to 2D-visible iBC (median, IQR: 20,25) (p=0.04). No differences were found for tumor markers and molecular subtype.

CONCLUSION

s Interreader analysis shows there is poor agreement on AD detection for both s2D and TOMO AD. Negative MRI is suitable for downgrading AD to low suspicion for malignancy and perhaps defer biopsy. A higher proportion of benign and high-risk s2D-occult AD explains a decreased PPV for malignancy arising from AD in the DBT era. iBC arising from 2D-occult TOMO AD that were previously undetectable by 2D MMG are similar in tumor biology than their 2D-visible counterparts, but smaller in size.

CLINICAL RELEVANCE/APPLICATION

DBT finds identical, yet smaller, iBC than s2D mammography. Pertinent clinical and imaging factors could sway the breast imager to consider short-term follow-up or pre-biopsy Breast MRI for a particular subset of low-risk AD and patients.

R2-SPCA

Cardiac Thursday Poster Discussions

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - CA DPS

Sub-Events

R2-SPCA-1 Comparison Study of Myocardial Radiomics Feature Properties on Energy-Integrating and Photon-Counting Detector CT

Participants
Matthias Froelich, MD, Mannheim, Germany (*Presenter*) Consultant, Smart Reporting GmbH;Consultant, Guerbet SA

PURPOSE

The implementation of radiomics-based, quantitative imaging parameters is hampered by lack of stability and standardization. Photon-Counting computed tomography (PCCT), compared to Energy-Integrating computed tomography (EICT), does rely on an entirely novel detector technology and promises better spatial resolution, lower beam hardening artefacts and better contrast-to-noise ratio. However, its effect on radiomics feature properties is yet unknown. This work investigates this topic in myocardial imaging.

METHODS AND MATERIALS

In this retrospective, single-center IRB-approved study, the left ventricular myocardium was segmented on short axis reconstructions of CT and radiomics features were extracted using pyradiomics. To compare features between scanners, t-test for non-paired samples and F-test was performed with a threshold of 0.05 set as a benchmark for significance. Feature correlations were calculated by Pearson correlation coefficient. Visualization was performed with unclustered and clustered heatmaps.

RESULTS

A total of 50 patients (56 % male, 44 % female, mean age 56) were enrolled in this study with equal proportions on PCCT and EICT. First-order features were nearly totally comparable between both groups. However, higher-order features showed a partially significant difference between PCCT and EICT.

CONCLUSION

s While first-order radiomics features of left ventricular myocardium show comparability between PCCT and EICT, detected differences of higher-order features may indicate a possible impact of improved spatial resolution, better detection of lower-energy photons, and better signal-to-noise ratio on texture analysis on PCCT.

CLINICAL RELEVANCE/APPLICATION

The implementation of photon-counting detector CT may novel cardiac CT imaging by lower beam-hardening artefacts, better spatial resolution und contrast-to-noise ratio and paves the way for radiomics analysis of left ventricular myocardium in CT imaging.

R2-SPCA-2 Multicenter Consistency Assessment of Rapid CMR Strain Quantification

Participants
Moritz Halfmann, MD, Mainz, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Strain parameters have been under scrutiny for their reproducibility and generalizability, partly due to the black-box model used for the calculation. This multicenter study evaluated the interobserver agreement of a simplified rapid-strain algorithm depending solely on longitudinal ventricular shortening in a real-world setting.

METHODS AND MATERIALS

A total of 4 sites each retrospectively identified 20 patients with various cardiomyopathies and 20 healthy controls who had undergone cardiac MRI at their respective centers using locally available scanners from 2 manufacturers with both 1.5 and 3T field strengths and local imaging protocols. First, conventional and rapid longitudinal strains were evaluated at each site and then independently re-evaluated by a core lab. The core lab did not contribute data in order to reduce potential bias towards their own data. Intraclass correlation coefficients (ICC) and Bland-Altmann plots were used to assess interobserver agreement. Pearson's correlation was used to evaluate agreement with conventional strain.

RESULTS

ICCs demonstrated excellent agreement between sites for left ventricular rapid strains (ICC =0.95 for all sites). Bland-Altmann plots showed no significant bias between site and core lab readings and limits of agreement (LoA) were well within clinically acceptable margins (Mean difference: -0.06%, 95% CI: -3.8 to 3.7%). In addition, there was a strong-to-excellent correlation between conventional and rapid ventricular longitudinal strain measurements (r= 0.89). Regression analyses showed that neither field strengths nor scanner vendors were significant confounders for the simplified ventricular strain algorithm.

CONCLUSION

s Independently of scanner manufacturers, field strengths, and local imaging protocols, the simplified rapid ventricular strain algorithm could reliably assess left ventricular strain longitudinal strain.

CLINICAL RELEVANCE/APPLICATION

Advanced post-processing imaging biomarkers such as strain need careful reproducibility-assessment in real-world scenarios using different scanners, field strengths and local imaging protocols.

R2-SPCA-3 Missed Patent Foramen Ovale Using Coronary CT Angiography in Patients with Cardiac Symptoms

Participants
Hui Zhou, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to determine the proportion of patent foramen ovale (PFO) in patients with cardiac symptoms who received coronary CT angiography (CCTA) imaging and to examine whether PFO were missed using CCTA.

METHODS AND MATERIALS

This population-based retrospective cohort study assessed patients with cardiac symptoms who received CCTA imaging in a large-scale comprehensive university hospital, July 2018 to May 2020. CT findings of PFO were defined as follows: (a) distinct left atrial flap in expected location of septum primum, (b) channel-like appearance of the interatrial septum (IAS) and (c) a contrast agent jet from left atrium (LA) to right atrium (RA). The CCTA images and the initial radiology reports were retrospectively reinterpreted by two subspecialty cardiovascular radiologists with more than 5 years' experience. The morphological quantitative features and potential causes for missed diagnosis of PFO were recorded.

RESULTS

Among 5715 qualifying patients, 455(8.0%)met all three CT criteria of PFO. None of the 455 patients were diagnosed with PFO in the initial CCTA report. In 288 patients who underwent both echocardiography and CCTA, only 11 (3.8%) cases were diagnosed with PFO by echocardiography. The lengths of channel-like appearance of IAS, distinct left atrial flap, and the contrast agent jet from LA to RA were 8.54±3.27 mm, 12.59±3.80 mm, and 10.62±4.00 mm, respectively. The width of the LA opening, middle and RA openings of channel-like appearance of IAS were 1.77±0.65 mm, 1.98±0.74 mm, 1.73±0.63 mm, respectively. Atrial septal aneurysm (ASA) accompanying PFO were present in 5 patients (1.1%). Neurological symptoms of migraine or syncope were observed in 16 (3.5%) patients, and cerebral infarction were detected by brain MRI in 7 (1.5%) patients.

CONCLUSION

s There were a large number of missed PFO in CCTA which could be avoided. Increased recognition of the manifestations of PFO and concomitant ASA in CCTA are recommended to minimize missed diagnosis of PFO.

CLINICAL RELEVANCE/APPLICATION

PFO diagnosed by CCTA are frequently missed, which appeared to be due to a lack of recognition of the CT criteria for the diagnosis of PFO. Increased education among radiologists and clinicians regarding these imaging pitfalls should be encouraged.

ICCs demonstrated excellent agreement between sites for left ventricular rapid strains (ICC =0.95 for all sites). Bland-Altmann plots showed no significant bias between site and core lab readings and limits of agreement (LoA) were well within clinically acceptable margins (Mean difference: -0.06%, 95% CI: -3.8 to 3.7%). In addition, there was a strong-to-excellent correlation between conventional and rapid ventricular longitudinal strain measurements (r= 0.89). Regression analyses showed that neither field strengths nor scanner vendors were significant confounders for the simplified ventricular strain algorithm.

CONCLUSION

s Independently of scanner manufacturers, field strengths, and local imaging protocols, the simplified rapid ventricular strain algorithm could reliably assess left ventricular strain longitudinal strain.

CLINICAL RELEVANCE/APPLICATION

Advanced post-processing imaging biomarkers such as strain need careful reproducibility-assessment in real-world scenarios using different scanners, field strengths and local imaging protocols.

R2-SPCA-3

Missed Patent Foramen Ovale Using Coronary CT Angiography in Patients with Cardiac Symptoms

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - CA DPS

Participants
Hui Zhou, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to determine the proportion of patent foramen ovale (PFO) in patients with cardiac symptoms who received coronary CT angiography (CCTA) imaging and to examine whether PFO were missed using CCTA.

METHODS AND MATERIALS

This population-based retrospective cohort study assessed patients with cardiac symptoms who received CCTA imaging in a large-scale comprehensive university hospital, July 2018 to May 2020. CT findings of PFO were defined as follows: (a) distinct left atrial flap in expected location of septum primum, (b) channel-like appearance of the interatrial septum (IAS) and (c) a contrast agent jet from left atrium (LA) to right atrium (RA). The CCTA images and the initial radiology reports were retrospectively reinterpreted by two subspecialty cardiovascular radiologists with more than 5 years' experience. The morphological quantitative features and potential causes for missed diagnosis of PFO were recorded.

RESULTS

Among 5715 qualifying patients, 455(8.0%)met all three CT criteria of PFO. None of the 455 patients were diagnosed with PFO in the initial CCTA report. In 288 patients who underwent both echocardiography and CCTA, only 11 (3.8%) cases were diagnosed with PFO by echocardiography. The lengths of channel-like appearance of IAS, distinct left atrial flap, and the contrast agent jet from LA to RA were 8.54±3.27 mm, 12.59±3.80 mm, and 10.62±4.00 mm, respectively. The width of the LA opening, middle and RA openings of channel-like appearance of IAS were 1.77±0.65 mm, 1.98±0.74 mm, 1.73±0.63 mm, respectively. Atrial septal aneurysm (ASA) accompanying PFO were present in 5 patients (1.1%). Neurological symptoms of migraine or syncope were observed in 16 (3.5%) patients, and cerebral infarction were detected by brain MRI in 7 (1.5%) patients.

CONCLUSION

s There were a large number of missed PFO in CCTA which could be avoided. Increased recognition of the manifestations of PFO and concomitant ASA in CCTA are recommended to minimize missed diagnosis of PFO.

CLINICAL RELEVANCE/APPLICATION

PFO diagnosed by CCTA are frequently missed, which appeared to be due to a lack of recognition of the CT criteria for the diagnosis of PFO. Increased education among radiologists and clinicians regarding these imaging pitfalls should be encouraged.

R2-SPCH-1 Automatic Detection of Enlarged Chest Lymph Nodes in Contrast Non-Contrast Chest CT: An External Evaluation

Participants
Dazhou Guo, Columbia, SC (*Presenter*) Nothing to Disclose

PURPOSE

Accurate determination of lymph node (LN) status directly affects the treatment strategy and prognosis of patients with different diseases. We developed a deep learning system to detect enlarged chest LNs in CT. In this study, we evaluate its generalizability on external data of diverse sources.

METHODS AND MATERIALS

Our algorithm is a two-stage detector (Fig. a). We trained it on two private datasets and a public dataset with 262 patients and 4338 annotated LNs in total. Mediastinal, hilar, and supraclavicular LNs were annotated on contrast-enhanced (CE) CTs, and non-contrast (NC) training data are added by registering the NC CT to its CE counterpart. To improve robustness, we added intensive data augmentation in training. We selected test data from 4 external cohorts: 100 random in-house CTs without filtering patients' diseases, 40 esophageal cancer patients, 35 lung cancer patients from TCIA public data, and 12 COVID patients from TCIA. One radiologist (more than 10 years of experience in thoracic imaging) read the CT scans and verified the detection results with a short axial diameter of at least 5 mm. Detections are classified into LN requiring follow-up, LN not requiring follow-up (e.g. LNs with necrosis, calcification, and short diameter less than 1cm), and non-LN. LNs not detected were manually added.

RESULTS

A total of 1733 LNs were labeled on 187 images. At 2 FPs per patient, our algorithm achieves lesion-level detection sensitivity (Sens) of 93.1%, 82.7%, 82.9%, and 73.1% for the in-house, esophageal, lung, and COVID cohorts, respectively, (Fig. b). The accuracy is better in in-house but worse in COVID cohort, probably because fewer patients have severe diseases in the in-house cohort, while the COVID CTs have more pathological changes (e.g. mediastinitis) which interfered with the algorithm. The model performs similarly on CE vs. NC CT (Sens=84.7% vs. 87.5%@2FP, Fig. c), meanwhile more accurately in CTs with thick than with thin slices (Sens=96.4% vs. 87.2%@2FP, Fig. d). LNs annotated in thick-slice CTs are fewer and in average larger thus easier to detect, which partially explains its higher accuracy. Our algorithm works well at LNs in the aortic and subcarinal regions. Clusters of LNs can also be detected. FPs come from cervical/mediastinal vessels (39.3%), partial volume effects in mediastinum and bronchial wall at the bifurcation (16.3% and 16.0%), esophagus or esophageal tumors (11.2%), etc.

CONCLUSION

s The algorithm shows good accuracy and generalizability. It has room to improve on images with severe pathological changes.

CLINICAL RELEVANCE/APPLICATION

Our algorithm can be widely applied in chest CT examination (e.g. tumor and COVID patients) to help radiologists with the challenging LN detection task, reducing their workload and missing rate.

R2-SPCH-2 CT Features of Interstitial Lung Disease Associated with Systemic Lupus Erythematosus

Participants
Marie-Pierre Debray, MD, Paris, France (*Presenter*) Speaker, Boehringer Ingelheim GmbH

PURPOSE

To describe the initial and follow-up CT features of interstitial lung disease associated with systemic lupus erythematosus (SLE-ILD)

METHODS AND MATERIALS

Multicentric retrospective study of SLE-ILD extending from 2005 to 2021, including 67 patients (24 patients without and 43 patients with another connective tissue disease (CTD) associated with SLE, mainly Sjögren syndrome, n=25, and systemic sclerosis, n=12). The chest CT performed closest to the time of SLE-ILD diagnosis was analyzed by one thoracic radiologist specialized in ILD, for the pattern and extent of ILD. Evolution of CT signs of fibrosis (increase or decrease in extent, change in texture or lung volume) and overall disease extent was analyzed on the latest available chest CT in 45 patients (median follow-up 78 months, IQR [51; 130]).

RESULTS

Significant ground-glass opacities, reticulations, traction bronchiectasis, honeycombing and cysts were observed in 41/67 (61%), 54/67 (81%), 39/67 (58%), 28/67 (42%) and 28/67 (42%) patients, respectively. Lesions showed a basal and subpleural predominant distribution in 55/67 (82%) and 36/67 (54%) patients. Chest CT was most often classified as indeterminate, in 18/67 (27%), or evocative of non specific interstitial pneumonia, in 28/67 (42%) patients with organizing pneumonia features in 7 of the latter. The pattern was typical of usual interstitial pneumonia in 10/67 (15%) patients, among those 7 patients showed exuberant honeycombing. There was no significant difference in CT pattern distribution between patients without and patients with another associated CTD. The latest available chest CT showed an increase of CT signs of fibrosis, in 29/45 (64%) patients, whereas lesions appeared unchanged or decreased in 13/67 (19%) patients.

CONCLUSION

s SLE-ILD most often shows an indeterminate or a non specific interstitial pneumonia pattern. After a median follow-up of 78 months, two thirds of patients have an increase of CT signs of fibrosis.

CLINICAL RELEVANCE/APPLICATION

ILD is a rare manifestation of SLE, frequently showing progressive signs of fibrosis. In this series, no distinctive CT features were observed between isolated SLE and other CTD associated SLE.

R2-SPCH-3 Application of CT Lymphangiography in Diagnosing Chest Complex Lymphatic Anomaly

Participants
Yan Zhang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the clinical value of CT lymphangiography (CTL) in diagnosing chest complex lymphatic anomaly.

METHODS AND MATERIALS

59 patients diagnosed as chest complex lymphatic anomaly (CLA) clinically were analyzed retrospectively. All patients underwent CTL. All patients underwent CTL (Somatom Sensation Cardiac 16, Siemens Healthcare or Brilliance iCT, Philips Medical Healthcare, Best, the Netherlands). All CTL and chest CT images were double-blind reviewed by two radiologists with 15 years of experience. The contrast agent(lipiodol) reflux and abnormal deposition of lymphatic vessels in the chest were observed. After the contrast agent (lipiodol) has been injected into the superficial lymphatic vessels of the unilateral foot, the lipiodol follows the lymphatic fluid up the lumbar trunk and converges into the cisterna chyli, then into the thoracic duct, and finally into the blood at the angle of the left jugular vein. During this process, it is considered abnormal distribution if lipiodol deposits in any other part of the body, such as the diaphragm, peritracheal region, pericardium, pleura, and hilum. Such deposits represent the presence of dilated lymphatic vessels hyperplasia, reflux, or fistula.

RESULTS

CTL showed contrast agent abnormally deposited in all 59 patients: the end of thoracic duct was seen in 42 cases (71.2%), the end of right lymphatic duct in 13 cases (22.0%), mediastinum in 34 cases (57.6%), hilar in 19 cases (32.2%), pleura in 18 cases (30.5%), lung in 10 cases (16.9%), above the diaphragm in 4 cases (6.8%). Abnormal CT changes including: the thickening of bronchovascular bundle in 21 cases (35.6%), the thickening of interlobular septum in 15 cases (25.4%), ground glass opacity in 30 cases (50.8%), atelectasis in 17 cases (28.8%), consolidation in 1 case (1.7%), the crazy-paving sign in 3 cases (5.1%), cystic low-density foci in mediastinum in 44 cases (74.6%), pleural effusion in 36 cases (61.0%), pericardial effusion in 14 cases (23.7%), above the diaphragm in 4 cases (6.8%).

CONCLUSION

s CT L can show lymphatic abnormalities of chest CLA and other chest CT abnormalities. This method provides an important imaging basis for the diagnosis and differentiation of the disease.

CLINICAL RELEVANCE/APPLICATION

CT L can show lymphatic abnormalities of chest CLA and other chest CT abnormalities. This method provides an important imaging basis for the diagnosis and differentiation of the disease.

R2-SPCH-5 Topology-aware Aortic Lumen and Wall Segmentation on Computed Tomography Scans

Participants
Prateek Prasanna, PhD, Stony Brook, NY (*Presenter*) Nothing to Disclose

PURPOSE

Accurate assessment of the aorta via imaging is important for downstream morphological assessment tasks. The wall is often very thin in aneurysmal portions of the aorta and cannot be accurately segmented by current deep learning (DL) models. The simultaneous segmentation of the lumen and the wall is a multi-class semantic segmentation problem involving a topological constraint driven by organ anatomy, i.e., the wall completely separates the lumen from the background. DL methods have achieved impressive performances, but are limited in their ability to encode topological interactions/constraints among different classes; here the topological constraint is that the aortic lumen is always enclosed by the wall. To address this we propose a novel method to encode such interactions, w.r.t fine-scale aortic anatomy, into deep neural networks (DNNs). The efficacy of our method is validated on a proprietary aorta dataset.

METHODS AND MATERIALS

28 CT scans were obtained from an institutional database of patients with thoracic and-or abdominal aortic aneurysm. Inclusion criteria for patients included known aneurysmal disease of the aorta and history of undergoing contrast-enhanced CT with arterial-phase contrast injection. Ground truth lumen and wall annotations were obtained by 4 expert readers working in consensus. We developed a novel method to learn the topological interactions for multi-class segmentation DNNs. Key observation is that lumen and background voxels can never be adjacent. Our method has two stages - a convolution-based method which generates a critical voxels map, followed by a custom loss function. Fig 1b gives an overview of the proposed DL framework.

RESULTS

Our proposed method improves segmentation results both qualitatively (Fig 1a) and quantitatively (Fig 1c). It fixes the interaction errors by forcing the lumen to always be enclosed by the wall. We see in Fig 1a that we are able to reconstruct broken lumen and wall structures, and also improve quantitative measures for both. The measures used are Dice, Hausdorff distance (HD), Avg. Symmetric Surface Distance (ASSD) and a proposed metric called percentage-violations which is the number of voxels violating the constraint as a fraction of the total number of foreground voxels.

CONCLUSION

s We propose a new method for multi-class segmentation that focuses on topological interactions. By incorporating our method into the training of DNNs, we enforce them to learn better feature representations, resulting in improved segmentation quality.

CLINICAL RELEVANCE/APPLICATION

Accurate aorta segmentation is crucial to downstream analysis tasks such as measurement of diameter and tortuosity, and assessment of aneurysms. Our method can improve aorta segmentation quality in both 2D and 3D settings.

R2-SPCH-6 Development and Validation of Deep Learning-based Computer-aided Detection System for Pulmonary Embolism on Chest Computed Tomography

Participants
YeRa Choi, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a deep learning-based computer-aided detection system (DL-CAD) to detect pulmonary embolism (PE) on chest computed tomography (CT) images.

METHODS AND MATERIALS

For the development of CAD, CT pulmonary angiographies (CTPAs) of patients with PE were retrospectively collected from two institutions. Two thoracic radiologists made voxel-wise annotations for areas of PE on each transverse CT image. The DL-CAD consisted of three elements based on convolutional neural networks (CNNs): 1) segmentation of pulmonary arteries for extraction of regions of interest, 2) detection of candidate lesions for PE, and 3) reduction of false-positive detections. For the evaluation of DL-CAD, a separate test dataset was built, comprising CT images from the same institutions without overlap in patients with the developmental dataset. The CT images for test dataset were conveniently collected to exhibit 1:1 ratio between 1) CTs with and without PE, 2) CTPAs and general contrast-enhanced chest CT (CECT)s, and 3) CT with thin-slice (<1.5 mm slice thickness) and thick-slice images. The performance of DL CAD was evaluated with examination-level sensitivity, specificity, PPV (positive predictive value), and NPV (negative predictive value) for discrimination of CTs with and without PE.

RESULTS

A total of 370 CTPA examinations with PE were used for the development of DL-CAD. The test dataset included 320 CT examinations (160 with PE; 160 CTPAs and 160 general CECTs; 160 with thin-slice images). The DL-CAD exhibited sensitivity, specificity, PPV, and NPV of 88.8%, 85.0%, 85.5%, and 88.3%, respectively for identification of CT examinations with PE. The DL-CAD exhibited slightly higher sensitivity in CTPAs compared to general CECT (92.5% vs. 85.0%; P=.133) at the same specificity (85.0%). Meanwhile, the DL-CAD exhibited significantly higher sensitivity in CTs with thin-slice images (97.5% vs. 80.0%; P<.001) and lower specificity (77.5% vs. 92.5%; P=.008) compared to CTs with thick-slice images.

CONCLUSION

s The DL-CAD could successfully identify PE not only in CTPA images but also in general CECT images.

CLINICAL RELEVANCE/APPLICATION

Automated detection of PE on chest CTs can improve the quality and efficiency of interpretation and help timely treatment for patients.

R2-SPCH-7 Accuracy of Airway Thickness Measurements in Low-dose High-resolution photon-counting-detector CT

Participants
Chelsea Dunning, DPHIL, Rochester, MN (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the accuracy of bronchial airway thickness in low-dose chest CT using a clinical photon-counting-detector (PCD) CT compared to conventional energy-integrating-detector (EID) CT.

METHODS AND MATERIALS

Twelve 3D-printed acrylic tubes of assorted wall thicknesses (0.33 - 1.6 mm) and inner diameters (0.42 - 3.4 mm) were placed throughout an anthropomorphic chest phantom (Lungman, Kyoto Kagaku). The phantom was scanned on a whole-body PCD-CT (NAEOTOM Alpha, Siemens) at 100 kV with an additional tin filter (Sn100) in single-source ultra-high-resolution mode (detector configuration: 120 x 0.2 mm) at three dose levels (volume CT dose index (CTDIvol): 0.2, 0.4, and 0.8 mGy). The phantom was also scanned on a conventional EID-CT scanner (SOMATOM Force, Siemens) using Sn100 kV in single-source mode (detector configuration: 96 x 0.6 mm). A reference high-dose scan was also acquired at 120 kV and 12 mGy for both scanners. All images were reconstructed with quantitative kernels and iterative reconstruction with a strength setting of 3; Qr54-3 for standard resolution (SR) EID-CT, Qr56-3 for SR PCD-CT , and Qr89-3 for ultra-high-resolution (UHR) PCD-CT. The image noise was measured as the standard deviation in a region of interest within the mediastinum. The wall thickness of each tube was measured by taking the radial profile in multiple slices and measuring the average full width at half maximum (FWHM). The airway thickness accuracy was expressed using linear regression (R^2 and RMSE) between the measured wall thickness at each dose level.

RESULTS

At matched spatial resolution (Qr54 for EID-CT and Qr56 for PCD-CT), PCD-CT reduced image noise by 53%, 57%, and 56% at 0.2 mGy, 0.4 mGy, and 0.8 mGy dose levels compared to EID-CT. At 0.2 mGy, 0.4 mGy, and 0.8 mGy, the wall thickness RMSE values

were 0.37, 0.36, and 0.57 mm for EID-CT ; 0.49, 0.46, and 0.47 mm for SR PCD-CT; and 0.18, 0.15, and 0.11 mm for UHR PCD-CT. The UHR PCD-CT had the closest R^2 values to unity across all dose levels ($R^2 > 0.963$), compared to EID-CT ($R^2 > 0.816$) and SR PCD-CT ($R^2 > 0.823$).

CONCLUSION

s More accurate airway wall thickness measurements can be achieved for UHR PCD-CT compared to EID-CT or SR PCD-CT at radiation dose levels at or lower than in lung cancer screening exams.

CLINICAL RELEVANCE/APPLICATION

High accuracy measurements of bronchial airway wall thickness in high-resolution low-dose PCD-CT can enable reliable diagnosis of lung diseases such as COPD or cystic fibrosis.

R2-SPCH-8 Value-added Opportunistic Screening: Prediction Model of Arterial Stiffness Based on Clinical and Thoracic Aorta Imaging Risk Factors

Participants
Jinrong Yang, (*Presenter*) Nothing to Disclose

PURPOSE

This study is to establish and verify a nomogram model based on clinical and thoracic aorta imaging risk factors for predicting the risk of arterial stiffness (AS).

METHODS AND MATERIALS

This is a cross-sectional study. A total of 815 patients were enrolled and the baseline clinical data, biochemical indicators, concomitant diseases and AI data (the diameter, area at 9 levels and volume, length at two adjacent levels of thoracic aorta recommended by AHA Guidelines (2010)) of them were collected. They were randomly divided into the training set of 570 cases (70%) and the validation set of 245 cases (30%). Based on the recommendations of the Committee on Physiological Diagnostic Criteria for Vascular Failure, 8= cardio-ankle vascular index (CAVI) < 9 indicates pre-AS, CAVI=9 indicates AS. In the training set, variance, t-test (for normal distribution) /Mann-Whitney U-test (for non-normal distribution), least absolute shrinkage and selection operator (LASSO) were used for selecting thoracic aorta imaging risk factors to construct AI measurement score and multivariate logistic backward stepwise regression were used to analyze the influencing factors of hypertension. According to the clinical application for different data conditions, five nomogram prediction models were constructed, named AIMeasure model, BasicClinical model, TotalClinical model, AIBasicClinical model, AITotalClinical model. Moreover, receiver operating characteristic (ROC) curve, calibration curve and decision curve analyses (DCA) were used to test the distinction, accuracy and clinical applicability of the model both in training set and validation set.

RESULTS

The results showed age, BMI, systolic blood pressure (SBP), smoking, serum sodium, serum magnesium and thoracic aortic dilatation were all related to the occurrence of AS. The area under the ROC curve of the above five models was 0.763, 0.826, 0.842, 0.831, 0.843 in the training set and was 0.794, 0.793, 0.803, 0.819, 0.827 in the verification set, respectively. Moreover, the calibration curves and DCAs performed well on accuracy and clinical practicality.

CONCLUSION

s The risk prediction nomogram models have good predictive ability and clinical value, which could be used as an effective tool for the risk prediction of arterial stiffness. Furthermore, they would facilitate earlier intervention to prevent the future development of arterial stiffness.

CLINICAL RELEVANCE/APPLICATION

Based on clinical data and thoracic aorta data measured by AI on non-contrast enhanced chest CT, prediction models were constructed for different clinical scenarios, so as to carry out opportunistic screening of arterial stiffness.

Automatic Detection of Enlarged Chest Lymph Nodes in Contrast Non-Contrast Chest CT: An External Evaluation

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Dazhou Guo, Columbia, SC (*Presenter*) Nothing to Disclose

PURPOSE

Accurate determination of lymph node (LN) status directly affects the treatment strategy and prognosis of patients with different diseases. We developed a deep learning system to detect enlarged chest LNs in CT. In this study, we evaluate its generalizability on external data of diverse sources.

METHODS AND MATERIALS

Our algorithm is a two-stage detector (Fig. a). We trained it on two private datasets and a public dataset with 262 patients and 4338 annotated LNs in total. Mediastinal, hilar, and supraclavicular LNs were annotated on contrast-enhanced (CE) CTs, and non-contrast (NC) training data are added by registering the NC CT to its CE counterpart. To improve robustness, we added intensive data augmentation in training. We selected test data from 4 external cohorts: 100 random in-house CTs without filtering patients' diseases, 40 esophageal cancer patients, 35 lung cancer patients from TCIA public data, and 12 COVID patients from TCIA. One radiologist (more than 10 years of experience in thoracic imaging) read the CT scans and verified the detection results with a short axial diameter of at least 5 mm. Detections are classified into LN requiring follow-up, LN not requiring follow-up (e.g. LNs with necrosis, calcification, and short diameter less than 1cm), and non-LN. LNs not detected were manually added.

RESULTS

A total of 1733 LNs were labeled on 187 images. At 2 FPs per patient, our algorithm achieves lesion-level detection sensitivity (Sens) of 93.1%, 82.7%, 82.9%, and 73.1% for the in-house, esophageal, lung, and COVID cohorts, respectively, (Fig. b). The accuracy is better in in-house but worse in COVID cohort, probably because fewer patients have severe diseases in the in-house cohort, while the COVID CTs have more pathological changes (e.g. mediastinitis) which interfered with the algorithm. The model performs similarly on CE vs. NC CT (Sens=84.7% vs. 87.5%@2FP, Fig. c), meanwhile more accurately in CTs with thick than with thin slices (Sens=96.4% vs. 87.2%@2FP, Fig. d). LNs annotated in thick-slice CTs are fewer and in average larger thus easier to detect, which partially explains its higher accuracy. Our algorithm works well at LNs in the aortic and subcarinal regions. Clusters of LNs can also be detected. FPs come from cervical/mediastinal vessels (39.3%), partial volume effects in mediastinum and bronchial wall at the bifurcation (16.3% and 16.0%), esophagus or esophageal tumors (11.2%), etc.

CONCLUSION

s The algorithm shows good accuracy and generalizability. It has room to improve on images with severe pathological changes.

CLINICAL RELEVANCE/APPLICATION

Our algorithm can be widely applied in chest CT examination (e.g. tumor and COVID patients) to help radiologists with the challenging LN detection task, reducing their workload and missing rate.

CT Features of Interstitial Lung Disease Associated with Systemic Lupus Erythematosus

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Marie-Pierre Debray, MD, Paris, France (*Presenter*) Speaker, Boehringer Ingelheim GmbH

PURPOSE

To describe the initial and follow-up CT features of interstitial lung disease associated with systemic lupus erythematosus (SLE-ILD)

METHODS AND MATERIALS

Multicentric retrospective study of SLE-ILD extending from 2005 to 2021, including 67 patients (24 patients without and 43 patients with another connective tissue disease (CTD) associated with SLE, mainly Sjögren syndrome, n=25, and systemic sclerosis, n=12). The chest CT performed closest to the time of SLE-ILD diagnosis was analyzed by one thoracic radiologist specialized in ILD, for the pattern and extent of ILD. Evolution of CT signs of fibrosis (increase or decrease in extent, change in texture or lung volume) and overall disease extent was analyzed on the latest available chest CT in 45 patients (median follow-up 78 months, IQR [51; 130]).

RESULTS

Significant ground-glass opacities, reticulations, traction bronchiectasis, honeycombing and cysts were observed in 41/67 (61%), 54/67 (81%), 39/67 (58%), 28/67 (42%) and 28/67 (42%) patients, respectively. Lesions showed a basal and subpleural predominant distribution in 55/67 (82%) and 36/67 (54%) patients. Chest CT was most often classified as indeterminate, in 18/67 (27%), or evocative of non specific interstitial pneumonia, in 28/67 (42%) patients with organizing pneumonia features in 7 of the latter. The pattern was typical of usual interstitial pneumonia in 10/67 (15%) patients, among those 7 patients showed exuberant honeycombing. There was no significant difference in CT pattern distribution between patients without and patients with another associated CTD. The latest available chest CT showed an increase of CT signs of fibrosis, in 29/45 (64%) patients, whereas lesions appeared unchanged or decreased in 13/67 (19%) patients.

CONCLUSION

s SLE-ILD most often shows an indeterminate or a non specific interstitial pneumonia pattern. After a median follow-up of 78 months, two thirds of patients have an increase of CT signs of fibrosis.

CLINICAL RELEVANCE/APPLICATION

ILD is a rare manifestation of SLE, frequently showing progressive signs of fibrosis. In this series, no distinctive CT features were observed between isolated SLE and other CTD associated SLE.

R2-SPCH-3

Application of CT Lymphangiography in Diagnosing Chest Complex Lymphatic Anomaly

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Yan Zhang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the clinical value of CT lymphangiography (CTL) in diagnosing chest complex lymphatic anomaly.

METHODS AND MATERIALS

59 patients diagnosed as chest complex lymphatic anomaly (CLA) clinically were analyzed retrospectively. All patients underwent CTL. All patients underwent CTL (Somatom Sensation Cardiac 16, Siemens Healthcare or Brilliance iCT, Philips Medical Healthcare, Best, the Netherlands). All CTL and chest CT images were double-blind reviewed by two radiologists with 15 years of experience. The contrast agent(lipiodol) reflux and abnormal deposition of lymphatic vessels in the chest were observed. After the contrast agent (lipiodol) has been injected into the superficial lymphatic vessels of the unilateral foot, the lipiodol follows the lymphatic fluid up the lumbar trunk and converges into the cisterna chyli, then into the thoracic duct, and finally into the blood at the angle of the left jugular vein. During this process, it is considered abnormal distribution if lipiodol deposits in any other part of the body, such as the diaphragm, peritracheal region, pericardium, pleura, and hilum. Such deposits represent the presence of dilated lymphatic vessels hyperplasia, reflux, or fistula.

RESULTS

CTL showed contrast agent abnormally deposited in all 59 patients: the end of thoracic duct was seen in 42 cases (71.2%), the end of right lymphatic duct in 13 cases (22.0%), mediastinum in 34 cases (57.6%), hilar in 19 cases (32.2%), pleura in 18 cases (30.5%), lung in 10 cases (16.9%), above the diaphragm in 4 cases (6.8%). Abnormal CT changes including: the thickening of bronchovascular bundle in 21 cases (35.6%), the thickening of interlobular septum in 15 cases (25.4%), ground glass opacity in 30 cases (50.8%), atelectasis in 17 cases (28.8%), consolidation in 1 case (1.7%), the crazy-paving sign in 3 cases (5.1%), cystic low-density foci in mediastinum in 44 cases (74.6%), pleural effusion in 36 cases (61.0%), pericardial effusion in 14 cases (23.7%), above the diaphragm in 4 cases (6.8%).

CONCLUSION

s CT L can show lymphatic abnormalities of chest CLA and other chest CT abnormalities. This method provides an important imaging basis for the diagnosis and differentiation of the disease.

CLINICAL RELEVANCE/APPLICATION

CT L can show lymphatic abnormalities of chest CLA and other chest CT abnormalities. This method provides an important imaging basis for the diagnosis and differentiation of the disease.

Topology-aware Aortic Lumen and Wall Segmentation on Computed Tomography Scans

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Prateek Prasanna, PhD, Stony Brook, NY (*Presenter*) Nothing to Disclose

PURPOSE

Accurate assessment of the aorta via imaging is important for downstream morphological assessment tasks. The wall is often very thin in aneurysmal portions of the aorta and cannot be accurately segmented by current deep learning (DL) models. The simultaneous segmentation of the lumen and the wall is a multi-class semantic segmentation problem involving a topological constraint driven by organ anatomy, i.e., the wall completely separates the lumen from the background. DL methods have achieved impressive performances, but are limited in their ability to encode topological interactions/constraints among different classes; here the topological constraint is that the aortic lumen is always enclosed by the wall. To address this we propose a novel method to encode such interactions, w.r.t fine-scale aortic anatomy, into deep neural networks (DNNs). The efficacy of our method is validated on a proprietary aorta dataset.

METHODS AND MATERIALS

28 CT scans were obtained from an institutional database of patients with thoracic and-or abdominal aortic aneurysm. Inclusion criteria for patients included known aneurysmal disease of the aorta and history of undergoing contrast-enhanced CT with arterial-phase contrast injection. Ground truth lumen and wall annotations were obtained by 4 expert readers working in consensus. We developed a novel method to learn the topological interactions for multi-class segmentation DNNs. Key observation is that lumen and background voxels can never be adjacent. Our method has two stages - a convolution-based method which generates a critical voxels map, followed by a custom loss function. Fig 1b gives an overview of the proposed DL framework.

RESULTS

Our proposed method improves segmentation results both qualitatively (Fig 1a) and quantitatively (Fig 1c). It fixes the interaction errors by forcing the lumen to always be enclosed by the wall. We see in Fig 1a that we are able to reconstruct broken lumen and wall structures, and also improve quantitative measures for both. The measures used are Dice, Hausdorff distance (HD), Avg. Symmetric Surface Distance (ASSD) and a proposed metric called percentage-violations which is the number of voxels violating the constraint as a fraction of the total number of foreground voxels.

CONCLUSION

s We propose a new method for multi-class segmentation that focuses on topological interactions. By incorporating our method into the training of DNNs, we enforce them to learn better feature representations, resulting in improved segmentation quality.

CLINICAL RELEVANCE/APPLICATION

Accurate aorta segmentation is crucial to downstream analysis tasks such as measurement of diameter and tortuosity, and assessment of aneurysms. Our method can improve aorta segmentation quality in both 2D and 3D settings.

Development and Validation of Deep Learning-based Computer-aided Detection System for Pulmonary Embolism on Chest Computed Tomography

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
YeRa Choi, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a deep learning-based computer-aided detection system (DL-CAD) to detect pulmonary embolism (PE) on chest computed tomography (CT) images.

METHODS AND MATERIALS

For the development of CAD, CT pulmonary angiographies (CTPAs) of patients with PE were retrospectively collected from two institutions. Two thoracic radiologists made voxel-wise annotations for areas of PE on each transverse CT image. The DL-CAD consisted of three elements based on convolutional neural networks (CNNs): 1) segmentation of pulmonary arteries for extraction of regions of interest, 2) detection of candidate lesions for PE, and 3) reduction of false-positive detections. For the evaluation of DL-CAD, a separate test dataset was built, comprising CT images from the same institutions without overlap in patients with the developmental dataset. The CT images for test dataset were conveniently collected to exhibit 1:1 ratio between 1) CTs with and without PE, 2) CTPAs and general contrast-enhanced chest CT (CECT)s, and 3) CT with thin-slice (<1.5 mm slice thickness) and thick-slice images. The performance of DL CAD was evaluated with examination-level sensitivity, specificity, PPV (positive predictive value), and NPV (negative predictive value) for discrimination of CTs with and without PE.

RESULTS

A total of 370 CTPA examinations with PE were used for the development of DL-CAD. The test dataset included 320 CT examinations (160 with PE; 160 CTPAs and 160 general CECTs; 160 with thin-slice images). The DL-CAD exhibited sensitivity, specificity, PPV, and NPV of 88.8%, 85.0%, 85.5%, and 88.3%, respectively for identification of CT examinations with PE. The DL-CAD exhibited slightly higher sensitivity in CTPAs compared to general CECT (92.5% vs. 85.0%; P=.133) at the same specificity (85.0%). Meanwhile, the DL-CAD exhibited significantly higher sensitivity in CTs with thin-slice images (97.5% vs. 80.0%; P<.001) and lower specificity (77.5% vs. 92.5%; P=.008) compared to CTs with thick-slice images.

CONCLUSION

s The DL-CAD could successfully identify PE not only in CTPA images but also in general CECT images.

CLINICAL RELEVANCE/APPLICATION

Automated detection of PE on chest CTs can improve the quality and efficiency of interpretation and help timely treatment for patients.

R2-SPCH-7

Accuracy of Airway Thickness Measurements in Low-dose High-resolution photon-counting-detector CT

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Chelsea Dunning, DPHIL, Rochester, MN (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the accuracy of bronchial airway thickness in low-dose chest CT using a clinical photon-counting-detector (PCD) CT compared to conventional energy-integrating-detector (EID) CT.

METHODS AND MATERIALS

Twelve 3D-printed acrylic tubes of assorted wall thicknesses (0.33 - 1.6 mm) and inner diameters (0.42 - 3.4 mm) were placed throughout an anthropomorphic chest phantom (Lungman, Kyoto Kagaku). The phantom was scanned on a whole-body PCD-CT (NAEOTOM Alpha, Siemens) at 100 kV with an additional tin filter (Sn100) in single-source ultra-high-resolution mode (detector configuration: 120 x 0.2 mm) at three dose levels (volume CT dose index (CTDIvol): 0.2, 0.4, and 0.8 mGy). The phantom was also scanned on a conventional EID-CT scanner (SOMATOM Force, Siemens) using Sn100 kV in single-source mode (detector configuration: 96 x 0.6 mm). A reference high-dose scan was also acquired at 120 kV and 12 mGy for both scanners. All images were reconstructed with quantitative kernels and iterative reconstruction with a strength setting of 3; Qr54-3 for standard resolution (SR) EID-CT, Qr56-3 for SR PCD-CT , and Qr89-3 for ultra-high-resolution (UHR) PCD-CT. The image noise was measured as the standard deviation in a region of interest within the mediastinum. The wall thickness of each tube was measured by taking the radial profile in multiple slices and measuring the average full width at half maximum (FWHM). The airway thickness accuracy was expressed using linear regression (R^2 and RMSE) between the measured wall thickness at each dose level.

RESULTS

At matched spatial resolution (Qr54 for EID-CT and Qr56 for PCD-CT), PCD-CT reduced image noise by 53%, 57%, and 56% at 0.2 mGy, 0.4 mGy, and 0.8 mGy dose levels compared to EID-CT. At 0.2 mGy, 0.4 mGy, and 0.8 mGy, the wall thickness RMSE values were 0.37, 0.36, and 0.57 mm for EID-CT ; 0.49, 0.46, and 0.47 mm for SR PCD-CT; and 0.18, 0.15, and 0.11 mm for UHR PCD-CT. The UHR PCD-CT had the closest R^2 values to unity across all dose levels ($R^2 > 0.963$), compared to EID-CT ($R^2 > 0.816$) and SR PCD-CT ($R^2 > 0.823$).

CONCLUSION

s More accurate airway wall thickness measurements can be achieved for UHR PCD-CT compared to EID-CT or SR PCD-CT at radiation dose levels at or lower than in lung cancer screening exams.

CLINICAL RELEVANCE/APPLICATION

High accuracy measurements of bronchial airway wall thickness in high-resolution low-dose PCD-CT can enable reliable diagnosis of lung diseases such as COPD or cystic fibrosis.

R2-SPCH-8

Value-added Opportunistic Screening: Prediction Model of Arterial Stiffness Based on Clinical and Thoracic Aorta Imaging Risk Factors

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - CH DPS

Participants
Jinrong Yang, (*Presenter*) Nothing to Disclose

PURPOSE

This study is to establish and verify a nomogram model based on clinical and thoracic aorta imaging risk factors for predicting the risk of arterial stiffness (AS).

METHODS AND MATERIALS

This is a cross-sectional study. A total of 815 patients were enrolled and the baseline clinical data, biochemical indicators, concomitant diseases and AI data (the diameter, area at 9 levels and volume, length at two adjacent levels of thoracic aorta recommended by AHA Guidelines (2010)) of them were collected. They were randomly divided into the training set of 570 cases (70%) and the validation set of 245 cases (30%). Based on the recommendations of the Committee on Physiological Diagnostic Criteria for Vascular Failure, 8= cardio-ankle vascular index (CAVI) < 9 indicates pre-AS, CAVI=9 indicates AS. In the training set, variance, t-test (for normal distribution) /Mann-Whitney U-test (for non-normal distribution), least absolute shrinkage and selection operator (LASSO) were used for selecting thoracic aorta imaging risk factors to construct AI measurement score and multivariate logistic backward stepwise regression were used to analyze the influencing factors of hypertension. According to the clinical application for different data conditions, five nomogram prediction models were constructed, named AIMeasure model, BasicClinical model, TotalClinical model, AIBasicClinical model, AITotalClinical model. Moreover, receiver operating characteristic (ROC) curve, calibration curve and decision curve analyses (DCA) were used to test the distinction, accuracy and clinical applicability of the model both in training set and validation set.

RESULTS

The results showed age, BMI, systolic blood pressure (SBP), smoking, serum sodium, serum magnesium and thoracic aortic dilatation were all related to the occurrence of AS. The area under the ROC curve of the above five models was 0.763, 0.826, 0.842, 0.831, 0.843 in the training set and was 0.794, 0.793, 0.803, 0.819, 0.827 in the verification set, respectively. Moreover, the calibration curves and DCAs performed well on accuracy and clinical practicality.

CONCLUSION

s The risk prediction nomogram models have good predictive ability and clinical value, which could be used as an effective tool for the risk prediction of arterial stiffness. Furthermore, they would facilitate earlier intervention to prevent the future development of arterial stiffness.

CLINICAL RELEVANCE/APPLICATION

Based on clinical data and thoracic aorta data measured by AI on non-contrast enhanced chest CT, prediction models were constructed for different clinical scenarios, so as to carry out opportunistic screening of arterial stiffness.

R2-SPER-1 Subcostal And Right Lateral Views Are Not Equivalent in Obtaining IVC Measurements Using Ultrasound in Healthy Adults

Participants
Fadi Haroun, BS, (*Presenter*) Nothing to Disclose

PURPOSE

The objective of this study is to assess concordance between the subcostal and right lateral view for ultrasonographic inferior vena cava (IVC) measurements including the end-inspiratory diameter, end-expiratory diameter, and respiratory variation represented by the caval index in spontaneously breathing healthy adults.

METHODS AND MATERIALS

We recruited a convenience sample of 33 healthy adults. A phased array ultrasound probe was used to obtain IVC measurements from a subcostal view in the sagittal plane and from a right lateral view in the coronal plane with B mode ultrasound. End-inspiratory diameter, end-expiratory diameter, and caval index were obtained for each view. A two-tailed t-test was performed to compare the caval indices obtained by the two views. Bland-Altman analysis was used to obtain the limits of agreement for the IVC diameter and caval index across the two views.

RESULTS

Subcostal and right lateral caval indices across all participants were significantly different according to a paired t-test ($p<0.0001$). The Bland-Altman analysis showed wide limits of agreement in end-inspiratory diameter (-0.97 and 0.50 cm) and in end-expiratory diameter (-0.94 and 0.90 cm). The right lateral view underestimated the IVC caval index relative to the subcostal view.

CONCLUSION

s The subcostal and right lateral views are not equivalent in obtaining IVC measurements in spontaneously breathing healthy adults. Current cut off values for measurement-based applications of IVC ultrasound, including fluid responsiveness using caval indices, may not be accurate when values are obtained from the right lateral view in the coronal plane of the IVC in patients.

CLINICAL RELEVANCE/APPLICATION

Though previous studies have demonstrated the discordance between measurements of the IVC obtained from the subcostal and right lateral views, our study is the first study to demonstrate this in adult non-ICU populations. This expands to a new population the conclusion that cut-off values for measurement-based applications of IVC ultrasound should not be used interchangeably for these two views since most of these cut-offs were established using the subcostal view only.

R2-SPGI-1 Pancreatic Ductal Adenocarcinoma (PDAC) Regional Nodal Disease: Is MRI Accurate for identifying node-positive patients?

Participants
Sami Adham, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Multiple studies have demonstrated that metastatic regional lymph nodes have prognostic value in patients with PDAC. The purpose of this study is to determine the diagnostic accuracy of MRI for evaluating the presence of regional nodal disease in patients with biopsy-confirmed PDAC.

METHODS AND MATERIALS

With IRB approval, all adult patients with pancreatic MRI performed from 2011 to 2021 within 3 months of a Whipple resection including regional nodal dissection at our institution were eligible for inclusion in this single-centre retrospective cohort study. Patients with an incomplete MRI or those who received neoadjuvant therapy were excluded. Each MRI was independently reviewed by two experienced fellowship-trained abdominal radiologists. The following characteristics were evaluated at the patient level: primary tumour size, largest regional lymph node short and long axes length, number of regional lymph nodes, and an apparent diffusion coefficient (ADC) node-to-spleen signal index was calculated and absolute ADC values were documented. Additionally, the presence of the following lymph node characteristics was evaluated: round shape, indistinct margin, peri-nodal fat-stranding, the presence of one or more regional lymph nodes with heterogeneous T2 signal, or restricted diffusion greater than the spleen, and Radiologists documented subjectively whether or not they believed a patient was node positive. Surgical pathology was the reference standard.

RESULTS

Of 75 included patients, 85% (64/75) were positive for regional nodal disease. None of the categorical variables evaluated on MRI were associated with pathologic regional nodes including the presence of one or more node with heterogeneous T2-weighted signal, a round shape, indistinct margin, peri-nodal fat stranding, restricted diffusion greater than the spleen, or subjective radiologist opinion (P>0.05 each). Median primary tumor maximum diameter was slightly larger for patients with pathologic regional lymph nodes compared to those without, 18 mm (10-42 mm) vs. 16 mm (9-22 mm), P = 0.027. None of the other continuous variables evaluated on MRI were associated with pathologic regional nodes.

CONCLUSION

s Pre-operative MRI has low accuracy for evaluating regional nodal disease in patients with PDAC. A larger median primary tumour maximum diameter was the only feature that was associated with regional nodal disease.

CLINICAL RELEVANCE/APPLICATION

Multiple lymph node morphologic features routinely assessed on MRI for malignancies elsewhere in the body are likely not applicable when assessing for PDAC regional nodal disease.

R2-SPGI-10 Inter-rater agreement of tumor measurements for assessment of neoadjuvant treatment response in pancreatic ductal adenocarcinoma

Participants
Jon Heiselman, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate inter-rater variability of pancreatic ductal adenocarcinoma (PDAC) diameters and volumes on baseline and restaging CT after neoadjuvant therapy.

METHODS AND MATERIALS

Thirty patients with resectable PDAC enrolled in an IRB-approved Phase II clinical trial for neoadjuvant chemotherapy were retrospectively analyzed. For each patient, three raters independently segmented whole tumor and pancreas volumes of interest from contrast-enhanced CT images acquired pre- and post-neoadjuvant treatment. Each rater also measured axial plane lesion diameters in both images to evaluate treatment response (PR: partial response, SD: stable disease, PD: progressive disease) according to the response evaluation criteria in solid tumors guidelines (RECIST v1.1). Variability in spatial overlap was quantified

via generalized conformity index (GCI) and compared with Wilcoxon signed rank tests. Volume and diameter measurements were compared by intra-class correlation coefficient (ICC), and variations in RECIST groups assessed with Fleiss' Kappa (k).

RESULTS

Inter-rater agreement of pancreas segmentations was moderate (pre-treatment GCI 0.60, ICC 0.52; post-treatment GCI 0.57, ICC 0.61), while tumor segmentations showed significantly lower spatial overlap ($p < 0.005$) despite concordant gross volumes (pre-treatment GCI 0.46, ICC 0.63; post-treatment GCI 0.38, ICC 0.81). GCI of tumor segmentations were significantly lower in post- than pre-treatment imaging ($p < 0.01$). When evaluating pre- to post-treatment differences in tumor volume identified by each rater, agreement was very poor (ICC 0.12). Similarly, the percent change in the sum of longest diameters measured by individual raters agreed poorly (ICC 0.25). RECIST category across each patient was found to depend on the reader, with only slight agreement observed ($k = 0.18$). Complete agreement of RECIST group between all three raters occurred in only 60% of patients (18 of 30; 0 PR, 17 SD, 1 PD); raters disagreed between PR/SD in 8 of 12 remaining patients, between SD/PD in 3 of 12, and between PR/SD/PD in 1 patient.

CONCLUSION

s Longitudinal changes in PDAC tumor size are associated with high measurement variability, which suggests more reliable methods for measuring treatment response are needed.

CLINICAL RELEVANCE/APPLICATION

PDAC often presents with ill-defined radiographic borders, yet standard methods for assessing therapeutic response require dimensional measurement of tumor diameters or volumes throughout treatment. The high variability we observe suggests more precise quantitative measures of longitudinal treatment response should be pursued to better inform PDAC treatment course and improve outcome prediction.

R2-SPGI-2 CT characteristics of recurrent acute pancreatitis at different onset times

Participants
Ju Zhang, MMEd, Chengdu, Sichuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the CT characteristic of recurrent acute pancreatitis (RAP) at different onset times.

METHODS AND MATERIALS

RAP data were obtained over the past 5 years. RAP patients were divided into five subgroups according to the time from RAP onset to performing CT examination: 1-3 days, 4-7 days, 8-14 days, 15-30 days, and after 30 days. RAP was categorized into the early phase (first week) and late phase (after the first week) based on the 2012 revised Atlanta classification (RAC). Evaluation and pairwise comparison of patients' demographic data, RAC, CT findings, CT severity index (CTSI) score, and extrapancreatic inflammation on CT (EPIC) score were conducted.

RESULTS

In the 690 patients with RAP, hypertriglyceridemia was the most common cause. The proportion of mild RAP patients on both RAC and CTSI in the early stage of onset was higher than those in the late stage of onset (both P<.005). The proportion of moderately severe RAP and NP patients on CT at 15-30 days of onset was higher than those in the early phase of onset (both P<.005), and the percentage of severe RAP patients after 14 days of onset was higher than that in the early stage of onset.

CONCLUSION

s In the 690 patients with RAP, hypertriglyceridemia was the most common cause. The proportion of mild RAP patients on both RAC and CTSI in the early stage of onset was higher than those in the late stage of onset (both P<.005). The proportion of moderately severe RAP and NP patients on CT at 15-30 days of onset was higher than those in the early phase of onset (both P<.005), and the percentage of severe RAP patients after 14 days of onset was higher than that in the early stage of onset.

CLINICAL RELEVANCE/APPLICATION

Recognizing the characteristics of RAP at different onset times, and accurately grasping the changes in the condition of RAP patients can help clinicians to give reasonable treatment according to the changes of the disease, and then effectively prevent the onset of chronic pancreatitis.

R2-SPGI-3 Diagnostic value of pancreatic ECV in patients with diabetes: a comparative study of HU value and iodine density method

Participants
Xiaoyi Cai, MBBS, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the correlation between extracellular volume (ECV) fraction and HbA1c value in patients with diabetes mellitus, and compare absolute contrast enhancement (ECV-HU) method and dual-energy iodine density (ECV-ID) method.

METHODS AND MATERIALS

In this study, 92 patients with suspected abdominal diseases were retrospectively enrolled, all of whom received abdominal CT precontrast scan (120kV) and dual-energy CT enhanced scan. Patients were divided into two groups according to HbA1c value: the diabetes group (HbA1c=6.5%,39 patients) and the non-diabetes group (HbA1<6.5%,53 patients). ECV fraction of pancreas was calculated using two methods: ECV-HU method, ECV-HU=(HU pancreas-equilibrium phase -HU pancreas - precontrast)/(HU abdominal aorta - equilibrium phase - HU abdominal aorta - precontrast)×(100-Hct); ECV-ID method, ECV-ID=(ID pancreas - equilibrium phase /ID abdominal aorta - equilibrium phase)×(100-Hct). Independent sample T-test was used to analyze the differences in ECV between two groups, and Spearman correlation analysis was performed to analyze the correlation between ECV and HbA1c value. The diagnostic performance of pancreatic ECV-HU and ECV-ID in differentiating diabetic mellitus was evaluated by receiver operating characteristic (ROC) curve analysis.

RESULTS

HbA1c value was positively correlated with ECV-HU and ECV-ID in whole patients (rs=0.571, rs=0.629, respectively; both P<0.001). ECV-HU and ECV-ID in diabetes group were significantly higher than those in non-diabetes group (25.03±2.13 vs. 22.33±2.40, 34.58±2.03 vs. 31.59±2.23, respectively; both P<0.05). For diabetes differentiation, the area under the curve (AUC) of ECV-ID was higher than that of ECV-HU (0.835 vs. 0.808, P=0.418). When the cut-off value was set at 32.70%, the sensitivity and specificity of ECV-ID were 87.2% and 66.0%, respectively.

CONCLUSION

s Both ECV-ID and ECV-HU of pancreas are potential indices to diagnose diabetes mellitus and can reflect the status of HbA1c value.

CLINICAL RELEVANCE/APPLICATION

Pancreatic ECV obtained by CT is a reliable index which can not only monitor HbA1c for patients with diabetes, but also assist in diagnosis of diabetes mellitus.

R2-SPGI-4 Texture analysis of IVIM-DWI in early postoperative MRI to predict post-pancreatectomy acute pancreatitis after pancreaticoduodenectomy.

Participants
Giulia A. Zamboni, MD, Verona, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Pancreaticoduodenectomy can be burdened by significant morbidity and mortality. Post-pancreatectomy acute pancreatitis (PPAP) is one of the most common complications and can lead to more severe complications such as postoperative fistula, with prolonged hospitalization and poor outcome. The purpose of this study is to assess if early postoperative MRI after pancreaticoduodenectomy can predict post-pancreatectomy acute pancreatitis (PPAP) by identifying early microstructural changes that lead to inflammation and microcirculation changes.

METHODS AND MATERIALS

In this IRB-approved prospective study, 65 patients underwent MRI on a 1.5 T scanner (Philips Ingenia) on postoperative day 3 (POD3) after pancreaticoduodenectomy. The scan protocol included a combination of standard sequences, post-gadolinium acquisitions, and IVIM DWI. The IVIM DICOM images were analyzed with in-house software that produced F, D and D* maps and allowed to calculate the texture parameters of the ROIs. One reader drew 3 ROIs on the pancreatic stump on each MRI: adjacent to the resection margin, on the tail further from the margin, and on the entire pancreatic remnant. The 2021 ISGPS definition of PPAP was used to dichotomize patients into a group with POH/PPAP and a group without that complication. Texture parameters and radiological findings were compared between the two groups.

RESULTS

20 patients developed POH and 6 of these PPAP grade B or C. Significant differences in texture analysis results were identified between the POH/PPAP and the non-POH/PPAP group for mean ADC value ((1.33 ± 0.22)×10-3 vs (1.56 ± 0.28)×10-3 mm2/s; p=0.006), mean D value (0.11 ± 0.14 vs 0.22 ± 0.15; p=0.03), F entropy (4.5, SE 0.10 vs 4.1, SE 0.08; p=0.004) and D* (2.7, SE 0.73 vs 1.3, SE 0.38; p=0.01) entropy of ROIs including the pancreatic stump. Similar results were obtained for the ROIs of the tail and the entire pancreatic remnant. No imaging findings consistent with PPAP were identified at MRI in the POH/PPAP group.

CONCLUSION

s Texture analysis of IVIM-derived parameters on early postoperative MRI after pancreaticoduodenectomy can help identify patients who will develop PPAP.

CLINICAL RELEVANCE/APPLICATION

earlier identification of patients who will develop POH/PPAD can lead to a better treatment and patient outcome

R2-SPGI-6 Role of preoperative regional lymph node metastasis detected on CT and/or FDG-PET scans in the prediction of early recurrence of pancreatic adenocarcinoma after curative resection

Participants
Ja Kyung Yoon, (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to evaluate the role of regional lymph node (LN) metastasis detected on preoperative CT and/or 18F-fluoro-2-deoxyglucose-positron emission tomography (FDG-PET) scans in the prediction of early tumor recurrence after curative surgical resection of pancreatic ductal adenocarcinoma (PDAC).

METHODS AND MATERIALS

This retrospective study included 137 patients who underwent upfront surgery with R0 resection of PDAC between 2013 and 2016. Regional LN metastasis was identified using two criteria: both preoperative CT and FDG-PET scans (LNAND) or preoperative CT or FDG-PET scans (LNOR). Cox proportional hazard regression analysis was used to determine the preoperative risk factors for early tumor recurrence. The significant risk factors for early tumor recurrence were used to create a predictive nomogram for early tumor recurrence.

RESULTS

Fifty-five patients had early tumor recurrence within 12 months after curative resection. Regional LN metastasis (both LNOR and LNAND criteria), preoperative carbohydrate antigen 19-9 (CA19-9) levels, and preoperative locally advanced status were significant risk factors for early tumor recurrence. Compared with the LNAND criteria, the LNOR criteria provided higher sensitivity (22.4% vs. 15.5%, p = 0.046) and a higher negative predictive value (61.9% vs. 59.8%, p = 0.046). LNOR, preoperative CA19-9 level, and resectability were included in the predictive nomogram with an adjusted C-index of 0.589.

CONCLUSION

s The preoperative LN metastasis on CT or FDG-PET scans, elevated serum CA19-9 levels, and locally advanced status were significant risk factors for early recurrence of PDAC after surgery. The predictive nomogram, including these factors, may help guide the first-line treatment of PDAC.

CLINICAL RELEVANCE/APPLICATION

Preoperative LN metastasis identified on CT or FDG-PET scans may help predict early recurrence of pancreatic adenocarcinoma after curative resection.

R2-SPGI-7 MRI vs. CT for pancreatic adenocarcinoma vascular invasion and resectability: Comparative diagnostic test accuracy systematic review and meta-analysis

Participants
Ankush Jajodia, MD, MBBS, New Delhi, India (*Presenter*) Nothing to Disclose

PURPOSE

To perform a systematic review evaluating the diagnostic test accuracy of MRI vs CT for assessing pancreatic ductal adenocarcinoma (PDAC) vascular invasion and resectability.

METHODS AND MATERIALS

MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL) and Scopus were searched until December 2021 for all studies directly comparing the accuracy of MRI vs CT for vascular invasion and resectability of pathologically confirmed PDAC in the same patients. Findings on curative resection or exploratory laparotomy were the preferred reference standard. Data extraction, risk of bias and applicability assessment was performed by two authors using QUADAS-C, a tool for assessing risk of bias in comparative diagnostic accuracy studies. A bivariate random-effects model was used with meta-regression for test comparison and covariate analysis with 95% confidence intervals (95%CI). Hierarchal summary receiver operating characteristic (ROC) curves and coupled forest plots were generated.

RESULTS

Five studies met inclusion criteria consisting of 215 patients, 635 vessels and 124 resectable tumors. There was no difference between MRI and CT for diagnosing PDAC vascular invasion: MRI sensitivity/specificity were 73% (95%CI: 50-88%)/97% (94-99%) and for CT, 75% (56-88%)/97% (94-98%). Similarly, no difference was seen between MRI and CT for resectability assessment: MRI sensitivity/specificity were 85% (77-90%)/67% (46-82%) and for CT, 84% (75-90%)/75% (60-86%). Sources of bias included selection bias from a subset of CT patients undergoing MRI, and verification bias for patients with unresectable disease not proceeding to surgical confirmation. Study risk of bias did not impact MRI or CT performance on meta-regression.

CONCLUSION

s Limited data suggest there is no difference between MRI and CT for assessing PDAC vascular invasion or resectability; however, further research is needed to improve confidence in this finding.

CLINICAL RELEVANCE/APPLICATION

MRI is more sensitive than CT for detecting PDAC liver metastases; if also more accurate at assessing vascular invasion and resectability, then it could be a "one-stop shop" for PDAC detection and staging.

R2-SPGI-8 Development and validation of a radiomics model for predicting malignant IPMN compared with the revised Fukuoka guidelines

Participants
Doo Young Lee, MD, MS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The revised international consensus Fukuoka guidelines (Fukuoka guidelines) are commonly used for evaluating pancreatic intraductal papillary mucinous neoplasms (IPMNs). However, assessment of radiomics model in comparison with Fukuoka guidelines by radiologists has been lacking. Thus, this study aimed to evaluate CT-based radiomics model for determining malignant IPMNs and compare its performance with Fukuoka guidelines.

METHODS AND MATERIALS

This retrospective study included a total of 194 consecutive patients with surgically resected pancreatic IPMNs from January 2008 to December 2020. Surgical histopathologic analysis was the reference standard for malignancy. Radiomic features were extracted from preoperative contrast-enhanced CT, and radiomics model was built using the least absolute shrinkage and selection operator with fivefold cross-validation. CT and MR images were independently reviewed based on Fukuoka guidelines by two board-certified abdominal radiologists, who arrived at a consensus in cases of discrepancy. The performance of Fukuoka guidelines was compared with that of the radiomics model. Areas under the curve (AUCs) were compared by using the DeLong method.

RESULTS

A total of 194 patients with pancreatic IPMNs (benign, 83 [43%], malignant, 111 [57%]) were included. The patients were chronologically divided into training set (n = 141; mean age 65 + SD 8.6; men 88) and temporal validation set (n = 53; mean age 66 + SD 9.7; men 31). The diagnostic performance of Fukuoka guidelines was not statistically different between CT and MRI (AUC 0.71 vs. 0.71, P = 0.93). Thus, CT was selected for further comparison between Fukuoka guidelines and radiomics model. The CT radiomics model showed higher diagnostic performance (AUC, 0.85 vs 0.71 [P = 0.038]), specificity (84.6% vs 61.5% [P = 0.041]), and positive predictive value (84.0% vs 66.7% [P = 0.044]) than Fukuoka guidelines in the validation set.

CONCLUSION

s A CT radiomics model exhibited better diagnostic performance than the revised Fukuoka guidelines by experienced radiologists for classifying malignant IPMNs.

CLINICAL RELEVANCE/APPLICATION

The CT radiomics model performed better than the revised Fukuoka guidelines in determining the malignancy of IPMN. Therefore, the radiomics model will facilitate proper treatment decision making.

R2-SPGI-9 Vascular involvement and resectability of pancreatic ductal adenocarcinoma on contrast-enhanced MRI: comparison with pancreatic protocol CT

Participants
Yukako Iritani, MD, Gifu, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To compare the diagnostic performance for detecting vascular involvement and determining resectability differences regarding pancreatic ductal adenocarcinoma (PDAC) between contrast-enhanced CT and MRI.

METHODS AND MATERIALS

This retrospective study evaluated 82 patients (73 years, 46 men) with PDAC who underwent both preoperative contrast-enhanced CT and MRI from January 2008 to March 2021. Two radiologists independently categorized vascular involvements for celiac, superior mesenteric, splenic, and common hepatic arteries, and portal, superior mesenteric, and splenic veins into no tumor contact, solid soft-tissue contact =180°, or solid soft-tissue contact >180°. The radiologists also classified resectability into resectable, borderline resectable, or locally advanced. Receiver-operating-characteristic (ROC) analysis was conducted to evaluate the diagnostic performances for detecting vascular involvements which were confirmed by pathological or intraoperative findings. The proportion of resectability classifications was compared between CT and MRI by the Fisher's exact test.

RESULTS

No statistical difference was found in the diagnostic performances for detecting vascular involvement in CT (area under the ROC curve [AUC], 0.50-0.89) and MRI (AUC, 0.51-0.75) (P = .06->.99). Resectabilities on CT were 79% and 68%, 20% and 26%, and 1% and 6% for resectable, borderline resectable, and locally advanced tumors for reviewers 1 and 2; those on MRI were 87% and 81%, 12% and 13%, and 1% and 6%, respectively. The proportion of resectability was not different between CT and MRI (P = .48 and = .15 for reviewers 1 and 2, respectively).

CONCLUSION

s The diagnostic performance for detecting vascular involvement and determining resectability of PDAC on contrast-enhanced MRI were comparable with pancreatic protocol CT.

CLINICAL RELEVANCE/APPLICATION

Diagnostic performance for detecting vascular involvement and determining resectability of pancreatic ductal adenocarcinoma on contrast-enhanced MRI were statistically comparable with pancreatic protocol CT.

Pancreatic Ductal Adenocarcinoma (PDAC) Regional Nodal Disease: Is MRI Accurate for identifying node-positive patients?

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Sami Adham, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Multiple studies have demonstrated that metastatic regional lymph nodes have prognostic value in patients with PDAC. The purpose of this study is to determine the diagnostic accuracy of MRI for evaluating the presence of regional nodal disease in patients with biopsy-confirmed PDAC.

METHODS AND MATERIALS

With IRB approval, all adult patients with pancreatic MRI performed from 2011 to 2021 within 3 months of a Whipple resection including regional nodal dissection at our institution were eligible for inclusion in this single-centre retrospective cohort study. Patients with an incomplete MRI or those who received neoadjuvant therapy were excluded. Each MRI was independently reviewed by two experienced fellowship-trained abdominal radiologists. The following characteristics were evaluated at the patient level: primary tumour size, largest regional lymph node short and long axes length, number of regional lymph nodes, and an apparent diffusion coefficient (ADC) node-to-spleen signal index was calculated and absolute ADC values were documented. Additionally, the presence of the following lymph node characteristics was evaluated: round shape, indistinct margin, peri-nodal fat-stranding, the presence of one or more regional lymph nodes with heterogeneous T2 signal, or restricted diffusion greater than the spleen, and Radiologists documented subjectively whether or not they believed a patient was node positive. Surgical pathology was the reference standard.

RESULTS

Of 75 included patients, 85% (64/75) were positive for regional nodal disease. None of the categorical variables evaluated on MRI were associated with pathologic regional nodes including the presence of one or more node with heterogeneous T2-weighted signal, a round shape, indistinct margin, peri-nodal fat stranding, restricted diffusion greater than the spleen, or subjective radiologist opinion (P>0.05 each). Median primary tumor maximum diameter was slightly larger for patients with pathologic regional lymph nodes compared to those without, 18 mm (10-42 mm) vs. 16 mm (9-22 mm), P = 0.027. None of the other continuous variables evaluated on MRI were associated with pathologic regional nodes.

CONCLUSION

s Pre-operative MRI has low accuracy for evaluating regional nodal disease in patients with PDAC. A larger median primary tumour maximum diameter was the only feature that was associated with regional nodal disease.

CLINICAL RELEVANCE/APPLICATION

Multiple lymph node morphologic features routinely assessed on MRI for malignancies elsewhere in the body are likely not applicable when assessing for PDAC regional nodal disease.

R2-SPGI-10

Inter-rater agreement of tumor measurements for assessment of neoadjuvant treatment response in pancreatic ductal adenocarcinoma

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Jon Heiselman, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate inter-rater variability of pancreatic ductal adenocarcinoma (PDAC) diameters and volumes on baseline and restaging CT after neoadjuvant therapy.

METHODS AND MATERIALS

Thirty patients with resectable PDAC enrolled in an IRB-approved Phase II clinical trial for neoadjuvant chemotherapy were retrospectively analyzed. For each patient, three raters independently segmented whole tumor and pancreas volumes of interest from contrast-enhanced CT images acquired pre- and post-neoadjuvant treatment. Each rater also measured axial plane lesion diameters in both images to evaluate treatment response (PR: partial response, SD: stable disease, PD: progressive disease) according to the response evaluation criteria in solid tumors guidelines (RECIST v1.1). Variability in spatial overlap was quantified via generalized conformity index (GCI) and compared with Wilcoxon signed rank tests. Volume and diameter measurements were compared by intra-class correlation coefficient (ICC), and variations in RECIST groups assessed with Fleiss' Kappa (k).

RESULTS

Inter-rater agreement of pancreas segmentations was moderate (pre-treatment GCI 0.60, ICC 0.52; post-treatment GCI 0.57, ICC 0.61), while tumor segmentations showed significantly lower spatial overlap ($p < 0.005$) despite concordant gross volumes (pre-treatment GCI 0.46, ICC 0.63; post-treatment GCI 0.38, ICC 0.81). GCI of tumor segmentations were significantly lower in post- than pre-treatment imaging ($p < 0.01$). When evaluating pre- to post-treatment differences in tumor volume identified by each rater, agreement was very poor (ICC 0.12). Similarly, the percent change in the sum of longest diameters measured by individual raters agreed poorly (ICC 0.25). RECIST category across each patient was found to depend on the reader, with only slight agreement observed ($k = 0.18$). Complete agreement of RECIST group between all three raters occurred in only 60% of patients (18 of 30; 0 PR, 17 SD, 1 PD); raters disagreed between PR/SD in 8 of 12 remaining patients, between SD/PD in 3 of 12, and between PR/SD/PD in 1 patient.

CONCLUSION

s Longitudinal changes in PDAC tumor size are associated with high measurement variability, which suggests more reliable methods for measuring treatment response are needed.

CLINICAL RELEVANCE/APPLICATION

PDAC often presents with ill-defined radiographic borders, yet standard methods for assessing therapeutic response require dimensional measurement of tumor diameters or volumes throughout treatment. The high variability we observe suggests more precise quantitative measures of longitudinal treatment response should be pursued to better inform PDAC treatment course and improve outcome prediction.

R2-SPGI-2

CT characteristics of recurrent acute pancreatitis at different onset times

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Ju Zhang, MMEd, Chengdu, Sichuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the CT characteristic of recurrent acute pancreatitis (RAP) at different onset times.

METHODS AND MATERIALS

RAP data were obtained over the past 5 years. RAP patients were divided into five subgroups according to the time from RAP onset to performing CT examination: 1-3 days, 4-7 days, 8-14 days, 15-30 days, and after 30 days. RAP was categorized into the early phase (first week) and late phase (after the first week) based on the 2012 revised Atlanta classification (RAC). Evaluation and pairwise comparison of patients' demographic data, RAC, CT findings, CT severity index (CTSI) score, and extrapancreatic inflammation on CT (EPIC) score were conducted.

RESULTS

In the 690 patients with RAP, hypertriglyceridemia was the most common cause. The proportion of mild RAP patients on both RAC and CTSI in the early stage of onset was higher than those in the late stage of onset (both P<.005). The proportion of moderately severe RAP and NP patients on CT at 15-30 days of onset was higher than those in the early phase of onset (both P<.005), and the percentage of severe RAP patients after 14 days of onset was higher than that in the early stage of onset.

CONCLUSION

s In the 690 patients with RAP, hypertriglyceridemia was the most common cause. The proportion of mild RAP patients on both RAC and CTSI in the early stage of onset was higher than those in the late stage of onset (both P<.005). The proportion of moderately severe RAP and NP patients on CT at 15-30 days of onset was higher than those in the early phase of onset (both P<.005), and the percentage of severe RAP patients after 14 days of onset was higher than that in the early stage of onset.

CLINICAL RELEVANCE/APPLICATION

Recognizing the characteristics of RAP at different onset times, and accurately grasping the changes in the condition of RAP patients can help clinicians to give reasonable treatment according to the changes of the disease, and then effectively prevent the onset of chronic pancreatitis.

R2-SPGI-3

Diagnostic value of pancreatic ECV in patients with diabetes: a comparative study of HU value and iodine density method

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Xiaoyi Cai, MBBS, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the correlation between extracellular volume (ECV) fraction and HbA1c value in patients with diabetes mellitus, and compare absolute contrast enhancement (ECV-HU) method and dual-energy iodine density (ECV-ID) method.

METHODS AND MATERIALS

In this study, 92 patients with suspected abdominal diseases were retrospectively enrolled, all of whom received abdominal CT precontrast scan (120kV) and dual-energy CT enhanced scan. Patients were divided into two groups according to HbA1c value: the diabetes group (HbA1c=6.5%,39 patients) and the non-diabetes group (HbA1<6.5%,53 patients). ECV fraction of pancreas was calculated using two methods: ECV-HU method, ECV-HU=(HU pancreas-equilibrium phase -HU pancreas - precontrast)/(HU abdominal aorta - equilibrium phase - HU abdominal aorta - precontrast)×(100-Hct); ECV-ID method, ECV-ID=(ID pancreas - equilibrium phase /ID abdominal aorta - equilibrium phase)×(100-Hct). Independent sample T-test was used to analyze the differences in ECV between two groups, and Spearman correlation analysis was performed to analyze the correlation between ECV and HbA1c value. The diagnostic performance of pancreatic ECV-HU and ECV-ID in differentiating diabetic mellitus was evaluated by receiver operating characteristic (ROC) curve analysis.

RESULTS

HbA1c value was positively correlated with ECV-HU and ECV-ID in whole patients (rs=0.571, rs=0.629, respectively; both P<0.001). ECV-HU and ECV-ID in diabetes group were significantly higher than those in non-diabetes group (25.03±2.13 vs. 22.33±2.40, 34.58±2.03 vs. 31.59±2.23, respectively; both P<0.05). For diabetes differentiation, the area under the curve (AUC) of ECV-ID was higher than that of ECV-HU (0.835 vs. 0.808, P=0.418). When the cut-off value was set at 32.70%, the sensitivity and specificity of ECV-ID were 87.2% and 66.0%, respectively.

CONCLUSION

s Both ECV-ID and ECV-HU of pancreas are potential indices to diagnose diabetes mellitus and can reflect the status of HbA1c value.

CLINICAL RELEVANCE/APPLICATION

Pancreatic ECV obtained by CT is a reliable index which can not only monitor HbA1c for patients with diabetes, but also assist in diagnosis of diabetes mellitus.

R2-SPGI-4

Texture analysis of IVIM-DWI in early postoperative MRI to predict post-pancreatectomy acute pancreatitis after pancreaticoduodenectomy.

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Giulia A. Zamboni, MD, Verona, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Pancreaticoduodenectomy can be burdened by significant morbidity and mortality. Post-pancreatectomy acute pancreatitis (PPAP) is one of the most common complications and can lead to more severe complications such as postoperative fistula, with prolonged hospitalization and poor outcome. The purpose of this study is to assess if early postoperative MRI after pancreaticoduodenectomy can predict post-pancreatectomy acute pancreatitis (PPAP) by identifying early microstructural changes that lead to inflammation and microcirculation changes.

METHODS AND MATERIALS

In this IRB-approved prospective study, 65 patients underwent MRI on a 1.5 T scanner (Philips Ingenia) on postoperative day 3 (POD3) after pancreaticoduodenectomy. The scan protocol included a combination of standard sequences, post-gadolinium acquisitions, and IVIM DWI. The IVIM DICOM images were analyzed with in-house software that produced F, D and D* maps and allowed to calculate the texture parameters of the ROIs. One reader drew 3 ROIs on the pancreatic stump on each MRI: adjacent to the resection margin, on the tail further from the margin, and on the entire pancreatic remnant. The 2021 ISGPS definition of PPAP was used to dichotomize patients into a group with POH/PPAP and a group without that complication. Texture parameters and radiological findings were compared between the two groups.

RESULTS

20 patients developed POH and 6 of these PPAP grade B or C. Significant differences in texture analysis results were identified between the POH/PPAP and the non-POH/PPAP group for mean ADC value ((1.33 ± 0.22)×10-3 vs (1.56 ± 0.28)×10-3 mm2/s; p=0.006), mean D value (0.11 ± 0.14 vs 0.22 ± 0.15; p=0.03), F entropy (4.5, SE 0.10 vs 4.1, SE 0.08; p=0.004) and D* (2.7, SE 0.73 vs 1.3, SE 0.38; p=0.01) entropy of ROIs including the pancreatic stump. Similar results were obtained for the ROIs of the tail and the entire pancreatic remnant. No imaging findings consistent with PPAP were identified at MRI in the POH/PPAP group.

CONCLUSION

s Texture analysis of IVIM-derived parameters on early postoperative MRI after pancreaticoduodenectomy can help identify patients who will develop PPAP.

CLINICAL RELEVANCE/APPLICATION

earlier identification of patients who will develop POH/PPAD can lead to a better treatment and patient outcome

R2-SPGI-6

Role of preoperative regional lymph node metastasis detected on CT and/or FDG-PET scans in the prediction of early recurrence of pancreatic adenocarcinoma after curative resection

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Ja Kyung Yoon, (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to evaluate the role of regional lymph node (LN) metastasis detected on preoperative CT and/or 18F-fluoro-2-deoxyglucose-positron emission tomography (FDG-PET) scans in the prediction of early tumor recurrence after curative surgical resection of pancreatic ductal adenocarcinoma (PDAC).

METHODS AND MATERIALS

This retrospective study included 137 patients who underwent upfront surgery with R0 resection of PDAC between 2013 and 2016. Regional LN metastasis was identified using two criteria: both preoperative CT and FDG-PET scans (LNAND) or preoperative CT or FDG-PET scans (LNOR). Cox proportional hazard regression analysis was used to determine the preoperative risk factors for early tumor recurrence. The significant risk factors for early tumor recurrence were used to create a predictive nomogram for early tumor recurrence.

RESULTS

Fifty-five patients had early tumor recurrence within 12 months after curative resection. Regional LN metastasis (both LNOR and LNAND criteria), preoperative carbohydrate antigen 19-9 (CA19-9) levels, and preoperative locally advanced status were significant risk factors for early tumor recurrence. Compared with the LNAND criteria, the LNOR criteria provided higher sensitivity (22.4% vs. 15.5%, p = 0.046) and a higher negative predictive value (61.9% vs. 59.8%, p = 0.046). LNOR, preoperative CA19-9 level, and resectability were included in the predictive nomogram with an adjusted C-index of 0.589.

CONCLUSION

s The preoperative LN metastasis on CT or FDG-PET scans, elevated serum CA19-9 levels, and locally advanced status were significant risk factors for early recurrence of PDAC after surgery. The predictive nomogram, including these factors, may help guide the first-line treatment of PDAC.

CLINICAL RELEVANCE/APPLICATION

Preoperative LN metastasis identified on CT or FDG-PET scans may help predict early recurrence of pancreatic adenocarcinoma after curative resection.

Development and validation of a radiomics model for predicting malignant IPMN compared with the revised Fukuoka guidelines

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - GI DPS

Participants
Doo Young Lee, MD, MS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The revised international consensus Fukuoka guidelines (Fukuoka guidelines) are commonly used for evaluating pancreatic intraductal papillary mucinous neoplasms (IPMNs). However, assessment of radiomics model in comparison with Fukuoka guidelines by radiologists has been lacking. Thus, this study aimed to evaluate CT-based radiomics model for determining malignant IPMNs and compare its performance with Fukuoka guidelines.

METHODS AND MATERIALS

This retrospective study included a total of 194 consecutive patients with surgically resected pancreatic IPMNs from January 2008 to December 2020. Surgical histopathologic analysis was the reference standard for malignancy. Radiomic features were extracted from preoperative contrast-enhanced CT, and radiomics model was built using the least absolute shrinkage and selection operator with fivefold cross-validation. CT and MR images were independently reviewed based on Fukuoka guidelines by two board-certified abdominal radiologists, who arrived at a consensus in cases of discrepancy. The performance of Fukuoka guidelines was compared with that of the radiomics model. Areas under the curve (AUCs) were compared by using the DeLong method.

RESULTS

A total of 194 patients with pancreatic IPMNs (benign, 83 [43%], malignant, 111 [57%]) were included. The patients were chronologically divided into training set (n = 141; mean age 65 + SD 8.6; men 88) and temporal validation set (n = 53; mean age 66 + SD 9.7; men 31). The diagnostic performance of Fukuoka guidelines was not statistically different between CT and MRI (AUC 0.71 vs. 0.71, P = 0.93). Thus, CT was selected for further comparison between Fukuoka guidelines and radiomics model. The CT radiomics model showed higher diagnostic performance (AUC, 0.85 vs 0.71 [P = 0.038]), specificity (84.6% vs 61.5% [P = 0.041]), and positive predictive value (84.0% vs 66.7% [P = 0.044]) than Fukuoka guidelines in the validation set.

CONCLUSION

s A CT radiomics model exhibited better diagnostic performance than the revised Fukuoka guidelines by experienced radiologists for classifying malignant IPMNs.

CLINICAL RELEVANCE/APPLICATION

The CT radiomics model performed better than the revised Fukuoka guidelines in determining the malignancy of IPMN. Therefore, the radiomics model will facilitate proper treatment decision making.

R2-SPGU-1 Preoperative prediction of pathological grade of bladder cancer with low VI-RADS score by decision tree model

Participants
Bohong Cao, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore a new model to predict the pathological high-grade (HG) of low VI-RADS (=2) bladder cancer (BC). Meanwhile, the diagnostic efficiency of VI-RADS in predicting muscular-invasive BC (MIBC) will be prospectively validated.

METHODS AND MATERIALS

From March 2020 to February 2022, prospective, preoperative multiparametric MRI was performed on primary patients. VI-RADS scores were performed on the whole group. The pathological findings were considered to be the gold standard of diagnostic assessment. The low VI-RADS group was isolated from the entire cohort. The diagnostic efficiency of the whole group and the subgroup in predicting HGBC, and the whole group in predicting MIBC was assessed. In the subgroup, the correlation of the VI-RADS score main points, which also included other baseline clinical data and imaging characteristics, with the pathological grade of BC were analyzed. Univariate and multivariable logistic regression analysis was used to obtain independent significant factors. The decision tree algorithm was used to construct the prediction model and the ROC curve is used to analyze diagnostic efficiency for the subgroup.

RESULTS

A total of 89 patients were enrolled. The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for predicting HGBC in the whole group were 38.7%, 100.0 %, 100.0% and 41.5%; the AUC was 0.697. For the subgroup, the sensitivity, specificity, PPV, and NPV were 79.0%, 22.2%, 58.8% and 42.9%; the AUC was 0.506. For predicting MIBC in the whole group, sensitivity, specificity, PPV, and NPV were 94.7%, 91.4%, 75.0%, and 98.5%; the AUC was 0.965. The four independent significant factors obtained by logistic regression analysis, gender, age, maximum tumor diameter and tumor contact length accounted for 0.138, 0.339, 0.298 and 0.224, respectively. The AUC of the decision tree model is 0.892

CONCLUSION

s For primary patients, VI-RADS is worthy of promotion as a preoperative standard T-staging method. When VI-RADS = 3, it has excellent positive predictive efficiency for the diagnosis of HGBC. The decision tree model can potentially provide a good preoperative imaging grading method for low VI-RADS primary BC and should be investigated further.

CLINICAL RELEVANCE/APPLICATION

The majority of BC with VI-RADS =3 were high-grade. The decision tree model has good diagnostic efficacy for predicting high-grade BC with VI-RADS =2, and the treatment threshold can be moved forward.

R2-SPGU-2 Diagnosis of Lipid-poor Adrenal Adenomas: Performance Comparison between Non-contrast Spectral CT versus Chemical-Shift MRI

Participants
Yasunori Nagayama, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To compare the diagnostic performance of noncontrast spectral CT and chemical-shift MRI for the discrimination of lipid-poor adrenal adenomas (>10 HU) from nonadenomas.

METHODS AND MATERIALS

This retrospective study included 96 patients with indeterminate adrenal lesions (67 patients with lipid-poor adenomas and 29 patients with nonadenomas [14 metastases, 9 pheochromocytomas (PHEOs), 2 hematomas, 1 adrenocortical carcinoma, 1 cyst, 1 schwannoma, and 1 medullary hyperplasia]) who underwent noncontrast abdominal CT on a dual-layer spectral-detector scanner and chemical-shift MRI on 3-T systems. For each lesion, noncontrast attenuation on conventional 120-kVp images (HUconv) and MonoE 40- and 140-keV images (HUMono40 and HUMono140, respectively) was quantified. ?HU index (= {[HUMono140 - HUMono40]/HUconv} × 100) were calculated as a possible parameter for the adenoma diagnoses (a high ?HU index indicated lipid-poor adenomas). For chemical-shift MRI, the signal intensity (SI) index was calculated as follows: ([SI on in phase - SI on opposed phase]/SI on in phase) × 100. Each imaging parameter was compared between lipid-poor adenomas and nonadenomas using the Mann-Whitney U test. Receiver operating characteristic (ROC) analysis was performed to determine the area under the ROC curve (AUC) for the diagnosis of lipid-poor adenomas. The AUC of each parameter was compared using the DeLong method.

RESULTS

HUconv was significantly lower in adenomas than in nonadenomas (23.7 ± 7.9 vs. 33.5 ± 8.4 HU, P < 0.001), whereas adenomas showed higher ?HU index (135 ± 105 vs. 12.4 ± 21.5) and SI index (41.4 ± 20.2 vs. 7.0 ± 7.9) than nonadenomas (both P < 0.01). The AUC of ?HU index was significantly higher than that of HUconv (0.93 [95% confidence interval (CI), 0.86-0.97] vs. 0.80 [95% CI, 0.71-0.88], P < 0.01) and almost equivalent to that of SI index (0.94 [95% CI, 0.87-0.98], P = 0.88).

CONCLUSION

s Noncontrast spectral CT allowed the discrimination of lipid-poor adenomas from nonadenomas with diagnostic performance almost equivalent to chemical-shift MRI.

CLINICAL RELEVANCE/APPLICATION

The use of spectral CT technology can eliminate the need for chemical-shift MRI and adrenal washout CT for most lipid-poor adrenal lesions identified on noncontrast CT.

R2-SPGU-3 Impact of dynamic contrast-enhanced MRI in 1.5T versus 3T MRI for clinically significant prostate cancer detection

Participants
Lars Schimmoeller, MD, Dusseldorf, Germany (*Presenter*) Nothing to Disclose

PURPOSE

This study analyzes the value of dynamic contrast-enhanced MRI (DCE) of the prostate on 1.5T and 3T examinations in patients within PI-RADS category 4.

METHODS AND MATERIALS

In this retrospective, bi-centric, cohort study all consecutive patients classified as PI-RADS 4 in mpMRI with 100 verified prostate cancers (PCa) in subsequent MRI/US-guided fusion biopsy were included for 1.5T and 3T, each. PCa detection in peripheral zone (PZ) lesions upgraded to PI-RADS 4 based on positive DCE findings was compared between 1.5T and 3T. Secondary objectives are the comparison of false positive lesions and distribution of ISUP groups.

RESULTS

In total, 293 patients within PI-RADS category 4, including 152 (mean 66±8y; median PSA 6.4ng/ml) in the 1.5T group and 141 (mean 65±8y; median PSA 7.2ng/ml) in the 3T group were included. Overall amount of PCa (66%vs.71%; p=0.346) and portion of upgraded lesions (28%vs.21%; p=0.126) did not differ significantly. At 1.5T PCa detection was higher in upgraded lesions compared to 3T (67%vs.48%) with fewer false positives (33%vs.52%). The amount of clinically significant (cs)PCa positive, upgraded lesions was significantly higher at 1.5T versus 3T (11%vs.2.8%; p=0.002). 28% (12/43; 1.5T) and 34% (10/29; 3T) of the upgraded lesions were ISUP1 PCa.

CONCLUSION

s DCE enabled the detection of a substantial amount of additional csPCA in prostate mpMRI at 1.5T. Although, DCE also allowed the detection of additional csPCA at 3T, the effect was smaller at the higher filed strength and was accompanied by a higher risk of overdiagnosis due to detection of additional low-risk PCa.

CLINICAL RELEVANCE/APPLICATION

At 1.5 T, DCE still has great impact in diagnosing prostate cancer, as especially csPCA often show increased perfusion. Whereas cancer was often already obvious after T2w- and DWI-imaging at 3T, DCE plays an important role for the detection when imaging is conducted at lower field strength.

R2-SPGU-1

Preoperative prediction of pathological grade of bladder cancer with low VI-RADS score by decision tree model

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - GU DPS

Participants
Bohong Cao, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore a new model to predict the pathological high-grade (HG) of low VI-RADS (=2) bladder cancer (BC). Meanwhile, the diagnostic efficiency of VI-RADS in predicting muscular-invasive BC (MIBC) will be prospectively validated.

METHODS AND MATERIALS

From March 2020 to February 2022, prospective, preoperative multiparametric MRI was performed on primary patients. VI-RADS scores were performed on the whole group. The pathological findings were considered to be the gold standard of diagnostic assessment. The low VI-RADS group was isolated from the entire cohort. The diagnostic efficiency of the whole group and the subgroup in predicting HGBC, and the whole group in predicting MIBC was assessed. In the subgroup, the correlation of the VI-RADS score main points, which also included other baseline clinical data and imaging characteristics, with the pathological grade of BC were analyzed. Univariate and multivariable logistic regression analysis was used to obtain independent significant factors. The decision tree algorithm was used to construct the prediction model and the ROC curve is used to analyze diagnostic efficiency for the subgroup.

RESULTS

A total of 89 patients were enrolled. The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for predicting HGBC in the whole group were 38.7%, 100.0 %, 100.0% and 41.5%; the AUC was 0.697. For the subgroup, the sensitivity, specificity, PPV, and NPV were 79.0%, 22.2%, 58.8% and 42.9%; the AUC was 0.506. For predicting MIBC in the whole group, sensitivity, specificity, PPV, and NPV were 94.7%, 91.4%, 75.0%, and 98.5%; the AUC was 0.965. The four independent significant factors obtained by logistic regression analysis, gender, age, maximum tumor diameter and tumor contact length accounted for 0.138, 0.339, 0.298 and 0.224, respectively. The AUC of the decision tree model is 0.892

CONCLUSION

s For primary patients, VI-RADS is worthy of promotion as a preoperative standard T-staging method. When VI-RADS = 3, it has excellent positive predictive efficiency for the diagnosis of HGBC. The decision tree model can potentially provide a good preoperative imaging grading method for low VI-RADS primary BC and should be investigated further.

CLINICAL RELEVANCE/APPLICATION

The majority of BC with VI-RADS =3 were high-grade. The decision tree model has good diagnostic efficacy for predicting high-grade BC with VI-RADS =2, and the treatment threshold can be moved forward.

R2-SPHN-1 Development of A Machine Learning-based Fine-grained Risk Stratification System for Thyroid Nodules Using Predefined Clinicoradiological Features

Participants
Jayoung Moon, MD, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

An explainable artificial intelligence-based fine-grained risk stratification is necessary to improve diagnostic specificity and personalized management of thyroid nodules. We constructed and validated a machine learning-based malignancy risk estimation model using ultrasonography, and evaluate its clinical utility for personalized management of thyroid nodules.

METHODS AND MATERIALS

In total, 5,708 biopsy-proven benign (n = 4,597) and malignant (n = 1,111) thyroid nodules were collected from 5,081 consecutive patients from 26 institutions. Seventeen experienced radiologists evaluated nodule composition, echogenicity, orientation, margin, and calcifications on ultrasonographic images. Eight predictive models were used to stratify thyroid nodules according to malignancy risk; model performance was assessed via nested 10-fold cross-validation. The best-performing algorithm was externally validated using 454 thyroid nodules from a tertiary hospital, then compared to the Thyroid Imaging Reporting and Data System (TIRADS)-based interpretations of experienced radiologists.

RESULTS

The area under the receiver operating characteristic (AUROC) curves of the new algorithms ranged from 0.773 to 0.862. The sensitivities, specificities, positive predictive values, and negative predictive values of the best-performing models were 73.6-75.9%, 81.5-83.8%, 49.8-52.4%, and 92.9-93.3%, respectively. For the external validation set, the ElasticNet values were 83.2%, 89.2%, 81.8%, and 90.1%, respectively. The corresponding TIRADS values (generated by radiologists) were 76.0-85.0%, 61.3-80.8%, 53.4-72.1%, and 81.5-90.3%, respectively. The new model exhibited a significantly higher AUROC and specificity than did the TIRADS risk stratification, although its sensitivity was similar. An interactive version of our algorithm can be found at http://tirads.cdss.co.kr.

CONCLUSION

s We developed a reliable machine learning-based predictive model that demonstrated enhanced specificity when stratifying thyroid nodules according to malignancy risk. This system will contribute to improved personalized management of thyroid nodules.

CLINICAL RELEVANCE/APPLICATION

1. The AUROC, sensitivity, and specificity of our model were 0.914, 83.2%, and 89.2%, respectively (derived from the validation data set). 2. Compared to the TIRADS values, the AUROC and specificity are significantly higher, while the sensitivity is similar. 3. An interactive version of our AI algorithm is at http://tirads.cdss.co.kr. 4. On the basis of our findings, an explainable AI-based risk stratification system based on the predefined US features could enhance clinical applicability alongside the radiologists.

R2-SPHN-3 Can Ultrasonography Be Used to Differentiate Parathyroid Masses Abutting Thyroid Gland and Thyroid Masses Extending into Parathyroid Area?

Participants
Chae Woon Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To determine the ultrasonographic (US) features that could help to distinguish between parathyroid masses abutting thyroid gland and thyroid masses extending into parathyroid area.

METHODS AND MATERIALS

Two blinded readers retrospectively evaluated the US images of histopathologically confirmed 76 parathyroid masses abutting thyroid gland and 34 thyroid masses extending into parathyroid area. Maximal diameter, transverse diameter/anterior-posterior diameter (T/AP) ratio, longitudinal diameter/AP diameter (L/AP) ratio, margin, shape, echogenicity, echotexture, and echogenic interface were evaluated and compared between the two groups.

RESULTS

The echogenic interface ($p < 0.0001$) and L/AP ratio ($p < 0.0005$) were identified as statistically significant US features in the differentiation between parathyroid and thyroid masses. Other US features did not show any statistical significance in both groups.

Interobserver agreements were excellent for all US features. The sensitivity/specificity of the presence of echogenic interface and L/AP ratio > 2.0 were 85.5%/100% and 43.2%/82.4% in distinguishing parathyroid from thyroid masses, respectively.

CONCLUSION

s The presence of echogenic interface and L/AP ratio > 2.0 were useful US features of parathyroid masses abutting thyroid gland in differentiating from thyroid masses extending into parathyroid area.

CLINICAL RELEVANCE/APPLICATION

In US differentiation between parathyroid masses abutting thyroid gland and thyroid masses extending into parathyroid area, echogenic interface sign and L/AP ratio > 2.0 would be helpful.

R2-SPIN-1 Functional MRI Data Analysis by Large-scale Kernelized Granger Causality for Identification of Schizophrenia Patients

Participants
Ali Vosoughi, Rochester, NY (*Presenter*) Nothing to Disclose

PURPOSE

To develop and evaluate a novel machine learning method for identifying patients with schizophrenia using large-scale Kernelized Granger Causality (lsKGC) by capturing connectivity differences in resting-state functional MRI (rsfMRI).

METHODS AND MATERIALS

From the publicly available Centers of Biomedical Research Excellence (COBRE) fMRI data repository on 146 subjects (72 schizophrenia patients, 62 controls), we included the subsample of all 62 subjects under the age of 32 years (29 schizophrenia patients, 33 controls) using standard preprocessing by the Nilearn Python library and the NIAK resting-state pipeline, with functional parcellation into 122 brain regions [Bellec, NIAK, 2016]. For calculating directed functional connectivity between brain regions, we have recently developed the large-scale Kernelized Granger Causality (lsKGC) algorithm [Citation blinded for review] that combines nonlinear dimension reduction with multivariate predictive causal modeling in high-dimensional fMRI time series. A 100-iteration cross-validation approach with 80%/20% train/test ratio was applied, where feature selection was performed on each training set using Kendall's tau rank correlation, followed by support vector machine classification. To quantitatively evaluate diagnostic accuracy of lsKGC for correctly classifying schizophrenia patients and normal controls, we compare its performance with both a recent state-of-the-art causal discovery method (PCMCI, [Runge et al., Science, 2019]), and the current clinical fMRI analysis standard of cross-correlation (CC), reporting accuracy, area under ROC curve (AUC), and f1-score.

RESULTS

The lsKGC rsfMRI analysis method significantly outperformed both PCMCI and the clinical standard CC techniques at classifying schizophrenia patients from healthy subjects, with accuracy/AUC/f1 score of 100%/1.0/100% for lsKGC, 86.4%/0.81/78.4% for PCMCI, and 65.8%/0.62/60.4% for CC, respectively.

CONCLUSION

s Our results suggest that lsKGC significantly improves the diagnostic accuracy of correctly identifying patients with schizophrenia from rsfMRI neuroimaging. We conclude that, when compared to both conventional CC analysis and state-of-the-art PCMCI, lsKGC is better suited to capture disease-related brain network connectivity changes in schizophrenia patients.

CLINICAL RELEVANCE/APPLICATION

The lsKGC method classifies schizophrenia subjects and controls by identifying relevant changes in fMRI connectivity, suggesting its potential use as a diagnostic imaging biomarker for neurologic disease.

R2-SPIN-2 A Machine Learning (ML) Model Based on Radiomic Feature From Pre-treatment CT to Predict Response to 1st-line single agent Immunotherapy in Advanced Non-Small Cell Lung Cancer (NSCLC) with High PDL1 Expression

Participants
Ian Janzen, BSc, Vancouver, BC (*Presenter*) Nothing to Disclose

PURPOSE

Lung cancer is the leading cancer-caused death globally, mainly due to most diagnoses being made at incurable advanced stages. More than 75% advanced stage patients have no driver mutation therefore cytotoxic chemotherapy is the primary treatment option. Recent trials have shown immunotherapy (IO) pembrolizumab (Pem) is superior to chemotherapy in the 1st-line setting. Identifying patients most likely respond to IO remains challenging as no convincing clinicopathological features or biomarkers are available; including PDL1, the most widely used biomarker. Patient pre-selection is more critical in the cohort of similar high PDL1 levels (gt;=50%), as half of this sub-cohort can benefit best from single agent Pem, but others may require combined Pem and chemotherapy. The objective of this study is to develop a ML model trained on radiomic features extracted from baseline CT to predict response to Pem in advanced NSCLC with PDL1gt;=50%.

METHODS AND MATERIALS

This study included 97 stage IIIB/IV NSCLC patients with PDL1=50%, no driver mutations, and received 1st-line Pem (56F:41M, 73±6 yo; 96% smoker; 40±26 py; ECOG range: 0-4). All had CT at baseline and the 1st FU occurred 9-12 weeks after starting treatment. Response was assessed using RECIST 1.1 standard definitions (n=60 "disease control, DC"; n=37 "progressive disease,

PD"). Radiologists quantified "disease burden" at baseline CT using the largest dimension of target lung tumor and the total number organs with metastases. An in-house radiomic feature extraction pipeline calculated radiomic features from lung tumor lesions. 5-fold cross validated ML models (Linear Discriminant Analysis) were trained using clinical- and radiomic-based feature sets to predict response (i.e., DC vs. PD). Models were compared using ROC and the model with the highest AUC was used to classify patients into "high- vs. "low-probability responder" using the predicted response probability. Time-to-progression and time-to-death was compared between two groups using Kaplan-Meier plots.

RESULTS

The ML model including both lung tumor radiomics and clinical factors demonstrates optimal performance in classifying treatment response (AUC: 0.94). The OS and PFS prediction is significantly different between the model's predicted "high- vs. low- probability responders" (plt;0.0001).

CONCLUSION

s An LDA model trained on clinical features and radiomic features derived from lung tumors on the baseline CT images prior to treatment start can predict NSCLC treatment response to Pem.

CLINICAL RELEVANCE/APPLICATION

A ML model can serve as a decision-making tool in choosing the optimal 1st- line treatment for advanced NSCLC with PDL1 gt;=50%, which is a currently an unresolved clinical dilemma.

R2-SPIN-3 Modeling Pulmonary Nodule Growth in CT over Time using Spatio-Temporal Neural Network

Participants
Prince Wang, BA, Berkeley, CA (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning-based lung nodule risk stratification is a well-established topic of study, but most existing convolutional neural network models are restricted to a single time point. Doubling time is an important predictor of malignancy risk of a nodule. This study aims to develop and validate a radiology-specific Spatio-Temporal Convolutional-Long Short Term Memory (ST-ConvLSTM) model that can analyze changes in 3D radiological images across two time points, specifically doubling time and steady growth, thus enabling improved risk stratification.

METHODS AND MATERIALS

A synthetic 3D-transformed MNIST handwritten digit pairs dataset with doubling time labels and a real-world longitudinal nodule image pairs dataset with volumetric segmentations from the National Lung Cancer Screening (NLST) CT dataset were created using commercial software. The ST-ConvLSTM architecture was modified and optimized using the synthetic 3D-MNIST dataset, originally adapted from the convolutional LSTM architecture to allow for 3D image and temporal input. The model was trained for both regression and classification tasks of predicting doubling times and growth at a specific range of rates. Evaluation metrics on the holdout test set included Mean Squared Error (MSE) for regression and AUC-ROC for classification.

RESULTS

The ST-ConvLSTM was trained and optimized on 10,000 3D-MNIST digit pairs with known doubling times. The optimal model was tested on 1,000 holdout digit pairs set, achieving a test-time averaged Mean Squared Error (MSE) of 43.2 (error range: ± 6.57 days). The model was then adapted to the NLST training data of 4,274 nodule image pairs. Doubling time of 60-1,000 days was labeled as 'steady growth' and others were considered 'not steady growth' to model typical malignant lung nodule behavior. The model achieved test-time accuracy of 95.27% for correctly predicting steady growth on the test sequence of 300 pairs. Our test-time result also achieved a ROC AUC of 0.986. All code is to be made available at presentation.

CONCLUSION

s We have developed and optimized an ST-ConvLSTM neural network model that can analyze visual and temporal trends in image pairs and then evaluated it on synthetic 3D digit pairs and NLST lung nodule pairs datasets.

CLINICAL RELEVANCE/APPLICATION

We developed and validated a neural network model that can compare two CT images of pulmonary nodules to assess interval growth, allowing for more accurate risk stratification.

R2-SPIN-4 Focal Loss Improves Clinical Deployability of Deep Learning Models

Participants
Syed Rakin Ahmed, (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning (DL) models for clinical diagnosis, prognosis and treatment need to be trustworthy and robust for clinical deployment, given that model predictions often directly inform a subsequent course of action, where individual patient lives are at stake. Central to model robustness is repeatability, or the ability of a model to generate near-identical predictions under identical conditions. The purpose of this study is to utilize focal loss, with and without the presence of Monte Carlo (MC) Dropout in order to improve model repeatability.

METHODS AND MATERIALS

We conduct our experiments on two datasets: the publicly available longitudinal Multicenter Osteoarthritis Study (MOST) dataset for knee osteoarthritis grading, and the Digital Mammographic Imaging Screening Trial (DMIST) dataset, a multi-institutional screening dataset for breast density classification; both represent clinically important classification tasks. We begin with two baseline models optimized for classification performance in each dataset, utilizing cross-entropy loss for (A) MOST, and (B) DMIST, with or without MC dropout and all other parameters identical for each corresponding dataset. We subsequently train models with focal loss, using parameters ?=2 and a=0.25 following hyperparameter tuning, with and without MC dropout. We compare each focal loss experimental result with the corresponding MC or non-MC versions of the baseline.

RESULTS

We find that, in all instances, focal loss improves repeatability from the respective baseline, reflected in statistically significant decreases in the 95% limits of agreement (LoA) on the Bland-Altman plots, while not affecting classification performance, reflected in no statistically significant difference in the corresponding accuracy.

CONCLUSION

s Given that small changes in an image can produce significantly different DL model predictions, it is essential that models designed for clinical deployment be specifically optimized for improved repeatability. Our demonstration that focal loss improves model repeatability without harming classification performance is a critical result, facilitating reliability and trust on clinical DL models.

CLINICAL RELEVANCE/APPLICATION

Improved repeatability utilizing focal loss leads to robust, reliable predictions from clinically deployed deep learning models, preventing incorrect courses of action that might jeopardize patients.

R2-SPIN-5 Generative Adversarial Networks with Dual Discriminator in Image and Fourier Domains for Denoising of Low Dose CT

Participants
Sunggu Kyung, MS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Reduced radiation dosage causes more noise and artifacts, which makes the CT scan more difficult to interpret. Deep learning-based denoising has recently emerged as a potential solution for low-dose CT (LDCT) denoising. However, there are still no satisfactory results due to the over-denoising and artifacts. In this study, we attempted to achieve high denoising metrics using a generative adversarial network (GAN) with dual discriminators in image and Fourier domains.

METHODS AND MATERIALS

The head and neck CT scans for Low Dose training dataset were retrospectively obtained by Asan Medical Center. First, unlike other existing methods, we did not apply the windowing in data preprocessing but used windowing in the discriminator for the applications in the real world. Second, we used the generative adversarial network framework which consists of a generator and two discriminators. We constructed the generator with a Fourier transform convolution to perform more effective denoising and adopted the U-Net structure as a discriminator for concentrating on the image's contexts from global to local details. Third, we combined a discriminator in the Fourier domain to compensate for the information not recognized in the image domain.

RESULTS

In the test set, the proposed model outperformed other models in all metrics, including peak signal-to-noise ratio (PSNR), structural similarity index measure (SSIM), and root mean square error (RMSE) of 33.327, 0.901, and 0.033, respectively. In visualized images, our proposed model showed domain unspecific and high-quality denoising image reconstruction for the brain CT scans. We can analyze that the outputs from low-dose images preserved clinically important signals like the sulcus and gyrus in the brain with high qualities.

CONCLUSION

s Introducing the Fourier domain to the existing GAN of the image domain improved denoising performances. In this study, the Fourier transform convolution in the generator and the discriminator in the Fourier domain were helpful for denoising GAN training. The evaluation results showed that our framework achieved state-of-the-art denoising results compared with existing methods.

CLINICAL RELEVANCE/APPLICATION

Unlike existing methods, our model is robust to windowing preprocessing and achieve high performance in denoising task. Thus, our model can be applied to the real medical world and high PSNR low-dose images can be helpful for patients and radiologists.

Functional MRI Data Analysis by Large-scale Kernelized Granger Causality for Identification of Schizophrenia Patients

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IN DPS

Participants
Ali Vosoughi, Rochester, NY (*Presenter*) Nothing to Disclose

PURPOSE

To develop and evaluate a novel machine learning method for identifying patients with schizophrenia using large-scale Kernelized Granger Causality (lsKGC) by capturing connectivity differences in resting-state functional MRI (rsfMRI).

METHODS AND MATERIALS

From the publicly available Centers of Biomedical Research Excellence (COBRE) fMRI data repository on 146 subjects (72 schizophrenia patients, 62 controls), we included the subsample of all 62 subjects under the age of 32 years (29 schizophrenia patients, 33 controls) using standard preprocessing by the Nilearn Python library and the NIAK resting-state pipeline, with functional parcellation into 122 brain regions [Bellec, NIAK, 2016]. For calculating directed functional connectivity between brain regions, we have recently developed the large-scale Kernelized Granger Causality (lsKGC) algorithm [Citation blinded for review] that combines nonlinear dimension reduction with multivariate predictive causal modeling in high-dimensional fMRI time series. A 100-iteration cross-validation approach with 80%/20% train/test ratio was applied, where feature selection was performed on each training set using Kendall's tau rank correlation, followed by support vector machine classification. To quantitatively evaluate diagnostic accuracy of lsKGC for correctly classifying schizophrenia patients and normal controls, we compare its performance with both a recent state-of-the-art causal discovery method (PCMCI, [Runge et al., Science, 2019]), and the current clinical fMRI analysis standard of cross-correlation (CC), reporting accuracy, area under ROC curve (AUC), and f1-score.

RESULTS

The lsKGC rsfMRI analysis method significantly outperformed both PCMCI and the clinical standard CC techniques at classifying schizophrenia patients from healthy subjects, with accuracy/AUC/f1 score of 100%/1.0/100% for lsKGC, 86.4%/0.81/78.4% for PCMCI, and 65.8%/0.62/60.4% for CC, respectively.

CONCLUSION

s Our results suggest that lsKGC significantly improves the diagnostic accuracy of correctly identifying patients with schizophrenia from rsfMRI neuroimaging. We conclude that, when compared to both conventional CC analysis and state-of-the-art PCMCI, lsKGC is better suited to capture disease-related brain network connectivity changes in schizophrenia patients.

CLINICAL RELEVANCE/APPLICATION

The lsKGC method classifies schizophrenia subjects and controls by identifying relevant changes in fMRI connectivity, suggesting its potential use as a diagnostic imaging biomarker for neurologic disease.

R2-SPIN-2

A Machine Learning (ML) Model Based on Radiomic Feature From Pre-treatment CT to Predict Response to 1st-line single agent Immunotherapy in Advanced Non-Small Cell Lung Cancer (NSCLC) with High PDL1 Expression

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IN DPS

Participants
Ian Janzen, BSc, Vancouver, BC (*Presenter*) Nothing to Disclose

PURPOSE

Lung cancer is the leading cancer-caused death globally, mainly due to most diagnoses being made at incurable advanced stages. More than 75% advanced stage patients have no driver mutation therefore cytotoxic chemotherapy is the primary treatment option. Recent trials have shown immunotherapy (IO) pembrolizumab (Pem) is superior to chemotherapy in the 1st-line setting. Identifying patients most likely respond to IO remains challenging as no convincing clinicopathological features or biomarkers are available; including PDL1, the most widely used biomarker. Patient pre-selection is more critical in the cohort of similar high PDL1 levels (gt;=50%), as half of this sub-cohort can benefit best from single agent Pem, but others may require combined Pem and chemotherapy. The objective of this study is to develop a ML model trained on radiomic features extracted from baseline CT to predict response to Pem in advanced NSCLC with PDL1gt;=50%.

METHODS AND MATERIALS

This study included 97 stage IIIB/IV NSCLC patients with PDL1=50%, no driver mutations, and received 1st-line Pem (56F:41M, 73±6 yo; 96% smoker; 40±26 py; ECOG range: 0-4). All had CT at baseline and the 1st FU occurred 9-12 weeks after starting treatment. Response was assessed using RECIST 1.1 standard definitions (n=60 "disease control, DC"; n=37 "progressive disease, PD"). Radiologists quantified "disease burden" at baseline CT using the largest dimension of target lung tumor and the total number organs with metastases. An in-house radiomic feature extraction pipeline calculated radiomic features from lung tumor lesions. 5-fold cross validated ML models (Linear Discriminant Analysis) were trained using clinical- and radiomic-based feature sets to predict response (i.e., DC vs. PD). Models were compared using ROC and the model with the highest AUC was used to classify patients into "high- vs. "low-probability responder" using the predicted response probability. Time-to-progression and time-to-death was compared between two groups using Kaplan-Meier plots.

RESULTS

The ML model including both lung tumor radiomics and clinical factors demonstrates optimal performance in classifying treatment response (AUC: 0.94). The OS and PFS prediction is significantly different between the model's predicted "high- vs. low- probability responders" (plt;0.0001).

CONCLUSION

s An LDA model trained on clinical features and radiomic features derived from lung tumors on the baseline CT images prior to treatment start can predict NSCLC treatment response to Pem.

CLINICAL RELEVANCE/APPLICATION

A ML model can serve as a decision-making tool in choosing the optimal 1st- line treatment for advanced NSCLC with PDL1 gt;=50%, which is a currently an unresolved clinical dilemma.

R2-SPIR

Interventional Thursday Poster Discussions

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IR DPS

Sub-Events

R2-SPIR-1 Efficacy of Selective Transarterial Chemoembolization with Radiotherapy Versus Y-90 Transarterial Radioembolization in Hepatocellular Carcinoma with Portal Vein Tumor Thrombus

Participants
Yanisa Jarusyingdumrong, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To compare the efficacy of selective transarterial chemoembolization (TACE) combined with radiotherapy (RT) and Y-90 transarterial radioembolization (TARE) in the treatment of hepatocellular carcinoma (HCC) with portal vein tumor thrombosis (PVTT).

METHODS AND MATERIALS

In retrospective cohort study, patients received treatment from January 2011 to October 2019 in a single center were recruited. The overall survival (OS) rate and median survival time were compared between the two groups. Survival curves were constructed using the Kaplan-Meier method and were compared using the log rank test. The confounding factors were adjusted using Laplace regression.

RESULTS

A total of 82 patients with HCC and PVTT received either selective TACE combined with radiotherapy (n = 48) or Y-90 TARE alone (n = 34). The OS rate was significantly lower (1-year HR 3.19; 95%CI 1.22, 8.31; p-value 0.012; 2-year HR 4.00; 95%CI 1.79, 8.94; p-value <0.001) and the median survival time was significantly shorter (4.5 vs 21.1 months, respectively; p-value 0.004) in combined selective TACE and RT group than in Y-90 TARE alone group.

CONCLUSION

s Group receiving selective TACE combined with RT has shorter survival time than group receiving Y-90 TARE alone in patients with HCC and PVTT.

CLINICAL RELEVANCE/APPLICATION

In many countries with limited resources, the systemic treatment recommended for treating advanced stage HCC may not be available. Therefore, a safe and effective alternative should be explored.

R2-SPIR-2 Nanoscale CaO2 Materials Provides a New Perspective for Trans-arterial Chemoembolization Therapy in VX2 Orthotopic Rabbit Liver Cancer Model

Participants
Yingliang Wang, (*Presenter*) Nothing to Disclose

PURPOSE

Transcatheter arterial chemoembolization (TACE) is extensively used in the treatment of liver cancer. However, the efficacy of TACE is usually limited to secondary tumor hypoxia and other progressive exacerbation of the abnormal tumor microenvironment (TME). Herein, we synthesized CaO2 nanoparticles (nano-CaO2) and applied them as a synergistic agent to improve the antitumor efficacy of TACE. Being injected into the tumor, nano-CaO2 would react with water to generate abundant oxygen, hydroxyl ions (OH-), and calcium ions (Ca2+), enabling relieve tumor hypoxia, neutralization of acidic TME, and Ca2+ overloading mediated antitumor, respectively. Moreover, the effect of chemotherapeutic drug within the TACE would be improved due to the improved TME.

METHODS AND MATERIALS

The nano-CaO2 was fabricated by the CaCl2-H2O2 reaction at alkaline pH and stabilized by polyvinyl pyrrolidone. The characteristics of the nanoparticle were evaluated by X-ray diffraction, X-ray photoelectron spectroscopy, Field Emission Transmission Electron Microscopy, and Dynamic light scattering. Measurement of dissolved O2 concentration, pH value and GSH content in solution. In vitro test was used to evaluate the cytotoxicity, apoptosis, intracellular O2, GSH, HIF-1a and VEGF level. In vivo test, twenty-five rabbits with VX2 liver tumor were randomly divided into five groups and injected different agents via hepatic artery (group A: normal saline; group B: lipiodol; group C: lipiodol + doxorubicin; group D: lipiodol + nano-CaO2; group E: lipiodol + nano-CaO2 + doxorubicin). The tumor growth rate, necrosis rate, proliferation index and apoptosis index, histological markers associated with angiogenesis (HIF-a, VEGF, MVD) and immune response (CD8+ T cell) were assessed by imaging and histopathology. Biosafety was evaluated by testing the hepatic and renal function (AST, ALT, BUN, and Cr) and HE staining of main organs in each group.

RESULTS

In vitro, nano-CaO2 could efficiently regulate the TME and improve the antitumor effect of doxorubicin under hypoxia condition. In vivo, compared to other groups, group E achieved lower tumor growth rate, higher tumor necrosis rate, lower expression of histological markers associated with hypoxia and angiogenesis, and higher CD8+ T cell recruitment. All rabbits in group B-E undergo temporary liver injury and recovered later.

CONCLUSION

s Nano-CaO2 could significantly improve the efficacy of TACE in the treatment of rabbit VX2 liver tumors.

CLINICAL RELEVANCE/APPLICATION

Nano-CaO2 could significantly improve the efficacy of TACE in the treatment of rabbit VX2 liver tumors and could recruit CD8+ T cell which may serve as a synergistic agent with immune checkpoint inhibitors. Thus, it has a broad clinical application prospect.

R2-SPIR-3 Gene Expression and DNA Methylation Patterns Highlight Disparities in Ethno-racial Status and Treatment Response in Hepatocellular Carcinoma Patients

Participants
Vishwaarth Vijayakumar, MD, Dunlap, IL (*Presenter*) Nothing to Disclose

PURPOSE

Since 85% of hepatocellular carcinoma (HCC) patients are ineligible for surgical resection or liver transplantation, Interventional Radiology offers locoregional therapies (LRT) as an additional option. However, response rates are modest and the biological factors that underlie tumor response are unclear. HCC rates vary based on ethno-racial status with little information about how these differences may correspond to tumor biology. Therefore, this study performed HCC epigenetic profiling to investigate tumor biology associated with ethno-racial patient populations and LRT response.

METHODS AND MATERIALS

DNA and RNA was extracted from formalin-fixed paraffin-embedded tumor samples representing 47 HCC patients (n=15 Black, n=22 White, n=10 Hispanic). Treatment response was determined using CT/MRI imaging 3 months post-treatment (n=24 complete response, n=15 retreatment candidates). RNA expression (RNA-seq) and DNA methylation (reduced representation bisulfite sequencing) levels were used to stratify patients based on ethno-racial status and treatment response using partial least-squares discriminant analysis (PLS-DA) with 300 runs of bootstrap subsampling. Results were validated using hierarchical clustering. Ingenuity pathway analysis was performed to identify upstream regulators and pathways enriched for identified genes.

RESULTS

PLS-DA identified 100 genes and 12 methylated regions that successfully differentiated between Black and White/Hispanic patients. Hierarchical clustering based on either the top 16 genes identified in >80% of the models or the top 5 methylation regions identified in >60% of the models resulted in successful clustering of Black from White and Hispanic patients. These genes were associated with pathways and upstream regulators related to metabolic regulation and protein translation. PLS-DA identified 100 genes and 150 methylated regions that successfully differentiated between complete responders and retreatment candidates. Hierarchical clustering based on either the top 30 genes identified in >50% of the models or the top 13 methylation regions identified in >85% of the models resulted in successful clustering of patients based on response. These genes, relevant upstream activators, and pathways were related to p53 signaling, DNA repair, and metabolism.

CONCLUSION

s Epigenetic profiles of HCC patients show that differences in metabolic regulation, protein translation, p53 signaling, and DNA repair may correspond to differences in ethno-racial status and treatment response.

CLINICAL RELEVANCE/APPLICATION

This study identified epigenetic profiles, upstream regulators, and enriched pathways which could be useful for identification of precision therapeutic targets for HCC.

R2-SPIR-4 Making a Mark: Follow-up of Outcomes for Combined Methylene Blue and Embolization Coil Marking for Lung Nodule Localization

Participants
Joe Khoury, DO, MBA, Manhasset, NY (*Presenter*) Nothing to Disclose

PURPOSE

To study the efficacy of lung nodule localization with a combined technique utilizing both methylene blue and embolization coils.

METHODS AND MATERIALS

This study was a retrospective mono-centric review of 93 patients who underwent amalgam technique of utilizing methylene blue and embolization coils for lung nodule marking. Inclusion criteria was limited to any patient who underwent lung marking utilizing this technique from 2010 to 2020.

RESULTS

Of the patients undergoing lung marking, 34% (32/93) were male and 66% (61/93) were female. The average age was 65 years, ranging from 3 to 88 years. One patient was excluded due to unavailability of operative documentation. One patient had two nodules that were marked. In these 92 patients, 100% (93/93) of the lung nodules were localized. Both methylene blue and the coil marker were identified in 88/92 (95.7%) patients. In the remaining 4 patients (4.3%), only methylene blue was noted in the pathology and operative reports. 93/93 (100%) of the marked nodules were successfully resected and confirmed by pathology. All of the nodules were successfully excised via VATS, with 0% (0/92) requiring conversion to open thoracotomy.Three patients had difficulties with coil deployment, which did not result in any patient morbidity. In one patient, the embolization coil was dislodged but methylene blue was administered and the nodule was resected. Two patients had coil migratory complications, which involved the coil extending proximally through the trocar tract. Eight patients developed pneumothoraces, with three requiring chest tubes.

CONCLUSION

s This study further supports our hypothesis that lung nodule localization utilizing both methylene blue and embolization microcoils is safe and allows for successful identification and resection of nodules utilizing VATS technique.

CLINICAL RELEVANCE/APPLICATION

Along with the advent of high resolution computed tomography, there has been increasing detection of small pulmonary nodules. These nodules are often not well visualized or palpable during minimally invasive wedge resection with Video Assisted Thoracic Surgery (VATS), which has historically led to an increased rate of conversion to open thoracotomy, as well as increased morbidity. The rate of conversion from VATS to open thoracotomy has been noted to be as high as 23% secondary to inability to properly locate these small nodules. The solution to this problem has been preoperative localization of these nodules with either hook wires, methylene blue, or embolization coils. This study aims to evaluate a combined technique of utilizing both methylene blue and embolization coils, with minimal additional technical effort, that may increase the detection of small pulmonary nodules and decrease perioperative morbidity.

R2-SPIR-5 Experience of Two Referral Centers in The Embolization of The Parenchymal Tract After Percutaneous Portal Vein Catheterization: What's the Best?

Participants
Francesco Carbone, MD, Bergamo, Italy (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study is to compare the outcomes, in terms of safety and efficacy, of different embolization techniques of the parenchymal tract after percutaneous catheterization of the portal vein.

METHODS AND MATERIALS

We retrospectively analyzed all the interventional procedures with percutaneous transhepatic or transplenic access to the portal vein from January 2010 to July 2021 in two tertiary hospitals; procedures of portal vein embolization were excluded. The following data were evaluated: access site, technique of embolization, technical success in terms of immediate thrombosis of the tract, safety and clinical efficacy in terms of hemorrhagic and thrombotic complications absence.

RESULTS

A total of 161 patients (80 females; median age 35.7 years, IQR 40.7) underwent 220 (range 1-6 procedures per patient) percutaneous transhepatic or transplenic portal vein catheterization procedures. The main indications were pancreatic islet transplantation, portal anastomotic stenosis after liver transplantation, and portal vein thrombosis recanalization. As embolic materials gelfoam was used in 105 cases, metallic micro-coils in 54 cases, and cyanoacrylic glue plus lipiodol in 44 cases; in 17 cases the parenchymal tract was not embolized. Technical success was 97.5% (100% gelfoam; 98.1% coils; 97.8% glue; 94% without embolization; p = 0.45). 18 abdominal post-procedural bleedings (8/105 gelfoam; 7/54 coils; 1/44 glue; 2/17 without embolization) occurred, but the difference among groups was not statistically significant (p = 0.25). We detected 12 intrahepatic portal branch thromboses not strictly related to an embolization technique (1/105 gelfoam, 4/54 coils, 3/44 glue, 4/17 without embolization; p = 0.001). Only 1 case of peripheral non-target embolization was documented with glue, without clinical consequences. Comparable technical success rates and clinical outcomes were observed among the transhepatic and the transplenic approaches.

CONCLUSION

s Embolization of the parenchymal tract after percutaneous portal catheterization is technically safe and effective. The use of cyanoacrylic glue in higher caliber accesses allows a better control of periprocedural bleeding, without adding significant embolic complications.

CLINICAL RELEVANCE/APPLICATION

Percutaneous access site hemostasis after percutaneous portal vein catheterization is a sensitive issue in IR suite, with several techniques described, but no global consensus on their effectiveness.

R2-SPIR-6 Risk Factors for Failure of Endovascular Aneurysm Repair with Acute Conversion to Open Aortic Repair

Participants
Waseem Wahood, MS, Burr Ridge, IL (*Presenter*) Nothing to Disclose

PURPOSE

Patients with abdominal aortic aneurysms who undergo failure of endovascular aneurysm repair and acute conversion to open aortic repair (EVAR-c) have a higher 30-day mortality than those treated with open repair alone. The purpose of this study was to identify patients at risk for EVAR-c.

METHODS AND MATERIALS

The National Surgical Quality Improvement Project Vascular-targeted database was queried from 2011 to 2019 for EVAR patients. Patient demographics were analyzed between EVAR and EVAR-c groups using chi-square and student t-tests. Multivariable logistic regression was conducted for risk factor assessment and 30-day reoperations.

RESULTS

18,387 underwent EVAR and 146 underwent EVAR-c. There was no statistical difference in age (p=0.47), gender (p=0.32), race (p=0.75) or BMI (p=0.61). The average aneurysm diameter was 5.83 cm (SD=1.69) in the EVAR group, and 6.43 cm (SD=1.65) in the EVAR-c group (p<0.001). Aneurysm diameter (OR: 1.07 per 1 cm increase; 95% CI: 1.01-1.14; p<0.001), distal extension involving the common iliac (OR: 2.38, 95% CI: 1.43-3.98, p=0.001), and distal extension inferior to the common iliac (OR: 2.40; 95% CI: 1.24-4.63; p=0.009) were associated with higher odds of EVAR-c. EVAR-c was associated with similar odds of 30-day reoperations compared to EVAR (OR: 1.57; 95% CI: 0.61-4.05; p=0.35).

CONCLUSION

s This study suggests that aneurysm morphology plays a dominant and important role when predicting patients who are at risk for failure of endovascular therapy. These results may help guide patient selection for interventional radiologists.

CLINICAL RELEVANCE/APPLICATION

The lack of patient demographic association with EVAR-c in the current study may be secondary to a decrease in access-related issues in patients with complex anatomy, as well as technological advancement and improved operator skillset leading to more successful EVAR procedures in patients with increased comorbidities.

R2-SPIR-7 Radiofrequency Ablation in Combination with Kyphoplasty for the Treatment of Painful Spine Metastases-Evaluation of VAS Pain Scale

Participants
Kenneth Richardson, Miami, FL (*Presenter*) Nothing to Disclose

PURPOSE

To determine the efficacy in pain improvement and safety of radiofrequency ablation (RF) in conjunction with kyphoplasty in treatment of patients with painful spinal metastases

METHODS AND MATERIALS

Between 3/2019 and 10/2021, a total of 51 painful spine tumors were treated among 43 patients and were reviewed retrospectively. The median age of the cohort was 64 years old (range, 33-79) with male-to-female ratio of 0.82. The primary neoplastic disease metastatic to spine were as follows: multiple myeloma (n=16, 31.4%), metastatic breast adenocarcinoma (n=13, 25.5%), metastatic prostate cancer (n=5, 9.8%), small cell lung cancer (n=4, 7.8%), colon adenocarcinoma, follicular lymphoma, pancreatic adenocarcinoma, squamous cell lung cancer (n=2, 3.9%), melanoma, renal cell carcinoma, metastatic thyroid cancer, urothelial cancer, and metastatic adenoid cystic tumor (n=1, 2%). Pain relief was evaluated by the visual analogue scale (VAS) score before and within 3-months after the procedure. The highest documented VAS pre- and post-procedure was recorded. A neurologic exam was also performed immediately before and immediately after the procedure. A two tailed P value <0.05 was considered statistically significant.

RESULTS

Technical success was achieved in all patients. Kyphoplasty and RF ablation was performed on thoracic vertebral bodies in 21 patients (41.2%), lumbar vertebral bodies in 25 patients (49%), and thoracolumbar vertebral bodies on 5 patients (9.8%). 32 patients (62.75%) had kyphoplasty at one vertebral level, 13 patients (25.49%) had two-level kyphoplasty, 5 patients (9.8%) had three-level kyphoplasty, and one patient (1.96%) had a four-level spinal kyphoplasty. The median VAS score decreased from 10 (IQR, 8-10) to 4(IQR, 2-5) in 3 months after procedure (median change -6 (IQR, -7 to -4), P <0.001). The median VAS score change was -6 (IQR, -7 to -4) for single level procedures and -6 (IQR, -7 to -4.25) for multilevel procedures (P= 0.85). Median VAS score change was -6 (IQR, -7 to -5) for thoracic procedures, -5 (IQR, -7 to -4) for lumbar procedures, and -5.5 (IQR, -7.5 to -3.75) for thoracolumbar procedures (P= 0.85). During one kyphoplasty procedure, the anterior margin of the vertebral body was inadvertently breached, but the procedure was completed successfully with no long-term sequelae.

CONCLUSION

s RFA in conjunction with Kyphoplasty appears to be safe and provides meaningful clinical improvement in VAS pain scale scores in patients with pain due to metastatic disease to the spine, when measured at post procedure follow up within 3 months of the procedure.

CLINICAL RELEVANCE/APPLICATION

These results highlight the role of kyphoplasty with RFA in the management of patients with painful spinal metastases and functional decline.

R2-SPIR-8 Safety and Efficacy of Provocative Visceral Angiography with tPA in Patient's With GI Bleed

Participants
Susan Win, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the efficacy and safety of provocative visceral angiography with catheter directed tPA in the diagnosis and management of patients presenting with occult GI bleed that could not be localized with routine diagnostic work-up.

METHODS AND MATERIALS

Radiology reports from a single institution were reviewed to identify patients who underwent provocative visceral angiography for GI bleed from 10/2015 to 7/2021. Clinical information was then collected regarding prior diagnostic studies, intra-procedural medications, immediate technical clinical outcomes, and long term outcomes.

RESULTS

A total of 44 provocative visceral angiograms were performed for both acute and chronic GI bleeds with an unidentified source despite traditional diagnostic work-up. Two cases were excluded as the patient did not receive catheter directed tPA during the procedure, for a total of 42 cases across 37 patients. Patients received up to 24 mg of catheter directed tPA and a combination of up to 5000u of IV heparin and/or 600 mcg Nitroglycerin. Bleeding was successfully induced in 36% (15/42) of patients who, on average, received 16.8 mg of tPA, 5000u of heparin, and 400 mcg Nitroglycerin. Of those, 87% (13/15) underwent intervention (12 IR embolization, 1 GI band ligation), with technical success achieved in all cases. Clinical success, as defined by no recurrent bleeding beyond the perioperative (30 day) period, was achieved in 85% (11/13) of cases. This includes 2 cases where the patient had a single remote episode of self-limited GI bleed following the initiation of systemic anticoagulation. Of the cases where embolization was not performed or was not clinically successful, all patients (4/4) required subsequent surgical intervention.The patients who underwent successful provocative angiography on average had 4 prior GI studies (endoscopy, colonoscopy, or capsule endoscopy). 8/15 had at least 1 prior CTA,11/15 had a prior RBC scan, 3/15 underwent prior negative provocative angiograms, and 6/15 underwent prior negative non-provoked visceral angiograms.Importantly, no post-procedural complications were identified across all patients.

CONCLUSION

s Provocative visceral angiography with tPA was capable of inducing GI bleed in approximately 1/3 of patients studied. In patients where a bleed was induced, intervention resulted in clinical success in 73% (11/15) of patients. No procedure related complications were identified in this study, suggesting that provocative visceral angiography is a safe and efficacious option for the management of GI bleeds.

CLINICAL RELEVANCE/APPLICATION

This study adds to the limited body of evidence demonstrating that provocative visceral angiogram is a safe and efficacious tool for the management of occult GI bleeds.

Efficacy of Selective Transarterial Chemoembolization with Radiotherapy Versus Y-90 Transarterial Radioembolization in Hepatocellular Carcinoma with Portal Vein Tumor Thrombus

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Yanisa Jarusyingdumrong, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To compare the efficacy of selective transarterial chemoembolization (TACE) combined with radiotherapy (RT) and Y-90 transarterial radioembolization (TARE) in the treatment of hepatocellular carcinoma (HCC) with portal vein tumor thrombosis (PVTT).

METHODS AND MATERIALS

In retrospective cohort study, patients received treatment from January 2011 to October 2019 in a single center were recruited. The overall survival (OS) rate and median survival time were compared between the two groups. Survival curves were constructed using the Kaplan-Meier method and were compared using the log rank test. The confounding factors were adjusted using Laplace regression.

RESULTS

A total of 82 patients with HCC and PVTT received either selective TACE combined with radiotherapy (n = 48) or Y-90 TARE alone (n = 34). The OS rate was significantly lower (1-year HR 3.19; 95%CI 1.22, 8.31; p-value 0.012; 2-year HR 4.00; 95%CI 1.79, 8.94; p-value <0.001) and the median survival time was significantly shorter (4.5 vs 21.1 months, respectively; p-value 0.004) in combined selective TACE and RT group than in Y-90 TARE alone group.

CONCLUSION

s Group receiving selective TACE combined with RT has shorter survival time than group receiving Y-90 TARE alone in patients with HCC and PVTT.

CLINICAL RELEVANCE/APPLICATION

In many countries with limited resources, the systemic treatment recommended for treating advanced stage HCC may not be available. Therefore, a safe and effective alternative should be explored.

Nanoscale CaO2 Materials Provides a New Perspective for Trans-arterial Chemoembolization Therapy in VX2 Orthotopic Rabbit Liver Cancer Model

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Yingliang Wang, (*Presenter*) Nothing to Disclose

PURPOSE

Transcatheter arterial chemoembolization (TACE) is extensively used in the treatment of liver cancer. However, the efficacy of TACE is usually limited to secondary tumor hypoxia and other progressive exacerbation of the abnormal tumor microenvironment (TME). Herein, we synthesized CaO2 nanoparticles (nano-CaO2) and applied them as a synergistic agent to improve the antitumor efficacy of TACE. Being injected into the tumor, nano-CaO2 would react with water to generate abundant oxygen, hydroxyl ions (OH-), and calcium ions (Ca2+), enabling relieve tumor hypoxia, neutralization of acidic TME, and Ca2+ overloading mediated antitumor, respectively. Moreover, the effect of chemotherapeutic drug within the TACE would be improved due to the improved TME.

METHODS AND MATERIALS

The nano-CaO2 was fabricated by the CaCl2-H2O2 reaction at alkaline pH and stabilized by polyvinyl pyrrolidone. The characteristics of the nanoparticle were evaluated by X-ray diffraction, X-ray photoelectron spectroscopy, Field Emission Transmission Electron Microscopy, and Dynamic light scattering. Measurement of dissolved O2 concentration, pH value and GSH content in solution. In vitro test was used to evaluate the cytotoxicity, apoptosis, intracellular O2, GSH, HIF-1a and VEGF level. In vivo test, twenty-five rabbits with VX2 liver tumor were randomly divided into five groups and injected different agents via hepatic artery (group A: normal saline; group B: lipiodol; group C: lipiodol + doxorubicin; group D: lipiodol + nano-CaO2; group E: lipiodol + nano-CaO2 + doxorubicin). The tumor growth rate, necrosis rate, proliferation index and apoptosis index, histological markers associated with angiogenesis (HIF-a, VEGF, MVD) and immune response (CD8+ T cell) were assessed by imaging and histopathology. Biosafety was evaluated by testing the hepatic and renal function (AST, ALT, BUN, and Cr) and HE staining of main organs in each group.

RESULTS

In vitro, nano-CaO2 could efficiently regulate the TME and improve the antitumor effect of doxorubicin under hypoxia condition. In vivo, compared to other groups, group E achieved lower tumor growth rate, higher tumor necrosis rate, lower expression of histological markers associated with hypoxia and angiogenesis, and higher CD8+ T cell recruitment. All rabbits in group B-E undergo temporary liver injury and recovered later.

CONCLUSION

s Nano-CaO2 could significantly improve the efficacy of TACE in the treatment of rabbit VX2 liver tumors.

CLINICAL RELEVANCE/APPLICATION

Nano-CaO2 could significantly improve the efficacy of TACE in the treatment of rabbit VX2 liver tumors and could recruit CD8+ T cell which may serve as a synergistic agent with immune checkpoint inhibitors. Thus, it has a broad clinical application prospect.

Gene Expression and DNA Methylation Patterns Highlight Disparities in Ethno-racial Status and Treatment Response in Hepatocellular Carcinoma Patients

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Vishwaarth Vijayakumar, MD, Dunlap, IL (*Presenter*) Nothing to Disclose

PURPOSE

Since 85% of hepatocellular carcinoma (HCC) patients are ineligible for surgical resection or liver transplantation, Interventional Radiology offers locoregional therapies (LRT) as an additional option. However, response rates are modest and the biological factors that underlie tumor response are unclear. HCC rates vary based on ethno-racial status with little information about how these differences may correspond to tumor biology. Therefore, this study performed HCC epigenetic profiling to investigate tumor biology associated with ethno-racial patient populations and LRT response.

METHODS AND MATERIALS

DNA and RNA was extracted from formalin-fixed paraffin-embedded tumor samples representing 47 HCC patients (n=15 Black, n=22 White, n=10 Hispanic). Treatment response was determined using CT/MRI imaging 3 months post-treatment (n=24 complete response, n=15 retreatment candidates). RNA expression (RNA-seq) and DNA methylation (reduced representation bisulfite sequencing) levels were used to stratify patients based on ethno-racial status and treatment response using partial least-squares discriminant analysis (PLS-DA) with 300 runs of bootstrap subsampling. Results were validated using hierarchical clustering. Ingenuity pathway analysis was performed to identify upstream regulators and pathways enriched for identified genes.

RESULTS

PLS-DA identified 100 genes and 12 methylated regions that successfully differentiated between Black and White/Hispanic patients. Hierarchical clustering based on either the top 16 genes identified in >80% of the models or the top 5 methylation regions identified in >60% of the models resulted in successful clustering of Black from White and Hispanic patients. These genes were associated with pathways and upstream regulators related to metabolic regulation and protein translation. PLS-DA identified 100 genes and 150 methylated regions that successfully differentiated between complete responders and retreatment candidates. Hierarchical clustering based on either the top 30 genes identified in >50% of the models or the top 13 methylation regions identified in >85% of the models resulted in successful clustering of patients based on response. These genes, relevant upstream activators, and pathways were related to p53 signaling, DNA repair, and metabolism.

CONCLUSION

s Epigenetic profiles of HCC patients show that differences in metabolic regulation, protein translation, p53 signaling, and DNA repair may correspond to differences in ethno-racial status and treatment response.

CLINICAL RELEVANCE/APPLICATION

This study identified epigenetic profiles, upstream regulators, and enriched pathways which could be useful for identification of precision therapeutic targets for HCC.

Making a Mark: Follow-up of Outcomes for Combined Methylene Blue and Embolization Coil Marking for Lung Nodule Localization

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Joe Khoury, DO, MBA, Manhasset, NY (*Presenter*) Nothing to Disclose

PURPOSE

To study the efficacy of lung nodule localization with a combined technique utilizing both methylene blue and embolization coils.

METHODS AND MATERIALS

This study was a retrospective mono-centric review of 93 patients who underwent amalgam technique of utilizing methylene blue and embolization coils for lung nodule marking. Inclusion criteria was limited to any patient who underwent lung marking utilizing this technique from 2010 to 2020.

RESULTS

Of the patients undergoing lung marking, 34% (32/93) were male and 66% (61/93) were female. The average age was 65 years, ranging from 3 to 88 years. One patient was excluded due to unavailability of operative documentation. One patient had two nodules that were marked. In these 92 patients, 100% (93/93) of the lung nodules were localized. Both methylene blue and the coil marker were identified in 88/92 (95.7%) patients. In the remaining 4 patients (4.3%), only methylene blue was noted in the pathology and operative reports. 93/93 (100%) of the marked nodules were successfully resected and confirmed by pathology. All of the nodules were successfully excised via VATS, with 0% (0/92) requiring conversion to open thoracotomy.Three patients had difficulties with coil deployment, which did not result in any patient morbidity. In one patient, the embolization coil was dislodged but methylene blue was administered and the nodule was resected. Two patients had coil migratory complications, which involved the coil extending proximally through the trocar tract. Eight patients developed pneumothoraces, with three requiring chest tubes.

CONCLUSION

s This study further supports our hypothesis that lung nodule localization utilizing both methylene blue and embolization microcoils is safe and allows for successful identification and resection of nodules utilizing VATS technique.

CLINICAL RELEVANCE/APPLICATION

Along with the advent of high resolution computed tomography, there has been increasing detection of small pulmonary nodules. These nodules are often not well visualized or palpable during minimally invasive wedge resection with Video Assisted Thoracic Surgery (VATS), which has historically led to an increased rate of conversion to open thoracotomy, as well as increased morbidity. The rate of conversion from VATS to open thoracotomy has been noted to be as high as 23% secondary to inability to properly locate these small nodules. The solution to this problem has been preoperative localization of these nodules with either hook wires, methylene blue, or embolization coils. This study aims to evaluate a combined technique of utilizing both methylene blue and embolization coils, with minimal additional technical effort, that may increase the detection of small pulmonary nodules and decrease perioperative morbidity.

Experience of Two Referral Centers in The Embolization of The Parenchymal Tract After Percutaneous Portal Vein Catheterization: What's the Best?

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Francesco Carbone, MD, Bergamo, Italy (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study is to compare the outcomes, in terms of safety and efficacy, of different embolization techniques of the parenchymal tract after percutaneous catheterization of the portal vein.

METHODS AND MATERIALS

We retrospectively analyzed all the interventional procedures with percutaneous transhepatic or transplenic access to the portal vein from January 2010 to July 2021 in two tertiary hospitals; procedures of portal vein embolization were excluded. The following data were evaluated: access site, technique of embolization, technical success in terms of immediate thrombosis of the tract, safety and clinical efficacy in terms of hemorrhagic and thrombotic complications absence.

RESULTS

A total of 161 patients (80 females; median age 35.7 years, IQR 40.7) underwent 220 (range 1-6 procedures per patient) percutaneous transhepatic or transplenic portal vein catheterization procedures. The main indications were pancreatic islet transplantation, portal anastomotic stenosis after liver transplantation, and portal vein thrombosis recanalization. As embolic materials gelfoam was used in 105 cases, metallic micro-coils in 54 cases, and cyanoacrylic glue plus lipiodol in 44 cases; in 17 cases the parenchymal tract was not embolized. Technical success was 97.5% (100% gelfoam; 98.1% coils; 97.8% glue; 94% without embolization; p = 0.45). 18 abdominal post-procedural bleedings (8/105 gelfoam; 7/54 coils; 1/44 glue; 2/17 without embolization) occurred, but the difference among groups was not statistically significant (p = 0.25). We detected 12 intrahepatic portal branch thromboses not strictly related to an embolization technique (1/105 gelfoam, 4/54 coils, 3/44 glue, 4/17 without embolization; p = 0.001). Only 1 case of peripheral non-target embolization was documented with glue, without clinical consequences. Comparable technical success rates and clinical outcomes were observed among the transhepatic and the transplenic approaches.

CONCLUSION

s Embolization of the parenchymal tract after percutaneous portal catheterization is technically safe and effective. The use of cyanoacrylic glue in higher caliber accesses allows a better control of periprocedural bleeding, without adding significant embolic complications.

CLINICAL RELEVANCE/APPLICATION

Percutaneous access site hemostasis after percutaneous portal vein catheterization is a sensitive issue in IR suite, with several techniques described, but no global consensus on their effectiveness.

Risk Factors for Failure of Endovascular Aneurysm Repair with Acute Conversion to Open Aortic Repair

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Waseem Wahood, MS, Burr Ridge, IL (*Presenter*) Nothing to Disclose

PURPOSE

Patients with abdominal aortic aneurysms who undergo failure of endovascular aneurysm repair and acute conversion to open aortic repair (EVAR-c) have a higher 30-day mortality than those treated with open repair alone. The purpose of this study was to identify patients at risk for EVAR-c.

METHODS AND MATERIALS

The National Surgical Quality Improvement Project Vascular-targeted database was queried from 2011 to 2019 for EVAR patients. Patient demographics were analyzed between EVAR and EVAR-c groups using chi-square and student t-tests. Multivariable logistic regression was conducted for risk factor assessment and 30-day reoperations.

RESULTS

18,387 underwent EVAR and 146 underwent EVAR-c. There was no statistical difference in age (p=0.47), gender (p=0.32), race (p=0.75) or BMI (p=0.61). The average aneurysm diameter was 5.83 cm (SD=1.69) in the EVAR group, and 6.43 cm (SD=1.65) in the EVAR-c group (p<0.001). Aneurysm diameter (OR: 1.07 per 1 cm increase; 95% CI: 1.01-1.14; p<0.001), distal extension involving the common iliac (OR: 2.38, 95% CI: 1.43-3.98, p=0.001), and distal extension inferior to the common iliac (OR: 2.40; 95% CI: 1.24-4.63; p=0.009) were associated with higher odds of EVAR-c. EVAR-c was associated with similar odds of 30-day reoperations compared to EVAR (OR: 1.57; 95% CI: 0.61-4.05; p=0.35).

CONCLUSION

s This study suggests that aneurysm morphology plays a dominant and important role when predicting patients who are at risk for failure of endovascular therapy. These results may help guide patient selection for interventional radiologists.

CLINICAL RELEVANCE/APPLICATION

The lack of patient demographic association with EVAR-c in the current study may be secondary to a decrease in access-related issues in patients with complex anatomy, as well as technological advancement and improved operator skillset leading to more successful EVAR procedures in patients with increased comorbidities.

Radiofrequency Ablation in Combination with Kyphoplasty for the Treatment of Painful Spine Metastases-Evaluation of VAS Pain Scale

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Kenneth Richardson, Miami, FL (*Presenter*) Nothing to Disclose

PURPOSE

To determine the efficacy in pain improvement and safety of radiofrequency ablation (RF) in conjunction with kyphoplasty in treatment of patients with painful spinal metastases

METHODS AND MATERIALS

Between 3/2019 and 10/2021, a total of 51 painful spine tumors were treated among 43 patients and were reviewed retrospectively. The median age of the cohort was 64 years old (range, 33-79) with male-to-female ratio of 0.82. The primary neoplastic disease metastatic to spine were as follows: multiple myeloma (n=16, 31.4%), metastatic breast adenocarcinoma (n=13, 25.5%), metastatic prostate cancer (n=5, 9.8%), small cell lung cancer (n=4, 7.8%), colon adenocarcinoma, follicular lymphoma, pancreatic adenocarcinoma, squamous cell lung cancer (n=2, 3.9%), melanoma, renal cell carcinoma, metastatic thyroid cancer, urothelial cancer, and metastatic adenoid cystic tumor (n=1, 2%). Pain relief was evaluated by the visual analogue scale (VAS) score before and within 3-months after the procedure. The highest documented VAS pre- and post-procedure was recorded. A neurologic exam was also performed immediately before and immediately after the procedure. A two tailed P value <0.05 was considered statistically significant.

RESULTS

Technical success was achieved in all patients. Kyphoplasty and RF ablation was performed on thoracic vertebral bodies in 21 patients (41.2%), lumbar vertebral bodies in 25 patients (49%), and thoracolumbar vertebral bodies on 5 patients (9.8%). 32 patients (62.75%) had kyphoplasty at one vertebral level, 13 patients (25.49%) had two-level kyphoplasty, 5 patients (9.8%) had three-level kyphoplasty, and one patient (1.96%) had a four-level spinal kyphoplasty. The median VAS score decreased from 10 (IQR, 8-10) to 4(IQR, 2-5) in 3 months after procedure (median change -6 (IQR, -7 to -4), P <0.001). The median VAS score change was -6 (IQR, -7 to -4) for single level procedures and -6 (IQR, -7 to -4.25) for multilevel procedures (P= 0.85). Median VAS score change was -6 (IQR, -7 to -5) for thoracic procedures, -5 (IQR, -7 to -4) for lumbar procedures, and -5.5 (IQR, -7.5 to -3.75) for thoracolumbar procedures (P= 0.85). During one kyphoplasty procedure, the anterior margin of the vertebral body was inadvertently breached, but the procedure was completed successfully with no long-term sequelae.

CONCLUSION

s RFA in conjunction with Kyphoplasty appears to be safe and provides meaningful clinical improvement in VAS pain scale scores in patients with pain due to metastatic disease to the spine, when measured at post procedure follow up within 3 months of the procedure.

CLINICAL RELEVANCE/APPLICATION

These results highlight the role of kyphoplasty with RFA in the management of patients with painful spinal metastases and functional decline.

Safety and Efficacy of Provocative Visceral Angiography with tPA in Patient's With GI Bleed

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - IR DPS

Participants
Susan Win, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the efficacy and safety of provocative visceral angiography with catheter directed tPA in the diagnosis and management of patients presenting with occult GI bleed that could not be localized with routine diagnostic work-up.

METHODS AND MATERIALS

Radiology reports from a single institution were reviewed to identify patients who underwent provocative visceral angiography for GI bleed from 10/2015 to 7/2021. Clinical information was then collected regarding prior diagnostic studies, intra-procedural medications, immediate technical clinical outcomes, and long term outcomes.

RESULTS

A total of 44 provocative visceral angiograms were performed for both acute and chronic GI bleeds with an unidentified source despite traditional diagnostic work-up. Two cases were excluded as the patient did not receive catheter directed tPA during the procedure, for a total of 42 cases across 37 patients. Patients received up to 24 mg of catheter directed tPA and a combination of up to 5000u of IV heparin and/or 600 mcg Nitroglycerin. Bleeding was successfully induced in 36% (15/42) of patients who, on average, received 16.8 mg of tPA, 5000u of heparin, and 400 mcg Nitroglycerin. Of those, 87% (13/15) underwent intervention (12 IR embolization, 1 GI band ligation), with technical success achieved in all cases. Clinical success, as defined by no recurrent bleeding beyond the perioperative (30 day) period, was achieved in 85% (11/13) of cases. This includes 2 cases where the patient had a single remote episode of self-limited GI bleed following the initiation of systemic anticoagulation. Of the cases where embolization was not performed or was not clinically successful, all patients (4/4) required subsequent surgical intervention.The patients who underwent successful provocative angiography on average had 4 prior GI studies (endoscopy, colonoscopy, or capsule endoscopy). 8/15 had at least 1 prior CTA,11/15 had a prior RBC scan, 3/15 underwent prior negative provocative angiograms, and 6/15 underwent prior negative non-provoked visceral angiograms.Importantly, no post-procedural complications were identified across all patients.

CONCLUSION

s Provocative visceral angiography with tPA was capable of inducing GI bleed in approximately 1/3 of patients studied. In patients where a bleed was induced, intervention resulted in clinical success in 73% (11/15) of patients. No procedure related complications were identified in this study, suggesting that provocative visceral angiography is a safe and efficacious option for the management of GI bleeds.

CLINICAL RELEVANCE/APPLICATION

This study adds to the limited body of evidence demonstrating that provocative visceral angiogram is a safe and efficacious tool for the management of occult GI bleeds.

R2-SPMK-1 Can Radiographic Changes of The Humerus Greater Tubercle Predict Superior Cuff Tear?

Participants
Hyemin Park, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to assess the diagnostic value of radiographic findings at humerus greater tubercle (GT) to predict various degrees of superior cuff tear (SCT).

METHODS AND MATERIALS

From January to March of 2019, 255 consecutive patients with shoulder pain who underwent radiographic evaluation followed by ultrasound (US) or magnetic resonance imaging (MRI) were included. Radiographs were reviewed by two musculoskeletal radiologists who were blinded to the US or MRI results for the following findings: sclerosis, erosion, spur and femoralization of humerus GT. Consensus was made in discordant cases. The odds ratio of each radiographic finding to predict the presence of SCT, high grade or more severe tear, full thickness tear (FTT), and FTT over 1cm in anteroposterior (AP) dimension was calculated. Also, the value of using at least one radiographic finding, or two or more findings to predict SCT was assessed.

RESULTS

Sclerosis, erosion, spur and femoralization of GT were all predictive of the presence of superior cuff tear (odds ratio [OR] = 5.95, OR = 15.7948, OR = 6.0992, OR = 8.6035, respectively), high grade or more severe degree of tear (OR = 4.3636, OR = 13.9703, OR = 9.6416, OR = 18.482, respectively), FTT (OR = 3.6959, OR = 25.3881, OR = 25.3881, OR = 36.7284, respectively) and FTT over 1cm in AP dimension(OR = 4.2895, OR = 18.3045, OR = 28.875, OR = 47.4923, respectively). GT sclerosis showed the lowest diagnostic accuracy (69.41%), and GT erosion showed the highest diagnostic accuracy (80.00%) to predict the presence of SCT. Femoralization showed the highest diagnostic accuracy (87.45%) to predict the FTT over 1cm in AP dimension and showed 100% of specificity to diagnose any degree of SCT. When two or more imaging findings were found, there was more solid association between the radiographic findings and SCT regardless of degree (OR = 9.1829, OR = 7.0707, OR = 6.9726, respectively, all p = 0.0001).

CONCLUSION

s Radiographic findings at humerus GT can predict SCT on US or MR. GT erosion showed the highest diagnostic accuracy (80.00%) to predict the presence of SCT.

CLINICAL RELEVANCE/APPLICATION

Radiograph of the shoulder can be used for the screening of SCT and can help the physician to identify the candidates for further examination of the rotator cuff with US or MRI.

R2-SPMK-3 Inter-Rater Reliability and Correlation of L1 Hounsfield Unit Measurements with DXA Scores

Participants
Steven Rothenberg, MD, Birmingham, AL (*Presenter*) Founder, Empower Therapeutics Inc ;Member, Translation Holdings LLC;Consultant, Radiostics LLC

PURPOSE

The opportunistic use of computed tomography (CT) in screening for osteoporosis has been previously reported; however, it’s broad applicability has yet to be demonstrated. Hounsfield units (HUs) are known to correlate well with dual-energy X-ray absorptiometry (DXA) based bone assessments and offer a clinically applicable method of estimating bone quality. While prior studies have generally reported rigorous protocols using prespecified CT scanner settings for HU measurements, the present study sought to report on the correlation between DXA and HUs recorded using several CT scanners with varying sequences, simulating measurements performed in “real-world” hospital and Emergency Department (ED) settings.

METHODS AND MATERIALS

Forty consecutive patients who underwent DXA and two abdominal CT scans, each on a Phillips and General Electric (GE) scanner within six months between the years of 2017 and 2021 at a level 1 tertiary care academic medical center were included in this study. Six raters performed HU measurements of trabecular bone at the L1 vertebral body for each patient on the two separate scanners. Inter-rater reliability of the HU measurements and their correlations with recorded DXA-based bone assessments were

determined on each scanner brand. Correlation coefficients were calculated for the HU measurements between scanner brands as well as for the CT HUs with each DXA measurement (femoral neck, total femur, L1 vertebra and total spine). Results were reported using the intraclass coefficient (ICC) statistic for reliability and Pearson's R for correlations.

RESULTS

The ICC for L1 HUs read on the Phillips and GE scanners were 0.85 and 0.82, respectively, indicating excellent agreement. The correlation coefficient for the mean HUs on the Phillips and GE scanners was 0.92, also indicating excellent correlation. For both scanner brands, the HU values most closely correlated with the total femur (Phillips: Rho = 0.52, p lt; 0.001; GE: Rho = 0.45, p = 0.003) and femoral neck (Phillips: Rho = 0.46, p = 0.003; GE: Rho = 0.38, p = 0.02) T-scores, respectively. L1 and total spine T-scores correlated less with L1 HU values.

CONCLUSION

s HU values recorded on a Phillips and GE scanner both demonstrated excellent inter-rater reliability. Correlations were strongest between L1 HU values and total femur DXA T-scores.

CLINICAL RELEVANCE/APPLICATION

Abdominal CT imaging across multiple hospital settings demonstrates reliable identification of patients with osteoporosis and represents an opportunity for minimizing radiation exposure and cost.

R2-SPMK-4 Electron Density As A Quantitative CT Metric To Evaluate Lumbar Intervertebral Disc Degeneration

Participants
Tsubasa Nakano, Kagoshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To preliminarily evaluate the usefulness of electron density (ED) as a quantitative CT metric to detect lumbar intervertebral disc degeneration.

METHODS AND MATERIALS

This study included 338 discs in 100 patients who underwent CT examination and MRI within one month. CT was performed using a spectral detector CT scanner, and images of conventional poly-energetic CT value (CTconv) and ED were obtained. Severity of degeneration for each disc was determined using modified Pfirrmann grade (mPG) based on T2-weighetd MRI. In each disc, three ROIs were drawn in the anterior and posterior annulus fibrosis (AAF and PAF) as well as in the nucleus pulposus (NP). Mean CTconv and ED for each ROI were correlated with mPG using Spearman's rank correlation coefficient. The CTconv and ED values in the 3 ROIs as well as their differences between AAF and NP (?AAF-NP) and between PAF and NP (?PAF-NP) were compared between normal (mPG1 and 2) and degenerated discs (mPG3-7) using the Mann-Whitney U test. ROC curve analysis was used to assess the diagnostic abilities of CTconv and ED values. The sensitivity, specificity, and accuracy for differentiating mPG3-7 from mPG1 and 2 were calculated using a threshold criterion determined by the largest Youden's index.

RESULTS

The mean CTconv was significantly positively correlated with mPG in NP (?=0.239, P<0.001), while it was significantly negatively correlated with mPG in AAF and PAF (?=-0.332, -0.287, P<0.001). The mean ED was more closely correlated with mPG than CTconv both in NP (?=0.446, P<0.001) and in AAF and PAF (?=-0.357, -0.291, P<0.001for each). The CTconv and ED of NP in degenerated discs were significantly higher than those of normal discs (P<0.001). In addition, the CTconv and ED of AF as well as ?AAF-NP and ?PAF-NP were significantly lower than those of normal discs (P<0.001 for each). The AUC values for CTconv and ED of AAF, PAF, and NP ranged from 0.617 to 0.758, those for ?AAF-NP and ?PAF-NP of CTconv and ED ranged from 0.765 to 0.915. The AUC value for ?AAF-NP of ED performed best (AUC = 0.915) among all indices.

CONCLUSION

s ED may be a useful quantitative CT metric to evaluate lumbar intervertebral disc degeneration.

CLINICAL RELEVANCE/APPLICATION

Our results demonstrated the potential of ED as a quantitative metric to evaluate lumber intervertebral disc dgeneration.

Electron Density As A Quantitative CT Metric To Evaluate Lumbar Intervertebral Disc Degeneration

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - MK DPS

Participants
Tsubasa Nakano, Kagoshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To preliminarily evaluate the usefulness of electron density (ED) as a quantitative CT metric to detect lumbar intervertebral disc degeneration.

METHODS AND MATERIALS

This study included 338 discs in 100 patients who underwent CT examination and MRI within one month. CT was performed using a spectral detector CT scanner, and images of conventional poly-energetic CT value (CTconv) and ED were obtained. Severity of degeneration for each disc was determined using modified Pfirrmann grade (mPG) based on T2-weighetd MRI. In each disc, three ROIs were drawn in the anterior and posterior annulus fibrosis (AAF and PAF) as well as in the nucleus pulposus (NP). Mean CTconv and ED for each ROI were correlated with mPG using Spearman's rank correlation coefficient. The CTconv and ED values in the 3 ROIs as well as their differences between AAF and NP (?AAF-NP) and between PAF and NP (?PAF-NP) were compared between normal (mPG1 and 2) and degenerated discs (mPG3-7) using the Mann-Whitney U test. ROC curve analysis was used to assess the diagnostic abilities of CTconv and ED values. The sensitivity, specificity, and accuracy for differentiating mPG3-7 from mPG1 and 2 were calculated using a threshold criterion determined by the largest Youden's index.

RESULTS

The mean CTconv was significantly positively correlated with mPG in NP (?=0.239, P<0.001), while it was significantly negatively correlated with mPG in AAF and PAF (?=-0.332, -0.287, P<0.001). The mean ED was more closely correlated with mPG than CTconv both in NP (?=0.446, P<0.001) and in AAF and PAF (?=-0.357, -0.291, P<0.001for each). The CTconv and ED of NP in degenerated discs were significantly higher than those of normal discs (P<0.001). In addition, the CTconv and ED of AF as well as ?AAF-NP and ?PAF-NP were significantly lower than those of normal discs (P<0.001 for each). The AUC values for CTconv and ED of AAF, PAF, and NP ranged from 0.617 to 0.758, those for ?AAF-NP and ?PAF-NP of CTconv and ED ranged from 0.765 to 0.915. The AUC value for ?AAF-NP of ED performed best (AUC = 0.915) among all indices.

CONCLUSION

s ED may be a useful quantitative CT metric to evaluate lumbar intervertebral disc degeneration.

CLINICAL RELEVANCE/APPLICATION

Our results demonstrated the potential of ED as a quantitative metric to evaluate lumber intervertebral disc dgeneration.

R2-SPMS-1 Sarcoidosis Like Reaction Mimics Progression in Patients Treated With Immune Checkpoint Inhibitors

Participants
Samy Ammari, MD, PhD, Villejuif, France (*Presenter*) Nothing to Disclose

PURPOSE

The use of immune checkpoint inhibitors (ICI), has revealed a new panel of unconventional immune-related phenomena in terms of tumor response or progression, and adverse events. Immune-related sarcoidosis-like reactions is frequently misdiagnosed as progressive or recurrent disease. This study aims to decipher the diagnosis hallmark of immune-related sarcoidosis-like reactions as well as its association with patients' outcome.

METHODS AND MATERIALS

we retrospectively included all patients with histologically proven immune-related sarcoidosis-like reaction from a single institution registry centralizing all immune-related adverse events in metastatic cancer patients treated with ICI in monotherapy or combination (anti-PD-1, anti-PD-L1, anti-PD-1 + anti-CTLA-4, anti-PD-L1 + anti-CTLA-4). Fifty-four variables were retrospectively recorded: clinical (n=17), biological (n=11) and radiological (CT and PET-CT scans) (n=26), as well as the percentage of objective response to treatment using the best overall response according to iRECIST.

RESULTS

Out of 3,200 patients treated with ICI, a total of 18 histologically proven sarcoidosis were diagnosed. In these 18 patients, the majority were female patients (n=11/18) treated for melanoma (n=14/18) or clear renal cell carcinoma (n=3/18). The median [range] time to diagnosis of a sarcoidosis-like reaction was 30 [5-126] weeks after ICI treatment initiation. On CT-scans, the most common radiological findings were: absence of radiographical progression of the primary tumor per RECIST1.1 (100%), bilateral symmetrical mediastinal lymphadenopathy (100%), symmetrical hilar lymphadenopathy (84%), and micronodules with lymphatic distribution (15%). On PET-CT, an extramediastinal and/or extrathoracic glucose uptake was observed in 65% of patients. The sites involved were pleural involvement, abdominal lymph nodes, liver, and spleen. Patients with immune-related sarcoidosis-like reactions were objective responders according to iRECIST in 84% (n=15/18) of patients, while only 15% had stable disease.

CONCLUSION

s In our series, immune-related sarcoidosis is characterized by the appearance of new mediastinal and/or pulmonary lesions, usually at 30 weeks after initiation of treatment, with stability of baseline target lesions. PET/CT demonstrated extramediastinal and/or extrathoracic uptake in 65% of patients. This should not be misinterpreted as disease progressive since 84% of patients will show an objective response to ICI.

CLINICAL RELEVANCE/APPLICATION

This study is a message for oncologists and radiologists who need to be aware of the different clinical and radiological aspects of sarcoidosis in order not to be misdiagnosed with tumor progression.

R2-SPNMMI-1 Metabolic Tumor Volume and Sites of Organ Involvement Predict Outcome in NSCLC Patients Receiving Immune-Checkpoint Inhibitor Therapy-a Prospective - Single-Center Study

Participants
Daria Kifjak, MD, Worcester, MA (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the ability of pre-treatment PET parameters and peripheral blood biomarkers for predicting progression free survival (PFS) and overall survival (OS) in NSCLC patients treated with immune-checkpoint inhibitor therapy (ICIT).

METHODS AND MATERIALS

This prospective, single-centre study included 87 patients who underwent a [18F]-FDG PET/CT before ICIT initiation. Organ specific and total metabolic tumor burden were measured using a semiautomatic software. The association between clinical, laboratory and imaging parameters with PFS and OS was assessed using the Log-rank test and cox-regression analysis.

RESULTS

Patients were followed-up for a median of 11 months (range 1-63 months). Metabolic tumor volume (MTV) increased with the sites of organ involvement (SOI) and was correlated with peripheral blood biomarkers including the neutrophil and lymphocyte cell count (Spearman's rho=.0272 or .32; p=.02 or .003; respectively). After adjusting for risk factors (e.g., PD-L1 expression and neutrophil cell count) the MTV and the SOI were independent risk factors for progression (per 100cm³; adjusted hazard ratio [aHR]: 1.13; 95% confidence interval [95%CI]: 1.0128; p=.04; single SOI vs. = 4 SOI: [aHR]: 2.26, [95%CI]: 1.0494; p=.04). MTV and the SOI were independent risk factors for OS (per 100cm³ [aHR]: 1.11, [95%CI]: 1.0123; p=.03; single SOI vs. = 4 SOI: [aHR]: 4.54, [95%CI]: 1.64.58; p=.04). The combination of MTV and SOI improved the risk stratification for PFS and OS (lognk test p<.001).

CONCLUSION

s Our study supports the prognostic value of [18F]FDG-PET/CT in NSCLC patients receiving ICIT. It further demonstrates the complementary value of MTV and metric of organ metastasis for risk assessment of disease progression and mortality.

CLINICAL RELEVANCE/APPLICATION

Incorporation of simple radiological parameters like MTV and SOI could greatly aid the risk assessment of NSCLC patients scheduled for ICIT treatment.

R2-SPNMMI-2 18F-FDG PET/CT Features of SMARCA4-deficient Non-small Cell Lung Cancer (SMARCA4-dNSCLC): Comparative Analysis of SMARCA4-dNSCLC and Non-SMARCA4-dNSCLC in Resection Specimens

Participants
Zhao Long, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The SMARCA4-deficient non-small cell lung cancer (SMARCA4-dNSCLCs) does not overlap with SMARCA4-thoracic sarcoma. There is limited knowledge on the Clinicopathological and 18F-FDG PET/CT features of these SMARCA4-dNSCLCs. This study aimed to retrospectively compare features of SMARCA4-dNSCLC and non-SMARCA4-dNSCLC.

METHODS AND MATERIALS

SMARCA4-dNSCLCs were retrospectively identified in 53 patients from June 2020 to January 2022. Additionally, as a comparative cohort, we consecutively enrolled patients who underwent surgical resection with newly diagnosed of non-SMARCA4-dNSCLC in July 2021. All diagnoses were histopathologic confirmed by surgical samples. The SUVmax of 18F-FDG uptake were calculated for the primary lesion.

RESULTS

A total of 53 SMARCA4-dNSCLC patients and 137 non-SMARCA4-dNSCLC patients were compared. The SMARCA4-dNSCLC occurred more frequently in males (92.5%, P < 0.001) and in smoker (86.8%, P < 0.001). The comparison of smoking history did not remain statistically significant by stratified analysis according to gender. Maximum diameter had no statistically significant difference among subgroups (P=0.910). The SMARCA4-dNSCLC was more frequently observed with higher SUVmax values (P = 0.001). For

predicting SMARCA4-dNSCLC, the receiver operating characteristic curve analysis showed that the area under the curve (AUC) values of the SUVmax and two factors (SUVmax and Male) was 0.663 (95%CI, 0.578-0.748; P = 0.001) and 0.727 (95%CI, 0.653-0.801; P < 0.001).

CONCLUSION

s The SMARCA4-dNSCLC tumors tend to be higher 18F-FDG uptake compared with non-SMARCA4-dNSCLC tumors.

CLINICAL RELEVANCE/APPLICATION

For the first time, we demonstrated that the metabolic characteristic was different between SMARCA4-dNSCLC and non-SMARCA4-dNSCLC. The implications for clinical practice and future research are valuable.

R2-SPNMMI-3 Low-Power MRgFUS Tumor Ablation upon Controlled Accumulation of Magnetic Nanoparticles by Cascade-Activated DNA Cross Linkers

Participants
Yi Zhu, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

Conventional MRgFUS requires high energy when used for tumor treatment and may cause damage to healthy tissue. We developed a new DNA strand surface-modified SPIO nanoparticle to act as a sensitizer to enhance MRgFUS ablation.

METHODS AND MATERIALS

It has been reported that the magnetic Fe3O4 nanoparticles can act as a dual-sensitizer to strengthen both MRI and ultrasound ablation. Herein, in order to reinforce such a dual-enhancing effect of Fe3O4 nanoparticle, a surface modification strategy is developed to prolong its blood circulation and tumor-environment-triggered accumulation and retention at the tumor site. Especially,DNA was selected as the pH-responsive motif because of its superior biocompatibility as well as the fast and sensitive responsive capability.

RESULTS

A DNA linker that can sensitively respond to the weak acidity of 6.5-6.8, corresponding to the extracellular pH of tumor tissues, is screened by DNA sequence optimization. Finally, the double-insured activation process significantly enhanced the delivery and retention amount of the magnetic nanoparticles at the tumor site; as a consequence, the MRI sensitivity was enhanced by 2.4 folds, and a comparable thermal ablation effect could be reached by lowering the ultrasound power by half.

CONCLUSION

s In summary, a modified Fe3O4 nanoparticle, FSIC5P, is designed and synthesized in order to reinforce the dual-enhancing effect of Fe3O4 nanoparticles for MRgFUS treatment application. The dual modifications with the ROS-responsive TK-PEG and pH-responsive DNA cross-linker were demonstrated to lead the Fe3O4 nanoparticles with improved MRI sensitivity by 1.7 folds and significantly enhanced the thermal ablation efficacy.

CLINICAL RELEVANCE/APPLICATION

Overall, this investigation demonstrates a feasible resolution to promote the MRgFUS treatment by enhancing the therapeutic efficacy and reducing the side effects, which will be helpful to guide the clinical practice in the future.

Metabolic Tumor Volume and Sites of Organ Involvement Predict Outcome in NSCLC Patients Receiving Immune-Checkpoint Inhibitor Therapy-a Prospective - Single-Center Study

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NMMI DPS

Participants
Daria Kifjak, MD, Worcester, MA (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the ability of pre-treatment PET parameters and peripheral blood biomarkers for predicting progression free survival (PFS) and overall survival (OS) in NSCLC patients treated with immune-checkpoint inhibitor therapy (ICIT).

METHODS AND MATERIALS

This prospective, single-centre study included 87 patients who underwent a [18F]-FDG PET/CT before ICIT initiation. Organ specific and total metabolic tumor burden were measured using a semiautomatic software. The association between clinical, laboratory and imaging parameters with PFS and OS was assessed using the Log-rank test and cox-regression analysis.

RESULTS

Patients were followed-up for a median of 11 months (range 1-63 months). Metabolic tumor volume (MTV) increased with the sites of organ involvement (SOI) and was correlated with peripheral blood biomarkers including the neutrophil and lymphocyte cell count (Spearman's rho=.0272 or .32; p=.02 or .003; respectively). After adjusting for risk factors (e.g., PD-L1 expression and neutrophil cell count) the MTV and the SOI were independent risk factors for progression (per 100cm³; adjusted hazard ratio [aHR]: 1.13; 95% confidence interval [95%CI]: 1.0128; p=.04; single SOI vs. = 4 SOI: [aHR]: 2.26, [95%CI]: 1.0494; p=.04). MTV and the SOI were independent risk factors for OS (per 100cm³ [aHR]: 1.11, [95%CI]: 1.0123; p=.03; single SOI vs. = 4 SOI: [aHR]: 4.54, [95%CI]: 1.64.58; p=.04). The combination of MTV and SOI improved the risk stratification for PFS and OS (lognk test p<.001).

CONCLUSION

s Our study supports the prognostic value of [18F]FDG-PET/CT in NSCLC patients receiving ICIT. It further demonstrates the complementary value of MTV and metric of organ metastasis for risk assessment of disease progression and mortality.

CLINICAL RELEVANCE/APPLICATION

Incorporation of simple radiological parameters like MTV and SOI could greatly aid the risk assessment of NSCLC patients scheduled for ICIT treatment.

18F-FDG PET/CT Features of SMARCA4-deficient Non-small Cell Lung Cancer (SMARCA4-dNSCLC): Comparative Analysis of SMARCA4-dNSCLC and Non-SMARCA4-dNSCLC in Resection Specimens

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NMMI DPS

Participants
Zhao Long, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The SMARCA4-deficient non-small cell lung cancer (SMARCA4-dNSCLCs) does not overlap with SMARCA4-thoracic sarcoma. There is limited knowledge on the Clinicopathological and 18F-FDG PET/CT features of these SMARCA4-dNSCLCs. This study aimed to retrospectively compare features of SMARCA4-dNSCLC and non-SMARCA4-dNSCLC.

METHODS AND MATERIALS

SMARCA4-dNSCLCs were retrospectively identified in 53 patients from June 2020 to January 2022. Additionally, as a comparative cohort, we consecutively enrolled patients who underwent surgical resection with newly diagnosed of non-SMARCA4-dNSCLC in July 2021. All diagnoses were histopathologic confirmed by surgical samples. The SUVmax of 18F-FDG uptake were calculated for the primary lesion.

RESULTS

A total of 53 SMARCA4-dNSCLC patients and 137 non-SMARCA4-dNSCLC patients were compared. The SMARCA4-dNSCLC occurred more frequently in males (92.5%, $P < 0.001$) and in smoker (86.8%, $P < 0.001$). The comparison of smoking history did not remain statistically significant by stratified analysis according to gender. Maximum diameter had no statistically significant difference among subgroups (P=0.910). The SMARCA4-dNSCLC was more frequently observed with higher SUVmax values ($P = 0.001$). For predicting SMARCA4-dNSCLC, the receiver operating characteristic curve analysis showed that the area under the curve (AUC) values of the SUVmax and two factors (SUVmax and Male) was 0.663 (95%CI, 0.578-0.748; $P = 0.001$) and 0.727 (95%CI, 0.653-0.801; $P < 0.001$).

CONCLUSION

s The SMARCA4-dNSCLC tumors tend to be higher 18F-FDG uptake compared with non-SMARCA4-dNSCLC tumors.

CLINICAL RELEVANCE/APPLICATION

For the first time, we demonstrated that the metabolic characteristic was different between SMARCA4-dNSCLC and non-SMARCA4-dNSCLC. The implications for clinical practice and future research are valuable.

Low-Power MRgFUS Tumor Ablation upon Controlled Accumulation of Magnetic Nanoparticles by Cascade-Activated DNA Cross Linkers

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NMMI DPS

Participants
Yi Zhu, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

Conventional MRgFUS requires high energy when used for tumor treatment and may cause damage to healthy tissue. We developed a new DNA strand surface-modified SPIO nanoparticle to act as a sensitizer to enhance MRgFUS ablation.

METHODS AND MATERIALS

It has been reported that the magnetic Fe3O4 nanoparticles can act as a dual-sensitizer to strengthen both MRI and ultrasound ablation. Herein, in order to reinforce such a dual-enhancing effect of Fe3O4 nanoparticle, a surface modification strategy is developed to prolong its blood circulation and tumor-environment-triggered accumulation and retention at the tumor site. Especially,DNA was selected as the pH-responsive motif because of its superior biocompatibility as well as the fast and sensitive responsive capability.

RESULTS

A DNA linker that can sensitively respond to the weak acidity of 6.5-6.8, corresponding to the extracellular pH of tumor tissues, is screened by DNA sequence optimization. Finally, the double-insured activation process significantly enhanced the delivery and retention amount of the magnetic nanoparticles at the tumor site; as a consequence, the MRI sensitivity was enhanced by 2.4 folds, and a comparable thermal ablation effect could be reached by lowering the ultrasound power by half.

CONCLUSION

s In summary, a modified Fe3O4 nanoparticle, FSIC5P, is designed and synthesized in order to reinforce the dual-enhancing effect of Fe3O4 nanoparticles for MRgFUS treatment application. The dual modifications with the ROS-responsive TK-PEG and pH-responsive DNA cross-linker were demonstrated to lead the Fe3O4 nanoparticles with improved MRI sensitivity by 1.7 folds and significantly enhanced the thermal ablation efficacy.

CLINICAL RELEVANCE/APPLICATION

Overall, this investigation demonstrates a feasible resolution to promote the MRgFUS treatment by enhancing the therapeutic efficacy and reducing the side effects, which will be helpful to guide the clinical practice in the future.

R2-SPNPM

Noninterpretive Skills/Quality Improvement/Practice Management Thursday Poster Discussions

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NPM DPS

Sub-Events

R2-SPNPM-1 A Critical Appraisal of The Quality of Vertigo Practice Guidelines Using the AGREE II Tool: A EuroAIM Initiative

Participants
Moreno Zanardo, PhD, San Donato Milanese, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Among the diagnostic tests aimed at the deepening of vertigo, an important role is played by neuroimaging. The aim of this review is to assess the methodological quality of guidelines for the management of vertigo and dizziness and to compare their recommendations, with specific focus on neuroimaging.

METHODS AND MATERIALS

No ethics committee approval was required for this systematic review. In May 2021, a systematic search was performed to find practice guidelines of management of vertigo and dizziness. Databases Reviewed: MEDLINE, EMBASE, National Guideline Clearinghouse, and National Institute for Health and Clinical Excellence database.The evaluation of guidelines quality was performed independently by four authors using the AGREE II tool. We excluded from the results those guidelines that were not primarily focused on vertigo and dizziness, such as national/international guidelines in which vertigo and dizziness were only briefly mentioned.

RESULTS

Our strategy of literature search identified 161 studies, and 15 guidelines published between 2012 and 2020 were selected for the appraisal. Only four guidelines reached the acceptance level in the overall result (at least 60%), with two of them reaching the highest scores (at least 80%). The highest scores were found in Domain 6 "Editorial Independence" (median value=65%) and Domain 4 "Clarity of presentation" (median value=61%). The remaining domains showed a low level of quality: Domain 2 "Stakeholder Involvement", Domain 3 "Rigor of development" and Domain 5 "Applicability" had median values of 21%, 26% and 22% respectively. Eight works out of 15 (53%) had authors coming from different subspecialties that composing the multidisciplinary group, while the other half had authors from a single specialty. The overall assessment of the guidelines correlates both with the number of authors (P = 0.003, Spearman's rho) and with the number of subspecialties involved in the author's group (P = 0.03, Spearman's rho). The quality of these guidelines was very low, because of low involvement of multidisciplinary teams in writing guidelines recommendations.

CONCLUSION

s From our analysis, the quality of the guidelines for the management of vertigo in clinical practice resulted low. This result is attributable to the partial adoption of high-quality standards as suggested by the international indications of AGREE-II for guideline drafting, the lack of randomized controlled trials on the topic of vertigo and dizziness management, and the characteristics of the panels defining guidelines, which were small and heterogeneous.

CLINICAL RELEVANCE/APPLICATION

Future guidelines might take this into account to improve clinical applicability.

R2-SPNPM-2 Frozen or Not? AI Algorithm for Identifying Motion Artifacts on Chest CT

Participants
Giridhar Dasegowda, MBBS, Boston, MA (*Presenter*) Nothing to Disclose

PURPOSE

Motion artifacts recognized at the time of reporting can result in suboptimal diagnostic interpretation (with missed or miscalled lesions) and patient recall. We developed and tested a deep learning (DL) model for identifying substantial motion artifacts on chest CT images that has a negative impact on diagnostic interpretation.

METHODS AND MATERIALS

With IRB approval and HIPAA compliance, we queried our multicenter radiology report database (mPower, Nuance) for chest CT reports between July 2015 - March 2022 for the following terms "motion artifacts," "respiratory motion," "technically inadequate," and "suboptimal" or "limited exam." All CT reports belonged to one of the quaternary (Site A, n= 335; B, n= 199) or community (C, n= 259) hospitals. A thoracic radiologist reviewed CT images of all positive hits for motion artifacts (present or absent) and their severity (no diagnostic effect or major diagnostic impairment). Coronal multiplanar images (2-2.5 mm) belonging to 793 chest CT exams were deidentified and exported offline into a DL model building prototype (Cognex Vision Pro, Cognex Inc.) to create (70% training dataset, n= 554) and test (30% test dataset, n= 239) a DL model to perform two-class classification ("motion" or "no

motion"). Separately, CT from two sites were used for training and testing and later validated on the images from the third hospital. A 5-fold repeated cross-validation was performed to evaluate the model performance with accuracy and receiver operating characteristics analysis (ROC).

RESULTS

Among the chest CT images from 793 patients (mean age 63 ± 17 years; 391 males, 402 females), 372 had no motion artifacts and 421 had substantial motion artifacts. The statistics for the average performance of the DL model after 5-fold repeated cross-validation for the two-class classification included 94% sensitivity, 91% specificity, 93% accuracy and 0.93 area under the ROC curve (AUC: 95% CI 0.89-0.97). Among the training datasets from sites A and B, the DL had 96% sensitivity, 91% specificity, 93% accuracy, 0.94 AUC (95% CI 0.88-0.99). On the external validation dataset from site C, DL had 85% sensitivity, 90% specificity, 87% accuracy with 0.88 AUC (95% CI 0.83-0.92).

CONCLUSION

s Our DL model can successfully identify chest CT exams with diagnostic interpretation limiting motion artifacts in multicenter training and test datasets.

CLINICAL RELEVANCE/APPLICATION

Our DL model deployed on the scanner graphic user interface (GUI) can help alert the technologists about substantial motion artifacts where a repeat image acquisition can help salvage diagnostic information.

R2-SPNR-1 Imaging Findings That Cause False Positive Predictions of Intracranial Hemorrhage by Artificial Intelligence, a Pictorial Review

Participants
Cody Savage, BS, Tuscaloosa, AL (*Presenter*) Nothing to Disclose

PURPOSE

To identify which imaging findings most often lead to false-positive predictions of intracranial hemorrhage (ICH) by artificial intelligence (AI).

METHODS AND MATERIALS

False-positive cases were collected from a single-center, prospective comparative effectiveness study of ICH detection by the FDA approved AI algorithm Aidoc. By evaluating written reports by the neuroradiologists, the cases marked positive for ICH by AI but read negative for ICH by the neuroradiologists were selected. A second neuroradiologist then reviewed the selected cases to establish ground truth. The second neuroradiologist's diagnosis was used as the gold standard of diagnosis. The false-positive cases by AI were then reviewed to detect the pattern of misclassification. Also, examples of false-positive cases are presented by pictorial review.

RESULTS

False positives by AI occurred in 223 (2.2%) of the 9978 cases, equating to a specificity of 97.5%. The sensitivity and accuracy were 96.9% and 95.2%, respectively. The most common imaging finding that resulted in a false positive was beam hardening under the skull (36.7%). Other imaging findings that resulted in false positives include hyperdensity of brain parenchyma by calcium deposition or mass (16.1 %), post-surgical changes (9.4%), hyperdense dura matter (9%), dense vessels (8%), motion artifact (5%), meningioma (3%), Laminar necrosis (3%), leptomeningeal thickening (carcinomatosis or meningitis) (2.6%), cavernoma (2.6%), contrast staining (1.7%), and choroid plexus calcification (0.4%).

CONCLUSION

s The beam-hardening CT artifact, hyperdense parenchymal structures, dural hyperdensity, iatrogenic imaging findings, dense vessels, and motion artifact are the most common cause of false-positive ICH predictions by AI algorithm. While less common, meningioma, laminar necrosis, leptomeningeal infiltration, cavernoma, and contrast staining can also contribute to false-positive predictions.

CLINICAL RELEVANCE/APPLICATION

The radiologists who use AI to screen the ICH should be aware of false-positive calls. Despite the sophisticated developing process of medical AI platforms, it seems that AI models for ICH detection work mainly by detecting hyperdensities that can end in false-positive calls.

R2-SPNR-11 Iterative Labeling and Review with Consensus and Conditional Probability Can Be Utilized to Decrease Variability for Artificial Intelligence Data Curation

Participants
Simas Glinskis, Ithaca, NY (*Presenter*) Employee, Covera Health, Inc

PURPOSE

Machine learning model performance depends on high quality and consistent data annotation, which can be difficult to obtain in the presence of inherent inter-reader labeling variability amongst radiologists. Guidelines can help reduce ambiguity when grading a pathology’s severity; however, guidelines themselves may contain ambiguous definitions. We hypothesized a labeling and review process for guidelines would minimize the inter-reader variability through an iterative process and implemented a method to test this hypothesis on a real life dataset.

METHODS AND MATERIALS

Cervical spine MRI studies were annotated independently for severity of cord compression, central canal stenosis, disc herniation, and neural foraminal stenosis by three subspeciality trained board certified radiologists with the same version of guidelines in batches of 25-50-50 randomly sampled studies. After completion of each batch, statistical methods based on conditional probability were used to measure the inter-reader pathology severity variability and agreement as a group and for each pair of annotators.

Pathology severities with high inter-reader variability or low agreement were targeted for guideline revision that was used in the next batch of MRI studies. The "measure-revise" process was repeated.

RESULTS

Inter-reader variability decreased from 23% to 3% for spinal cord compression when we revised the guidelines and added more granularity, splitting the not-compressed severity into normal, indentend, and flattened cord. Similarly, inter-reader agreement improved from 57% to 75% for severe central canal stenosis, from 74% to 84% for none or small disc herniation, and from 59% to 65% for large disc herniation when we iteratively redefined our guidelines for these pathology severities.

CONCLUSION

s Label agreement amongst our radiologists increased and generated more consistent training data for our machine learning models using the iterative labeling and review process. This approach is pathology agnostic and can be applied whenever clear severity definitions are required.

CLINICAL RELEVANCE/APPLICATION

Iterative labeling as performed with this methodology has the potential to reduce the variation for grading of pathologies in medical images and may improve the performance of AI models.

R2-SPNR-12 Brain Image Auto-Segmentation using 3D Capsule Networks

Participants
Arman Avesta, MD, New Haven, CT (*Presenter*) Stockholder, Hyperfine Research, Inc;

PURPOSE

To develop and validate 3D capsule networks (CapsNets) to segment brain images with features not represented in the training data.

METHODS AND MATERIALS

We used 3430 brain MRIs acquired in a multi-institutional study. We compared our CapsNets with U-Nets, the current standard, based on the accuracy in segmenting various brain structures and those with spatial features not represented in the training data. We also assessed performance when the models are trained using limited data, memory requirements, and computation times.

RESULTS

3D CapsNets segmented the third ventricle, thalamus, and hippocampus with Dice scores of 94%, 94%, and 91%, respectively. 3D CapsNets outperformed 3D U-Nets in segmenting brain images with features that were not represented in the training data, with Dice scores more than 30% higher (P-values < 0.01). 3D CapsNets had 93% fewer trainable parameters than 3D U-Nets. The 3D CapsNets were 25% faster to train compared with U-Nets. The two models were equally fast during testing.

CONCLUSION

s 3D CapsNets segment brain structures with high accuracy, outperform U-Nets in segmenting brain images with features that were not represented during training, and are more efficient compared with U-Nets, achieving similar results while their size is an order of magnitude smaller.

CLINICAL RELEVANCE/APPLICATION

In patients undergoing radiotherapy or neurosurgery, neuroanatomical segmentation is a critical aid that improves outcomes. 3D CapsNets outperformed current auto-segmentation methods in generalizability to brain images with features not represented in the training data.

R2-SPNR-13 Artificial Intelligence (AI) Model Based on Automatized Morphometry and Planimetric Data Obtained in Brain MRI, a Proof of Concepts: Lights Towards the Future for Differentiating Progressive Supranuclear Palsy From Parkinson's Disease

Participants
Francisco Mendoza, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To develop an AI model to differentiate Progressive Supranuclear Palsy (PSP) from Parkinson's disease (PD) and healthy subjects (HS) using automated volumetry and non-automated planimetric assessment data obtained in Magnetic Resonance Imaging (MRI).

METHODS AND MATERIALS

We retrospectively assessed a total of 141 patients with a clinical diagnosis of Parkinsonism paired by age and sex and with a group of HS (PSP n = 47, PD n = 68, HS= 26) between January 2003 and April 2021 and analyzed their brain MRI. Patients without T1 high resolution sequences were excluded, leaving 83 patients (PSP n = 29, PD n = 54). We included different clinical subtypes of PSP: PSP-RS (n= 19), PSP-P (n= 5), PSP-PGF (n= 4), and PSP-F (n= 1). Using automatized SyngoviaBrainMorphometry software (Siemens), we obtained 109 VOIs for each subject, including absolute and normalized values. Two independent radiologists blind to diagnosis performed a planimetric assessment (Massey ratio, Oba ratio, MPRI 1.0, and MRP 2.0). We developed a machine-learning model based on multivariate feature selection and an extreme gradient boosting (XGB) vs. univariate feature selection and random forest (RF) using both automated volumetric data and planimetric assessment to predict PSP, PD, and HS. All subjects were randomly divided into training (85%) and validation (15%) data sets with the same proportions for each clinical group. We assessed the diagnostic accuracy of the model and the most relevant features were ordered by importance score (F-score; where 1.0 represents perfect precision and recall). Additionally, we assessed the diagnostic accuracy of each feature using ROC curves.

RESULTS

The global diagnostic performance of the model to differentiate between the three groups was 82.3%. The diagnostic accuracy of the model to predict PSP from the other groups was 81.82 and for PD was 82.35. The most relevant features of the AI model were the mesencephalic area (0.22), mesencephalic width (0.13), left frontal fray gray matter normalized volume (0.088), and the left

thalamus absolute volume (0.059), and Oba Ratio (0.044). The AUC to differentiate PSP from PD and HS was for the mesencephalic area =0.94, for the mesencephalic width = 0.99, the left frontal fray matter normalized volume =0.50, and the left thalamus absolute volume = 0.69.

CONCLUSION

s The developed AI model using data obtained from brain MRI automated volumetry and non-automated planimetric assessment, showed high accurate discrimination between PSP, PD, and HS, especially for PSP in our study population.

CLINICAL RELEVANCE/APPLICATION

AI model using morphometry and planimetric data can differentiate patients with parkinsonism. It would be necessary to validate this model for its clinical application.

R2-SPNR-15 Neural Architecture Search Based MRI Sequence Design

Participants
Hongjun An, (*Presenter*) Nothing to Disclose

PURPOSE

Designing an MR sequence is very challenging, resulting that currently available sequences are constrained by human intuition. We proposed a new sequence design method using neural architecture search (NAS).

METHODS AND MATERIALS

Our method is designed to produce an optimal sequence for given and target objectives. Hence, these properties are inputted to the Bloch simulator to generate MR signals. Using the signals, a loss function defined by the objective is calculated for optimization. Then the sequence scheduler determines the sequence design using NAS (Fig. 1). NAS was utilized to optimize a series of operations (i.e., sequence) by replacing a neural architecture and its weight parameters with a sequence design and its scan parameters, respectively. To test, two experiments were performed repeatedly to design FLAIR-like sequences and spin-echo-like sequences.

RESULTS

In Experiment 1 (Fig. 1c1), a FLAIR-like sequence and non-intuitive sequence showing 4 RF pulses in place of inversion were generated while CSF signal suppression and gray/white matter signal recovery.In Experiment 2 (Fig. 1c2),, a conventional spin echo (CPMG), Hann-echo-like sequence, and a less intuitive sequence wit three or four RF pulse (12°-89°-168° and 5°-16°-85°-162°). In in-vivo experiment, the new three-RF sequence produced identical contrasts and similar SNR with the spin-echo images (new sequence SNR: 297.1±70.1 vs. spin-echo SNR: 295.8±78.2). The new sequences had reduced RF energy (90% of the spin-echo), while taking a longer duration (18.6 ms vs. 12.4 ms).

CONCLUSION

s A novel automatic sequence design method requiring no prior knowledge or training data was proposed, which successfully reproduced the conventional sequence and invented less-intuitive sequences. This study suggests a potential for automated sequence design that may explore possibilities beyond human intuition.

CLINICAL RELEVANCE/APPLICATION

Using our method, a new sequence can be automatically developed in the clinical considerations with non-intuitive behavior.

R2-SPNR-16 Age-Adjusted Atlas of Diffusion Metrics in Normal Neonatal Brains

Participants
Pratheek Bobba, BS, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

Diffusion weighted imaging (DWI) and diffusion tensor imaging (DTI) are increasingly used in the diagnosis and prognostication of neonatal brain injury. However, rapid changes of apparent diffusion coefficient (ADC) values from DWI and fractional anisotropy (FA) and mean diffusivity (MD) values from DTI complicate the interpretation of DWI and DTI scans in neonates. Thus, robust characterization of these metrics in neonatal brains is required.

METHODS AND MATERIALS

The medical and imaging records of all neonates (0-3 months) born since 2013 at our institution were analyzed. Subjects with normal MRI scans on both clinical report and visual inspection were included. DWI (and associated ADC maps) and DTI scans (and associated FA/MD maps) were then coregistered to a pediatric standard brain space. Voxel-wise general linear models (GLM) were applied to analyze the age-related changes of ADC values throughout the brain. Tract-based spatial statistics of DTI metrics was also applied along white matter tracts in the brain. Linear regression models were used to calculate the rate of change in ADC, FA, and MD values across 5mm cubic voxels. Age adjusted normative atlases of these metrics were generated by calculating the mean and standard deviation in each voxel.

RESULTS

565 neonates with DWI scans, of whom 162 also had DTI scans were included. The mean±SD gestational age (GA) at scan for the DWI cohort was 39.67±2.79 weeks and for the DTI cohort was 38.53±1.94 weeks. Increasing GA at scan was associated with significant reduction of ADC values throughout the brain and significant increase of FA and reduction of MD values throughout white matter tracts. The highest temporal rate of decline in ADC values was seen in the subcortical and cerebellar white matter and vermis. The highest temporal rate of increase in FA and rate of decrease in MD values was seen throughout the cortical white matter (Figure 1). After correcting for GA at scan, greater GA at birth was associated with significant reduction of ADC values in the corpus callosum and convexity cortex and significantly higher FA and lower MD values in the corpus callosum. Online interactive atlases displaying age-specific normative values of ADC (34.5-46.5 weeks), and DTI metrics (35-41 weeks) were developed.

CONCLUSION

s There is significant age-related reduction of ADC values throughout the neonatal brain, with steepest decline in the

s There is significant age-related reduction of ADC values throughout the neonatal brain, with steepest decline in the periventricular white matter. Similar trends in FA and MD values indicate that changes in ADC values are likely related to myelination of white matter in neonatal brains.

CLINICAL RELEVANCE/APPLICATION

Our age adjusted normative atlases can aid neuroradiologists in identification and diagnosis of subtle developmental anomalies and ischemic brain injury in neonates.

R2-SPNR-17 Clinical Feasibility of Reverse Encoding Distortion Correction for Brain DWI: Comparison With Conventional DWI

Participants
Atsushi Nakamoto, MD, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Single-shot echo-planar imaging is a widely used conventional diffusion-weighted imaging (C-DWI) technique, owing to its high speed, but is susceptible to magnetic field inhomogeneities which causes high image distortion. This study was conducted to evaluate whether reverse encoding distortion correction DWI (RDC-DWI), which acquires a pair of two opposite phase encoding polarities, can reduce image distortion for DWI of the brain.

METHODS AND MATERIALS

This study included 50 patients who underwent both RDC-DWI and C-DWI of the brain. Both DW images were obtained by two excitations with acquisition times of 121 and 107 seconds, respectively. Using a five-point scale, two neuroradiologists qualitatively evaluated the image distortion of the pons, cerebellum, temporal skull bases and frontal skull base, and the overall image quality. For quantitative analysis, distortion ratios (DR), the apparent diffusion coefficients (ADC) values, and signal-to-noise ratios (SNR) of the pons and frontal lobe were measured. For the pathologies, we qualitatively evaluated image distortion and measured the ADC values.

RESULTS

The scores for image distortions of all evaluated sites were significantly lower for RDC-DWI than for C-DWI ($p<0.01$), and those for overall image quality were significantly higher for RDC-DWI than for C-DWI ($p<0.01$). The DR of the pons and frontal lobe were significantly lower for RDC-DWI than for C-DWI ($p<0.01$). SNR of these sites were significantly higher for RDC-DWI than for C-DWI ($p=0.03$ and $p=0.01$, respectively). Mean ADC values of these sites did not significantly differ between the two techniques ($p=0.62$ and $p=0.66$, respectively). The scores for image distortions of intracranial lesions (n=22) did not differ significantly between the two techniques ($p=0.25$), whereas those of sinonasal lesions (n=7) was significantly lower for RDC-DWI than for C-DWI ($p=0.03$). Mean ADC values of both intracranial and sinonasal lesions did not differ between the two techniques ($p=0.16$ and $p=0.80$, respectively).

CONCLUSION

s RDC-DWI can significantly reduce image distortion and increase SNR with minimal additional acquisition time, compared with C-DWI.

CLINICAL RELEVANCE/APPLICATION

RDC-DWI can reduce image distortion in the tissue-air interface and improve delineation of sinonasal pathologies.

R2-SPNR-18 Diffusion Weighted Imaging with and without Reverse Encoding Distortion Correction (RDC): Influence to Image Quality and ADC Evaluation in Patients with Skull-based Brain Tumors

Participants
Kazuhiro Murayama, MD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation

PURPOSE

To evaluate influences of newly developed reverse encoding distortion correction (RDC) method for reducing image distortion to image quality and ADC evaluation on diffusion-weighted imaging (DWI) in patients with skull-based brain tumors.

METHODS AND MATERIALS

26 patients with suspected skull-based various brain tumors underwent DWIs with and without RDC at 3T systems. To compare image distortion between DWIs with and without RDC, the deformation ratio (DR) of each tumor was calculated from each tumor area difference between DWI and T2-weighted images. To compare image quality and ADC values between DWIs with and without RDC, the signal to noise ratio (SNR) of normal appearance white matter (NAWM) and ADC values of tumor were determined by ROI measurements in each patient. Moreover, overall image quality, lesion distortion and lesion conspicuity of each tumor were assessed by 5-point visual scoring system by two board-certified radiologists. For quantitative and qualitative image quality comparisons, DR and SNR were compared between DWIs with and without RDC by paired t-test. Kappa statistics with ?2 test was performed for each interobserver agreement evaluations. Then, each score was compared between DWIs with and without RDC by Wilcoxon's signed sum test. To determine the influence of RDC to ADC measurement, ADC value was correlated between DWIs with and without RDC by Spearman's correlation. Then, the limits of agreement of ADC between both DWIs were also determined.

RESULTS

DR of DWI with RDC technique was significantly smaller than that without RDC ($p<0.05$), although others had no significant differences between DWIs with and without RDC. Interobserver agreement for each image quality score was significantly substantial or excellent ($0.70=?=0.92$, $p<0.001$). Moreover, each image quality score of DWI with RDC was significantly higher than that without RDC ($p<0.05$). ADC had a significant and good correction between DWIs with and without RDC ($?=0.98$, $p<0.0001$). The limits of agreement between DWIs with and without RDC was $0.00 \pm 0.13 \times 10\text{-}3 s/mm2$.

CONCLUSION

s Newly developed RDC method has no influence to ADC evaluation and makes it possible to improve image quality on DWI in patients with skull-based brain tumors.

CLINICAL RELEVANCE/APPLICATION

Newly developed RDC method has no influence to ADC evaluation and makes it possible to improve image quality on DWI in patients with skull-based brain tumors.

R2-SPNR-19 Histogram Analysis Based on Neurite Orientation Dispersion and Density Imaging for Differentiation Between Solitary Brain Metastasis and Glioblastoma Multiforme: A Comparison of Two Different ROI Placements

Participants
Jinbo Qi, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To explore the value of histogram analysis based on NODDI in differentiating between solitary brain metastasis (SBM) and glioblastoma multiforme (GBM), and to compare the diagnostic performance of two different region of interest (ROI) placements.

METHODS AND MATERIALS

NODDI data were prospectively obtained from 109 patients with pathologically confirmed GBM (n = 57) and SBM (n = 52) were included. Two ROIs—the peritumoral edema area and whole-tumor area—were delineated across all slices. Eleven histogram parameters of intra-cellular volume fraction (ICVF), isotropic volume fraction (ISOVF) and orientation dispersion index (ODI) from both ROIs were extracted. The parameters of the histogram analysis were compared between SBM and GBM, using independent sample t-test or rank sum test, and then to make meaningful parameters based on logistic regression modeling. Receiver operating characteristic (ROC) analyses were conducted to evaluate the differential diagnosis performance and their performances were compared using DeLong's test.

RESULTS

In peritumoral edema area, ICVFminimum, ICVFmax, ICVFkurtosis, ISOVFskewness, ISOVFkurtosis, ODI10, ODI25 and ODIminimum were significantly higher for GBM than for SBM. ISOVF10, ISOVF25, ISOVF50, ISOVF75, ISOVFmean and ISOVFskewness were significantly lower for GBM than for SBM. The sensitivity of the corresponding logistic regression differential diagnosis model was 80.7%, specificity was 80.7%, and area under the curve (AUC) was 0.851. In whole-tumor area, ICVFmax, ICVFskewness, ICVFkurtosis, ISOVFskewness, ISOVFkurtosis and ODIkurtosis were significantly lower for GBM than for SBM. ISOVF10, ISOVF25, ISOVF50, ISOVF75, ISOVFminimum, ODI10, ODI25, ODI50, ODI75, ODI90, ODImean, ODIvariance, and ODIskewness were significantly lower for GBM than for SBM. The sensitivity of the corresponding logistic regression differential diagnosis model was 96.1%, specificity was 86%, and the area under curve (AUC) was 0.958. DeLong's test showed significant difference (P=0.014) in differential performance between two different ROI placements.

CONCLUSION

s GBM and SBM can be differentiated using the NODDI-based histogram analysis and the ROI on whole-tumor area would exhibit better performance.

CLINICAL RELEVANCE/APPLICATION

The NODDI compartment model theoretically distinguishes three types of water diffusion behavior (i.e., intracellular, extracellular, and CSF), it is more sensitive to microstructural changes, which might demonstrate the difference in water diffusion between tumor infiltration and vasogenic edema. Furthermore, NODDI techniques can identify more different tissue components within tumors than conventional imaging for differentiating the heterogeneity of GBM and SBM.

R2-SPNR-2 Successful Implementation of a Comprehensive CT Brain Artificial Intelligence Assist Device Improves Radiologist Performance

Participants
Peter R. Brotchie, MBBS, PhD, Fitzroy, Australia (*Presenter*) Consultant, Annalise-AI Pty Ltd

PURPOSE

To assess the effect on accuracy when radiologists are assisted by a comprehensive CT Brain (CTB) artificial intelligence device.

METHODS AND MATERIALS

CTB are one of the most common CT investigations in clinical radiology. Despite the extensive training of radiologists, missed diagnosis remains a problem. To assist radiologists in reducing errors, many artificial intelligence devices have been developed. However, most of these tools are capable of only detecting a single finding. With the aim to improve a radiologist's performance across a full range of findings on CTB, a comprehensive AI assist device capable of detecting 144 findings was developed. The deep learning model was trained on 212,484 CTB images and tested on a dataset of 2,848 images. The test set was ground truthed by at least 3 radiologists and adjudicated by a neuroradiologist. The performance of 32 radiologists was measured when reviewing the test dataset with and without AI assistance across several metrics including area under the receiver operating characteristic curve (AUC).

RESULTS

The radiologists AUC averaged 0.79 when assisted by the AI compared to 0.73 when unassisted. Significant improvement in AUC was observed across 91 findings. 17 findings showed decreases in AUC. Many of the largest gains in performance by the radiologists when using the AI, were for clinically critical findings, including findings signifying mass effect (basal cistern effacement, tonsillar and uncal herniation, midline shift, sulcal and ventricular effacement), intracranial haemorrhage (especially aneurysmal and convexity subarachnoid haemorrhage), trauma (intracranial haemorrhage and fractures), obstructive hydrocephalus, intra-axial lesions, aggressive extra-axial masses, orbital cellulitis and acute infarction.

CONCLUSION

s The use of a comprehensive CTB assist device significantly improved radiologist performance across a majority of clinical findings on CTB, demonstrating the potential safety improvements of comprehensive AI.

CLINICAL RELEVANCE/APPLICATION

The comprehensive AI device for CTB, after testing with a large selection of radiologists, showed improved performance by the assisted radiologist, and indicates a potential use case in a radiologists workflow.

R2-SPNR-20 Reliability of Functional and Diffusion Magnetic Resonance Imaging Near Cerebral Cavernous Malformations

Participants
Marco Colasurdo, MD, Pescara, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Surgical resection of cerebral cavernous malformations (CCMs) routinely employs fMRI and DTI for surgical planning to best preserve neurological function. However, hemosiderin-rich lesions such as CCMs may cause artefactual distortion of MRI signals in close proximity. This study investigates the reliability of fMRI and DTI near CCMs.

METHODS AND MATERIALS

Consecutive patients with CCMs undergoing pre-surgical fMRI and DTI mapping were identified from June 2002 to June 2019 at an academic medical centre. Each CCM lesion was hand-contoured using T2 sequences, and two sequential 4-mm expansion shells (S1 and S2) were created, generating three ROIs; every ROI was then flipped to the contralateral hemisphere to obtain control ROIs. Fractional anisotropy (FA) and Regional Homogeneity (ReHo) measurements were then extracted from each ROI. FA and ReHo values were compared with contralateral controls to calculate percentage error. Reliability, accuracy, and precision within ROIs were compared using Welch's t-tests, F-tests and Wilcoxon matched-pairs signed rank tests; p-values were adjusted for multiple comparisons as appropriate.

RESULTS

61 patients were identified and included. Overall, errors of FA were significantly lower than ReHo in S1 and S2 ($p=0.0001$ for both), suggesting that FA is more reliable than ReHo near CCMs. Proximity to CCM lesions significantly worsened the reliability of ReHo (S1 vs. S2, $p=0.0007$), but not FA ($p=0.24$). Further investigations of sources of error revealed that while FA was not significantly biased in any ROI ($p>0.05$ for all), ReHo was biased towards lower signals in CCMs, S1 and S2 ($p<0.05$), an effect that was attenuated with distance from CCMs ($p<0.05$). FA measurements were also more precise than ReHo in S1 and S2 ($p<0.0001$ for both), though proximity to CCMs did not impact precision of either modality ($p>0.05$ for both).

CONCLUSION

s Our findings suggest that DTI imaging is significantly more reliable than fMRI near CCMs. This difference appears largely driven by the negative bias of ReHo measurements near CCMs, a finding consistent with the hypothesis that hemosiderin-rich lesions may lead to artefactual depression of fMRI signals in a distance-dependent manner, phenomenon not seen with DTI in our study. Regardless of proximity to CCMs, DTI was also more precise than fMRI, a difference that may be intrinsic to the imaging modality itself and not due to CCM-related artifacts.

CLINICAL RELEVANCE/APPLICATION

Pre-surgical advanced MRI mapping near vascular rich lesion such as CCMs should be interpreted with caution. Clinicians should be aware that based on our findings, fMRI may not be reliable up to an 8 mm distance from CCMs while DTI appears to be consistently reliable even in close proximity.

R2-SPNR-3 Automated Detection of Cerebral Aneurysms on Time of Flight MR-Angiography using a Deep Learning Approach

Participants
Daniel Paech, MD, PhD, Heidelberg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance of an AI-based software solution designed to automatically detect intracranial aneurysms on time-of-flight MR angiography.

METHODS AND MATERIALS

191 MRI data sets were analyzed using the AI software solution mdbrain (Mediaire, Berlin, Germany) for the presence of intracranial aneurysms on 3D time-of-flight MR angiography obtained using two 3T MRI scanners or a 1.5T MRI scanner according to our clinical standard protocol. The results were compared to the expert reading of an experienced radiologist as a gold standard to measure sensitivity, specificity, positive and negative predictive values as well as the accuracy of the software solution. Additionally, detection rates depending on size, morphology and location of the aneurysms were evaluated.

RESULTS

A total of 54 aneurysms were detected by the expert reader. The software's overall sensitivity for the detection of cerebral aneurysms was 72.6%, the specificity was 87.2%, the accuracy was 82.6%. The positive predictive value was 67.9%, the negative predictive value was 88.5%. We observed high detection rates of 100% for saccular aneurysms larger than 5 mm with no signs of thrombosis, and low detection rates for fusiform and/or partially thrombosed aneurysms of 33.3% and 16.7%, respectively. Out of eight aneurysms that were not included in the initial written reports but that were detected by the expert reader retrospectively, four were detected by the software solution.

CONCLUSION

s Our data suggest that the software can be of assistance to radiologists reporting on time-of-flight MR angiograms. We found the software to be highly reliable in the case of saccular aneurysms, while fusiform aneurysms or aneurysms with partial thrombosis cannot be ruled out by the software. Further studies are needed to investigate the software's impact on detection rates, interrater reliability and reading times.

CLINICAL RELEVANCE/APPLICATION

The software solution we investigated is a CE-labelled product that has not yet been reported on in terms of diagnostic accuracy. Thus, our findings are of importance to radiologists using the software to understand its capabilities, but also its limitations.

R2-SPNR-4 ML-based Prediction of Tumor Etiology in Brain Metastases using Radiomic Features

Participants
Christopher Atkins, MD, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

Brain metastases (BM) are the most common adult brain malignancies. Upon diagnosis, the site of primary tumor is not known in up to 15% of patients. Knowing the likely primary however could alter patient management, and we proposed to create a machine learning-and radiomics-based approach to provide a non-invasive way to facilitate diagnosis.

METHODS AND MATERIALS

Contrast-enhanced T1w MR and FLAIR imaging from 164 patients with a total number of 584 treatment-naive brain metastases were collected. Volumetric segmentations were generated semiautomatically and were reviewed by a board-certified neuroradiologist. Radiomic features were extracted with PyRadiomics. Filter-based feature selection and XGBoost classification were performed in a nested cross-validation (CV) scheme. Classification performance (CP) was evaluated with "One-vs-Rest"-AUC, comparing each class prediction against the sum of all others, and class-weighted macro-AUC.

RESULTS

Most common primary cancers were non-small-cell-lung-cancer (NSCLC, n=88), melanoma (n=33), breast-cancer (n=13), gastrointestinal-cancers (n=13), small-cell-lung-cancer (both n=13), renal-cell-carcinoma (n=7), and others (n=10). XGBoost reached an AUC of 0.64 in internal 5-fold-CV and 0.46 in an external validation set (143 lesions in 42 patients). Best label-wise classification was achieved for NSCLC (One-vs-Rest-AUC=0.71). Integrating individual lesion predictions to predict patient-level outcomes via hard ensemble voting did not lead to improved CP. The clinical performance of the model was not significantly different for metastases with volumes larger versus smaller than a 10-mm-diameter sphere ($P > 0.05$).

CONCLUSION

s This study underlines the challenging nature of predicting the site of the primary tumor in brain metastases by using radiomic features alone. Diagnosis might require the addition of further functional image analysis and/or incorporation of clinical data.

CLINICAL RELEVANCE/APPLICATION

The technology detailed here could one day be applied to brain metastasis of unknown primary in order to more quickly target treatment and improve patient outcomes or survival rates.

R2-SPNR-5 Deep Learning Applied to Cranial Ultrasound for Prediction of Neurodevelopmental Impairment in Preterm Babies: Lessons Learned

Participants
Tahani Ahmad, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Cranial ultrasound (CUS) is widely used as a screening tool to assess brain injury in preterm infants. Severe abnormalities on CUS are known to be associated with Neurodevelopmental impairment (NDI) while, for less severe changes or apparently "normal" scans the prognostic outcome is variable. This study aims to train a deep learning prognostic model based on CUS to early assess NDI outcomes.

METHODS AND MATERIALS

Each CUS image was anonymized, pixels intensities were normalized, and resized to a standard 224x224 resolution. Regions outside of the brain were masked and set to intensity zero. The NDI outcome (i.e. patient outcome) and CUS diagnostic outcome (i.e. timepoint outcome) were imported based on the clinical assessment. The dataset is split into stratified training/test sets (90:10 percent split) grouped by the patient. The total number of patients is 619 with 4180 images. We trained the model using different deep learning approaches: from simple classic CNN to more advanced strategies (e.g. multi-view CNNs, to multiple instance learning).

RESULTS

We tested different CNN architectures and strategies. Preliminary results indicate an average of 0.722 AUC (0.664- 0.779 C.I.) using 10 bootstraps stratified sampling strategies using DenseNet169.

CONCLUSION

s This is a preliminary work to provide a tool to assist clinicians during early NDI assessment. During the preparation of this study, many challenges came to our attention (e.g. images acquired from multiple manufacturers, high presence of clinical confounding variables, scanty literature in this field) and we deployed different strategies to address each of them learning valuable lessons. Finally, although prognostic modeling is difficult, we expect the model performance to improve by including the clinical variable in the next stage.

CLINICAL RELEVANCE/APPLICATION

Prediction of NeuroDevelopmental Imapairemnt (NDI) in preterm infants enables early identification and referral of high-risk infants to intervention programs that have the potential to improve mobility and cognitive development.

R2-SPNR-6 Cost-Effectiveness of AI-Based Opportunistic Screening for Osteoporotic Compression Fractures on Existing Radiographs

Participants
Patti Curl, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Osteoporotic compression fractures (OCFs) are a highly prevalent source of morbidity and mortality, and preventative treatment has been demonstrated to be both effective and cost effective. Still, many patients with OCFs remain undiagnosed, and there is potential value in identifying undiagnosed fractures on radiographs obtained for other indications. Our study group is developing software to access existing radiographs for OCFs with high sensitivity and specificity using an established artificial intelligence deep learning algorithm. The purpose of this analysis is to assess the potential cost-effectiveness of implementing this software.

METHODS AND MATERIALS

Analysis was performed using TreeAge Pro Healthcare software. A deterministic expected-value cost-utility model, combining tree model and Markov model, was used to compare the strategies of opportunistic screening for osteoporotic compression fractures against usual care. The tree model was used to determine the likelihood a patient would receive treatment, and the expected value of each path was calculated with a separate Markov model. Total costs and total quality adjusted life years (QALYS) were calculated for each strategy. The baseline analysis assumed a population of women age 75, and a lifetime time horizon was used. Screening and treatment costs were considered from a societal perspective, at 2022 prices.

RESULTS

In the base case, assuming a cost of software implantation of 10 dollars per patient screened, the screening strategy dominated the non-screening strategy: it resulted in lower cost and increased QALYS. The lower cost was primarily due to the decreased costs associated with fracture treatment and decreased probability of requiring long-term care in patients who received preventative treatment. The screening strategy was dominant up to a cost of $156 per patient screened. At $157, screening was cost effective with an incremental cost effectiveness ratio of $100/QALY (Screening $5389/1.19 QALY No-screening $5388/1.18 QALY).

CONCLUSION

s Opportunistic screening for OCFs can be cost-effective from a societal perspective.

CLINICAL RELEVANCE/APPLICATION

Given the substantial population of patients with OCFs not receiving treatment, opportunistic diagnosis provides an opportunity to add value while also decreasing costs for the health care system as a whole.

R2-SPNR-7 Development and Validation of a Deep Learning-Based Automatic Classification Algorithm for the Medial Temporal Lobe Atrophy Scale Using a Multi-Modality Cascade Transformer

Participants
Dongsoo Lee, MPH,MPH, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Although medial temporal lobe atrophy (MTA) has been incorporated into the diagnostic criteria for Alzheimer's disease (AD) and mild cognitive impairment (MCI) in the NIA-AA guidelines, there might be concerns regarding interobserver variability because the MTA scale is a visual semi-quantitative method that requires training of the readers for confident uses. We aimed to develop and validate a deep learning-based automatic classification algorithm for the MTA scale in patients with cognitive impairment.

METHODS AND MATERIALS

We developed a multi-modality cascade transformer using Vision Transformer (ViT) and TabNet classifier that were used to handle tabular and image data simultaneously. This observational study included consecutive patients with cognitive impairment from a tertiary hospital. 793 patients for the training dataset and 150 patients for the test dataset in the first model were included from March 2017 to June 2018. To improve accuracy, we devised a second model by applying transfer learning with a large cohort to the first model. 1200 patients for the training dataset and 100 patients for the test dataset in the second model were included from June 2018 to June 2021. We clustered the MTA scales into 3 groups (0,1), (2), (3,4) by clinical significance. After analyzing both sides, the higher scale was determined. To compare the performance of the two models, the test dataset of each model and the ADNI dataset were applied and compared.

RESULTS

In first training dataset, group 0, 1, and 2 were 261 (33%), 202 (26%), and 330 (42%) patients, respectively. In the first test dataset, groups 0, 1, and 2 were all 50 (33%) patients, respectively. In second training dataset, group 0, 1, and 2 were 216 (18%), 586 (49%) and 398 (33%) patients, respectively. In second test dataset, group 0, 1 and 2 were 28 (28%), 37 (37%), and 35 (35%) patients, respectively. We conducted an ablation study to compare with various baseline models, and our proposed model achieved the best performance (precision 0.801, recall 0.787, and AUC 0.923). In the first model, the accuracy using the test dataset was 0.787. The accuracy of the second model using the same test dataset applied to the first model was 0.833. In ADNI test dataset, group 0, 1, and 2 were 67 (17%), 198 (50%), and 135 (34%), respectively. The accuracies of both models were 0.613 and 0.642 (the first model and second model), respectively.

CONCLUSION

s The deep learning-based automatic classification algorithm using a multi-modality cascade transformer may allow accurate classification of the MTA scale.

CLINICAL RELEVANCE/APPLICATION

It may be possible to reduce the inter/intra-observer variation in measuring the MTA scale using the deep learning model that we proposed.

R2-SPNR-8 Development and Validation of a Deep Learning-based Automatic Segmentation and Classification of Cerebral White Matter Hyperintensities

Participants
Wooseok Jung, MSc, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

White matter hyperintensities (WMH) commonly attribute to vascular dementia and represent neuroimaging markers of cerebral small vessel disease. Fazekas scale is used to quantify WMH severity in radiology research. An automatic quantification model covering both WMH segmentation and Fazekas scale classification has not yet been explored in depth. We aimed to develop and validate a deep learning-based automatic segmentation and classification of cerebral white matter hyperintensities in patients with cognitive impairment.

METHODS AND MATERIALS

This observational study included consecutive patients with cognitive impairment from a tertiary hospital. A segmentation model using the 2D UNet for training and validation was performed on the dataset of 511 and 64, respectively. An input FLAIR and the corresponding output mask of the segmentation model are concatenated to generate 2-channel input of Fazekas classification model. Two separated classification models for each WMH subtypes using 3D EfficientNetv2 for training and validation were performed on the dataset of 1661 and 110, respectively. Test of segmentation model was performed on the 278 the ADNI dataset. Test of the Fazekas scale classification model was performed on 100 ADNI dataset and 178 dataset of the tertiary hospital included. For the evaluation of the Fazekas scale classification, the datasets used in the test model were evaluated by four experienced neuroradiologists. Classification according to the Fazekas scale was divided into three categories (normal/mild, moderate, and severe), and locations were separately reported as periventricular (PWMH) and deep white matter (DWMH).

RESULTS

Dice score performance of the segmentation model on test dataset by target location subtype were 0.744±0.108, 0.904±0.054, 0.851±0.068 (PWMH and DWMH, PWMH only, DWMH only), respectively. Dice score only concerning PWMH on test dataset by the three categories were 0.907±0.044, 0.948±0.011, and 0.957±0.014, respectively. Dice score only concerning DWMH on the same test dataset by the three categories were 0.844±0.057, 0.946±0.023, and 0.954±0.015, respectively. The accuracy of performance of the Fazekas scale classification model by single rater were 0.86 and 0.87 at PWMH and DWMH, respectively. The accuracy evaluated against mean of multi-rater labels were 0.76 and 0.69 at PWMH and DWMH, respectively.

CONCLUSION

s These results demonstrate the excellent segmentation and classification performance of our models and their potential for deployment as accurate diagnostic support tools for quantified evaluation of WMH.

CLINICAL RELEVANCE/APPLICATION

It may be possible to segment and classify white matter hyperintensities using a deep learning model that we proposed.

Imaging Findings That Cause False Positive Predictions of Intracranial Hemorrhage by Artificial Intelligence, a Pictorial Review

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Cody Savage, BS, Tuscaloosa, AL (*Presenter*) Nothing to Disclose

PURPOSE

To identify which imaging findings most often lead to false-positive predictions of intracranial hemorrhage (ICH) by artificial intelligence (AI).

METHODS AND MATERIALS

False-positive cases were collected from a single-center, prospective comparative effectiveness study of ICH detection by the FDA approved AI algorithm Aidoc. By evaluating written reports by the neuroradiologists, the cases marked positive for ICH by AI but read negative for ICH by the neuroradiologists were selected. A second neuroradiologist then reviewed the selected cases to establish ground truth. The second neuroradiologist's diagnosis was used as the gold standard of diagnosis. The false-positive cases by AI were then reviewed to detect the pattern of misclassification. Also, examples of false-positive cases are presented by pictorial review.

RESULTS

False positives by AI occurred in 223 (2.2%) of the 9978 cases, equating to a specificity of 97.5%. The sensitivity and accuracy were 96.9% and 95.2%, respectively. The most common imaging finding that resulted in a false positive was beam hardening under the skull (36.7%). Other imaging findings that resulted in false positives include hyperdensity of brain parenchyma by calcium deposition or mass (16.1 %), post-surgical changes (9.4%), hyperdense dura matter (9%), dense vessels (8%), motion artifact (5%), meningioma (3%), Laminar necrosis (3%), leptomeningeal thickening (carcinomatosis or meningitis) (2.6%), cavernoma (2.6%), contrast staining (1.7%), and choroid plexus calcification (0.4%).

CONCLUSION

s The beam-hardening CT artifact, hyperdense parenchymal structures, dural hyperdensity, iatrogenic imaging findings, dense vessels, and motion artifact are the most common cause of false-positive ICH predictions by AI algorithm. While less common, meningioma, laminar necrosis, leptomeningeal infiltration, cavernoma, and contrast staining can also contribute to false-positive predictions.

CLINICAL RELEVANCE/APPLICATION

The radiologists who use AI to screen the ICH should be aware of false-positive calls. Despite the sophisticated developing process of medical AI platforms, it seems that AI models for ICH detection work mainly by detecting hyperdensities that can end in false-positive calls.

Iterative Labeling and Review with Consensus and Conditional Probability Can Be Utilized to Decrease Variability for Artificial Intelligence Data Curation

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Simas Glinskis, Ithaca, NY (*Presenter*) Employee, Covera Health, Inc

PURPOSE

Machine learning model performance depends on high quality and consistent data annotation, which can be difficult to obtain in the presence of inherent inter-reader labeling variability amongst radiologists. Guidelines can help reduce ambiguity when grading a pathology's severity; however, guidelines themselves may contain ambiguous definitions. We hypothesized a labeling and review process for guidelines would minimize the inter-reader variability through an iterative process and implemented a method to test this hypothesis on a real life dataset.

METHODS AND MATERIALS

Cervical spine MRI studies were annotated independently for severity of cord compression, central canal stenosis, disc herniation, and neural foraminal stenosis by three subspeciality trained board certified radiologists with the same version of guidelines in batches of 25-50-50 randomly sampled studies. After completion of each batch, statistical methods based on conditional probability were used to measure the inter-reader pathology severity variability and agreement as a group and for each pair of annotators. Pathology severities with high inter-reader variability or low agreement were targeted for guideline revision that was used in the next batch of MRI studies. The "measure-revise" process was repeated.

RESULTS

Inter-reader variability decreased from 23% to 3% for spinal cord compression when we revised the guidelines and added more granularity, splitting the not-compressed severity into normal, indentend, and flattened cord. Similarly, inter-reader agreement improved from 57% to 75% for severe central canal stenosis, from 74% to 84% for none or small disc herniation, and from 59% to 65% for large disc herniation when we iteratively redefined our guidelines for these pathology severities.

CONCLUSION

s Label agreement amongst our radiologists increased and generated more consistent training data for our machine learning models using the iterative labeling and review process. This approach is pathology agnostic and can be applied whenever clear severity definitions are required.

CLINICAL RELEVANCE/APPLICATION

Iterative labeling as performed with this methodology has the potential to reduce the variation for grading of pathologies in medical images and may improve the performance of AI models.

Brain Image Auto-Segmentation using 3D Capsule Networks

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Arman Avesta, MD, New Haven, CT (*Presenter*) Stockholder, Hyperfine Research, Inc;

PURPOSE

To develop and validate 3D capsule networks (CapsNets) to segment brain images with features not represented in the training data.

METHODS AND MATERIALS

We used 3430 brain MRIs acquired in a multi-institutional study. We compared our CapsNets with U-Nets, the current standard, based on the accuracy in segmenting various brain structures and those with spatial features not represented in the training data. We also assessed performance when the models are trained using limited data, memory requirements, and computation times.

RESULTS

3D CapsNets segmented the third ventricle, thalamus, and hippocampus with Dice scores of 94%, 94%, and 91%, respectively. 3D CapsNets outperformed 3D U-Nets in segmenting brain images with features that were not represented in the training data, with Dice scores more than 30% higher (P-values < 0.01). 3D CapsNets had 93% fewer trainable parameters than 3D U-Nets. The 3D CapsNets were 25% faster to train compared with U-Nets. The two models were equally fast during testing.

CONCLUSION

s 3D CapsNets segment brain structures with high accuracy, outperform U-Nets in segmenting brain images with features that were not represented during training, and are more efficient compared with U-Nets, achieving similar results while their size is an order of magnitude smaller.

CLINICAL RELEVANCE/APPLICATION

In patients undergoing radiotherapy or neurosurgery, neuroanatomical segmentation is a critical aid that improves outcomes. 3D CapsNets outperformed current auto-segmentation methods in generalizability to brain images with features not represented in the training data.

Artificial Intelligence (AI) Model Based on Automatized Morphometry and Planimetric Data Obtained in Brain MRI, a Proof of Concepts: Lights Towards the Future for Differentiating Progressive Supranuclear Palsy From Parkinson's Disease

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Francisco Mendoza, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To develop an AI model to differentiate Progressive Supranuclear Palsy (PSP) from Parkinson's disease (PD) and healthy subjects (HS) using automated volumetry and non-automated planimetric assessment data obtained in Magnetic Resonance Imaging (MRI).

METHODS AND MATERIALS

We retrospectively assessed a total of 141 patients with a clinical diagnosis of Parkinsonism paired by age and sex and with a group of HS (PSP n = 47, PD n = 68, HS= 26) between January 2003 and April 2021 and analyzed their brain MRI. Patients without T1 high resolution sequences were excluded, leaving 83 patients (PSP n = 29, PD n = 54). We included different clinical subtypes of PSP: PSP-RS (n= 19), PSP-P (n= 5), PSP-PGF (n= 4), and PSP-F (n= 1). Using automatized SyngoviaBrainMorphometry software (Siemens), we obtained 109 VOIs for each subject, including absolute and normalized values. Two independent radiologists blind to diagnosis performed a planimetric assessment (Massey ratio, Oba ratio, MPRI 1.0, and MRP 2.0). We developed a machine-learning model based on multivariate feature selection and an extreme gradient boosting (XGB) vs. univariate feature selection and random forest (RF) using both automated volumetric data and planimetric assessment to predict PSP, PD, and HS. All subjects were randomly divided into training (85%) and validation (15%) data sets with the same proportions for each clinical group. We assessed the diagnostic accuracy of the model and the most relevant features were ordered by importance score (F-score; where 1.0 represents perfect precision and recall). Additionally, we assessed the diagnostic accuracy of each feature using ROC curves.

RESULTS

The global diagnostic performance of the model to differentiate between the three groups was 82.3%. The diagnostic accuracy of the model to predict PSP from the other groups was 81.82 and for PD was 82.35. The most relevant features of the AI model were the mesencephalic area (0.22), mesencephalic width (0.13), left frontal fray gray matter normalized volume (0.088), and the left thalamus absolute volume (0.059), and Oba Ratio (0.044). The AUC to differentiate PSP from PD and HS was for the mesencephalic area =0.94, for the mesencephalic width = 0.99, the left frontal fray matter normalized volume =0.50, and the left thalamus absolute volume = 0.69.

CONCLUSION

s The developed AI model using data obtained from brain MRI automated volumetry and non-automated planimetric assessment, showed high accurate discrimination between PSP, PD, and HS, especially for PSP in our study population.

CLINICAL RELEVANCE/APPLICATION

AI model using morphometry and planimetric data can differentiate patients with parkinsonism. It would be necessary to validate this model for its clinical application.

Neural Architecture Search Based MRI Sequence Design

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Hongjun An, (*Presenter*) Nothing to Disclose

PURPOSE

Designing an MR sequence is very challenging, resulting that currently available sequences are constrained by human intuition. We proposed a new sequence design method using neural architecture search (NAS).

METHODS AND MATERIALS

Our method is designed to produce an optimal sequence for given and target objectives. Hence, these properties are inputted to the Bloch simulator to generate MR signals. Using the signals, a loss function defined by the objective is calculated for optimization. Then the sequence scheduler determines the sequence design using NAS (Fig. 1). NAS was utilized to optimize a series of operations (i.e., sequence) by replacing a neural architecture and its weight parameters with a sequence design and its scan parameters, respectively. To test, two experiments were performed repeatedly to design FLAIR-like sequences and spin-echo-like sequences.

RESULTS

In Experiment 1 (Fig. 1c1), a FLAIR-like sequence and non-intuitive sequence showing 4 RF pulses in place of inversion were generated while CSF signal suppression and gray/white matter signal recovery.In Experiment 2 (Fig. 1c2),, a conventional spin echo (CPMG), Hann-echo-like sequence, and a less intuitive sequence wit three or four RF pulse (12°-89°-168° and 5°-16°-85°-162°). In in-vivo experiment, the new three-RF sequence produced identical contrasts and similar SNR with the spin-echo images (new sequence SNR: 297.1±70.1 vs. spin-echo SNR: 295.8±78.2). The new sequences had reduced RF energy (90% of the spin-echo), while taking a longer duration (18.6 ms vs. 12.4 ms).

CONCLUSION

s A novel automatic sequence design method requiring no prior knowledge or training data was proposed, which successfully reproduced the conventional sequence and invented less-intuitive sequences. This study suggests a potential for automated sequence design that may explore possibilities beyond human intuition.

CLINICAL RELEVANCE/APPLICATION

Using our method, a new sequence can be automatically developed in the clinical considerations with non-intuitive behavior.

R2-SPNR-16

Age-Adjusted Atlas of Diffusion Metrics in Normal Neonatal Brains

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Pratheek Bobba, BS, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

Diffusion weighted imaging (DWI) and diffusion tensor imaging (DTI) are increasingly used in the diagnosis and prognostication of neonatal brain injury. However, rapid changes of apparent diffusion coefficient (ADC) values from DWI and fractional anisotropy (FA) and mean diffusivity (MD) values from DTI complicate the interpretation of DWI and DTI scans in neonates. Thus, robust characterization of these metrics in neonatal brains is required.

METHODS AND MATERIALS

The medical and imaging records of all neonates (0-3 months) born since 2013 at our institution were analyzed. Subjects with normal MRI scans on both clinical report and visual inspection were included. DWI (and associated ADC maps) and DTI scans (and associated FA/MD maps) were then coregistered to a pediatric standard brain space. Voxel-wise general linear models (GLM) were applied to analyze the age-related changes of ADC values throughout the brain. Tract-based spatial statistics of DTI metrics was also applied along white matter tracts in the brain. Linear regression models were used to calculate the rate of change in ADC, FA, and MD values across 5mm cubic voxels. Age adjusted normative atlases of these metrics were generated by calculating the mean and standard deviation in each voxel.

RESULTS

565 neonates with DWI scans, of whom 162 also had DTI scans were included. The mean±SD gestational age (GA) at scan for the DWI cohort was 39.67±2.79 weeks and for the DTI cohort was 38.53±1.94 weeks. Increasing GA at scan was associated with significant reduction of ADC values throughout the brain and significant increase of FA and reduction of MD values throughout white matter tracts. The highest temporal rate of decline in ADC values was seen in the subcortical and cerebellar white matter and vermis. The highest temporal rate of increase in FA and rate of decrease in MD values was seen throughout the cortical white matter (Figure 1). After correcting for GA at scan, greater GA at birth was associated with significant reduction of ADC values in the corpus callosum and convexity cortex and significantly higher FA and lower MD values in the corpus callosum. Online interactive atlases displaying age-specific normative values of ADC (34.5-46.5 weeks), and DTI metrics (35-41 weeks) were developed.

CONCLUSION

s There is significant age-related reduction of ADC values throughout the neonatal brain, with steepest decline in the periventricular white matter. Similar trends in FA and MD values indicate that changes in ADC values are likely related to myelination of white matter in neonatal brains.

CLINICAL RELEVANCE/APPLICATION

Our age adjusted normative atlases can aid neuroradiologists in identification and diagnosis of subtle developmental anomalies and ischemic brain injury in neonates.

R2-SPNR-17

Clinical Feasibility of Reverse Encoding Distortion Correction for Brain DWI: Comparison With Conventional DWI

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Atsushi Nakamoto, MD, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Single-shot echo-planar imaging is a widely used conventional diffusion-weighted imaging (C-DWI) technique, owing to its high speed, but is susceptible to magnetic field inhomogeneities which causes high image distortion. This study was conducted to evaluate whether reverse encoding distortion correction DWI (RDC-DWI), which acquires a pair of two opposite phase encoding polarities, can reduce image distortion for DWI of the brain.

METHODS AND MATERIALS

This study included 50 patients who underwent both RDC-DWI and C-DWI of the brain. Both DW images were obtained by two excitations with acquisition times of 121 and 107 seconds, respectively. Using a five-point scale, two neuroradiologists qualitatively evaluated the image distortion of the pons, cerebellum, temporal skull bases and frontal skull base, and the overall image quality. For quantitative analysis, distortion ratios (DR), the apparent diffusion coefficients (ADC) values, and signal-to-noise ratios (SNR) of the pons and frontal lobe were measured. For the pathologies, we qualitatively evaluated image distortion and measured the ADC values.

RESULTS

The scores for image distortions of all evaluated sites were significantly lower for RDC-DWI than for C-DWI ($p<0.01$), and those for overall image quality were significantly higher for RDC-DWI than for C-DWI ($p<0.01$). The DR of the pons and frontal lobe were significantly lower for RDC-DWI than for C-DWI ($p<0.01$). SNR of these sites were significantly higher for RDC-DWI than for C-DWI ($p=0.03$ and $p=0.01$, respectively). Mean ADC values of these sites did not significantly differ between the two techniques ($p=0.62$ and $p=0.66$, respectively). The scores for image distortions of intracranial lesions ($n=22$) did not differ significantly between the two techniques ($p=0.25$), whereas those of sinonasal lesions ($n=7$) was significantly lower for RDC-DWI than for C-DWI ($p=0.03$). Mean ADC values of both intracranial and sinonasal lesions did not differ between the two techniques ($p=0.16$ and $p=0.80$, respectively).

CONCLUSION

s RDC-DWI can significantly reduce image distortion and increase SNR with minimal additional acquisition time, compared with C-DWI.

CLINICAL RELEVANCE/APPLICATION

RDC-DWI can reduce image distortion in the tissue-air interface and improve delineation of sinonasal pathologies.

Diffusion Weighted Imaging with and without Reverse Encoding Distortion Correction (RDC): Influence to Image Quality and ADC Evaluation in Patients with Skull-based Brain Tumors

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Kazuhiro Murayama, MD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation

PURPOSE

To evaluate influences of newly developed reverse encoding distortion correction (RDC) method for reducing image distortion to image quality and ADC evaluation on diffusion-weighted imaging (DWI) in patients with skull-based brain tumors.

METHODS AND MATERIALS

26 patients with suspected skull-based various brain tumors underwent DWIs with and without RDC at 3T systems. To compare image distortion between DWIs with and without RDC, the deformation ratio (DR) of each tumor was calculated from each tumor area difference between DWI and T2-weighted images. To compare image quality and ADC values between DWIs with and without RDC, the signal to noise ratio (SNR) of normal appearance white matter (NAWM) and ADC values of tumor were determined by ROI measurements in each patient. Moreover, overall image quality, lesion distortion and lesion conspicuity of each tumor were assessed by 5-point visual scoring system by two board-certified radiologists. For quantitative and qualitative image quality comparisons, DR and SNR were compared between DWIs with and without RDC by paired t-test. Kappa statistics with ?2 test was performed for each interobserver agreement evaluations. Then, each score was compared between DWIs with and without RDC by Wilcoxon's signed sum test. To determine the influence of RDC to ADC measurement, ADC value was correlated between DWIs with and without RDC by Spearman's correlation. Then, the limits of agreement of ADC between both DWIs were also determined.

RESULTS

DR of DWI with RDC technique was significantly smaller than that without RDC ($p<0.05$), although others had no significant differences between DWIs with and without RDC. Interobserver agreement for each image quality score was significantly substantial or excellent ($0.70=?=0.92$, $p<0.001$). Moreover, each image quality score of DWI with RDC was significantly higher than that without RDC ($p<0.05$). ADC had a significant and good correction between DWIs with and without RDC ($?=0.98$, $p<0.0001$). The limits of agreement between DWIs with and without RDC was $0.00 \pm 0.13 \times 10\text{-}3 s/mm2$.

CONCLUSION

s Newly developed RDC method has no influence to ADC evaluation and makes it possible to improve image quality on DWI in patients with skull-based brain tumors.

CLINICAL RELEVANCE/APPLICATION

Newly developed RDC method has no influence to ADC evaluation and makes it possible to improve image quality on DWI in patients with skull-based brain tumors.

R2-SPNR-19

Histogram Analysis Based on Neurite Orientation Dispersion and Density Imaging for Differentiation Between Solitary Brain Metastasis and Glioblastoma Multiforme: A Comparison of Two Different ROI Placements

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Jinbo Qi, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To explore the value of histogram analysis based on NODDI in differentiating between solitary brain metastasis (SBM) and glioblastoma multiforme (GBM), and to compare the diagnostic performance of two different region of interest (ROI) placements.

METHODS AND MATERIALS

NODDI data were prospectively obtained from 109 patients with pathologically confirmed GBM (n = 57) and SBM (n = 52) were included. Two ROIs—the peritumoral edema area and whole-tumor area—were delineated across all slices. Eleven histogram parameters of intra-cellular volume fraction (ICVF), isotropic volume fraction (ISOVF) and orientation dispersion index (ODI) from both ROIs were extracted. The parameters of the histogram analysis were compared between SBM and GBM, using independent sample t-test or rank sum test, and then to make meaningful parameters based on logistic regression modeling. Receiver operating characteristic (ROC) analyses were conducted to evaluate the differential diagnosis performance and their performances were compared using DeLong's test.

RESULTS

In peritumoral edema area, ICVFminimum, ICVFmax, ICVFkurtosis, ISOVFskewness, ISOVFkurtosis, ODI10, ODI25 and ODIminimum were significantly higher for GBM than for SBM. ISOVF10, ISOVF25, ISOVF50, ISOVF75, ISOVFmean and ISOVFskewness were significantly lower for GBM than for SBM. The sensitivity of the corresponding logistic regression differential diagnosis model was 80.7%, specificity was 80.7%, and area under the curve (AUC) was 0.851. In whole-tumor area, ICVFmax, ICVFskewness, ICVFkurtosis, ISOVFskewness, ISOVFkurtosis and ODIkurtosis were significantly lower for GBM than for SBM. ISOVF10, ISOVF25, ISOVF50, ISOVF75, ISOVFminimum, ODI10, ODI25, ODI50, ODI75, ODI90, ODImean, ODIvariance, and ODIskewness were significantly lower for GBM than for SBM. The sensitivity of the corresponding logistic regression differential diagnosis model was 96.1%, specificity was 86%, and the area under curve (AUC) was 0.958. DeLong's test showed significant difference (P=0.014) in differential performance between two different ROI placements.

CONCLUSION

s GBM and SBM can be differentiated using the NODDI-based histogram analysis and the ROI on whole-tumor area would exhibit better performance.

CLINICAL RELEVANCE/APPLICATION

The NODDI compartment model theoretically distinguishes three types of water diffusion behavior (i.e., intracellular, extracellular, and CSF), it is more sensitive to microstructural changes, which might demonstrate the difference in water diffusion between tumor infiltration and vasogenic edema. Furthermore, NODDI techniques can identify more different tissue components within tumors than conventional imaging for differentiating the heterogeneity of GBM and SBM.

R2-SPNR-2

Successful Implementation of a Comprehensive CT Brain Artificial Intelligence Assist Device Improves Radiologist Performance

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Peter R. Brotchie, MBBS, PhD, Fitzroy, Australia (*Presenter*) Consultant, Annalise-AI Pty Ltd

PURPOSE

To assess the effect on accuracy when radiologists are assisted by a comprehensive CT Brain (CTB) artificial intelligence device.

METHODS AND MATERIALS

CTB are one of the most common CT investigations in clinical radiology. Despite the extensive training of radiologists, missed diagnosis remains a problem. To assist radiologists in reducing errors, many artificial intelligence devices have been developed. However, most of these tools are capable of only detecting a single finding. With the aim to improve a radiologist's performance across a full range of findings on CTB, a comprehensive AI assist device capable of detecting 144 findings was developed. The deep learning model was trained on 212,484 CTB images and tested on a dataset of 2,848 images. The test set was ground truthed by at least 3 radiologists and adjudicated by a neuroradiologist. The performance of 32 radiologists was measured when reviewing the test dataset with and without AI assistance across several metrics including area under the receiver operating characteristic curve (AUC).

RESULTS

The radiologists AUC averaged 0.79 when assisted by the AI compared to 0.73 when unassisted. Significant improvement in AUC was observed across 91 findings. 17 findings showed decreases in AUC. Many of the largest gains in performance by the radiologists when using the AI, were for clinically critical findings, including findings signifying mass effect (basal cistern effacement, tonsillar and uncal herniation, midline shift, sulcal and ventricular effacement), intracranial haemorrhage (especially aneurysmal and convexity subarachnoid haemorrhage), trauma (intracranial haemorrhage and fractures), obstructive hydrocephalus, intra-axial lesions, aggressive extra-axial masses, orbital cellulitis and acute infarction.

CONCLUSION

s The use of a comprehensive CTB assist device significantly improved radiologist performance across a majority of clinical findings on CTB, demonstrating the potential safety improvements of comprehensive AI.

CLINICAL RELEVANCE/APPLICATION

The comprehensive AI device for CTB, after testing with a large selection of radiologists, showed improved performance by the assisted radiologist, and indicates a potential use case in a radiologists workflow.

R2-SPNR-20

Reliability of Functional and Diffusion Magnetic Resonance Imaging Near Cerebral Cavernous Malformations

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Marco Colasurdo, MD, Pescara, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Surgical resection of cerebral cavernous malformations (CCMs) routinely employs fMRI and DTI for surgical planning to best preserve neurological function. However, hemosiderin-rich lesions such as CCMs may cause artefactual distortion of MRI signals in close proximity. This study investigates the reliability of fMRI and DTI near CCMs.

METHODS AND MATERIALS

Consecutive patients with CCMs undergoing pre-surgical fMRI and DTI mapping were identified from June 2002 to June 2019 at an academic medical centre. Each CCM lesion was hand-contoured using T2 sequences, and two sequential 4-mm expansion shells (S1 and S2) were created, generating three ROIs; every ROI was then flipped to the contralateral hemisphere to obtain control ROIs. Fractional anisotropy (FA) and Regional Homogeneity (ReHo) measurements were then extracted from each ROI. FA and ReHo values were compared with contralateral controls to calculate percentage error. Reliability, accuracy, and precision within ROIs were compared using Welch's t-tests, F-tests and Wilcoxon matched-pairs signed rank tests; p-values were adjusted for multiple comparisons as appropriate.

RESULTS

61 patients were identified and included. Overall, errors of FA were significantly lower than ReHo in S1 and S2 ($p=0.0001$ for both), suggesting that FA is more reliable than ReHo near CCMs. Proximity to CCM lesions significantly worsened the reliability of ReHo (S1 vs. S2, $p=0.0007$), but not FA ($p=0.24$). Further investigations of sources of error revealed that while FA was not significantly biased in any ROI ($p>0.05$ for all), ReHo was biased towards lower signals in CCMs, S1 and S2 ($p<0.05$), an effect that was attenuated with distance from CCMs ($p<0.05$). FA measurements were also more precise than ReHo in S1 and S2 ($p<0.0001$ for both), though proximity to CCMs did not impact precision of either modality ($p>0.05$ for both).

CONCLUSION

s Our findings suggest that DTI imaging is significantly more reliable than fMRI near CCMs. This difference appears largely driven by the negative bias of ReHo measurements near CCMs, a finding consistent with the hypothesis that hemosiderin-rich lesions may lead to artefactual depression of fMRI signals in a distance-dependent manner, phenomenon not seen with DTI in our study. Regardless of proximity to CCMs, DTI was also more precise than fMRI, a difference that may be intrinsic to the imaging modality itself and not due to CCM-related artifacts.

CLINICAL RELEVANCE/APPLICATION

Pre-surgical advanced MRI mapping near vascular rich lesion such as CCMs should be interpreted with caution. Clinicians should be aware that based on our findings, fMRI may not be reliable up to an 8 mm distance from CCMs while DTI appears to be consistently reliable even in close proximity.

Automated Detection of Cerebral Aneurysms on Time of Flight MR-Angiography using a Deep Learning Approach

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Daniel Paech, MD, PhD, Heidelberg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance of an AI-based software solution designed to automatically detect intracranial aneurysms on time-of-flight MR angiography.

METHODS AND MATERIALS

191 MRI data sets were analyzed using the AI software solution mdbrain (Mediaire, Berlin, Germany) for the presence of intracranial aneurysms on 3D time-of-flight MR angiography obtained using two 3T MRI scanners or a 1.5T MRI scanner according to our clinical standard protocol. The results were compared to the expert reading of an experienced radiologist as a gold standard to measure sensitivity, specificity, positive and negative predictive values as well as the accuracy of the software solution. Additionally, detection rates depending on size, morphology and location of the aneurysms were evaluated.

RESULTS

A total of 54 aneurysms were detected by the expert reader. The software's overall sensitivity for the detection of cerebral aneurysms was 72.6%, the specificity was 87.2%, the accuracy was 82.6%. The positive predictive value was 67.9%, the negative predictive value was 88.5%. We observed high detection rates of 100% for saccular aneurysms larger than 5 mm with no signs of thrombosis, and low detection rates for fusiform and/or partially thrombosed aneurysms of 33.3% and 16.7%, respectively. Out of eight aneurysms that were not included in the initial written reports but that were detected by the expert reader retrospectively, four were detected by the software solution.

CONCLUSION

s Our data suggest that the software can be of assistance to radiologists reporting on time-of-flight MR angiograms. We found the software to be highly reliable in the case of saccular aneurysms, while fusiform aneurysms or aneurysms with partial thrombosis cannot be ruled out by the software. Further studies are needed to investigate the software's impact on detection rates, interrater reliability and reading times.

CLINICAL RELEVANCE/APPLICATION

The software solution we investigated is a CE-labelled product that has not yet been reported on in terms of diagnostic accuracy. Thus, our findings are of importance to radiologists using the software to understand its capabilities, but also its limitations.

ML-based Prediction of Tumor Etiology in Brain Metastases using Radiomic Features

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Christopher Atkins, MD, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

Brain metastases (BM) are the most common adult brain malignancies. Upon diagnosis, the site of primary tumor is not known in up to 15% of patients. Knowing the likely primary however could alter patient management, and we proposed to create a machine learning-and radiomics-based approach to provide a non-invasive way to facilitate diagnosis.

METHODS AND MATERIALS

Contrast-enhanced T1w MR and FLAIR imaging from 164 patients with a total number of 584 treatment-naive brain metastases were collected. Volumetric segmentations were generated semiautomatically and were reviewed by a board-certified neuroradiologist. Radiomic features were extracted with PyRadiomics. Filter-based feature selection and XGBoost classification were performed in a nested cross-validation (CV) scheme. Classification performance (CP) was evaluated with "One-vs-Rest"-AUC, comparing each class prediction against the sum of all others, and class-weighted macro-AUC.

RESULTS

Most common primary cancers were non-small-cell-lung-cancer (NSCLC, n=88), melanoma (n=33), breast-cancer (n=13), gastrointestinal-cancers (n=13), small-cell-lung-cancer (both n=13), renal-cell-carcinoma (n=7), and others (n=10). XGBoost reached an AUC of 0.64 in internal 5-fold-CV and 0.46 in an external validation set (143 lesions in 42 patients). Best label-wise classification was achieved for NSCLC (One-vs-Rest-AUC=0.71). Integrating individual lesion predictions to predict patient-level outcomes via hard ensemble voting did not lead to improved CP. The clinical performance of the model was not significantly different for metastases with volumes larger versus smaller than a 10-mm-diameter sphere ($P > 0.05$).

CONCLUSION

s This study underlines the challenging nature of predicting the site of the primary tumor in brain metastases by using radiomic features alone. Diagnosis might require the addition of further functional image analysis and/or incorporation of clinical data.

CLINICAL RELEVANCE/APPLICATION

The technology detailed here could one day be applied to brain metastasis of unknown primary in order to more quickly target treatment and improve patient outcomes or survival rates.

Deep Learning Applied to Cranial Ultrasound for Prediction of Neurodevelopmental Impairment in Preterm Babies: Lessons Learned

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Tahani Ahmad, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Cranial ultrasound (CUS) is widely used as a screening tool to assess brain injury in preterm infants. Severe abnormalities on CUS are known to be associated with Neurodevelopmental impairment (NDI) while, for less severe changes or apparently "normal" scans the prognostic outcome is variable. This study aims to train a deep learning prognostic model based on CUS to early assess NDI outcomes.

METHODS AND MATERIALS

Each CUS image was anonymized, pixels intensities were normalized, and resized to a standard 224x224 resolution. Regions outside of the brain were masked and set to intensity zero. The NDI outcome (i.e. patient outcome) and CUS diagnostic outcome (i.e. timepoint outcome) were imported based on the clinical assessment. The dataset is split into stratified training/test sets (90:10 percent split) grouped by the patient. The total number of patients is 619 with 4180 images. We trained the model using different deep learning approaches: from simple classic CNN to more advanced strategies (e.g. multi-view CNNs, to multiple instance learning).

RESULTS

We tested different CNN architectures and strategies. Preliminary results indicate an average of 0.722 AUC (0.664- 0.779 C.I.) using 10 bootstraps stratified sampling strategies using DenseNet169.

CONCLUSION

s This is a preliminary work to provide a tool to assist clinicians during early NDI assessment. During the preparation of this study, many challenges came to our attention (e.g. images acquired from multiple manufacturers, high presence of clinical confounding variables, scanty literature in this field) and we deployed different strategies to address each of them learning valuable lessons. Finally, although prognostic modeling is difficult, we expect the model performance to improve by including the clinical variable in the next stage.

CLINICAL RELEVANCE/APPLICATION

Prediction of NeuroDevelopmental Imapairemnt (NDI) in preterm infants enables early identification and referral of high-risk infants to intervention programs that have the potential to improve mobility and cognitive development.

Cost-Effectiveness of AI-Based Opportunistic Screening for Osteoporotic Compression Fractures on Existing Radiographs

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Patti Curl, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Osteoporotic compression fractures (OCFs) are a highly prevalent source of morbidity and mortality, and preventative treatment has been demonstrated to be both effective and cost effective. Still, many patients with OCFs remain undiagnosed, and there is potential value in identifying undiagnosed fractures on radiographs obtained for other indications. Our study group is developing software to access existing radiographs for OCFs with high sensitivity and specificity using an established artificial intelligence deep learning algorithm. The purpose of this analysis is to assess the potential cost-effectiveness of implementing this software.

METHODS AND MATERIALS

Analysis was performed using TreeAge Pro Healthcare software. A deterministic expected-value cost-utility model, combining tree model and Markov model, was used to compare the strategies of opportunistic screening for osteoporotic compression fractures against usual care. The tree model was used to determine the likelihood a patient would receive treatment, and the expected value of each path was calculated with a separate Markov model. Total costs and total quality adjusted life years (QALYS) were calculated for each strategy. The baseline analysis assumed a population of women age 75, and a lifetime time horizon was used. Screening and treatment costs were considered from a societal perspective, at 2022 prices.

RESULTS

In the base case, assuming a cost of software implantation of 10 dollars per patient screened, the screening strategy dominated the non-screening strategy: it resulted in lower cost and increased QALYS. The lower cost was primarily due to the decreased costs associated with fracture treatment and decreased probability of requiring long-term care in patients who received preventative treatment. The screening strategy was dominant up to a cost of $156 per patient screened. At $157, screening was cost effective with an incremental cost effectiveness ratio of $100/QALY (Screening $5389/1.19 QALY No-screening $5388/1.18 QALY).

CONCLUSION

s Opportunistic screening for OCFs can be cost-effective from a societal perspective.

CLINICAL RELEVANCE/APPLICATION

Given the substantial population of patients with OCFs not receiving treatment, opportunistic diagnosis provides an opportunity to add value while also decreasing costs for the health care system as a whole.

R2-SPNR-7

Development and Validation of a Deep Learning-Based Automatic Classification Algorithm for the Medial Temporal Lobe Atrophy Scale Using a Multi-Modality Cascade Transformer

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Dongsoo Lee, MPH,MPH, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Although medial temporal lobe atrophy (MTA) has been incorporated into the diagnostic criteria for Alzheimer's disease (AD) and mild cognitive impairment (MCI) in the NIA-AA guidelines, there might be concerns regarding interobserver variability because the MTA scale is a visual semi-quantitative method that requires training of the readers for confident uses. We aimed to develop and validate a deep learning-based automatic classification algorithm for the MTA scale in patients with cognitive impairment.

METHODS AND MATERIALS

We developed a multi-modality cascade transformer using Vision Transformer (ViT) and TabNet classifier that were used to handle tabular and image data simultaneously. This observational study included consecutive patients with cognitive impairment from a tertiary hospital. 793 patients for the training dataset and 150 patients for the test dataset in the first model were included from March 2017 to June 2018. To improve accuracy, we devised a second model by applying transfer learning with a large cohort to the first model. 1200 patients for the training dataset and 100 patients for the test dataset in the second model were included from June 2018 to June 2021. We clustered the MTA scales into 3 groups (0,1), (2), (3,4) by clinical significance. After analyzing both sides, the higher scale was determined. To compare the performance of the two models, the test dataset of each model and the ADNI dataset were applied and compared.

RESULTS

In first training dataset, group 0, 1, and 2 were 261 (33%), 202 (26%), and 330 (42%) patients, respectively. In the first test dataset, groups 0, 1, and 2 were all 50 (33%) patients, respectively. In second training dataset, group 0, 1, and 2 were 216 (18%), 586 (49%) and 398 (33%) patients, respectively. In second test dataset, group 0, 1 and 2 were 28 (28%), 37 (37%), and 35 (35%) patients, respectively. We conducted an ablation study to compare with various baseline models, and our proposed model achieved the best performance (precision 0.801, recall 0.787, and AUC 0.923). In the first model, the accuracy using the test dataset was 0.787. The accuracy of the second model using the same test dataset applied to the first model was 0.833. In ADNI test dataset, group 0, 1, and 2 were 67 (17%), 198 (50%), and 135 (34%), respectively. The accuracies of both models were 0.613 and 0.642 (the first model and second model), respectively.

CONCLUSION

s The deep learning-based automatic classification algorithm using a multi-modality cascade transformer may allow accurate classification of the MTA scale.

CLINICAL RELEVANCE/APPLICATION

It may be possible to reduce the inter/intra-observer variation in measuring the MTA scale using the deep learning model that we proposed.

Development and Validation of a Deep Learning-based Automatic Segmentation and Classification of Cerebral White Matter Hyperintensities

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - NR DPS

Participants
Wooseok Jung, MSc, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

White matter hyperintensities (WMH) commonly attribute to vascular dementia and represent neuroimaging markers of cerebral small vessel disease. Fazekas scale is used to quantify WMH severity in radiology research. An automatic quantification model covering both WMH segmentation and Fazekas scale classification has not yet been explored in depth. We aimed to develop and validate a deep learning-based automatic segmentation and classification of cerebral white matter hyperintensities in patients with cognitive impairment.

METHODS AND MATERIALS

This observational study included consecutive patients with cognitive impairment from a tertiary hospital. A segmentation model using the 2D UNet for training and validation was performed on the dataset of 511 and 64, respectively. An input FLAIR and the corresponding output mask of the segmentation model are concatenated to generate 2-channel input of Fazekas classification model. Two separated classification models for each WMH subtypes using 3D EfficientNetv2 for training and validation were performed on the dataset of 1661 and 110, respectively. Test of segmentation model was performed on the 278 the ADNI dataset. Test of the Fazekas scale classification model was performed on 100 ADNI dataset and 178 dataset of the tertiary hospital included. For the evaluation of the Fazekas scale classification, the datasets used in the test model were evaluated by four experienced neuroradiologists. Classification according to the Fazekas scale was divided into three categories (normal/mild, moderate, and severe), and locations were separately reported as periventricular (PWMH) and deep white matter (DWMH).

RESULTS

Dice score performance of the segmentation model on test dataset by target location subtype were 0.744±0.108, 0.904±0.054, 0.851±0.068 (PWMH and DWMH, PWMH only, DWMH only), respectively. Dice score only concerning PWMH on test dataset by the three categories were 0.907±0.044, 0.948±0.011, and 0.957±0.014, respectively. Dice score only concerning DWMH on the same test dataset by the three categories were 0.844±0.057, 0.946±0.023, and 0.954±0.015, respectively. The accuracy of performance of the Fazekas scale classification model by single rater were 0.86 and 0.87 at PWMH and DWMH, respectively. The accuracy evaluated against mean of multi-rater labels were 0.76 and 0.69 at PWMH and DWMH, respectively.

CONCLUSION

s These results demonstrate the excellent segmentation and classification performance of our models and their potential for deployment as accurate diagnostic support tools for quantified evaluation of WMH.

CLINICAL RELEVANCE/APPLICATION

It may be possible to segment and classify white matter hyperintensities using a deep learning model that we proposed.

R2-SPOB-1 Comparison of Capability for Image Quality Improvements between Women's Pelvic Diffusion-Weighted Imaging with and without Reverse Encoding Distortion Correction at a 1.5 T MR System

Participants
Yoshiharu Ohno, MD, PhD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research Grant, Daiichi Sankyo Co, Ltd;Research Grant, Ministry of Education, Culture, Sports, Science and Technology

PURPOSE

To determine the capability for image quality improvements between women's pelvic diffusion weighted imaging (DWI) with and without reverse encoding distortion correction (RDC) at a 1.5 T MR system.

METHODS AND MATERIALS

Thirty-one consecutive female patients with various pelvic diseases underwent DWIs with and without RDC at a 1.5T MR system, and each ADC map was reconstructed. For quantitative image quality assessments, signal-to-noise ratio (SNR) on each DWI at b value as 1000mm2/s and ADC value of gluteal muscle were determined by ROI measurement. For qualitative image quality assessments, two board certified radiologists assessed overall image quality (OIQ), deformation severity (DS) and diagnostic confidence level (DCL) by 5-point scales, and each final score was determined as consensus of two readers. On quantitative image quality evaluations, SNR was compared between both DWIs by paired t-test. Correlation of ADC value between both DWIs were evaluated by Spearman's rank correlation coefficient. The limits of agreement of ADC between both DWIs were determined by Bland-Altman analysis. For qualitative image quality evaluations, inter-observer agreement on each DWI was assessed by ? statistics followed by ?2 test. Finally, both indexes were compared between two DWIs by Wilcoxon signed-rank test.

RESULTS

There was no significant difference of SNR between both DWIs ($p>0.05$). There were significant correlations of ADC values between DWIs with and without RDC (?=0.92, $p<0.001$). There were no significant differences of ADC values between two methods ($p>0.05$), the limits of agreement in the gluteal muscle were determined as 0.009 ± 0.017s/mm2. Inter-observer agreements for all qualitative indexes were determined as 'substantial' or 'excellent' (0.78<?<0.97, $p<0.0001$). OIQ and DCL of DWI with RDC (OIQ: Median 5, IQR 4-5; DCL: Median 5, IQR 5-5) were significantly higher than those without RDC (OIQ: Median 4, IQR 3-5, $p=0.0004$; DCL: Median 5, IQR 4-5, $p=0.03$). DS of DWI with RDC (Median 1, IQR 1-2) was significantly lower than that without RDC (Median 2, IQR 1-3, $p=0.0004$).

CONCLUSION

s RDC is able to improve image quality without any influence on ADC evaluation on women's pelvic DWI at 1.5 T system.

CLINICAL RELEVANCE/APPLICATION

RDC is useful for image quality improvement with reducing image deformation on women's pelvic DWI at 1.5 T system.

R2-SPPD-1 Neurological Consequences of COVID-19 in Children

Participants
Yunuen Rojas, CIUDAD NEZAHUALCOYOTL, Mexico (*Presenter*) Nothing to Disclose

PURPOSE

Long term neurological symptoms associated to COVID19 had been reported in adults ("Long Covid"). However, there is little information about possible neurological consequences in children. Speculations about the difficulties detecting neurological symptoms associated to COVID19 in this early stage of the neurological development had been made, pointing that these could be easily mislead towards other pathologies.

METHODS AND MATERIALS

We employed Resting State fMRI (rs-fMRI) to observe the underlaying behavior of the brains of a cohort of 14 post-COVID19 patients, with no record of other illness prior to infection, the scans were acquired at least 3 months after hospital discharge. The results were compared to those of a control cohort of 31 healthy volunteers without record of COVID19 at scan acquirement. Scans were analyzed using CONN: functional connectivity toolbox (Version 20.b).

RESULTS

The acquired results showed that the children who survived COVID19 has a higher temporal correlation when compared to controls in regions Vermis 3 (Culmen) and Middle Temporal Gyrus, Temporo-occipital part (toMTG).

CONCLUSION

s Results suggests that post-COVID19 children could be demanding more resources while activating regions associated to visual processing mechanism. Empirical data about the asociated symptoms.

CLINICAL RELEVANCE/APPLICATION

Employing functional Magnetic Resonance Imaging (fMRI), an study in post-COVID19 children was driven seeking after functional differences in the basal behavior of their brains directly correlated to the virus.

R2-SPPH-1 Local Diagnostic Reference Levels in North of Mexico

Participants
Maria del Carmen Franco, MS, Monterrey, Mexico (*Presenter*) Nothing to Disclose

PURPOSE

To establish local diagnostic reference levels (DRL) from adult patients in chest and abdominal CT.

METHODS AND MATERIALS

Observational, descriptive, and retrospective study, limited to the technical factors obtained in four different private and public hospitals in the north of Mexico. The data was obtained during a 9-month period using RIS/PACS system.Only examinations with complete patient information, older than 16 years old, and with normal CT abdominal or thorax protocol were included. Those with more than one body part scan and the ones with contrast materials were excluded. The size of the patient was determined by measuring thickness and anteroposterior diameters in the axial images. The water-equivalent diameter was used to determine the Size Especific Dose Estimate from volume CT dose index.

RESULTS

Local DRL for CTDIvol, SSDE and Dose-length product as the median value of each variable. For all CT scans, the DRL and SSDE were higher for patients of larger size than those of smaller size. The local DRLs were comparable to current published values in the United States.

CONCLUSION

s We were able to establish local DRLs for the most frequent CT scans in our institutions. These are within US DRL, which suggests that patient doses with our current protocols (yielding acceptable image quality) are within a typical practice in that Country. To our knowledge, this represents the first time in our country that DRLs are used in patients using their size.

CLINICAL RELEVANCE/APPLICATION

This study shows that in our country, other hospitals can adopt DRLs to their practice, which benefits the patient and protects the ALARA concept.

R2-SPPH-2 Setting Local Dose Reference Levels in Pediatric CT With a Dose Management Software

Participants
Maria Perez Fernandez, MSc, (*Presenter*) Nothing to Disclose

PURPOSE

To compare the doses administered in pediatric CT examinations with published dose reference levels (DRLs) and to establish local dose reference levels for a public hospital that provides care to a population of 400,000 people.

METHODS AND MATERIALS

The CTDIvol and DLP of all examinations performed between 2016 and 2020 in three CT scanners were collected with a dose management software. The data corresponding to pediatric patients were divided by age ranges and types of CTs procedures including "Head"(854 patients), "Thorax" (91 patients), "Abdomen" (62 patients) and "Joints" (183 patients). Other types of examinations were discarded. The 50th and 75th percentiles of each group were obtained.The 50th percentiles were compared to RP185 EDRLs to verify if the clinical practice is adequate in terms of patient´s radiological protection.The 75th percentiles obtained were set as local DRLs when their value were lower than the published DRL and the number of CT scans analyzed were more than 20.

RESULTS

The median CTDIvol and DLP obtained for each type of examination and age group are lower than the corresponding published DRL, with the exception of the head DLP of the older age group, which is slightly higher. This indicates the clinical practice is adequate.The following DRLs were set: HEAD Age group under 3 months: CTDIvol =12mGy, DLP=199mGy.cm; age group between 3 months and 1 year: CTDIvol =10mGy, DLP=159mGy.cm; age group between 1and 6 years: CTDIvol=21mGy, DLP=345mGy.cm; age group over 6 years: CTDIvol=49mGy.THORAX Age group between 1 month and 4 years: CTDIvol=1,3mGy, DLP=31mGy; age group

between 4 and 10 years: CTDIvol=2,4mGy.ABDOMEN Age group between 14 and 18 years: CTDIvol=7mGy, DLP= 323mGy.JOINTS Age group between 4 and 10 years: CTDIvol=4,8mGy, DLP=82mGy.cm; age group between 10 and 14 years: CTDIvol=4,8mGy, DLP=90mGy.cm; age group between 14 and 18 years: CTDIvol=4,8mGy, DLP=97mGy.cm.

CONCLUSION

s The scarce number of CT scans performed in children complicates setting reliable local DRLs. However, with a dose management software acceptable statistics can be obtained in a reasonable period of time.

CLINICAL RELEVANCE/APPLICATION

In this work, reliable local DRLs have been obtained with updated data for pediatric most common CT examinations with acceptable statistics thanks to the dose management software.

R2-SPPH-4 Multi-Parametric Diagnostic Reference Levels (DRL) For CT: Data From 4648 Patients From 12 Sites in Brazil

Participants
Shadi Ebrahimian, MD, Boston, MA (*Presenter*) Nothing to Disclose

PURPOSE

Diagnostic reference levels (DRL) can help in radiation dose optimization and monitoring. We conducted a prospective study on establishing multi-parametric, multi-site national (Brazil) DRL for CT exams based on patient gender, size, body regions, and clinical indications.

METHODS AND MATERIALS

With institutional review board approvals, we prospectively included 4648 adult patients (18-99 years; male: female 2674:1974) who underwent CT at 12 sites in Brazil between January and October 2021 including: head (n=1511 patients), chest (n=1227), and abdomen-pelvis [AP] (n=842). Following information was recorded: hospital name, patient age, gender, weight, height, body mass index [BMI], clinical indications, scanner information (vendor, scanner name, slice profile), scan parameters (number of scan phases, kV, mA, pitch) and dose indices (phase-specific CT dose index volume [CTDIvol] and phase-specific and total dose length products [DLP]). Patients were divided into under-, over-, normal- and obese-BMI groups per the WHO classification. Median and 75th percentile CTDIvol and DLP values were estimated and compared for different patient groups (gender and size), body region, clinical indications.

RESULTS

The estimated 75th percentile CTDIvol and DLP were head (46mGy, 1016mGy.cm), paranasal sinus (19mGy, 362mGy.cm), cervical spine (26mGy, 679mGy.cm), chest (11mGy, 362mGy.cm), and AP (14mGy, 753mGy.cm). The highest DLP were recorded for carotid CTA (1450mGy.cm), pulmonary CTA (602mGy.cm), oncologic abdomen CT (4667mGy.cm) ($p<0.001$). For identical body part, gender, BMI, and clinical indications, there were significant and several-fold differences in both CTDIvol and DLP values across the 12 Brazilian hospitals ($p<0.001$).

CONCLUSION

s In this study most Brazilian DRL (CTDIvol and DLP) were lower or similar to the US and European reported DRLs for corresponding CT exams and protocols with variations based on clinical indications and patient size.

CLINICAL RELEVANCE/APPLICATION

Substantial inter-site variations in radiation doses for similar BMI, body-region and clinical indications suggest an urgent need for CT technology upgrade and protocol optimization.

R2-SPPH-5 Skin Dosimetry Model for CT Acquisitions

Participants
Mahta Mazloumi, MA, (*Presenter*) Nothing to Disclose

PURPOSE

Skin is the first organ that is exposed to X-ray during a CT scan and it can receive a relatively high radiation dose in CT procedures with repeated exposure to the same skin area such as interventional or perfusion CT. The aim of this study is to provide a skin dose model based on CT acquisition parameters to allow dose follow-up for this organ at risk.

METHODS AND MATERIALS

A virtual cylindrical phantom was generated (32cm,L=20cm,pixel size=0.5mm2) in DICOM format. The phantom was used as a 3D geometrical model for Monte Carlo (MC) simulations with ImpactMC (Advanced Breast-CT). The impact of acquisition parameters including tube voltage (70,80,100,120, and 140kVp), bow-tie filter (medium filter, large filter), and position in the gantry (+14, +11, +7, +3, 0, -5, and -9cm along the y-axis) on skin dose were investigated with the MC simulations. The first layer at the surface of the phantom was considered as skin (thickness 0.5mm2). The dose values were normalized to CTDIvol (D_CTDI). In addition, the model was validated with experimental TLD measurements and MC simulations on the humanoid Rando Alderson (RA) phantom for the large filter at 120kVp and 80-mm collimation.

RESULTS

Results show increase in the skin dose for decreasing distance to the isocenter. For distances smaller than 120mm, four curves were fitted to the data based on high tube voltage (HV) at 100,120, and 140kVp, low tube voltage (LV) at 70 and 80kVp, medium filter (MF), and large (LF) with the equation D_CTDI=A*x(mm)2+B*x(mm)+C. The values of A, B, and C for the investigated tube voltages and filters are as follows; for HV-MF: A=-4.71E-05, B=-92.95E-05, C=2.09, for LV-MF: A=6.92E-05, B=-240E-05, C=2.59, for HV-LF: A=-3.96E-05, B=62.58E-05, C=1.80 and for LV-LF: A=-4.75E-05, B=25.49E-05, C=1.96. For distances larger than 120mm, the curves for the various kVp selections differ marginally, and one fitting formula is sufficient (A=3.74E-05, B=-0.02, C=2.79) to estimate skin dose for all combinations with an average error of 4.3% between this estimation and estimations of the exact equations. Additionally, the skin dose values of RA phantom were in good agreement with our model at 120kVp and LF. The average deviation between the experimental TLD measurement on the RA phantom and the MC simulations of the phantom was 9%.

CONCLUSION

s The developed skin dose model can estimate skin dose as a function of filter type, tube voltage, and skin-isocenter distance in CT imaging.

CLINICAL RELEVANCE/APPLICATION

The developed skin dose model in this study has the potential to enable the implementation of a systematic skin dose assessment and registration in clinical CT imaging. Additionally, it can estimate skin dose prior to the CT scan based on the localizer scan in combination with selected acquisition parameters.

R2-SPPH-6 Application of Deep Learning Image Reconstruction (DLIR) Algorithm to Improve Image Quality in CT Angiography of Children With Takayasu Arteritis

Participants
Ji Hang Sun, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Objective: To evaluate the image quality improvement in CT angiography (CTA) of children with Takayasu arteritis (TAK) using a deep learning image reconstruction (DLIR) in comparison to other reconstruction algorithms.

METHODS AND MATERIALS

32 patients (9.14±4.51 years old) with TAK underwent abdominal CTA with 100kVp were enrolled. Images were reconstructed at 0.625mm slice thickness using Filtered Back-Projection (FBP), 50% adaptive statistical iterative reconstruction-V (50%ASIR-V), 100%ASIR-V and DLIR with high setting (DLIR-H). The CT number and standard deviation (SD) of the descending aorta and back muscle were measured and contrast-to-noise ratio (CNR) for aorta was calculated. The vessel visualization, overall image noise and diagnostic confidence were evaluated using a 5-point scale (5, excellent; 3, acceptable) by 2 observers.

RESULTS

There was no significant difference in CT number across all reconstructions. The image noise values (in HU) were 31.36±6.01, 24.96±4.69, 18.46±3.91 and 15.58±3.65, and CNR values for aorta were 11.93±2.12, 15.66±2.37, 22.54±3.34 and 24.02±4.55 with FBP, 50%ASIR-V, 100%ASIR-V and DLIR-H, respectively. The DLIR-H images had the lowest image noise and highest CNR among all reconstructions. The subjective evaluation suggested that all images were diagnostic for large arteries, but only 50%ASIR-V and DLIR-H met the diagnostic requirement for small arteries (3.03±0.18 and 3.53±0.51) with the combination of image noise and spatial resolution.

CONCLUSION

s DLIR-H improves the CTA image quality and diagnostic confidence for TAK patients compared with 50%ASIR-V, and best balances image noise and spatial resolution compared with 100%ASIR-V.

CLINICAL RELEVANCE/APPLICATION

DLIR-H can be used in CTA for patients with Takayasu’s arteritis to improve overall image quality and the identification of small vessels.

R2-SPPH-7 Model-Specific Benchmarks for Non-contrast Head and Brain CT Imaging

Participants
Jered Wells, PhD, Glenwood, IL (*Presenter*) Employee, LANDAUER, Inc;Consultant, Vaxa Medical Physics;Research Consultant, Agfa-Gevaert Group

PURPOSE

Effective computed tomography (CT) protocol review includes comparison of average CTDIvol per protocol against available (national) benchmarks. While comparisons to benchmarks can be an effective gauge of individual system performance relative to the general practice of CT imaging, these benchmarks do not account for potential differences between CT scanner models and system implementation preferences. This work investigates the utility of model-specific CT benchmarks for non-contrast head and brain imaging and compares this against the variability in site-specific implementation.

METHODS AND MATERIALS

Anonymized adult CT HEAD BRAIN WO IVCON exposure data from calendar year 2021 were collected using LANDAUER OPTIMIZE dose monitoring software. Thirteen CT scanner models (70 individual scanners installed at 50 imaging facilities) qualified for analysis based on 66,057 eligible non-contrast head exams. A CT scanner model qualified for analysis if at least four scanners from at least two imaging facilities had at least 50 eligible image series per scanner. A two-way ANOVA test with significance threshold $a = 0.05$ was performed to analyze the effects of CT scanner model and imaging facility (i.e. site-specific implementation) on CTDIvol.

RESULTS

The overall median CTDIvol was 48.12 mGy (IQR = 43.92-52.79 mGy) which is comparable to established national benchmarks for CT HEAD BRAIN WO IVCON derived from Kanal, et. al. (2017) who report median CTDIvol (achievable dose) of 49 mGy and upper quartile (diagnostic reference level) of 56 mGy for this protocol. Two-way ANOVA analysis of CTDIvol showed that scanner model had a significant effect ($p = 0.022$), and imaging facility had a highly significant effect ($p << 0.001$). Interaction effects between CT scanner model and imaging facility were not statistically significant ($p = 0.109$).

CONCLUSION

s Scanner model is an important determinant of achievable CTDIvol for non-contrast head and brain CT imaging. Furthermore, site-specific scanner implementation was found to be an even greater source of CTDIvol variability than scanner model. This suggests that scanner options and institutional imaging protocol preferences have an outsized influence on CT dose over scanner base model. Even so, model-specific CT benchmarks are merited for better CT dose management in accordance with scanner model capabilities.

CLINICAL RELEVANCE/APPLICATION

Comparison of CTDIvol to national benchmarks is the current gold standard for CT dose management, but variation between scanner models and implementation preferences make it difficult to determine when protocols are truly optimized.

R2-SPPH-8 Potential CT Radiation Dose Reduction to the Female Breast by a Novel Risk-Minimizing Tube Current Modulation

Participants
Laura Klein, Heidelberg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To compare riskTCM, a recently proposed tube current modulation technique intended to minimize the patient radiation risk, with a conventional mAs-minimizing TCM (mAsTCM) and an established organ-specific TCM (osTCM) with special focus on the female breast.

METHODS AND MATERIALS

To reduce dose to the female breast in CT, different TCM methods are available. Typical methods used in clinical systems are the mAs-minimizing TCM (mAsTCM) as well as organ-specific TCMs (osTCM). Both methodologies do not account for the actual patient risk but minimize physical quantities. While mAsTCM minimizes the mAs-product at constant image quality, osTCM reduces the mAs for anterior views to spare the female breast. Herein, osTCM is implemented to be similar to the X-Care algorithm (Siemens Healthineers) which reduces the mAs for 120° in front of the patient compared to a reference value. We consider two cases: in the first case, the mAs in front of the patient is reduced to 25% (osTCM25%), in the other case it is reduced to 0% (osTCM0%) while keeping the total mAs-product constant. The actual patient risk is only considered in the riskTCM method. This is done by minimizing the effective dose to the patient. The prior knowledge required to do so can, e.g., be obtained by using a coarse reconstruction from topogram(s). The three TCM methods are retrospectively applied to thorax scans of seven patients using a tube voltage of 70 kV. The effective dose reduction for mAsTCM, osTCM0%, osTCM25%, and riskTCM are compared to a case with constant tube current (noTCM).

RESULTS

On average, the reduction of total effective dose for the entire chest compared to the case of noTCM is 14% for mAsTCM, 18% for osTCM25%, 21% for osTCM0%, and 33% for riskTCM. The reduction of dose delivered to breast tissue compared to noTCM is about 7% for mAsTCM, 28% for osTCM25%, 36% for osTCM0%, and 55% for riskTCM.

CONCLUSION

s The proposed riskTCM method allows for the highest reduction of effective dose and, surprisingly, of dose to the breast amongst all investigated TCMs.

CLINICAL RELEVANCE/APPLICATION

riskTCM can potentially further reduce the effective dose in CT examinations of the female breast compared to current clinically used algorithms.

R2-SPPH-1

Local Diagnostic Reference Levels in North of Mexico

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Maria del Carmen Franco, MS, Monterrey, Mexico (*Presenter*) Nothing to Disclose

PURPOSE

To establish local diagnostic reference levels (DRL) from adult patients in chest and abdominal CT.

METHODS AND MATERIALS

Observational, descriptive, and retrospective study, limited to the technical factors obtained in four different private and public hospitals in the north of Mexico. The data was obtained during a 9-month period using RIS/PACS system.Only examinations with complete patient information, older than 16 years old, and with normal CT abdominal or thorax protocol were included. Those with more than one body part scan and the ones with contrast materials were excluded. The size of the patient was determined by measuring thickness and anteroposterior diameters in the axial images. The water-equivalent diameter was used to determine the Size Especific Dose Estimate from volume CT dose index.

RESULTS

Local DRL for CTDIvol, SSDE and Dose-length product as the median value of each variable. For all CT scans, the DRL and SSDE were higher for patients of larger size than those of smaller size. The local DRLs were comparable to current published values in the United States.

CONCLUSION

s We were able to establish local DRLs for the most frequent CT scans in our institutions. These are within US DRL, which suggests that patient doses with our current protocols (yielding acceptable image quality) are within a typical practice in that Country. To our knowledge, this represents the first time in our country that DRLs are used in patients using their size.

CLINICAL RELEVANCE/APPLICATION

This study shows that in our country, other hospitals can adopt DRLs to their practice, which benefits the patient and protects the ALARA concept.

Setting Local Dose Reference Levels in Pediatric CT With a Dose Management Software

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Maria Perez Fernandez, MSc, (*Presenter*) Nothing to Disclose

PURPOSE

To compare the doses administered in pediatric CT examinations with published dose reference levels (DRLs) and to establish local dose reference levels for a public hospital that provides care to a population of 400,000 people.

METHODS AND MATERIALS

The CTDIvol and DLP of all examinations performed between 2016 and 2020 in three CT scanners were collected with a dose management software. The data corresponding to pediatric patients were divided by age ranges and types of CTs procedures including "Head"(854 patients), "Thorax" (91 patients), "Abdomen" (62 patients) and "Joints" (183 patients). Other types of examinations were discarded. The 50th and 75th percentiles of each group were obtained.The 50th percentiles were compared to RP185 EDRLs to verify if the clinical practice is adequate in terms of patient´s radiological protection.The 75th percentiles obtained were set as local DRLs when their value were lower than the published DRL and the number of CT scans analyzed were more than 20.

RESULTS

The median CTDIvol and DLP obtained for each type of examination and age group are lower than the corresponding published DRL, with the exception of the head DLP of the older age group, which is slightly higher. This indicates the clinical practice is adequate.The following DRLs were set: HEAD Age group under 3 months: CTDIvol =12mGy, DLP=199mGy.cm; age group between 3 months and 1 year: CTDIvol =10mGy, DLP=159mGy.cm; age group between 1and 6 years: CTDIvol=21mGy, DLP=345mGy.cm; age group over 6 years: CTDIvol=49mGy.THORAX Age group between 1 month and 4 years: CTDIvol=1,3mGy, DLP=31mGy; age group between 4 and 10 years: CTDIvol=2,4mGy.ABDOMEN Age group between 14 and 18 years: CTDIvol=7mGy, DLP= 323mGy.JOINTS Age group between 4 and 10 years: CTDIvol=4,8mGy, DLP=82mGy.cm; age group between 10 and 14 years: CTDIvol=4,8mGy, DLP=90mGy.cm; age group between 14 and 18 years: CTDIvol=4,8mGy, DLP=97mGy.cm.

CONCLUSION

s The scarce number of CT scans performed in children complicates setting reliable local DRLs. However, with a dose management software acceptable statistics can be obtained in a reasonable period of time.

CLINICAL RELEVANCE/APPLICATION

In this work, reliable local DRLs have been obtained with updated data for pediatric most common CT examinations with acceptable statistics thanks to the dose management software.

R2-SPPH-4

Multi-Parametric Diagnostic Reference Levels (DRL) For CT: Data From 4648 Patients From 12 Sites in Brazil

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Shadi Ebrahimian, MD, Boston, MA (*Presenter*) Nothing to Disclose

PURPOSE

Diagnostic reference levels (DRL) can help in radiation dose optimization and monitoring. We conducted a prospective study on establishing multi-parametric, multi-site national (Brazil) DRL for CT exams based on patient gender, size, body regions, and clinical indications.

METHODS AND MATERIALS

With institutional review board approvals, we prospectively included 4648 adult patients (18-99 years; male: female 2674:1974) who underwent CT at 12 sites in Brazil between January and October 2021 including: head (n=1511 patients), chest (n=1227), and abdomen-pelvis [AP] (n=842). Following information was recorded: hospital name, patient age, gender, weight, height, body mass index [BMI], clinical indications, scanner information (vendor, scanner name, slice profile), scan parameters (number of scan phases, kV, mA, pitch) and dose indices (phase-specific CT dose index volume [CTDIvol] and phase-specific and total dose length products [DLP]). Patients were divided into under-, over-, normal- and obese-BMI groups per the WHO classification. Median and 75th percentile CTDIvol and DLP values were estimated and compared for different patient groups (gender and size), body region, clinical indications.

RESULTS

The estimated 75th percentile CTDIvol and DLP were head (46mGy, 1016mGy.cm), paranasal sinus (19mGy, 362mGy.cm), cervical spine (26mGy, 679mGy.cm), chest (11mGy, 362mGy.cm), and AP (14mGy, 753mGy.cm). The highest DLP were recorded for carotid CTA (1450mGy.cm), pulmonary CTA (602mGy.cm), oncologic abdomen CT (4667mGy.cm) ($p<0.001$). For identical body part, gender, BMI, and clinical indications, there were significant and several-fold differences in both CTDIvol and DLP values across the 12 Brazilian hospitals ($p<0.001$).

CONCLUSION

s In this study most Brazilian DRL (CTDIvol and DLP) were lower or similar to the US and European reported DRLs for corresponding CT exams and protocols with variations based on clinical indications and patient size.

CLINICAL RELEVANCE/APPLICATION

Substantial inter-site variations in radiation doses for similar BMI, body-region and clinical indications suggest an urgent need for CT technology upgrade and protocol optimization.

R2-SPPH-5

Skin Dosimetry Model for CT Acquisitions

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Mahta Mazloumi, MA, (*Presenter*) Nothing to Disclose

PURPOSE

Skin is the first organ that is exposed to X-ray during a CT scan and it can receive a relatively high radiation dose in CT procedures with repeated exposure to the same skin area such as interventional or perfusion CT. The aim of this study is to provide a skin dose model based on CT acquisition parameters to allow dose follow-up for this organ at risk.

METHODS AND MATERIALS

A virtual cylindrical phantom was generated (32cm,L=20cm,pixel size=0.5mm2) in DICOM format. The phantom was used as a 3D geometrical model for Monte Carlo (MC) simulations with ImpactMC (Advanced Breast-CT). The impact of acquisition parameters including tube voltage (70,80,100,120, and 140kVp), bow-tie filter (medium filter, large filter), and position in the gantry (+14, +11, +7, +3, 0, -5, and -9cm along the y-axis) on skin dose were investigated with the MC simulations. The first layer at the surface of the phantom was considered as skin (thickness 0.5mm2). The dose values were normalized to CTDIvol (D_CTDI). In addition, the model was validated with experimental TLD measurements and MC simulations on the humanoid Rando Alderson (RA) phantom for the large filter at 120kVp and 80-mm collimation.

RESULTS

Results show increase in the skin dose for decreasing distance to the isocenter. For distances smaller than 120mm, four curves were fitted to the data based on high tube voltage (HV) at 100,120, and 140kVp, low tube voltage (LV) at 70 and 80kVp, medium filter (MF), and large (LF) with the equation D_CTDI=A*x(mm)2+B*x(mm)+C. The values of A, B, and C for the investigated tube voltages and filters are as follows; for HV-MF: A=-4.71E-05, B=-92.95E-05, C=2.09, for LV-MF: A=6.92E-05, B=-240E-05, C=2.59, for HV-LF: A=-3.96E-05, B=62.58E-05, C=1.80 and for LV-LF: A=-4.75E-05, B=25.49E-05, C=1.96. For distances larger than 120mm, the curves for the various kVp selections differ marginally, and one fitting formula is sufficient (A=3.74E-05, B=-0.02, C=2.79) to estimate skin dose for all combinations with an average error of 4.3% between this estimation and estimations of the exact equations. Additionally, the skin dose values of RA phantom were in good agreement with our model at 120kVp and LF. The average deviation between the experimental TLD measurement on the RA phantom and the MC simulations of the phantom was 9%.

CONCLUSION

s The developed skin dose model can estimate skin dose as a function of filter type, tube voltage, and skin-isocenter distance in CT imaging.

CLINICAL RELEVANCE/APPLICATION

The developed skin dose model in this study has the potential to enable the implementation of a systematic skin dose assessment and registration in clinical CT imaging. Additionally, it can estimate skin dose prior to the CT scan based on the localizer scan in combination with selected acquisition parameters.

R2-SPPH-6

Application of Deep Learning Image Reconstruction (DLIR) Algorithm to Improve Image Quality in CT Angiography of Children With Takayasu Arteritis

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Ji Hang Sun, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Objective: To evaluate the image quality improvement in CT angiography (CTA) of children with Takayasu arteritis (TAK) using a deep learning image reconstruction (DLIR) in comparison to other reconstruction algorithms.

METHODS AND MATERIALS

32 patients (9.14±4.51 years old) with TAK underwent abdominal CTA with 100kVp were enrolled. Images were reconstructed at 0.625mm slice thickness using Filtered Back-Projection (FBP), 50% adaptive statistical iterative reconstruction-V (50%ASIR-V), 100%ASIR-V and DLIR with high setting (DLIR-H). The CT number and standard deviation (SD) of the descending aorta and back muscle were measured and contrast-to-noise ratio (CNR) for aorta was calculated. The vessel visualization, overall image noise and diagnostic confidence were evaluated using a 5-point scale (5, excellent; 3, acceptable) by 2 observers.

RESULTS

There was no significant difference in CT number across all reconstructions. The image noise values (in HU) were 31.36±6.01, 24.96±4.69, 18.46±3.91 and 15.58±3.65, and CNR values for aorta were 11.93±2.12, 15.66±2.37, 22.54±3.34 and 24.02±4.55 with FBP, 50%ASIR-V, 100%ASIR-V and DLIR-H, respectively. The DLIR-H images had the lowest image noise and highest CNR among all reconstructions. The subjective evaluation suggested that all images were diagnostic for large arteries, but only 50%ASIR-V and DLIR-H met the diagnostic requirement for small arteries (3.03±0.18 and 3.53±0.51) with the combination of image noise and spatial resolution.

CONCLUSION

s DLIR-H improves the CTA image quality and diagnostic confidence for TAK patients compared with 50%ASIR-V, and best balances image noise and spatial resolution compared with 100%ASIR-V.

CLINICAL RELEVANCE/APPLICATION

DLIR-H can be used in CTA for patients with Takayasu's arteritis to improve overall image quality and the identification of small vessels.

Model-Specific Benchmarks for Non-contrast Head and Brain CT Imaging

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Jered Wells, PhD, Glenwood, IL (*Presenter*) Employee, LANDAUER, Inc;Consultant, Vaxa Medical Physics;Research Consultant, Agfa-Gevaert Group

PURPOSE

Effective computed tomography (CT) protocol review includes comparison of average CTDIvol per protocol against available (national) benchmarks. While comparisons to benchmarks can be an effective gauge of individual system performance relative to the general practice of CT imaging, these benchmarks do not account for potential differences between CT scanner models and system implementation preferences. This work investigates the utility of model-specific CT benchmarks for non-contrast head and brain imaging and compares this against the variability in site-specific implementation.

METHODS AND MATERIALS

Anonymized adult CT HEAD BRAIN WO IVCON exposure data from calendar year 2021 were collected using LANDAUER OPTIMIZE dose monitoring software. Thirteen CT scanner models (70 individual scanners installed at 50 imaging facilities) qualified for analysis based on 66,057 eligible non-contrast head exams. A CT scanner model qualified for analysis if at least four scanners from at least two imaging facilities had at least 50 eligible image series per scanner. A two-way ANOVA test with significance threshold a = 0.05 was performed to analyze the effects of CT scanner model and imaging facility (i.e. site-specific implementation) on CTDIvol.

RESULTS

The overall median CTDIvol was 48.12 mGy (IQR = 43.92-52.79 mGy) which is comparable to established national benchmarks for CT HEAD BRAIN WO IVCON derived from Kanal, et. al. (2017) who report median CTDIvol (achievable dose) of 49 mGy and upper quartile (diagnostic reference level) of 56 mGy for this protocol. Two-way ANOVA analysis of CTDIvol showed that scanner model had a significant effect ($p = 0.022$), and imaging facility had a highly significant effect ($p << 0.001$). Interaction effects between CT scanner model and imaging facility were not statistically significant ($p = 0.109$).

CONCLUSION

s Scanner model is an important determinant of achievable CTDIvol for non-contrast head and brain CT imaging. Furthermore, site-specific scanner implementation was found to be an even greater source of CTDIvol variability than scanner model. This suggests that scanner options and institutional imaging protocol preferences have an outsized influence on CT dose over scanner base model. Even so, model-specific CT benchmarks are merited for better CT dose management in accordance with scanner model capabilities.

CLINICAL RELEVANCE/APPLICATION

Comparison of CTDIvol to national benchmarks is the current gold standard for CT dose management, but variation between scanner models and implementation preferences make it difficult to determine when protocols are truly optimized.

R2-SPPH-8

Potential CT Radiation Dose Reduction to the Female Breast by a Novel Risk-Minimizing Tube Current Modulation

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - PH DPS

Participants
Laura Klein, Heidelberg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To compare riskTCM, a recently proposed tube current modulation technique intended to minimize the patient radiation risk, with a conventional mAs-minimizing TCM (mAsTCM) and an established organ-specific TCM (osTCM) with special focus on the female breast.

METHODS AND MATERIALS

To reduce dose to the female breast in CT, different TCM methods are available. Typical methods used in clinical systems are the mAs-minimizing TCM (mAsTCM) as well as organ-specific TCMs (osTCM). Both methodologies do not account for the actual patient risk but minimize physical quantities. While mAsTCM minimizes the mAs-product at constant image quality, osTCM reduces the mAs for anterior views to spare the female breast. Herein, osTCM is implemented to be similar to the X-Care algorithm (Siemens Healthineers) which reduces the mAs for 120° in front of the patient compared to a reference value. We consider two cases: in the first case, the mAs in front of the patient is reduced to 25% (osTCM25%), in the other case it is reduced to 0% (osTCM0%) while keeping the total mAs-product constant. The actual patient risk is only considered in the riskTCM method. This is done by minimizing the effective dose to the patient. The prior knowledge required to do so can, e.g., be obtained by using a coarse reconstruction from topogram(s). The three TCM methods are retrospectively applied to thorax scans of seven patients using a tube voltage of 70 kV. The effective dose reduction for mAsTCM, osTCM0%, osTCM25%, and riskTCM are compared to a case with constant tube current (noTCM).

RESULTS

On average, the reduction of total effective dose for the entire chest compared to the case of noTCM is 14% for mAsTCM, 18% for osTCM25%, 21% for osTCM0%, and 33% for riskTCM. The reduction of dose delivered to breast tissue compared to noTCM is about 7% for mAsTCM, 28% for osTCM25%, 36% for osTCM0%, and 55% for riskTCM.

CONCLUSION

s The proposed riskTCM method allows for the highest reduction of effective dose and, surprisingly, of dose to the breast amongst all investigated TCMs.

CLINICAL RELEVANCE/APPLICATION

riskTCM can potentially further reduce the effective dose in CT examinations of the female breast compared to current clinically used algorithms.

R2-SPRO-1 Racial Disparities in Patients Referred to Radiation Oncology for Palliation of Acute Pain Symptom

Participants
Elana Benishay, BS, (*Presenter*) Nothing to Disclose

PURPOSE

Despite the breadth of options available to treat pain symptoms, cancer patients are often under-treated for their level of pain. Further, there are known racial disparities in pain management. Studies have shown that patients identifying as Black or African American are significantly less likely to be prescribed pain medication or adequate doses of pain medications. The aim of this study is to investigate potential racial disparities in patients referred to the Radiation Oncology department for acute pain management.

METHODS AND MATERIALS

This retrospective review analyzed patients seen in consultation in the Radiation Oncology department for acute pain management between July 23, 2020, and July 23, 2021. Clinical data including patient and treatment characteristics, cancer type, pain scores and medication lists were abstracted for all identified patients. Statistical analysis was performed using univariate and multivariate logistic regression models to assess patient characteristics associated with severe pain.

RESULTS

The mean overall pain score was 5.95 (SD 2.53). In African American patients, the mean pain score was 6.72 (SD 2.54), while Caucasian patients had a mean pain score of 5.55 (SD 2.45). African American patients (OR 3.35, p=0.008) were more likely to present with severe pain compared to Caucasian patients. Amongst African American patients, 40% (n=10) reported mild to moderate pain (pain score 1-6) and 60% (n=15) reported severe pain (pain score 7-10). Comparatively, 69% (n=51) of Caucasian patients had mild to moderate pain and 31% (n=23) had severe pain.

CONCLUSION

s Patients referred to Radiation Oncology for management of acute pain are often under treated for their pain. Patients identifying as African American present with higher rates of severe pain in comparison to Caucasian patients. The findings of this study should promote the continued exposure of unjust delivery of care. Standardized practice and implicit bias training can help eliminate these disparities.

CLINICAL RELEVANCE/APPLICATION

Inadequate treatment of pain may lead to racial disparities, poor quality of life, and higher healthcare costs.

R2-SPRO-1

Racial Disparities in Patients Referred to Radiation Oncology for Palliation of Acute Pain Symptom

Thursday, Dec. 1 9:00AM - 9:30AM Room: Learning Center - RO DPS

Participants
Elana Benishay, BS, (*Presenter*) Nothing to Disclose

PURPOSE

Despite the breadth of options available to treat pain symptoms, cancer patients are often under-treated for their level of pain. Further, there are known racial disparities in pain management. Studies have shown that patients identifying as Black or African American are significantly less likely to be prescribed pain medication or adequate doses of pain medications. The aim of this study is to investigate potential racial disparities in patients referred to the Radiation Oncology department for acute pain management.

METHODS AND MATERIALS

This retrospective review analyzed patients seen in consultation in the Radiation Oncology department for acute pain management between July 23, 2020, and July 23, 2021. Clinical data including patient and treatment characteristics, cancer type, pain scores and medication lists were abstracted for all identified patients. Statistical analysis was performed using univariate and multivariate logistic regression models to assess patient characteristics associated with severe pain.

RESULTS

The mean overall pain score was 5.95 (SD 2.53). In African American patients, the mean pain score was 6.72 (SD 2.54), while Caucasian patients had a mean pain score of 5.55 (SD 2.45). African American patients (OR 3.35, p=0.008) were more likely to present with severe pain compared to Caucasian patients. Amongst African American patients, 40% (n=10) reported mild to moderate pain (pain score 1-6) and 60% (n=15) reported severe pain (pain score 7-10). Comparatively, 69% (n=51) of Caucasian patients had mild to moderate pain and 31% (n=23) had severe pain.

CONCLUSION

s Patients referred to Radiation Oncology for management of acute pain are often under treated for their pain. Patients identifying as African American present with higher rates of severe pain in comparison to Caucasian patients. The findings of this study should promote the continued exposure of unjust delivery of care. Standardized practice and implicit bias training can help eliminate these disparities.

CLINICAL RELEVANCE/APPLICATION

Inadequate treatment of pain may lead to racial disparities, poor quality of life, and higher healthcare costs.

Sub-Events

R5A-SPBR-1 Benefits of Reading Artificial Intelligence-enhanced Synthetic Thick Slabs Instead of Standard Thin Slices in Digital Breast Tomosynthesis

Participants
Stephanie Sauer, Wuerzburg, 97080, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Digital breast tomosynthesis provides additional value over standard mammography, albeit at the cost of longer reading time. The aim of this study was to investigate the impact of reading synthetic 6-mm slabs instead of conventional 1-mm slices on interpretation time, diagnostic confidence and accuracy.

METHODS AND MATERIALS

For this retrospective study, radiologists with 6 (R1), 4 (R2), and 2 (R3) years of breast imaging experience reviewed 111 digital breast tomosynthesis scans in either craniocaudal (21), mediolateral (12) or mediolateral oblique orientation (78). Two datasets were interpreted independently for each examination, with one set containing standard 1-mm slices, while the other set comprised artificial intelligence-enhanced synthetic 6-mm slabs with 3-mm overlap. Blinded to histologic results and follow-up imaging, readers noted the estimated BIRADS score, maximum lesion diameter, and diagnostic confidence, while reading time was recorded. Among 111 tomosynthesis examinations, 70 findings had histologic follow-up, including 56 malignancies (4 DCIS, 42 NST, 7 lobular, and 3 other carcinomas).

RESULTS

Diagnostic accuracy was comparable for 6-mm thick slab and 1-mm slice readings (R1: 87.0% vs. 87.0%; R2: 86.1% vs. 87.0%; R3: 80.0% vs. 84.4%; p=0.125), with 1 of 3 radiologists reporting higher confidence when interpreting 1-mm slices (R1: p=0.033). Correspondingly, a significant measurement discrepancy between slabs and slices was ascertained for 1 of 3 readers (R1: mean difference of 0.8 mm; p=0.010). No difference was found between the BIRADS scores assigned with access to 1-mm and 6-mm datasets (p=0.317), while interrater agreement was comparably high for slabs and slices (ICC 0.848 vs. 0.865). Reading time was substantially shorter when interpreting synthetic 6-mm slabs compared to 1-mm slices (R1: 33.5 vs. 46.2 sec; R2: 49.1 vs. 64.8 sec; R3: 39.5 vs. 67.2 sec; all p<0.001).

CONCLUSION

s Employing a reconstruction protocol with artificial intelligence-enhanced 6-mm slabs instead of 1-mm slices for digital breast tomosynthesis facilitates similar diagnostic performance with reduced interpretation time.

CLINICAL RELEVANCE/APPLICATION

Interpretation of synthetic thick slabs instead of standard thin slices allows for substantial time saving without decreasing the diagnostic accuracy of radiologists.

R5A-SPBR-2 Distinction Between Benign and Malignant Breast Masses of Digital Breast Tomosynthesis Using Deep Learning Method with Mask-R Convolutional Neural Network

Participants
Huizhi Cao, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to use deep learning with Mask-R convolutional neural network (Mask-R-CNN) to discriminate between benign and malignant breast mass images from digital breast tomosynthesis.

METHODS AND MATERIALS

In total, 2000 patients (1196 benign masses and 804 malignant masses) were randomly divided into the training cohort (1600 patients) and the two validation cohorts (200 patients for each cohort). Deep learning model was constructed using Mask-R-CNN architecture in two views (craniocaudal, CC and mediolateral oblique, MLO). The performance of the trained neural network was tested with this one validation cohort. Four radiologists (2 senior and 2 junior) interpreted the test data set. In a second step, the neural network was re-trained with all cases and then was tested with another validation cohort. Sensitivity, specificity, accuracy, positive predictive value (PPV), negative predictive value(NPV)and area under the receiver operating characteristic curve (AUC) were compared between readers and the neural network.

RESULTS

For initially constructed Mask-R-CNN model, the Sensitivity, specificity, accuracy, PPV, NPV and AUC in CC view and MLO view were 92.30% Vs. 96.20%, 85.40% Vs. 81.30%, 89% Vs. 89%, 85.70% Vs. 87.40%, 91.90% Vs. 95.10%, 0.845 Vs. 0.858, respectively. The proposed model achieved better classification performance than the junior radiologists and inferior to that of senior radiologists ($P < 0.05$). With the re-trained Mask-R-CNN model, the Sensitivity, specificity, accuracy, PPV, NPV and AUC in CC view and MLO view were 96.10% Vs. 96.10%, 95.90% Vs. 91.80%, 96% Vs. 94%, 96.10% Vs. 92.50%, 95.90% Vs. 95.70%, 0.949 Vs. 0.908, respectively. There was no significant difference in classification performance between AI model and senior radiologists ($P < 0.05$).

CONCLUSION

s The results obtained demonstrate that the proposed Mask-R convolutional neural network is performant and can indeed be used to predict if the mass lesions are benign or malignant.

CLINICAL RELEVANCE/APPLICATION

The study demonstrates that deep learning with Mask-R-CNN have higher performance in classifying mass lesions of digital breast tomosynthesis.

R5A-SPBR-3 Breast Cancer Screening in the Real-World: A Multi-Site Database of Women Screened for Breast Cancer

Participants
Emily F. Conant, MD, Philadelphia, PA (*Presenter*) Research Grant, Hologic, Inc;Advisory Panel, Hologic, Inc;Research Grant, OM1, Inc;Research Grant, iCad, Inc;Advisory Panel, iCad, Inc;Speaker, WebMD LLC

PURPOSE

Mammographic imaging is the standard for early detection of breast cancer (BC). Digital breast tomosynthesis (DBT) improves recall and cancer detection rates over digital mammography (DM). Yet few studies describe benefits and risks of these imaging modalities in a real-world setting, including in underrepresented patient subgroups. This study provides real-world evidence (RWE) for BC screening outcomes in a large population of women in the United States (US) receiving DBT or DM screenings.

METHODS AND MATERIALS

This retrospective, observational study included women who received routine DM or DBT screenings between 2014 and 2020 at five large healthcare organizations. Integrated electronic medical record, radiology information system, and tumor registry data were used. Women 40-79 years old with >1 screening and no history of BC were included. Outcomes of recall rate (RR), cancer detection rate (CDR), positive predictive value of recall (PPV1), and biopsy rate, and corresponding 95% confidence intervals (CI), were assessed overall and by screening modality. Logistic regression models adjusted for age, breast density, site, and exam year.

RESULTS

The cohort included 1,100,447 women and 2,528,063 screenings (2,071,741 from women with >2 observed screens). Women were on average 57.3 (standard deviation 10.3) years of age, primarily white (74.5%), and post-menopausal (66.8%) with a breast density of 'scattered fibroglandular densities' (47.5%). DBT screens led to significantly reduced RR (DBT 8.9%, DM 10.3%, $p<0.001$), and increased CDR (DBT 4.3/1000, DM 4.9/1000, $p<0.001$), PPV1 (DBT 5.5%, DM 4.2%, $p<0.001$), and biopsy rates (DBT 18.1/1000, DM 14.8/1000, $p<0.001$) (see Figure). These associations remained in adjusted analyses, and were consistent across patient subgroups defined by age, race, breast density, and risk status.

CONCLUSION

s This ongoing US study of over 2.5 million mammograms offers a rich platform to explore outstanding questions around the real-world benefits and risks of breast cancer screening, particularly in key patient subgroups. In this cohort, DBT screenings were associated with reduced RR and increased CDR, PPV1, and rate of biopsy.

CLINICAL RELEVANCE/APPLICATION

Routine screening with DBT, compared to DM, may reduce recall and increase cancer detection, biopsy rates and positive predictive value of recall.

R5A-SPBR-4 Improved Cancer Detection with Digital Breast Tomosynthesis compared to Digital Mammography using Deep Learning Model

Participants
Ray Mayo III, MD, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

There is evidence of improved reader performance using digital breast tomosynthesis (DBT) compared to full field digital mammograms (FFDM). We compared the performance of an artificial intelligence-based computer aided detection (AI-CAD) software on a set of patients who had both DBT and FFDM exams.

METHODS AND MATERIALS

We tested performance of an AI-CAD (cmAssist™, CureMetrix, Inc, La Jolla, CA). The test set is composed of 933 patients (age range: 30-88, average 56 years) who underwent both DBT and FFDM at their screening exams, obtained between 2012 and 2018 from 2 sites in Northeastern and Southeastern United States and using 2 equipment vendors. There were 508 patients with biopsy confirmed cancer and 425 normal patients who had at least one year of followup as confirmation of benignity. Of the cancer patients, 156 had calcification lesions and 352 had mass or architectural distortion lesions. Bootstrap analysis was used to generate area under the curve (AUC) of the receiver operating characteristic which was measured at 95% confidence interval (CI) for both FFDM and DBT exams.

RESULTS

For FFDM, cmAssist has an AUC of 0.95 [CI: 0.93 - 0.96] for calcifications. For mass and architectural distortion lesions, the AUC is 0.75 [CI: 0.72 - 0.78]. For DBT, cmAssist has an AUC of 0.96 [CI: 0.95 - 0.97] for calcifications. For mass and architectural

distortions, the AUC is 0.89 [CI: 0.87 - 0.91].

CONCLUSION

s There was improved performance of cmAssist AI-CAD using DBT compared to FFDM. The improvement was more robust for mass and architectural distortions as expected; many of the cancers were only visible on DBT in this cancer-enriched sample of patients who underwent both FFDM and DBT. For calcifications, this AI-CAD achieves similar high performance for DBT and FFDM.

CLINICAL RELEVANCE/APPLICATION

AI-CAD (cmAssist) shows improved performance with digital breast tomosynthesis compared to full field digital mammography and appears to be a promising aid to the radiologist in enhancing cancer detection.

R5A-SPBR-5 Analysis of False Negative Digital BreastTomosynthesisScreening Exams

Participants
Sydney Payne, MD, BS, Palo Alto, CA (*Presenter*) Nothing to Disclose

PURPOSE

To determine reasons for false negative (FN) digital breast tomosynthesis (DBT) screening mammograms (MG).

METHODS AND MATERIALS

2 MQSA-certified radiologists classified FN DBT screenings from 3/31/2014- 3/31/2022 as negative studies (NS) or detectable, listing factors contributing to non-detection. We queried the EMR for patient breast cancer risk factors and cancer presentation/characteristics.

RESULTS

There were 69,594 screens with 416 screen-detected cancers (CDR 6/1000, 416/69,592) and 56 FN (0.8/1000, 56/69,594) studies. 7/56 FN were excluded for no DBT, leaving 49 women (age 28-82 years old, mean 60 yo) with 51 cancers comprising the study (11 DCIS, 11 IDC, 24 ILC, 1 IDC/ILC and 4 other cancers) found at an average 7.5 months (range 0.5-12 mo) post screening. Most women (61%,30/49) had risk factors and dense tissue (46.9%,23/49 heterogeneously dense; 26.6%,13/49 extremely dense). Detection was by screening MRI (24/51,47%), clinical findings (23/51,45%; 19 palpation, 2 pain, 2 palpation/pain), or imaging (1 screening MG,1 screening US, 1 PET-CT, 1 CT). 35/51(57%) cancers were NS, and 16/51 (31%) were non-detected masses (14/16,87.5%) or calcifications (2/16,12.5%). Screening MRI found DCIS more often (9/11,81.2%) than palpation and/or pain (2/11,18.2%). ILC was markedly represented in the pathology (24/51,47%) and was detected more often clinically (15/24,62.5%) than on screening MRI (8/24,33.3%) or US (1/24,0.4%). Factors contributing to non-detection were dense tissue (8/16,50%), one view findings (6/16,37.5%),developing asymmetries (4/16,25%), distracting findings (3/16,18.8%), post-surgical changes (2/16,12.5%), benign appearing mass (2/16,12.5%), at image edge (2/16,12.5%), positioning (1/16,0.1%),too few calcifications (1/16,0.1%) or poor image quality (1/16,0.1%).

CONCLUSION

s Almost half of cancers not detected by DBT were found on screening breast MRI (47%) and were ILC pathology (47%). Dense tissue and one-view findings were the most common factors contributing to non-detection.

CLINICAL RELEVANCE/APPLICATION

The most common reason for missed cancers on DBT is dense breast tissue or one-view findings, with a predominance of ILC. Screening breast MRI found almost half of the missed cancers.

R5A-SPBR-6 Screening Tomosynthesis Detected Breast Cancer in Women with Dense Tissue

Participants
Stamatia Destounis, MD, Rochester, NY (*Presenter*) Medical Advisory Board, iCad, Inc

PURPOSE

To report the cancer detection rate and tumor characteristics in women with dense breast tissue having screening Digital Breast Tomosynthesis (DBT).

METHODS AND MATERIALS

This retrospective review identified patients with dense breast tissue who had a breast cancer diagnosis that was detected on a screening Digital Breast Tomosynthesis (DBT) examination between the years of 2016 and 2021. This resulted in an analysis of 194,340 exams in 60,884 patients. VolparaDensity was utilized in real time to assess breast density versions (v1.5.3 - v4.2.2). Lesion type, lymph node status, stage, and grade were collected.

RESULTS

Overall, 1076 cancers were detected in 913 patients by screening DBT between the years of 2016 and 2021. Most of these cancers were masses (576/1076, 54%). Of the 1076 cancers 79% (n=855) were invasive cancers and 221 (21%) were ductal carcinoma in situ. DBT was able to detect nine lymph nodes that were pathologically proven to be metastatic. In the 913 patients that were diagnosed, the cancers were Grade 1 or Grade 2 (298 (33%) and 297 (32.5%), respectively), and a majority were of early stage (Stage 0, Stage 1) (855/1076, 79%). At surgery, 73% (n=665) patients had negative nodes.

CONCLUSION

s This retrospective review demonstrated that DBT found lower grade and early-stage malignancies in women with dense breast tissue. DBT was also able to detect metastatic lymph nodes.

CLINICAL RELEVANCE/APPLICATION

Some facilities are only offering DBT as a diagnostic tool. Utilizing DBT for screening can aid in the detection of breast cancer in patients with dense tissue as thus far it has been shown to detect lower grade, and early-stage cancers. Greater adoption will occur with proven utility of DBT in this population.

R5A-SPBR-7 Automated Breast Ultrasound vs Handheld Ultrasound in Moderate Risk Breast Cancer Women With Dense Breast

Participants
MARIA TERESA FERNANDEZ-TARANILLA, PhD, Madrid, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To determine if Automated Breast UltraSound (ABUS) is at least as effective as handheld ultrasound (HHUS) in detecting lesions in intermediate risk breast cancer patients with dense breast.To compare the degree of interobserver agreement between BI-RADS categorization with ABUS vs HHUS.

METHODS AND MATERIALS

200 patients (350 breast) were evaluated the same day with ABUS and HHUS between June 2020 to July 2021 in a tertiary hospital. Women with dense breast C or D according the American College Radiology and intermediate risk were included. Previous personal breast cancer(pBC), known family history of BC (fBC) , prior lesion of uncertain malignant potential (B3 lesions) and certain syndromes and gene mutations were considered as intermediate risk subcategories. BI-RADS categorization was used to determine the agreement between both techniques with Kappa index.

RESULTS

Mean age of women were 47 years old, 45% had type C and 55% type D breast densities. The most frequent group of patients were the pBC (67%) and mostly were BI-RADS 2. The mean time of ABUS lecture were 4 minutes. The Kappa index was almost perfect (0.84) in the radiologist interpretation with BI-RADS between ABUS vs HHUS ($p<0,001$). Moderate agreement (0.52) was observed on pBC ($p<0,005$) always referring to the remaining breast after radical surgery. Excellent agreement (0.89) was observed on patients with fBC ($p<0,001$) and on syndromes with intermediate risk($p<0,005$). On B3 lesions the results were not significant ($p<0,07$).

CONCLUSION

s ABUS could be a valuable and cost-effective screening tool for women with dense breast and moderate risk in combination with mammography.

CLINICAL RELEVANCE/APPLICATION

The screening for breast cancer on patients with dense breast is still a challenge, even more if those patients had an increased risk of cancer (15-20%). Our proposal is to introduce a cost-effective tool like ABUS in the routine screening programs to increase sensibility and specificity on patients with dense breast and moderate risk cancer.

Benefits of Reading Artificial Intelligence-enhanced Synthetic Thick Slabs Instead of Standard Thin Slices in Digital Breast Tomosynthesis

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Stephanie Sauer, Wuerzburg, 97080, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Digital breast tomosynthesis provides additional value over standard mammography, albeit at the cost of longer reading time. The aim of this study was to investigate the impact of reading synthetic 6-mm slabs instead of conventional 1-mm slices on interpretation time, diagnostic confidence and accuracy.

METHODS AND MATERIALS

For this retrospective study, radiologists with 6 (R1), 4 (R2), and 2 (R3) years of breast imaging experience reviewed 111 digital breast tomosynthesis scans in either craniocaudal (21), mediolateral (12) or mediolateral oblique orientation (78). Two datasets were interpreted independently for each examination, with one set containing standard 1-mm slices, while the other set comprised artificial intelligence-enhanced synthetic 6-mm slabs with 3-mm overlap. Blinded to histologic results and follow-up imaging, readers noted the estimated BIRADS score, maximum lesion diameter, and diagnostic confidence, while reading time was recorded. Among 111 tomosynthesis examinations, 70 findings had histologic follow-up, including 56 malignancies (4 DCIS, 42 NST, 7 lobular, and 3 other carcinomas).

RESULTS

Diagnostic accuracy was comparable for 6-mm thick slab and 1-mm slice readings (R1: 87.0% vs. 87.0%; R2: 86.1% vs. 87.0%; R3: 80.0% vs. 84.4%; p=0.125), with 1 of 3 radiologists reporting higher confidence when interpreting 1-mm slices (R1: p=0.033). Correspondingly, a significant measurement discrepancy between slabs and slices was ascertained for 1 of 3 readers (R1: mean difference of 0.8 mm; p=0.010). No difference was found between the BIRADS scores assigned with access to 1-mm and 6-mm datasets (p=0.317), while interrater agreement was comparably high for slabs and slices (ICC 0.848 vs. 0.865). Reading time was substantially shorter when interpreting synthetic 6-mm slabs compared to 1-mm slices (R1: 33.5 vs. 46.2 sec; R2: 49.1 vs. 64.8 sec; R3: 39.5 vs. 67.2 sec; all p<0.001).

CONCLUSION

s Employing a reconstruction protocol with artificial intelligence-enhanced 6-mm slabs instead of 1-mm slices for digital breast tomosynthesis facilitates similar diagnostic performance with reduced interpretation time.

CLINICAL RELEVANCE/APPLICATION

Interpretation of synthetic thick slabs instead of standard thin slices allows for substantial time saving without decreasing the diagnostic accuracy of radiologists.

R5A-SPBR-2

Distinction Between Benign and Malignant Breast Masses of Digital Breast Tomosynthesis Using Deep Learning Method with Mask-R Convolutional Neural Network

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Huizhi Cao, PhD, (*Presenter*) Nothing to Disclose

PURPOSE

We aimed to use deep learning with Mask-R convolutional neural network (Mask-R-CNN) to discriminate between benign and malignant breast mass images from digital breast tomosynthesis.

METHODS AND MATERIALS

In total, 2000 patients (1196 benign masses and 804 malignant masses) were randomly divided into the training cohort (1600 patients) and the two validation cohorts (200 patients for each cohort). Deep learning model was constructed using Mask-R-CNN architecture in two views (craniocaudal, CC and mediolateral oblique, MLO). The performance of the trained neural network was tested with this one validation cohort. Four radiologists (2 senior and 2 junior) interpreted the test data set. In a second step, the neural network was re-trained with all cases and then was tested with another validation cohort. Sensitivity, specificity, accuracy, positive predictive value (PPV), negative predictive value(NPV)and area under the receiver operating characteristic curve (AUC) were compared between readers and the neural network.

RESULTS

For initially constructed Mask-R-CNN model, the Sensitivity, specificity, accuracy, PPV, NPV and AUC in CC view and MLO view were 92.30% Vs. 96.20%, 85.40% Vs. 81.30%, 89% Vs. 89%, 85.70% Vs. 87.40%, 91.90% Vs. 95.10%, 0.845 Vs. 0.858, respectively. The proposed model achieved better classification performance than the junior radiologists and inferior to that of senior radiologists ($P < 0.05$). With the re-trained Mask-R-CNN model, the Sensitivity, specificity, accuracy, PPV, NPV and AUC in CC view and MLO view were 96.10% Vs. 96.10%, 95.90% Vs. 91.80%, 96% Vs. 94%, 96.10% Vs. 92.50%, 95.90% Vs. 95.70%, 0.949 Vs. 0.908, respectively. There was no significant difference in classification performance between AI model and senior radiologists ($P < 0.05$).

CONCLUSION

s The results obtained demonstrate that the proposed Mask-R convolutional neural network is performant and can indeed be used to predict if the mass lesions are benign or malignant.

CLINICAL RELEVANCE/APPLICATION

The study demonstrates that deep learning with Mask-R-CNN have higher performance in classifying mass lesions of digital breast tomosynthesis.

Breast Cancer Screening in the Real-World: A Multi-Site Database of Women Screened for Breast Cancer

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Emily F. Conant, MD, Philadelphia, PA (*Presenter*) Research Grant, Hologic, Inc;Advisory Panel, Hologic, Inc;Research Grant, OM1, Inc;Research Grant, iCad, Inc;Advisory Panel, iCad, Inc;Speaker, WebMD LLC

PURPOSE

Mammographic imaging is the standard for early detection of breast cancer (BC). Digital breast tomosynthesis (DBT) improves recall and cancer detection rates over digital mammography (DM). Yet few studies describe benefits and risks of these imaging modalities in a real-world setting, including in underrepresented patient subgroups. This study provides real-world evidence (RWE) for BC screening outcomes in a large population of women in the United States (US) receiving DBT or DM screenings.

METHODS AND MATERIALS

This retrospective, observational study included women who received routine DM or DBT screenings between 2014 and 2020 at five large healthcare organizations. Integrated electronic medical record, radiology information system, and tumor registry data were used. Women 40-79 years old with >1 screening and no history of BC were included. Outcomes of recall rate (RR), cancer detection rate (CDR), positive predictive value of recall (PPV1), and biopsy rate, and corresponding 95% confidence intervals (CI), were assessed overall and by screening modality. Logistic regression models adjusted for age, breast density, site, and exam year.

RESULTS

The cohort included 1,100,447 women and 2,528,063 screenings (2,071,741 from women with >2 observed screens). Women were on average 57.3 (standard deviation 10.3) years of age, primarily white (74.5%), and post-menopausal (66.8%) with a breast density of 'scattered fibroglandular densities' (47.5%). DBT screens led to significantly reduced RR (DBT 8.9%, DM 10.3%, $p<0.001$), and increased CDR (DBT 4.3/1000, DM 4.9/1000, $p<0.001$), PPV1 (DBT 5.5%, DM 4.2%, $p<0.001$), and biopsy rates (DBT 18.1/1000, DM 14.8/1000, $p<0.001$) (see Figure). These associations remained in adjusted analyses, and were consistent across patient subgroups defined by age, race, breast density, and risk status.

CONCLUSION

s This ongoing US study of over 2.5 million mammograms offers a rich platform to explore outstanding questions around the real-world benefits and risks of breast cancer screening, particularly in key patient subgroups. In this cohort, DBT screenings were associated with reduced RR and increased CDR, PPV1, and rate of biopsy.

CLINICAL RELEVANCE/APPLICATION

Routine screening with DBT, compared to DM, may reduce recall and increase cancer detection, biopsy rates and positive predictive value of recall.

R5A-SPBR-4

Improved Cancer Detection with Digital Breast Tomosynthesis compared to Digital Mammography using Deep Learning Model

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Ray Mayo III, MD, Houston, TX (*Presenter*) Nothing to Disclose

PURPOSE

There is evidence of improved reader performance using digital breast tomosynthesis (DBT) compared to full field digital mammograms (FFDM). We compared the performance of an artificial intelligence-based computer aided detection (AI-CAD) software on a set of patients who had both DBT and FFDM exams.

METHODS AND MATERIALS

We tested performance of an AI-CAD (cmAssist™, CureMetrix, Inc, La Jolla, CA). The test set is composed of 933 patients (age range: 30-88, average 56 years) who underwent both DBT and FFDM at their screening exams, obtained between 2012 and 2018 from 2 sites in Northeastern and Southeastern United States and using 2 equipment vendors. There were 508 patients with biopsy confirmed cancer and 425 normal patients who had at least one year of followup as confirmation of benignity. Of the cancer patients, 156 had calcification lesions and 352 had mass or architectural distortion lesions. Bootstrap analysis was used to generate area under the curve (AUC) of the receiver operating characteristic which was measured at 95% confidence interval (CI) for both FFDM and DBT exams.

RESULTS

For FFDM, cmAssist has an AUC of 0.95 [CI: 0.93 - 0.96] for calcifications. For mass and architectural distortion lesions, the AUC is 0.75 [CI: 0.72 - 0.78]. For DBT, cmAssist has an AUC of 0.96 [CI: 0.95 - 0.97] for calcifications. For mass and architectural distortions, the AUC is 0.89 [CI: 0.87 - 0.91].

CONCLUSION

s There was improved performance of cmAssist AI-CAD using DBT compared to FFDM. The improvement was more robust for mass and architectural distortions as expected; many of the cancers were only visible on DBT in this cancer-enriched sample of patients who underwent both FFDM and DBT. For calcifications, this AI-CAD achieves similar high performance for DBT and FFDM.

CLINICAL RELEVANCE/APPLICATION

AI-CAD (cmAssist) shows improved performance with digital breast tomosynthesis compared to full field digital mammography and appears to be a promising aid to the radiologist in enhancing cancer detection.

R5A-SPBR-5

Analysis of False Negative Digital BreastTomosynthesisScreening Exams

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Sydney Payne, MD, BS, Palo Alto, CA (*Presenter*) Nothing to Disclose

PURPOSE

To determine reasons for false negative (FN) digital breast tomosynthesis (DBT) screening mammograms (MG).

METHODS AND MATERIALS

2 MQSA-certified radiologists classified FN DBT screenings from 3/31/2014- 3/31/2022 as negative studies (NS) or detectable, listing factors contributing to non-detection. We queried the EMR for patient breast cancer risk factors and cancer presentation/characteristics.

RESULTS

There were 69,594 screens with 416 screen-detected cancers (CDR 6/1000, 416/69,592) and 56 FN (0.8/1000, 56/69,594) studies. 7/56 FN were excluded for no DBT, leaving 49 women (age 28-82 years old, mean 60 yo) with 51 cancers comprising the study (11 DCIS, 11 IDC, 24 ILC, 1 IDC/ILC and 4 other cancers) found at an average 7.5 months (range 0.5-12 mo) post screening. Most women (61%,30/49) had risk factors and dense tissue (46.9%,23/49 heterogeneously dense; 26.6%,13/49 extremely dense). Detection was by screening MRI (24/51,47%), clinical findings (23/51,45%; 19 palpation, 2 pain, 2 palpation/pain), or imaging (1 screening MG,1 screening US, 1 PET-CT, 1 CT). 35/51(57%) cancers were NS, and 16/51 (31%) were non-detected masses (14/16,87.5%) or calcifications (2/16,12.5%). Screening MRI found DCIS more often (9/11,81.2%) than palpation and/or pain (2/11,18.2%). ILC was markedly represented in the pathology (24/51,47%) and was detected more often clinically (15/24,62.5%) than on screening MRI (8/24,33.3%) or US (1/24,0.4%). Factors contributing to non-detection were dense tissue (8/16,50%), one view findings (6/16,37.5%),developing asymmetries (4/16,25%), distracting findings (3/16,18.8%), post-surgical changes (2/16,12.5%), benign appearing mass (2/16,12.5%), at image edge (2/16,12.5%), positioning (1/16,0.1%),too few calcifications (1/16,0.1%) or poor image quality (1/16,0.1%).

CONCLUSION

s Almost half of cancers not detected by DBT were found on screening breast MRI (47%) and were ILC pathology (47%). Dense tissue and one-view findings were the most common factors contributing to non-detection.

CLINICAL RELEVANCE/APPLICATION

The most common reason for missed cancers on DBT is dense breast tissue or one-view findings, with a predominance of ILC. Screening breast MRI found almost half of the missed cancers.

R5A-SPBR-6

Screening Tomosynthesis Detected Breast Cancer in Women with Dense Tissue

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
Stamatia Destounis, MD, Rochester, NY (*Presenter*) Medical Advisory Board, iCad, Inc

PURPOSE

To report the cancer detection rate and tumor characteristics in women with dense breast tissue having screening Digital Breast Tomosynthesis (DBT).

METHODS AND MATERIALS

This retrospective review identified patients with dense breast tissue who had a breast cancer diagnosis that was detected on a screening Digital Breast Tomosynthesis (DBT) examination between the years of 2016 and 2021. This resulted in an analysis of 194,340 exams in 60,884 patients. VolparaDensity was utilized in real time to assess breast density versions (v1.5.3 - v4.2.2). Lesion type, lymph node status, stage, and grade were collected.

RESULTS

Overall, 1076 cancers were detected in 913 patients by screening DBT between the years of 2016 and 2021. Most of these cancers were masses (576/1076, 54%). Of the 1076 cancers 79% (n=855) were invasive cancers and 221 (21%) were ductal carcinoma in situ. DBT was able to detect nine lymph nodes that were pathologically proven to be metastatic. In the 913 patients that were diagnosed, the cancers were Grade 1 or Grade 2 (298 (33%) and 297 (32.5%), respectively), and a majority were of early stage (Stage 0, Stage 1) (855/1076, 79%). At surgery, 73% (n=665) patients had negative nodes.

CONCLUSION

s This retrospective review demonstrated that DBT found lower grade and early-stage malignancies in women with dense breast tissue. DBT was also able to detect metastatic lymph nodes.

CLINICAL RELEVANCE/APPLICATION

Some facilities are only offering DBT as a diagnostic tool. Utilizing DBT for screening can aid in the detection of breast cancer in patients with dense tissue as thus far it has been shown to detect lower grade, and early-stage cancers. Greater adoption will occur with proven utility of DBT in this population.

R5A-SPBR-7

Automated Breast Ultrasound vs Handheld Ultrasound in Moderate Risk Breast Cancer Women With Dense Breast

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - BR DPS

Participants
MARIA TERESA FERNANDEZ-TARANILLA, PhD, Madrid, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To determine if Automated Breast UltraSound (ABUS) is at least as effective as handheld ultrasound (HHUS) in detecting lesions in intermediate risk breast cancer patients with dense breast.To compare the degree of interobserver agreement between BI-RADS categorization with ABUS vs HHUS.

METHODS AND MATERIALS

200 patients (350 breast) were evaluated the same day with ABUS and HHUS between June 2020 to July 2021 in a tertiary hospital. Women with dense breast C or D according the American College Radiology and intermediate risk were included. Previous personal breast cancer(pBC), known family history of BC (fBC) , prior lesion of uncertain malignant potential (B3 lesions) and certain syndromes and gene mutations were considered as intermediate risk subcategories. BI-RADS categorization was used to determine the agreement between both techniques with Kappa index.

RESULTS

Mean age of women were 47 years old, 45% had type C and 55% type D breast densities. The most frequent group of patients were the pBC (67%) and mostly were BI-RADS 2. The mean time of ABUS lecture were 4 minutes. The Kappa index was almost perfect (0.84) in the radiologist interpretation with BI-RADS between ABUS vs HHUS (p<0,001). Moderate agreement (0.52) was observed on pBC (p<0,005) always referring to the remaining breast after radical surgery. Excellent agreement (0.89) was observed on patients with fBC (p<0,001) and on syndromes with intermediate risk(p<0,005). On B3 lesions the results were not significant (p<0,07).

CONCLUSION

s ABUS could be a valuable and cost-effective screening tool for women with dense breast and moderate risk in combination with mammography.

CLINICAL RELEVANCE/APPLICATION

The screening for breast cancer on patients with dense breast is still a challenge, even more if those patients had an increased risk of cancer (15-20%). Our proposal is to introduce a cost-effective tool like ABUS in the routine screening programs to increase sensibility and specificity on patients with dense breast and moderate risk cancer.

Cardiac Thursday Poster Discussions - A

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - CA DPS

Sub-Events

R5A-SPCA-1 Cardiac Resonance Imaging Parameters Show Association Between Myocardial Abnormalities and Severity of Chronic Kidney Disease

Participants
Xi Jia, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the relationship between myocardial abnormalities and the severity of chronic kidney disease (CKD), as well as the effects of hemodialysis, using cardiac magnetic resonance (CMR) imaging.

METHODS AND MATERIALS

We enrolled 84 patients with various stages of CKD (group I: CKD stages 1-3, n = 23; group II: CKD stages 4-5, n = 20; group III: hemodialysis patients, n = 41) and 32 healthy subjects. The demographics and biochemical parameters of the study subjects were evaluated. All subjects underwent non-contrast CMR scans. Myocardial strain, native T1, and T2 values were calculated from the scanning results. Analysis of covariance (ANCOVA) was used to compare the CMR imaging parameters between group I-III and the controls.

RESULTS

The left ventricular ejection fraction (LVEF), global radial strain (GRS) and global circumferential strain (GCS) values were significantly lower in group III patients compared with the controls (LVEF: 49% vs. 56%, $p = 0.021$; GRS: 29 vs. 37, $p = 0.019$; GCS: -17.4 vs. -20.6, $p < 0.001$). Furthermore, the global longitudinal strain (GLS) values were significantly lower in group II and III patients compared with the controls (-13.7 and -12.9 vs. -16.2, $p < 0.05$). Compared with the controls, the native T1 values were significantly higher in groups II and III patients (1041±7 and 1053±6 vs. 1009±6, $p < 0.05$), and T2 values were obviously higher in group I-III CKD patients (49.9±0.6 and 53.2±0.7 and 50.1±0.5 vs. 46.6±0.5, $p < 0.001$). The advanced CKD stages showed significant positive correlation with GLS ($r = 0.436$, $p < 0.001$), GCS ($r = 0.386$, $p < 0.001$), native T1 ($r = 0.5$, $p < 0.001$) and T2 ($r = 0.467$, $p < 0.001$) values. In comparison with the group II patients, hemodialysis patients showed significantly lower T2 values (53.2±0.7 vs. 50.1±0.5, $p = 0.002$), and higher T1 values (1041±7 vs. 1053±6) without significant difference.

CONCLUSION

s Our study showed that myocardial strain, native T1, and T2 values were associated with the CKD stages. Furthermore, CMR image parameters demonstrated that hemodialysis improved myocardial edema but did not ameliorate myocardial fibrosis.

CLINICAL RELEVANCE/APPLICATION

Non-contrast CMR can be used to non-invasively estimate the cardiac pathologic changes in CKD patients and improve constant medical attention to prevent an early occurrence of CVD.

R5A-SPCA-3 Cardiac Magnetic Resonance for Diagnosing Heart Failure with Preserved Ejection Fraction

Participants
Ming-Yen Ng, MBBS, Hong Kong, Hong Kong (*Presenter*) Education Grant, General Electric Company;Education Grant, Bayer AG;Education Grant, Circle Cardiovascular Imaging Inc;Education Grant, TeraRecon, Inc;Education Grant, Arterys Inc;Speakers Bureau, Boehringer Ingelheim GmbH

PURPOSE

Cardiac magnetic resonance (CMR) feature tracking (CMR-FT), PC imaging, tagging extracellular volume (ECV) have long been suggested as having potential to diagnose heart failure with preserved ejection fraction (HFpEF) potentially complement echocardiography especially when echocardiography is indeterminate for HFpEF. However, data is limited or absent. We conducted a prospective case-control study assessing diagnostic accuracy of cardiac magnetic resonance (CMR) feature tracking (CMR-FT), phase contrast (PC) imaging, tagging ECV to diagnose HFpEF.

METHODS AND MATERIALS

121 suspected HFpEF patients, 26 angina patients and 26 normal volunteers were recruited into this study from four centres. Patients and volunteers underwent echocardiography, CMR and NT-proBNP measurements within 24 hours. After initial examinations with or without catheter pressure measurements or stress echocardiography to confirm HFpEF, there were 48 HFpEF, 23 angina, 17 normal volunteers, and 14 deconditioned patients. HFpEF patients were confirmed using the European Society of Cardiology 2019 expert recommendations. For patients suspected of having HFpEF but were indeterminate after echo and NT-proBNP, left ventricular pressure measurements or stress echocardiography was performed. As per guidelines, if pressure measurements or stress echocardiography confirmed diastolic dysfunction, HFpEF was confirmed otherwise patients were diagnosed as

deconditioned.

RESULTS

CMR-FT radial early diastolic strain rate (SR), radial systolic SR circumferential strain showed the highest accuracy (Area under the curve (AUC) 0.734, 0.731, 0.731 respectively) to differentiate HFpEF and non-HFpEF patients indicating acceptable power of discrimination.PC had relatively poor to reasonable diagnostic power with E/A ratio (AUC 0.536), septal and lateral wall e' AUC 0.514, 0.601 respectively), E/e' ratio (AUC 0.597), S/D ratio (AUC 0.555). CMR tagging circumferential radial strain had reasonable power of discrimination (AUC values of 0.693 and 0.611 respectively).CMR left atrial volume indexed had the highest AUC 0.795. ECV had poor discrimination (AUC 0.534).

CONCLUSION

s CMR-FT parameters radial early diastolic SR, radial systolic SR and circumferential strain show potential in being utilised for identifying HFpEF. PC imaging, tagging and ECV had low to reasonable diagnostic accuracy to diagnose HFpEF. CMR left atrial volume indexed had the highest AUC. CMR-FT holds promise in being able to help identify patients with HFpEF.

CLINICAL RELEVANCE/APPLICATION

CMR-FT shows promise in diagnosing HFpEF. However, the best CMR parameter for HFpEF diagnosis was left atrial volume indexed. PC imaging tagging may not be as useful as initially thought at diagnosing HFpEF.

R5A-SPCH-1 Non-ECG-gated Low-dose Chest CT-based DL Model for Coronary Calcification Scoring Predicts Subjective Radiologist Grading and Agatston Scores from ECG-gated Coronary Calcium Scoring CT

Participants
Lina Karout, MD, Boston, MA (*Presenter*) Nothing to Disclose

PURPOSE

Coronary arterial calcification (CAC) on low-dose chest CT (LDCT) is an important, reportable finding in lung cancer screening patients. We assessed if non-ECG-gated low-dose chest CT-based CAC scoring with a deep learning (DL) model with three HU thresholds (90, 110, 130 HU) can predict subjective radiologist CAC grading and Agatston scores from ECG-gated coronary calcium scoring CT (CCS-CT).

METHODS AND MATERIALS

With IRB approval, we processed thin-section LDCT chest images (<1.25mm) of 107 adults patients (age >55 years; male: female 66:38) with a DL model (Riverain Tech) to obtain separate CAC scores at 90, 110, and 130 HU thresholds since LDCTs are acquired at different KV (80-120) unlike CCS-CT (120 kV). Each patient also had a CCS-CT within one year of LDCT, from which we obtained Agatston scores. In addition, two thoracic radiologists graded CAC subjectively as none, mild (<1/3 of coronary length calcified), moderate (1/3-2/3 calcified), and heavy (>2/3 calcified) as per prior recommendation. Data were analyzed with Pearson correlation and area under precision-recall curve (AUPRC) analysis for asymmetric data distribution.

RESULTS

Each of the three HU thresholds could differentiate between the radiologists' CAC grading into mild (90HU: 282±1106; 110HU: 752 ±383, 130HU: 4762 ±3787), moderate (90HU: 242 ±965; 110HU: 653 ±330, 130HU: 4187 ±3356), and heavy (90HU: 203 ±821; 110HU: 560±278, 130HU: 3685±3000) categories ($p<0.001$). There was a strong linear, direct correlation between DL-CAC from LDCT and Agatston score from CCS-CT ($r=0.939$; $p<0.001$). The AUPRC for DL-CAC in differentiating mild, moderate, and severe subjective CAC grading was 0.82 ($p<0.001$).

CONCLUSION

s DL-CAC scoring can help automate subjective grading of CAC on non-ECG-gated, low-dose chest CT with high performance; it has an excellent linear correlation with Agatston score.

CLINICAL RELEVANCE/APPLICATION

Estimation of DL-CAC scores can replace subjective CAC grading and decrease the need for dedicated CCS-CT in patients who have undergone LDCT of the chest.

R5A-SPCH-3 Diagnostic Evaluation of Pseudo-continuous ASL-MRI for The Detection of Pulmonary Embolism: A Prospective Single Center Trial

Participants
Ferdinand Seith, MD, BSc, Tubingen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To prospectively evaluate pseudo-continuous ASL-MRI (PCASL-MRI) for the detection of acute pulmonary embolism (PE).

METHODS AND MATERIALS

Within 12 months, 97 hemodynamically stable adult patients (48f, median age 61) with suspected PE, CT pulmonary angiography (CTPA) within the last 72h and without MRI-contraindications were prospectively included. PCASL-MRI was performed in three orthogonal planes under free breathing at 1.5T: labeling the pulmonary trunk during systole, post-labeling delay 1000ms, bSSFP image acquisition. Additionally, multi-slice coronal bSSFP imaging of the whole lungs was performed. Two radiologists performed a blinded assessment regarding overall image quality, artifacts and diagnostic confidence (5-point Likert-scale, 5=best). The readers categorized patients as positive or negative for PE and conducted a lobe-wise assessment (5 lobes per patient) of PCASL-MRI and CTPA. Sensitivity and specificity were calculated for MRI on patient-level with final clinical diagnosis serving as reference standard. Furthermore, interchangeability between MRI and CTPA was tested using the individual equivalence index and defined as discordant judgement of less than 5% in the lobe-wise analyses.

RESULTS

PCASL-MRI was performed successfully in all included patients with excellent scores for image quality, artifact and diagnostic confidence (median scores=5; inter-rater agreement: k>0.74). 38/97 Patients were positive for PE. PCASL-MRI detected PE correctly in 35/38 patients and yielded 3 false positive and 3 false negative findings resulting in a sensitivity of 0.921 (95%-CI 0.808-0.980) and a specificity of 0.949 (95%-CI 0.873-0.978). A high degree of interchangeability between MRI and CTPA was detected with an individual equivalency index of 2.58% (95%-CI 1.20-3.82%).

CONCLUSION

s PCASL-MRI can reliably detect deficits in lung perfusion caused by acute pulmonary embolism and should be considered as a radiation- and contrast-agent free alternative for individual patients.

CLINICAL RELEVANCE/APPLICATION

PCASL-MRI could be a radiation- and contrast-agent free alternative to diagnose PE in individual patients.

R5A-SPCH-4 The Evaluation of The Variation Pattern of The Pulmonary Vein: Preoperative Identification by Thin-section CT and 3D-CTPA

Participants
Makiko Murota, MD, Kitagun, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Understanding pulmonary vein (PV) branches and their variations is a key to successful anatomical lung resection. The right top PV is defined as an anomalous branch of the right superior PV (SPV) draining into the left atrium (LA). There have been a few reports of the right top PV, but no detail reports of the left top PV. The aim of the present study was to evaluate the PV variations including right and left top PV using thin-section CT (TSCT) images and 3D-CTPA.

METHODS AND MATERIALS

The study included 1437 patients in right side and 1454 patients in left side consecutive patients who were suspected with lung cancer and underwent CTPA. We assessed the presence of the PV variations including the right and left top PV on TSCT and 3D-CTPA images.

RESULTS

The most common PV variation draining into the LA on the right side was the PV of the middle lobe draining into the right inferior PV (IPV) in 4.2% (61/1437), whereas the common trunk of the left PV in 14.4% (210/1454). The left IPV receiving venous branch from the lingula segment was found in 6.9% (100/1454). The right top PV was found in 9.1% (131/1437) (?=0.88), whereas the left top PV in 2.9% (42/1454) (?=0.45).

CONCLUSION

s The variations of the PV branching pattern could be evaluated using TSCT and 3D-CTPA images. They provided precise preoperative information.

CLINICAL RELEVANCE/APPLICATION

The most common variation of PV is the common trunk of the left PV. The right top PV is not so rare, and the left top PV should also be recognized.

R5A-SPCH-5 Prognostic Value of Vascular Abnormalities in Dual Energy CT Compared with Visual CT Severity Score in Patients Suspected of COVID-19 and Acute Pulmonary Artery Embolism

Participants
Abass Noor, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose

PURPOSE

High prevalence of pulmonary iodine distribution abnormalities on DECT has been reported as a feature of COVID19 pneumonia. The objective of this study was to evaluate the added benefit of using iodine maps from dual energy chest CT in patients suspected of COVID-19 and acute pulmonary artery embolism. The null hypothesis was that DECT iodine maps offered no additional clinical value in evaluating patients.

METHODS AND MATERIALS

This IRB-approved retrospective study was developed as part of a quality improvement project evaluating the use of DECT in patients suspected of COVID-19 and pulmonary artery embolism. In a single hospital, 100 consecutive patients were examined with DECT using a protocol including iodine distribution maps between December 2020- March 2021. Two subspecialty trained thoracic radiologists examined iodine map abnormalities and pulmonary opacities. Visual lung damage CT score was calculated. Percent of lung involved by either increased or decreased pulmonary iodine density was visually estimated and categorized into quartiles. Statistical analysis included kappa statistics for inter-observer agreements and Cox proportional survival analysis.

RESULTS

Patients with positive SARS-CoV-2 RT PCR were more likely to present with fever, myalgia, and fatigue ($p < 0.05$). Pulmonary embolism was observed in 12 patients (12%), with no difference observed in prevalence of pulmonary embolism between patients with and without positive PCR result ($p = 0.985$). Overall, 70 (70%) patients were admitted to the hospital, with 25 (25%) admitted to the Intensive Care Unit (ICU)—15 (15%) of whom demonstrated a positive SARS-CoV-2 RT PCR on the date of admission. Patients with positive SARS-CoV-2 RT PCR had longer hospital ($p = 0.019$) and ICU stays ($p = 0.047$). No significant difference was observed in occurrence of intubation ($p = 0.866$) or mortality ($p = 0.368$). There was moderate agreement for visual lung damage CT score (k: 0.695; CI 95%: 0.611 to 0.780), and little agreement observed in evaluation of pulmonary iodine density (k: 0.056; CI 95% -0.045 to 0.158).There was a significant decrease in overall survival with increased visual lung damage CT score for both raters ($p = 0.002$ and $p = 0.001$). Percent increased or decreased pulmonary iodine density was not related to overall survival.

CONCLUSION

s Our study has redemonstrated correlation between survival and visual CT severity score but did not show correlation with pulmonary iodine density on DECT.

CLINICAL RELEVANCE/APPLICATION

Vascular abnormalities on DECT in patients with COVID-19 is of uncertain clinical significance. This study has shown disagreement among interpreters regarding iodine distribution map findings and may not offer more clinical value than observing the severity of pneumonia.

R5A-SPCH-6 Prospective Comparative Effectiveness Study of Radiologist Performance With and Without AI for Incidental PE Detection

Participants
Steven Rothenberg, MD, Birmingham, AL (*Presenter*) Founder, Empower Therapeutics Inc ;Member, Translation Holdings LLC;Consultant, Radiostics LLC

PURPOSE

To compare the effectiveness of radiologist performance at detecting incidental PE on CT images with and without AI triage (CADt).

METHODS AND MATERIALS

For this IRB-approved prospective single center study, 4652 consecutive patients who underwent cross sectional imaging of the chest or abdomen were recruited in two phases. Patients who underwent CT angiography with a PE protocol were excluded. In phase 1, consecutive CTs (N=1467) were evaluated independently by a radiologist and by a FDA-cleared AI triage algorithm. This data was used to establish a baseline for unassisted radiologist and AI interpretations. Following this, all radiologists interpreting CT (N=??) were trained to review the results of the AI algorithm and triage system concurrently during image evaluation and reporting. In phase 2, consecutive CTs (N=3185) were evaluated by radiologists using AI assistance for all cases. Reports and addendums were manually reviewed for the presence or absence of PE. A chest radiologist determined the number of missed incidental PEs by reviewing the image data and reports of all potential misses. The miss rate of iPE was calculated along with the sensitivity, specificity, and accuracy of the AI algorithm.

RESULTS

In phase 1 and 2, 1.4% (21/1467) and 1.8% (57/3185) of CTs were positive for PE, respectively (p=0.374). In phase 1 and 2, 19.0% (4/21) and 1.8% (1/57) of incidental PEs were missed (p=0.006). The percentage of missed iPEs per exam decreased from 0.27% to 0.03% (p=0.019). The triage algorithm's accuracy, sensitivity, and specificity was 0.993, 0.628, and 0.999 respectively.

CONCLUSION

s In a single-center prospective real-world study, the miss rate for detection of iPE on CT was statistically higher than the miss rate of radiologists assisted by an algorithm for detection and triage.

CLINICAL RELEVANCE/APPLICATION

Incidental pulmonary emboli (iPE) are easily missed when the purpose of an examination is for an alternative indication, however, the presence of a PE is critical finding that often changes clinical management.

R5A-SPCH-7 Added Value of An Artificial Intelligence Tool For Prioritization of Incidental Pulmonary Embolism on Chest CT

Participants
Laurens Topff, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic efficacy of commercially available artificial intelligence (AI) software to detect incidental pulmonary embolism (IPE) on chest CT and shorten the time to diagnosis using worklist prioritization.

METHODS AND MATERIALS

In this prospective study, AI software was deployed in a clinical environment to analyze routinely acquired chest CT scans of adult oncology patients. Three time periods of 15 weeks each were compared: routine workflow without AI, manual triage without AI, and worklist prioritization with AI. Diagnostic accuracy of the tool was evaluated on both prospectively and retrospectively collected data. Temporal endpoints including Detection and Notification Times (DNT) were assessed.

RESULTS

A total of 11 736 CT scans were evaluated. Prevalence of IPE was 1.2% (n=143). The AI software detected 131 true positives, 12 false negatives, 31 false positives, and 11559 true negatives. Sensitivity was 91.6%, specificity 99.7%, NPV 99.9%, and PPV 80.9%. When applied retrospectively, the AI software found IPEs in 47 CTs (44.8%) that were missed in the radiology report. The median DNT for IPE positive examinations was 7714, 4973, 87 min for the respective time periods. The difference in DNT between positive and negative CTs was largest when using AI assistance and was significantly different from both workflows without AI. In contrast, no statistically significant difference was found between routine workflow and manual triage without AI.

CONCLUSION

s A commercially available AI tool was found to have a high diagnostic efficacy in detecting IPE on CT of oncology patients. AI assisted worklist prioritization was shown to be effective in significantly reducing the time to diagnosis of IPE cases compared to the routine clinical workflow.

CLINICAL RELEVANCE/APPLICATION

Incidental pulmonary embolism is a common comorbidity in oncology patients. Despite being clinically unsuspected, IPE can be an urgent and life-threatening event. AI based worklist prioritization can assist the radiologist to shorten the time to diagnosis of

critical imaging findings.

Non-ECG-gated Low-dose Chest CT-based DL Model for Coronary Calcification Scoring Predicts Subjective Radiologist Grading and Agatston Scores from ECG-gated Coronary Calcium Scoring CT

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - CH DPS

Participants
Lina Karout, MD, Boston, MA (*Presenter*) Nothing to Disclose

PURPOSE

Coronary arterial calcification (CAC) on low-dose chest CT (LDCT) is an important, reportable finding in lung cancer screening patients. We assessed if non-ECG-gated low-dose chest CT-based CAC scoring with a deep learning (DL) model with three HU thresholds (90, 110, 130 HU) can predict subjective radiologist CAC grading and Agatston scores from ECG-gated coronary calcium scoring CT (CCS-CT).

METHODS AND MATERIALS

With IRB approval, we processed thin-section LDCT chest images (<1.25mm) of 107 adults patients (age >55 years; male: female 66:38) with a DL model (Riverain Tech) to obtain separate CAC scores at 90, 110, and 130 HU thresholds since LDCTs are acquired at different KV (80-120) unlike CCS-CT (120 kV). Each patient also had a CCS-CT within one year of LDCT, from which we obtained Agatston scores. In addition, two thoracic radiologists graded CAC subjectively as none, mild (<1/3 of coronary length calcified), moderate (1/3-2/3 calcified), and heavy (>2/3 calcified) as per prior recommendation. Data were analyzed with Pearson correlation and area under precision-recall curve (AUPRC) analysis for asymmetric data distribution.

RESULTS

Each of the three HU thresholds could differentiate between the radiologists' CAC grading into mild (90HU: 282±1106; 110HU: 752 ±383, 130HU: 4762 ±3787), moderate (90HU: 242 ±965; 110HU: 653 ±330, 130HU: 4187 ±3356), and heavy (90HU: 203 ±821; 110HU: 560±278, 130HU: 3685±3000) categories ($p<0.001$). There was a strong linear, direct correlation between DL-CAC from LDCT and Agatston score from CCS-CT ($r=0.939$; $p<0.001$). The AUPRC for DL-CAC in differentiating mild, moderate, and severe subjective CAC grading was 0.82 ($p<0.001$).

CONCLUSION

s DL-CAC scoring can help automate subjective grading of CAC on non-ECG-gated, low-dose chest CT with high performance; it has an excellent linear correlation with Agatston score.

CLINICAL RELEVANCE/APPLICATION

Estimation of DL-CAC scores can replace subjective CAC grading and decrease the need for dedicated CCS-CT in patients who have undergone LDCT of the chest.

Diagnostic Evaluation of Pseudo-continuous ASL-MRI for The Detection of Pulmonary Embolism: A Prospective Single Center Trial

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - CH DPS

Participants
Ferdinand Seith, MD, BSc, Tubingen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To prospectively evaluate pseudo-continuous ASL-MRI (PCASL-MRI) for the detection of acute pulmonary embolism (PE).

METHODS AND MATERIALS

Within 12 months, 97 hemodynamically stable adult patients (48f, median age 61) with suspected PE, CT pulmonary angiography (CTPA) within the last 72h and without MRI-contraindications were prospectively included. PCASL-MRI was performed in three orthogonal planes under free breathing at 1.5T: labeling the pulmonary trunk during systole, post-labeling delay 1000ms, bSSFP image acquisition. Additionally, multi-slice coronal bSSFP imaging of the whole lungs was performed. Two radiologists performed a blinded assessment regarding overall image quality, artifacts and diagnostic confidence (5-point Likert-scale, 5=best). The readers categorized patients as positive or negative for PE and conducted a lobe-wise assessment (5 lobes per patient) of PCASL-MRI and CTPA. Sensitivity and specificity were calculated for MRI on patient-level with final clinical diagnosis serving as reference standard. Furthermore, interchangeability between MRI and CTPA was tested using the individual equivalence index and defined as discordant judgement of less than 5% in the lobe-wise analyses.

RESULTS

PCASL-MRI was performed successfully in all included patients with excellent scores for image quality, artifact and diagnostic confidence (median scores=5; inter-rater agreement: k>0.74). 38/97 Patients were positive for PE. PCASL-MRI detected PE correctly in 35/38 patients and yielded 3 false positive and 3 false negative findings resulting in a sensitivity of 0.921 (95%-CI 0.808-0.980) and a specificity of 0.949 (95%-CI 0.873-0.978). A high degree of interchangeability between MRI and CTPA was detected with an individual equivalency index of 2.58% (95%-CI 1.20-3.82%).

CONCLUSION

s PCASL-MRI can reliably detect deficits in lung perfusion caused by acute pulmonary embolism and should be considered as a radiation- and contrast-agent free alternative for individual patients.

CLINICAL RELEVANCE/APPLICATION

PCASL-MRI could be a radiation- and contrast-agent free alternative to diagnose PE in individual patients.

R5A-SPCH-4

The Evaluation of The Variation Pattern of The Pulmonary Vein: Preoperative Identification by Thin-section CT and 3D-CTPA

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - CH DPS

Participants
Makiko Murota, MD, Kitagun, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Understanding pulmonary vein (PV) branches and their variations is a key to successful anatomical lung resection. The right top PV is defined as an anomalous branch of the right superior PV (SPV) draining into the left atrium (LA). There have been a few reports of the right top PV, but no detail reports of the left top PV. The aim of the present study was to evaluate the PV variations including right and left top PV using thin-section CT (TSCT) images and 3D-CTPA.

METHODS AND MATERIALS

The study included 1437 patients in right side and 1454 patients in left side consecutive patients who were suspected with lung cancer and underwent CTPA. We assessed the presence of the PV variations including the right and left top PV on TSCT and 3D-CTPA images.

RESULTS

The most common PV variation draining into the LA on the right side was the PV of the middle lobe draining into the right inferior PV (IPV) in 4.2% (61/1437), whereas the common trunk of the left PV in 14.4% (210/1454). The left IPV receiving venous branch from the lingula segment was found in 6.9% (100/1454). The right top PV was found in 9.1% (131/1437) (?=0.88), whereas the left top PV in 2.9% (42/1454) (?=0.45).

CONCLUSION

s The variations of the PV branching pattern could be evaluated using TSCT and 3D-CTPA images. They provided precise preoperative information.

CLINICAL RELEVANCE/APPLICATION

The most common variation of PV is the common trunk of the left PV. The right top PV is not so rare, and the left top PV should also be recognized.

Prognostic Value of Vascular Abnormalities in Dual Energy CT Compared with Visual CT Severity Score in Patients Suspected of COVID-19 and Acute Pulmonary Artery Embolism

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - CH DPS

Participants
Abass Noor, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose

PURPOSE

High prevalence of pulmonary iodine distribution abnormalities on DECT has been reported as a feature of COVID19 pneumonia. The objective of this study was to evaluate the added benefit of using iodine maps from dual energy chest CT in patients suspected of COVID-19 and acute pulmonary artery embolism. The null hypothesis was that DECT iodine maps offered no additional clinical value in evaluating patients.

METHODS AND MATERIALS

This IRB-approved retrospective study was developed as part of a quality improvement project evaluating the use of DECT in patients suspected of COVID-19 and pulmonary artery embolism. In a single hospital, 100 consecutive patients were examined with DECT using a protocol including iodine distribution maps between December 2020- March 2021. Two subspecialty trained thoracic radiologists examined iodine map abnormalities and pulmonary opacities. Visual lung damage CT score was calculated. Percent of lung involved by either increased or decreased pulmonary iodine density was visually estimated and categorized into quartiles. Statistical analysis included kappa statistics for inter-observer agreements and Cox proportional survival analysis.

RESULTS

Patients with positive SARS-CoV-2 RT PCR were more likely to present with fever, myalgia, and fatigue ($p < 0.05$). Pulmonary embolism was observed in 12 patients (12%), with no difference observed in prevalence of pulmonary embolism between patients with and without positive PCR result ($p = 0.985$). Overall, 70 (70%) patients were admitted to the hospital, with 25 (25%) admitted to the Intensive Care Unit (ICU)—15 (15%) of whom demonstrated a positive SARS-CoV-2 RT PCR on the date of admission. Patients with positive SARS-CoV-2 RT PCR had longer hospital ($p = 0.019$) and ICU stays ($p = 0.047$). No significant difference was observed in occurrence of intubation ($p = 0.866$) or mortality ($p = 0.368$). There was moderate agreement for visual lung damage CT score (k: 0.695; CI 95%: 0.611 to 0.780), and little agreement observed in evaluation of pulmonary iodine density (k: 0.056; CI 95% -0.045 to 0.158).There was a significant decrease in overall survival with increased visual lung damage CT score for both raters ($p = 0.002$ and $p = 0.001$). Percent increased or decreased pulmonary iodine density was not related to overall survival.

CONCLUSION

s Our study has redemonstrated correlation between survival and visual CT severity score but did not show correlation with pulmonary iodine density on DECT.

CLINICAL RELEVANCE/APPLICATION

Vascular abnormalities on DECT in patients with COVID-19 is of uncertain clinical significance. This study has shown disagreement among interpreters regarding iodine distribution map findings and may not offer more clinical value than observing the severity of pneumonia.

R5A-SPER-1 Investigating the Sonographic Murphy Sign and the Diagnosis of Acute Cholecystitis After Non-Opioid Analgesia Administration

Participants
Karina Marcelo, MD, Triper AMC, HI (*Presenter*) Nothing to Disclose

PURPOSE

There is no single clinical, laboratory, or radiology exam sufficient to diagnose acute cholecystitis (AC). This increases reliance on highly correlated findings such as maximum abdominal pain elicited by a probe during right upper quadrant ultrasound (RUQUS), also known as the sonographic Murphy sign (SMS). Controversy exists regarding the effect of premedication with opioid analgesia on the SMS. The purpose of this study was to examine the use of non-opioid analgesia (NOA), such as acetaminophen or non-steroidal anti-inflammatory drugs, prior to RUQUS and the effect on the SMS and the radiologic accuracy of diagnosing AC.

METHODS AND MATERIALS

The research subjects (n=682) consisted of adult emergency department patients at a tertiary hospital who underwent a RUQUS over a 21 month period. A retrospective cohort chart review analyzed the SMS in patients who received NOA prior to RUQUS versus patients who did not (control) and the effect on diagnosis of AC. Radiology results were compared to final pathology diagnosis as a gold standard.

RESULTS

The average age of patients at the time of their RUQUS was 38.5 years. Four hundred forty-nine patients (65.8%) were female and 233 (34.2%) were male. The racial/ethnic composition of the study participants were as follows: Caucasian 43.1%, African American/Black 13.5%, Asian/Pacific Islander 16.3%, Native American 0.4%, Other 19%, Unknown 7.6%. Patients receiving NOA prior to RUQUS (n=248), when compared to the control group (n=434), did not experience significantly different rates of positive (31 cases vs 54 cases, respectively), negative (174 cases vs 332 cases, respectively), or indeterminate (43 cases vs 48 cases, respectively) SMS (p=0.06). There was no significant difference between NOA vs control in SMS sensitivity (33.3% [17.3%-52.8%] vs. 46.2% [32.2%-60.5%], respectively), specificity (90.4% [85.6%-93.9%] vs 92.1% [89.0%-94.6%], respectively), positive predictive value (PPV; 32.2% [19.9%-47.7%] vs 44.4% [33.7%-55.7%], respectively), or negative predictive value (NPV; 90.7% [88.4%-92.7%] vs 92.6% [90.7%-94.2%], respectively) in diagnosing AC.

CONCLUSION

s NOA administration prior to RUQUS does not affect the rate of finding a positive, negative or indeterminate SMS. Additionally, NOA does not significantly change the sensitivity, specificity, PPV, or NPV of the SMS in diagnosing AC. Future investigative opportunities include evaluating the effects of NOA administration timing, route (oral vs intravenous), dosing, and type.

CLINICAL RELEVANCE/APPLICATION

Despite controversy surrounding opioid premedication on the SMS, these results suggest that NOA prior to RUQUS in patients under evaluation for AC is of little diagnostic consequence.

R5A-SPGI-1 Multiparametric MRI for prediction of tumor response to systemic chemotherapy in pancreatic ductal adenocarcinoma

Participants
Yoshihiko Fukukura, MD, PhD, Kagoshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Despite recent advances in diagnostic techniques, >80% of patients with PDAC are diagnosed at an advanced surgically unresectable stage and systemic chemotherapy is the mainstay of life-prolonging treatment. In recent years, neoadjuvant chemotherapy has emerged as a new alternative approach for patients with resectable diseases. Therefore, systemic chemotherapy is considered an essential first-line treatment for all stages of PDAC, in both the neoadjuvant and palliative settings. However, patients with PDAC respond differently to chemotherapy. There is a critical need for reliable predictive biomarkers to predict the treatment response is required for selecting the optimal therapeutic option. Therefore, this study aimed to identify multiparametric MRI biomarkers to predict the tumor response to chemotherapy in PDAC.

METHODS AND MATERIALS

This retrospective study included 81 consecutive patients (50 men, 31 women; mean age, 68.5 years; range, 47-83) with histologically confirmed PDAC who underwent multiparametric MRI including T1, T2, T2* mappings, diffusion-weighted imaging (DWI), and dynamic contrast-enhanced MRI (DCE-MRI) before gemcitabine-based first-line chemotherapy. T1, T2, and T2* relaxation times, apparent diffusion coefficient (ADC) obtained with DWI, and pharmacokinetic parameters (ktrans, kep, ve, and iAUC) calculated with DCE-MRI were measured using ROI measurements within PDAC. Clinical factors and multiparametric MRI parameters to predict the responders determined after the third cycle of gemcitabine-based chemotherapy and those to predict progression-free survival (PFS) and overall survival (OS) were evaluated using multivariable logistic regression and the Cox proportional hazard model.

RESULTS

Among the clinical factors and MRI parameters, tumor size and pharmacokinetic parameter (ve) of DCE-MRI were independent predictors for tumor response. The area under the receiver operating characteristic curve of combined use of the tumor size and pharmacokinetic parameter (ve) was 0.842 with a sensitivity of 78.8% and specificity of 79.2% (cut off, <26 mm for tumor size and <21% for ve). The pharmacokinetic parameter (ve) was also identified as one of the independent predictors for PFS and OS.

CONCLUSION

s Tumor pharmacokinetic parameters calculated with DCE-MRI may be useful to predict tumor response and survival in patients with PDAC receiving chemotherapy.

CLINICAL RELEVANCE/APPLICATION

DCE-MRI allows for the prediction of favorable tumor response and patient survival after chemotherapy.

R5A-SPGI-10 Characterization of Non-alcoholic Fatty Liver Disease using Ultrasound Texture Parameters with Various Beamforming Sound Speeds

Participants
Kibo Nam, PhD, Philadelphia, PA (*Presenter*) Equipment support, Canon Medical Systems Corporation;Equipment support, General Electric Company ;Support, Lantheus Medical Imaging;Research funded, Canon Medical Systems Corporation

PURPOSE

To investigate if ultrasound texture features extracted using various beamforming speed of sounds (SOSs) can improve the characterization of non-alcoholic fatty liver disease (NAFLD).

METHODS AND MATERIALS

Patients with suspected NAFLD undergoing liver biopsy or MRI-PDFF, have been prospectively enrolled. Subjects were imaged with a C1-6 probe on a Logiq E9 scanner (GE Healthcare). The radio-frequency data from subjects' right and left lobes were collected using 9 beamforming SOSs: 1300, 1350, 1400, 1450, 1500, 1540, 1600, 1650, and 1700 m/s and analyzed offline using Matlab (MathWorks). The texture parameters, i.e. contrast, correlation, energy, and homogeneity from gray-level co-occurrence matrix of normalized envelope were obtained from the liver parenchyma. The diagnostic accuracy of texture parameters from each

beamforming SOS was assessed independently and in combination (using a generalized linear regression) by ROC analyses.

RESULTS

64 subjects were included in the analysis. 43 subjects were diagnosed of steatosis (27 by biopsy steatosis = 5% and 16 by MRI-PDFF = 6.5%) and 28 of them had fibrosis (grade 1-4). 21 subjects had no steatosis (7 by biopsy and 14 by MRI-PDFF) and 6 of them had fibrosis. In detecting steatosis, homogeneity showed the AUC of 0.73-0.82 and 0.58-0.81 for left and right lobes, respectively with varying beamforming SOSs. The combined homogeneity over 1300-1700 m/s from left and right lobes showed the AUC 0.92 and 0.84, respectively. Moreover, the combined homogeneity from left and right lobes over 1300-1700 m/s improved the AUC to 0.96. In detecting fibrosis, correlation showed the AUC of 0.52-0.60 and 0.50-0.70 for left and right lobes, respectively with varying beamforming SOSs. The combined correlation over 1300-1700 m/s from left and right lobes showed the AUC 0.77 and 0.80, respectively. Finally, the combination of correlation from left and right lobes over 1300-1700 m/s showed the AUC of 0.86. However, no independent or combined value differentiated all 4 groups, i.e., normal liver, steatosis only, fibrosis only, and steatosis with fibrosis.

CONCLUSION

s The diagnostic reliability of ultrasound texture parameter in NAFLD patients was improved with various beamforming SOSs.

CLINICAL RELEVANCE/APPLICATION

Ultrasound texture parameters extracted from the images acquired with various beamforming SOSs may improve the characterization of NAFLD.

R5A-SPGI-2 Dual-energy CT with virtual monoenergetic images iodine maps improve tumor conspicuity in patients with pancreatic ductal adenocarcinoma

Participants
Yongmei Li, Chongqing, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the value of monoenergetic images (MEI [+]) and iodine maps in dual-source dual-energy computed tomography (DECT) for assessing pancreatic ductal adenocarcinoma (PDAC), including the visually isoattenuating PDAC.

METHODS AND MATERIALS

Seventy-five patients with PDAC underwent contrast-enhanced DECT were retrospectively included in this study. Conventional polyenergetic image (PEI) and 40-80 keV MEI (+) (10-keV increments) were reconstructed. The tumor contrast, contrast-to-noise ratio (CNR) of the tumor and peripancreatic vessels, the signal-to-noise ratio (SNR) of the pancreas and tumor, and the tumor diameters were quantified. On iodine maps, the normalized iodine concentration (NIC) in the tumor and parenchyma were quantified and compared. For subjective analysis, two radiologists independently evaluated images on a 5-point scale.

RESULTS

All the quantitative parameters were maximized at 40-keV MEI (+) and decreased gradually with increasing energy. The tumor contrast, SNR of pancreas and CNRs in 40-60 keV MEI (+) were significantly higher than those in PEI ($p<0.05$). For visually isoattenuating PDAC, 40-50 keV MEI (+) provided significantly higher CNR of the tumor compared to PEI ($p<0.05$). The reproducibility in tumor measurements were highest in 40-keV MEI (+) between the two radiologists. The NIC value of tumor and parenchyma were 1.28±0.65 and 3.38±0.72 mg/mL, respectively ($p<0.001$). 40-50 keV MEI (+) provided the highest subjective scores for all criteria, compared to PEI ($p<0.001$).

CONCLUSION

s Low-keV MEI (+) of DECT substantially improve the subjective and objective image quality and tumor conspicuity in patients with PDAC. Combining the low-keV MEI (+) and iodine maps may be allowed for earlier diagnosis of PDAC.

CLINICAL RELEVANCE/APPLICATION

• Low-keV MEI (+) increases subjective and objective image quality compared with PEI in patients with PDAC.• Tumor conspicuity and reproducibility in tumor sizes were maximized at 40-keV MEI (+) in patients with PDAC.• Combining low-keV MEI (+) and iodine maps may achieve earlier diagnosis and thus improve PDAC prognosis.

R5A-SPGI-3 How Often Is Pancreatic Cancer Missed on CT or MRI Imaging? A Novel Root Cause Analysis System To Establish the Most Plausible Explanation for Post Imaging Pancreatic Cancer.

Participants
Melisa Sia, FRCR, MBChB, (*Presenter*) Nothing to Disclose

PURPOSE

Pancreatic cancer (PC) often has a short time window for curative surgery. Missing PC on cross-sectional imaging (post imaging pancreatic cancer or PIPC) may therefore result in worse clinical outcomes in a cancer with already poor outcomes. We have undertaken root cause analysis of potentially missed PIPC to establish the most plausible explanations if imaging signs of PC were missed.

METHODS AND MATERIALS

Electronic records of adults diagnosed with PC between 2019-21 at two NHS providers were examined. PIPC was defined as a PC diagnosed 6 to 18 months after abdominal cross-sectional imaging (CT or MRI) that did not diagnose PC. The imaging that did not diagnose the PC and the later diagnostic imaging were reviewed by two radiologists independently. An algorithm was developed to categorise PIPC and identify the most plausible explanation.

RESULTS

Of 600 PC studied, 47 (7.8%) were categorised as PIPC. 47% of PIPC were located in the pancreatic head, 23.4% in the body, 21.3% in the body and tail, 6.40% in the head and neck and 2% in the entire pancreas. 44 CT and four MRI scans in PIPC patients

performed within 6 to 18 months of PC diagnosis were reviewed. Of 44 CT scans reviewed, 15 were CT thorax abdomen and pelvis, 17 were CT abdomen and pelvis, 2 CT colons, 4 CT thorax, 2 CT Pancreas, 1 CT Urogram, 1 CT neck, thorax, abdomen and pelvis, 1 CT lumbar spine and 1 CT neck and thorax. 7 CT scans were without contrast. MRI scans were MRI liver, MRI renal, MRI abdomen and MRCP. PIPC were categorised as: Type 1 - missed PC lesion, imaging inadequate to exclude lesion (10.6%); Type 2 - missed PC lesion, adequate imaging and lesion visible on review - perceptual error (25.5%); Type 3 - PC associated abnormality detected (e.g. pancreatic or bile duct dilatation but no focal lesion) but inadequate follow up plan - management error (10.6%); Type 4 - PC associated abnormality detected, with adequate subsequent management, but still PIPC (12.8%); Type 5 - Genuine new PC lesion - no abnormality detected on initial imaging and imaging adequate to exclude lesion (40.4%). 36% of PIPC were considered potentially avoidable.

CONCLUSION

s This is the first study to undertake detailed root cause analysis of potentially missed PC on imaging. Missed opportunities to potentially avoid PIPC were identified in 36%.

CLINICAL RELEVANCE/APPLICATION

This root cause analysis system can standardize future investigation of PIPC and guide quality improvement efforts to improve outcomes in PC.

R5A-SPGI-5 Predictors for Proton Density Fat Fraction (PDFF) Reduction in Patients Undergoing Very Low Calorie Liquid Diet in a Weight Loss Study

Participants
Patricia Burns, MD, San Diego, CA (*Presenter*) Nothing to Disclose

PURPOSE

Nonalcoholic fatty liver disease (NAFLD) is the hepatic manifestation of metabolic syndrome. MRI-derived proton density fat fraction (PDFF) is a non-invasive quantitative imaging biomarker that depicts distribution of hepatic steatosis. It has been suggested that metabolic derangements are responsible for the rapid reduction of PDFF early in the intense caloric restriction and surgery treatment option. Previous studies have investigated the effect of intense caloric restriction on PDFF, however, predictors for the amount of PDFF reduction while undergoing intense caloric restriction are not known. Thus, the purpose of this study is to identify predictors for PDFF reduction during a low caloric liquid diet period in a Weight Loss Study population with obesity assigned to a caloric restriction model.

METHODS AND MATERIALS

Twenty-nine adults with obesity (26 female, 3 male, mean age 48 yrs) scheduled for bariatric surgery were recruited prospectively to participate in an ongoing pilot research study which includes collection of age, sex, BMI, waist/hip ratio (a marker of abdominal adiposity), lipid panel, and HbA1C. MR exams were performed on a 3T scanner (GE Signa Premier, or GE Discovery MR750, GE Healthcare, Waukesha WI) at baseline (visit 1) and 2-3 days prior to surgery (visit 2). Mean hepatic PDFF was calculated by a 9-ROI approach as previously described. Rates of PDFF change were estimated for each subject between visits 1 and 2. Bayesian Information Criterion (BIC)-based stepwise linear regression was used to search for baseline predictors of change for each of these periods. Clinical, serological, and imaging predictors were considered.

RESULTS

PDFF decreased (-2.849 PDFF%/month, $p<0.001$) from 9.64% to 6.66%. PDFF at baseline (regression coefficient = -0.56, $p < 0.001$) and waist/hip ratio at baseline (regression coefficient = 16.40, $p < 0.001$) were selected as best predictors of change during the diet period.

CONCLUSION

s PDFF decreased after a period of low caloric liquid diet. Prediction models support that baseline PDFF and waist/hip ratio are associated with rate of PDFF change. A higher baseline PDFF predicts a more rapid decline in PDFF, but a higher baseline waist/hip ratio predicts a slower decline of PDFF. This suggests that increased abdominal adiposity, as assessed by waist/hip ratio, may result in resistance to fat mobilization from the liver during intense caloric restriction. Further research is needed to validate our findings, ideally including populations with a more equal male:female distribution and less severe caloric restriction.

CLINICAL RELEVANCE/APPLICATION

Abdominal adiposity may be a marker of resistance to fat mobilization from the liver during intense caloric restriction weight loss.

R5A-SPGI-6 The value of constructing a nomogram model based on preoperative contrast-enhanced CT to predict R0 resection of pancreatic ductal adenocarcinoma

Participants
Zhengxiao Li, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the value of preoperative enhanced CT scan features combined with clinical features to construct a nomogram model to predict R0 resection of pancreatic ductal adenocarcinoma (PDAC).

METHODS AND MATERIALS

The preoperative contrast-enhanced CT imaging data of 106 patients with PDAC who were confirmed by surgery and pathology and whose resection margin status was evaluated from January 2015 to November 2021 in our hospital were retrospectively analyzed. According to the resection margin status, they were divided into R0 resection group and R1 resection group. . The preoperative CA199, CA125, CEA and other clinical data of the patients were analyzed; the tumor location, the transverse diameter of the tumor, and the maximum angle between the tumor and the surrounding blood vessels (T/arterial angle, T/portal vein angle, T/super mesenteric angle) were observed. Vein), peritumoral fat space, and lymph node metastasis. Then, univariate and multivariate Logistic regression was used to construct a nomogram model to predict the value of preoperative PDAC tumor R0 resection.

RESULTS

There were significant differences between the R0 resection group and the R1 resection group in tumor transverse diameter, CA199, CA125, CEA, T/arterial angle, T/portal vein angle, T/superior mesenteric vein and lymph node metastasis ($p<0.05$). Univariate and multivariate logistic regression analysis of lymph node metastasis [OR: 0.205 (CI: 0.043-0.972), $p < 0.05$], T/arterial angle [OR: 0.085 (CI: 0.017-0.434), $p < 0.01$], T /Portal vein angle [OR: 0.155 (CI: 0.031-0.783), $p < 0.05$], tumor diameter [OR: 1.073 (CI: 1.004-1.146), $p < 0.05$], CA199 [OR: 1.003 (CI: 1.001] -1.005), $p<0.01$] was an independent risk factor for R0 resection. The model constructed by multivariate logistic regression can effectively predict the R0 resection of PDAC tumors. The calibration curve shows that the predicted probability of the nomogram model can better fit the actual probability, and the calibration degree is high.

CONCLUSION

s Preoperative lower level of CA199, shorter tumor transverse diameter, T/arterial angle and T/portal vein angle <180°, and non-lymph node metastasis status were independent predictors of R0 resection of PDAC tumors, and the nomogram model can effectively Prediction of preoperative R0 resection status for PDAC tumors.

CLINICAL RELEVANCE/APPLICATION

To investigate the value of preoperative enhanced CT scan features combined with clinical features to construct a nomogram model to predict R0 resection of pancreatic ductal adenocarcinoma (PDAC).

R5A-SPGI-7 Pancreatic neuroendocrine tumors: Correlation between dynamic contrast enhanced ultrasound and pathological tumor grades

Participants
Yi Dong, MD, PhD, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

Tumor grade is one of the major prognostic factors for pancreatic neuroendocrine tumors' (pNETs). Pathologically, pNETs are classified into Grade 1 (G1), Grade 2 (G2), and Grade 3 (G3) tumors based on the Ki-67 proliferation index and the mitotic activity. Early differential diagnosis between G1 and G2/G3 is important on therapeutic strategy and survival duration. The aim of this study was to investigate whether the dynamic contrast enhanced ultrasound (D-CEUS) features with quantitative parameters could effectively predicting pNETs grades before operation according to WHO classification.

METHODS AND MATERIALS

This prospective study was approved by the institutional review board of our institution. Informed consent was waived before CEUS examination. Patients suspected of pNETs underwent D-CEUS of pancreas within one week prior to the surgery. Time intensity curves (TICs) were created and quantitative indexes of D-CEUS were analyzed. Patient demographics, CEUS findings, and quantitative parameters were compared to histopathological features using the Mann-Whitney U test. Diagnostic accuracy was assessed by ROC-AUC analysis, sensitivity and specificity were assessed for each quantitative parameter.

RESULTS

Finally, a total of 36 patients with histopathologically confirmed pNETs met the inclusion criteria, including 12 cases of G1, 16 cases of G2, and 8 cases of G3 patients. Compared with G1, G2/G3 pNETs showed ill-defined margin (62.5 %) and hypoenhancement during the late phase (41.6 %). Liver metastases were detected in 15 G2/G3 patients during the late phase scan of the whole liver. Among all CEUS quantitative indexes, area under curve (AUC) was significantly higher in G2/G3 pNETs with ROC-AUC 0.731, sensitivity 81.8 % (95 % CI: 62.2-91.3) and specificity 65.2 % (95 % CI: 43.7-80.1) ($P < 0.05$).

CONCLUSION

s D-CEUS analysis might be helpful in preoperative predicting tumor grades and liver metastases of pNETs. AUC is the potential D-CEUS parameter for identification of G2/G3 from G1 pNETs.

CLINICAL RELEVANCE/APPLICATION

Dynamic CEUS analysis and quantitative parameters could be used as non-invasive imaging method to predict tumor histological grades of pNETs.

R5A-SPGI-8 Correlations between POPF and delayed imaging findings in Patients who underwent Distal Pancreatectomy

Participants
Giulia A. Zamboni, MD, Verona, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To analyze correlations between the presence of delayed fluid collections (FC) and postoperative pancreatic fistula (POPF), as defined by the International Study Group of Pancreatic Fistula (ISGPF), in patients who underwent Distal Pancreatectomy (DP).

METHODS AND MATERIALS

This is a IRB approved prospective study. Patients who underwent DP between 2018 and 2020 and had a contrast-enhanced postoperative MR 1 month after surgery were included. They were divided into 3 groups based on ISGPF grade: 0: no fistula; B: persistent drainage for more than 3 weeks, need for clinical management changes, percutaneous or endoscopic drainage, angiographic procedures for bleeding and development of signs of infection; C: reoperation, organ failure, death. Group 0 was further subdivided in patients without fistula and patients with biochemical leak (BL), who had drainage amylase >3 times the upper limit of normal serum amylase value. BL is not considered a fistula as no intervention is required to improve clinical outcome. Two readers in consensus analyzed the MRI scans and logged presence of: pancreatic enhancement inhomogeneity; main pancreatic duct (MPD) dilation; presence of fluid collections adjacent to pancreatic stump, their content and major dimensions.

RESULTS

107 patients (51 males, 56 females; mean age 60 years) who underwent DP in our Institution from August 2018 to August 2020 were included. 91 patients (86%) were classified as grade 0 (30 patients -29%- had BL), 14 patients (12%) as grade B and 2

patients (2%) as grade C. Group C was too small to be analyzed significantly. 4 patients (3.7%) presented with inhomogenous pancreatic stump enhancement and MPD dilation, without correlation to ISGPF grade. 87 Patients (83%) had a FC one month after DP. No statistically significant correlation between POPF and the presence of FCs, collection signal intensity, inhomogeneity in T1 and T2 weighted sequences and FC size was found.

CONCLUSION

s Delayed FCs are a common finding after DPs. They do not correlate with the presence of POPF and their relevance is still unclear.

CLINICAL RELEVANCE/APPLICATION

The aim of this preliminary study is to investigate the features of different) delayed findings after pancreatic resections and their clinical relevance in patients' management. FCs are common postoperative findings and may persist for more than one month, but their clinical significance is unclear. Excluding a correlation between POPF and delayed FCs formation may help clinicians in the patient follow-up. Further multidisciplinary studies are required to describe which clinical symptoms and biochemical alterations could lead to delayed FCs development and their clinical importance.

R5A-SPGI-9 CT Texture-analysis of pancreatic adenocarcinoma after neo-adjuvant treatment: can we predict pathological response?

Participants
Giulia A. Zamboni, MD, Verona, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Standard imaging criteria for pancreatic adenocarcinoma (PDAC) have been demonstrated to perform poorly after neoadjuvant treatment in predicting resectability and response to treatment. Our purpose was to assess if texture analysis of CT images after neoadjuvant treatment can predict response at pathology.

METHODS AND MATERIALS

Standard imaging criteria for pancreatic adenocarcinoma (PDAC) have been demonstrated to perform poorly after neoadjuvant treatment in predicting resectability and response to treatment. Our purpose was to assess if texture analysis of CT images after neoadjuvant treatment can predict response at pathology. MM This is a retrospective study on patients collected in our institutional registry; informed consent for the utilization of clinical and radiologic data had been provided by all patients (PAD-R registry, n1101CESC). We included resected patients with histologically confirmed PDAC for which we had contrast-enhanced CT before and after neoadjuvant treatment, and for which the tumor regression grade (TRG) had been calculated on the resected specimen using three scores (Evans, CAP, MD Anderson). Two radiologists in consensus reviewed the scans for tumor size, location, margins, indirect signs (MPD, CBD dilation), vascular infiltration, resectability according to NCCN criteria, and overall disease assessment at post-NAT CT (response, stable disease, progression). One radiologist performed CT-Texture analysis on all post-NAT scans using commercially available software (LifeX) and derived first and second-order parameters. Texture parameters were compared with TRG scores by using ANOVA.

RESULTS

Qualitative imaging features and NCCN criteria were not correlated with TRG scores. TRG expressed by CAP was significantly correlated with asymmetry ($p<0.0001$), kurtosis ($p<0.0001$), and energy ($p<0.0430$). Energy was also significantly correlated with TRG according to the MD Anderson score ($p<0.0465$). Among the second-order features, only GLCM_entropy_log 10 was correlated with the CAP score ($p<0.0382$). No first or second-order parameter correlated with the Evans score.

CONCLUSION

s CT-derived texture parameters may correlate with tumor regression grade at pathology and therefore provide a preoperative noninvasive prediction of tumor response and, ultimately patient prognosis.

CLINICAL RELEVANCE/APPLICATION

a more accurate preoperative prediction of response to treatment could aid in better treatment selection, for example sparing from surgery patients who have not responded and whose prognosis would not be improved by resection

Multiparametric MRI for prediction of tumor response to systemic chemotherapy in pancreatic ductal adenocarcinoma

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Yoshihiko Fukukura, MD, PhD, Kagoshima, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Despite recent advances in diagnostic techniques, >80% of patients with PDAC are diagnosed at an advanced surgically unresectable stage and systemic chemotherapy is the mainstay of life-prolonging treatment. In recent years, neoadjuvant chemotherapy has emerged as a new alternative approach for patients with resectable diseases. Therefore, systemic chemotherapy is considered an essential first-line treatment for all stages of PDAC, in both the neoadjuvant and palliative settings. However, patients with PDAC respond differently to chemotherapy. There is a critical need for reliable predictive biomarkers to predict the treatment response is required for selecting the optimal therapeutic option. Therefore, this study aimed to identify multiparametric MRI biomarkers to predict the tumor response to chemotherapy in PDAC.

METHODS AND MATERIALS

This retrospective study included 81 consecutive patients (50 men, 31 women; mean age, 68.5 years; range, 47-83) with histologically confirmed PDAC who underwent multiparametric MRI including T1, T2, T2* mappings, diffusion-weighted imaging (DWI), and dynamic contrast-enhanced MRI (DCE-MRI) before gemcitabine-based first-line chemotherapy. T1, T2, and T2* relaxation times, apparent diffusion coefficient (ADC) obtained with DWI, and pharmacokinetic parameters (ktrans, kep, ve, and iAUC) calculated with DCE-MRI were measured using ROI measurements within PDAC. Clinical factors and multiparametric MRI parameters to predict the responders determined after the third cycle of gemcitabine-based chemotherapy and those to predict progression-free survival (PFS) and overall survival (OS) were evaluated using multivariable logistic regression and the Cox proportional hazard model.

RESULTS

Among the clinical factors and MRI parameters, tumor size and pharmacokinetic parameter (ve) of DCE-MRI were independent predictors for tumor response. The area under the receiver operating characteristic curve of combined use of the tumor size and pharmacokinetic parameter (ve) was 0.842 with a sensitivity of 78.8% and specificity of 79.2% (cut off, <26 mm for tumor size and <21% for ve). The pharmacokinetic parameter (ve) was also identified as one of the independent predictors for PFS and OS.

CONCLUSION

s Tumor pharmacokinetic parameters calculated with DCE-MRI may be useful to predict tumor response and survival in patients with PDAC receiving chemotherapy.

CLINICAL RELEVANCE/APPLICATION

DCE-MRI allows for the prediction of favorable tumor response and patient survival after chemotherapy.

Characterization of Non-alcoholic Fatty Liver Disease using Ultrasound Texture Parameters with Various Beamforming Sound Speeds

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Kibo Nam, PhD, Philadelphia, PA (*Presenter*) Equipment support, Canon Medical Systems Corporation;Equipment support, General Electric Company ;Support, Lantheus Medical Imaging;Research funded, Canon Medical Systems Corporation

PURPOSE

To investigate if ultrasound texture features extracted using various beamforming speed of sounds (SOSs) can improve the characterization of non-alcoholic fatty liver disease (NAFLD).

METHODS AND MATERIALS

Patients with suspected NAFLD undergoing liver biopsy or MRI-PDFF, have been prospectively enrolled. Subjects were imaged with a C1-6 probe on a Logiq E9 scanner (GE Healthcare). The radio-frequency data from subjects' right and left lobes were collected using 9 beamforming SOSs: 1300, 1350, 1400, 1450, 1500, 1540, 1600, 1650, and 1700 m/s and analyzed offline using Matlab (MathWorks). The texture parameters, i.e. contrast, correlation, energy, and homogeneity from gray-level co-occurrence matrix of normalized envelope were obtained from the liver parenchyma. The diagnostic accuracy of texture parameters from each beamforming SOS was assessed independently and in combination (using a generalized linear regression) by ROC analyses.

RESULTS

64 subjects were included in the analysis. 43 subjects were diagnosed of steatosis (27 by biopsy steatosis = 5% and 16 by MRI-PDFF = 6.5%) and 28 of them had fibrosis (grade 1-4). 21 subjects had no steatosis (7 by biopsy and 14 by MRI-PDFF) and 6 of them had fibrosis. In detecting steatosis, homogeneity showed the AUC of 0.73-0.82 and 0.58-0.81 for left and right lobes, respectively with varying beamforming SOSs. The combined homogeneity over 1300-1700 m/s from left and right lobes showed the AUC 0.92 and 0.84, respectively. Moreover, the combined homogeneity from left and right lobes over 1300-1700 m/s improved the AUC to 0.96. In detecting fibrosis, correlation showed the AUC of 0.52-0.60 and 0.50-0.70 for left and right lobes, respectively with varying beamforming SOSs. The combined correlation over 1300-1700 m/s from left and right lobes showed the AUC 0.77 and 0.80, respectively. Finally, the combination of correlation from left and right lobes over 1300-1700 m/s showed the AUC of 0.86. However, no independent or combined value differentiated all 4 groups, i.e., normal liver, steatosis only, fibrosis only, and steatosis with fibrosis.

CONCLUSION

s The diagnostic reliability of ultrasound texture parameter in NAFLD patients was improved with various beamforming SOSs.

CLINICAL RELEVANCE/APPLICATION

Ultrasound texture parameters extracted from the images acquired with various beamforming SOSs may improve the characterization of NAFLD.

Dual-energy CT with virtual monoenergetic images iodine maps improve tumor conspicuity in patients with pancreatic ductal adenocarcinoma

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Yongmei Li, Chongqing, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the value of monoenergetic images (MEI [+]) and iodine maps in dual-source dual-energy computed tomography (DECT) for assessing pancreatic ductal adenocarcinoma (PDAC), including the visually isoattenuating PDAC.

METHODS AND MATERIALS

Seventy-five patients with PDAC underwent contrast-enhanced DECT were retrospectively included in this study. Conventional polyenergetic image (PEI) and 40-80 keV MEI (+) (10-keV increments) were reconstructed. The tumor contrast, contrast-to-noise ratio (CNR) of the tumor and peripancreatic vessels, the signal-to-noise ratio (SNR) of the pancreas and tumor, and the tumor diameters were quantified. On iodine maps, the normalized iodine concentration (NIC) in the tumor and parenchyma were quantified and compared. For subjective analysis, two radiologists independently evaluated images on a 5-point scale.

RESULTS

All the quantitative parameters were maximized at 40-keV MEI (+) and decreased gradually with increasing energy. The tumor contrast, SNR of pancreas and CNRs in 40-60 keV MEI (+) were significantly higher than those in PEI ($p<0.05$). For visually isoattenuating PDAC, 40-50 keV MEI (+) provided significantly higher CNR of the tumor compared to PEI ($p<0.05$). The reproducibility in tumor measurements were highest in 40-keV MEI (+) between the two radiologists. The NIC value of tumor and parenchyma were 1.28±0.65 and 3.38±0.72 mg/mL, respectively ($p<0.001$). 40-50 keV MEI (+) provided the highest subjective scores for all criteria, compared to PEI ($p<0.001$).

CONCLUSION

s Low-keV MEI (+) of DECT substantially improve the subjective and objective image quality and tumor conspicuity in patients with PDAC. Combining the low-keV MEI (+) and iodine maps may be allowed for earlier diagnosis of PDAC.

CLINICAL RELEVANCE/APPLICATION

• Low-keV MEI (+) increases subjective and objective image quality compared with PEI in patients with PDAC.• Tumor conspicuity and reproducibility in tumor sizes were maximized at 40-keV MEI (+) in patients with PDAC.• Combining low-keV MEI (+) and iodine maps may achieve earlier diagnosis and thus improve PDAC prognosis.

Melisa Sia, FRCR, MBChB, (*Presenter*) Nothing to Disclose

PURPOSE

Pancreatic cancer (PC) often has a short time window for curative surgery. Missing PC on cross-sectional imaging (post imaging pancreatic cancer or PIPC) may therefore result in worse clinical outcomes in a cancer with already poor outcomes. We have undertaken root cause analysis of potentially missed PIPC to establish the most plausible explanations if imaging signs of PC were missed.

METHODS AND MATERIALS

Electronic records of adults diagnosed with PC between 2019-21 at two NHS providers were examined. PIPC was defined as a PC diagnosed 6 to 18 months after abdominal cross-sectional imaging (CT or MRI) that did not diagnose PC. The imaging that did not diagnose the PC and the later diagnostic imaging were reviewed by two radiologists independently. An algorithm was developed to categorise PIPC and identify the most plausible explanation.

RESULTS

Of 600 PC studied, 47 (7.8%) were categorised as PIPC. 47% of PIPC were located in the pancreatic head, 23.4% in the body, 21.3% in the body and tail, 6.40% in the head and neck and 2% in the entire pancreas. 44 CT and four MRI scans in PIPC patients performed within 6 to 18 months of PC diagnosis were reviewed. Of 44 CT scans reviewed, 15 were CT thorax abdomen and pelvis, 17 were CT abdomen and pelvis, 2 CT colons, 4 CT thorax, 2 CT Pancreas, 1 CT Urogram, 1 CT neck, thorax, abdomen and pelvis, 1 CT lumbar spine and 1 CT neck and thorax. 7 CT scans were without contrast. MRI scans were MRI liver, MRI renal, MRI abdomen and MRCP. PIPC were categorised as: Type 1 - missed PC lesion, imaging inadequate to exclude lesion (10.6%); Type 2 - missed PC lesion, adequate imaging and lesion visible on review - perceptual error (25.5%); Type 3 - PC associated abnormality detected (e.g. pancreatic or bile duct dilatation but no focal lesion) but inadequate follow up plan - management error (10.6%); Type 4 - PC associated abnormality detected, with adequate subsequent management, but still PIPC (12.8%); Type 5 - Genuine new PC lesion - no abnormality detected on initial imaging and imaging adequate to exclude lesion (40.4%). 36% of PIPC were considered potentially avoidable.

CONCLUSION

s This is the first study to undertake detailed root cause analysis of potentially missed PC on imaging. Missed opportunities to potentially avoid PIPC were identified in 36%.

CLINICAL RELEVANCE/APPLICATION

This root cause analysis system can standardize future investigation of PIPC and guide quality improvement efforts to improve outcomes in PC.

Predictors for Proton Density Fat Fraction (PDFF) Reduction in Patients Undergoing Very Low Calorie Liquid Diet in a Weight Loss Study

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Patricia Burns, MD, San Diego, CA (*Presenter*) Nothing to Disclose

PURPOSE

Nonalcoholic fatty liver disease (NAFLD) is the hepatic manifestation of metabolic syndrome. MRI-derived proton density fat fraction (PDFF) is a non-invasive quantitative imaging biomarker that depicts distribution of hepatic steatosis. It has been suggested that metabolic derangements are responsible for the rapid reduction of PDFF early in the intense caloric restriction and surgery treatment option. Previous studies have investigated the effect of intense caloric restriction on PDFF, however, predictors for the amount of PDFF reduction while undergoing intense caloric restriction are not known. Thus, the purpose of this study is to identify predictors for PDFF reduction during a low caloric liquid diet period in a Weight Loss Study population with obesity assigned to a caloric restriction model.

METHODS AND MATERIALS

Twenty-nine adults with obesity (26 female, 3 male, mean age 48 yrs) scheduled for bariatric surgery were recruited prospectively to participate in an ongoing pilot research study which includes collection of age, sex, BMI, waist/hip ratio (a marker of abdominal adiposity), lipid panel, and HbA1C. MR exams were performed on a 3T scanner (GE Signa Premier, or GE Discovery MR750, GE Healthcare, Waukesha WI) at baseline (visit 1) and 2-3 days prior to surgery (visit 2). Mean hepatic PDFF was calculated by a 9-ROI approach as previously described. Rates of PDFF change were estimated for each subject between visits 1 and 2. Bayesian Information Criterion (BIC)-based stepwise linear regression was used to search for baseline predictors of change for each of these periods. Clinical, serological, and imaging predictors were considered.

RESULTS

PDFF decreased (-2.849 PDFF%/month, $p<0.001$) from 9.64% to 6.66%. PDFF at baseline (regression coefficient = -0.56, $p < 0.001$) and waist/hip ratio at baseline (regression coefficient = 16.40, $p < 0.001$) were selected as best predictors of change during the diet period.

CONCLUSION

s PDFF decreased after a period of low caloric liquid diet. Prediction models support that baseline PDFF and waist/hip ratio are associated with rate of PDFF change. A higher baseline PDFF predicts a more rapid decline in PDFF, but a higher baseline waist/hip ratio predicts a slower decline of PDFF. This suggests that increased abdominal adiposity, as assessed by waist/hip ratio, may result in resistance to fat mobilization from the liver during intense caloric restriction. Further research is needed to validate our findings, ideally including populations with a more equal male:female distribution and less severe caloric restriction.

CLINICAL RELEVANCE/APPLICATION

Abdominal adiposity may be a marker of resistance to fat mobilization from the liver during intense caloric restriction weight loss.

R5A-SPGI-6

The value of constructing a nomogram model based on preoperative contrast-enhanced CT to predict R0 resection of pancreatic ductal adenocarcinoma

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Zhengxiao Li, (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the value of preoperative enhanced CT scan features combined with clinical features to construct a nomogram model to predict R0 resection of pancreatic ductal adenocarcinoma (PDAC).

METHODS AND MATERIALS

The preoperative contrast-enhanced CT imaging data of 106 patients with PDAC who were confirmed by surgery and pathology and whose resection margin status was evaluated from January 2015 to November 2021 in our hospital were retrospectively analyzed. According to the resection margin status, they were divided into R0 resection group and R1 resection group. . The preoperative CA199, CA125, CEA and other clinical data of the patients were analyzed; the tumor location, the transverse diameter of the tumor, and the maximum angle between the tumor and the surrounding blood vessels (T/arterial angle, T/portal vein angle, T/super mesenteric angle) were observed. Vein), peritumoral fat space, and lymph node metastasis. Then, univariate and multivariate Logistic regression was used to construct a nomogram model to predict the value of preoperative PDAC tumor R0 resection.

RESULTS

There were significant differences between the R0 resection group and the R1 resection group in tumor transverse diameter, CA199, CA125, CEA, T/arterial angle, T/portal vein angle, T/superior mesenteric vein and lymph node metastasis ($p<0.05$). Univariate and multivariate logistic regression analysis of lymph node metastasis [OR: 0.205 (CI: 0.043-0.972), $p < 0.05$], T/arterial angle [OR: 0.085 (CI: 0.017-0.434), $p < 0.01$], T /Portal vein angle [OR: 0.155 (CI: 0.031-0.783), $p < 0.05$], tumor diameter [OR: 1.073 (CI: 1.004-1.146), $p < 0.05$], CA199 [OR: 1.003 (CI: 1.001] -1.005), $p<0.01$] was an independent risk factor for R0 resection. The model constructed by multivariate logistic regression can effectively predict the R0 resection of PDAC tumors. The calibration curve shows that the predicted probability of the nomogram model can better fit the actual probability, and the calibration degree is high.

CONCLUSION

s Preoperative lower level of CA199, shorter tumor transverse diameter, T/arterial angle and T/portal vein angle <180°, and non-lymph node metastasis status were independent predictors of R0 resection of PDAC tumors, and the nomogram model can effectively Prediction of preoperative R0 resection status for PDAC tumors.

CLINICAL RELEVANCE/APPLICATION

To investigate the value of preoperative enhanced CT scan features combined with clinical features to construct a nomogram model to predict R0 resection of pancreatic ductal adenocarcinoma (PDAC).

Pancreatic neuroendocrine tumors: Correlation between dynamic contrast enhanced ultrasound and pathological tumor grades

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Yi Dong, MD, PhD, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

Tumor grade is one of the major prognostic factors for pancreatic neuroendocrine tumors' (pNETs). Pathologically, pNETs are classified into Grade 1 (G1), Grade 2 (G2), and Grade 3 (G3) tumors based on the Ki-67 proliferation index and the mitotic activity. Early differential diagnosis between G1 and G2/G3 is important on therapeutic strategy and survival duration. The aim of this study was to investigate whether the dynamic contrast enhanced ultrasound (D-CEUS) features with quantitative parameters could effectively predicting pNETs grades before operation according to WHO classification.

METHODS AND MATERIALS

This prospective study was approved by the institutional review board of our institution. Informed consent was waived before CEUS examination. Patients suspected of pNETs underwent D-CEUS of pancreas within one week prior to the surgery. Time intensity curves (TICs) were created and quantitative indexes of D-CEUS were analyzed. Patient demographics, CEUS findings, and quantitative parameters were compared to histopathological features using the Mann-Whitney U test. Diagnostic accuracy was assessed by ROC-AUC analysis, sensitivity and specificity were assessed for each quantitative parameter.

RESULTS

Finally, a total of 36 patients with histopathologically confirmed pNETs met the inclusion criteria, including 12 cases of G1, 16 cases of G2, and 8 cases of G3 patients. Compared with G1, G2/G3 pNETs showed ill-defined margin (62.5 %) and hypoenhancement during the late phase (41.6 %). Liver metastases were detected in 15 G2/G3 patients during the late phase scan of the whole liver. Among all CEUS quantitative indexes, area under curve (AUC) was significantly higher in G2/G3 pNETs with ROC-AUC 0.731, sensitivity 81.8 % (95 % CI: 62.2-91.3) and specificity 65.2 % (95 % CI: 43.7-80.1) ($P < 0.05$).

CONCLUSION

s D-CEUS analysis might be helpful in preoperative predicting tumor grades and liver metastases of pNETs. AUC is the potential D-CEUS parameter for identification of G2/G3 from G1 pNETs.

CLINICAL RELEVANCE/APPLICATION

Dynamic CEUS analysis and quantitative parameters could be used as non-invasive imaging method to predict tumor histological grades of pNETs.

R5A-SPGI-8

Correlations between POPF and delayed imaging findings in Patients who underwent Distal Pancreatectomy

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Giulia A. Zamboni, MD, Verona, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To analyze correlations between the presence of delayed fluid collections (FC) and postoperative pancreatic fistula (POPF), as defined by the International Study Group of Pancreatic Fistula (ISGPF), in patients who underwent Distal Pancreatectomy (DP).

METHODS AND MATERIALS

This is a IRB approved prospective study. Patients who underwent DP between 2018 and 2020 and had a contrast-enhanced postoperative MR 1 month after surgery were included. They were divided into 3 groups based on ISGPF grade: 0: no fistula; B: persistent drainage for more than 3 weeks, need for clinical management changes, percutaneous or endoscopic drainage, angiographic procedures for bleeding and development of signs of infection; C: reoperation, organ failure, death. Group 0 was further subdivided in patients without fistula and patients with biochemical leak (BL), who had drainage amylase >3 times the upper limit of normal serum amylase value. BL is not considered a fistula as no intervention is required to improve clinical outcome. Two readers in consensus analyzed the MRI scans and logged presence of: pancreatic enhancement inhomogeneity; main pancreatic duct (MPD) dilation; presence of fluid collections adjacent to pancreatic stump, their content and major dimensions.

RESULTS

107 patients (51 males, 56 females; mean age 60 years) who underwent DP in our Institution from August 2018 to August 2020 were included. 91 patients (86%) were classified as grade 0 (30 patients -29%- had BL), 14 patients (12%) as grade B and 2 patients (2%) as grade C. Group C was too small to be analyzed significantly. 4 patients (3.7%) presented with inhomogenous pancreatic stump enhancement and MPD dilation, without correlation to ISGPF grade. 87 Patients (83%) had a FC one month after DP. No statistically significant correlation between POPF and the presence of FCs, collection signal intensity, inhomogeneity in T1 and T2 weighted sequences and FC size was found.

CONCLUSION

s Delayed FCs are a common finding after DPs. They do not correlate with the presence of POPF and their relevance is still unclear.

CLINICAL RELEVANCE/APPLICATION

The aim of this preliminary study is to investigate the features of different) delayed findings after pancreatic resections and their clinical relevance in patients' management. FCs are common postoperative findings and may persist for more than one month, but their clinical significance is unclear. Excluding a correlation between POPF and delayed FCs formation may help clinicians in the patient follow-up. Further multidisciplinary studies are required to describe which clinical symptoms and biochemical alterations could lead to delayed FCs development and their clinical importance.

R5A-SPGI-9

CT Texture-analysis of pancreatic adenocarcinoma after neo-adjuvant treatment: can we predict pathological response?

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - GI DPS

Participants
Giulia A. Zamboni, MD, Verona, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Standard imaging criteria for pancreatic adenocarcinoma (PDAC) have been demonstrated to perform poorly after neoadjuvant treatment in predicting resectability and response to treatment. Our purpose was to assess if texture analysis of CT images after neoadjuvant treatment can predict response at pathology.

METHODS AND MATERIALS

Standard imaging criteria for pancreatic adenocarcinoma (PDAC) have been demonstrated to perform poorly after neoadjuvant treatment in predicting resectability and response to treatment. Our purpose was to assess if texture analysis of CT images after neoadjuvant treatment can predict response at pathology. MM This is a retrospective study on patients collected in our institutional registry; informed consent for the utilization of clinical and radiologic data had been provided by all patients (PAD-R registry, n1101CESC). We included resected patients with histologically confirmed PDAC for which we had contrast-enhanced CT before and after neoadjuvant treatment, and for which the tumor regression grade (TRG) had been calculated on the resected specimen using three scores (Evans, CAP, MD Anderson). Two radiologists in consensus reviewed the scans for tumor size, location, margins, indirect signs (MPD, CBD dilation), vascular infiltration, resectability according to NCCN criteria, and overall disease assessment at post-NAT CT (response, stable disease, progression). One radiologist performed CT-Texture analysis on all post-NAT scans using commercially available software (LifeX) and derived first and second-order parameters. Texture parameters were compared with TRG scores by using ANOVA.

RESULTS

Qualitative imaging features and NCCN criteria were not correlated with TRG scores. TRG expressed by CAP was significantly correlated with asymmetry ($p<0.0001$), kurtosis ($p<0.0001$), and energy ($p<0.0430$). Energy was also significantly correlated with TRG according to the MD Anderson score ($p<0.0465$). Among the second-order features, only GLCM_entropy_log 10 was correlated with the CAP score ($p<0.0382$). No first or second-order parameter correlated with the Evans score.

CONCLUSION

s CT-derived texture parameters may correlate with tumor regression grade at pathology and therefore provide a preoperative noninvasive prediction of tumor response and, ultimately patient prognosis.

CLINICAL RELEVANCE/APPLICATION

a more accurate preoperative prediction of response to treatment could aid in better treatment selection, for example sparing from surgery patients who have not responded and whose prognosis would not be improved by resection

Genitourinary Thursday Poster Discussions - A

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - GU DPS

Sub-Events

R5A-SPGU-1 The learning curve in bladder MRI using VIRADS assessment score during an interactive dedicated training program.

Participants
Emanuele Messina, MD, Roma, Italy (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of the study was to evaluate the effect of an interactive training program on the learning curve of radiology residents for bladder MRI interpretation using the VI-RADS score.

METHODS AND MATERIALS

Three radiology residents with minimal experience in bladder MRI served as readers. They blindly evaluated 200 studies divided into 4 subsets of 50 cases over a 3-month period. After 2 months, the first subset was reassessed, resulting in a total of 250 evaluations. An interactive training program was provided and included educational lessons and case-based practice. The learning curve was constructed by plotting mean agreement as the ratio of correct evaluations per batch. Inter-reader agreement and diagnostic performance analysis were performed with kappa statistics and ROC analysis.

RESULTS

As for the VI-RADS scoring agreement, the kappa differences between pre-training and post-training evaluation of the same group of cases were 0.555 to 0.852 for reader 1, 0.522 to 0.695 for reader 2, and 0.481 to 0.794 for reader 3. Using VI- RADS = 3 as cut-off for muscle invasion, sensitivity ranged from 84 to 89% and specificity from 91 to 94%, while the AUCs from 0.89 (95% CI:0.84, 0.94) to 0.90 (95% CI:0.86, 0.95). Mean evaluation time decreased from 5.21 ± 1.12 to 3.52 ± 0.69 min in subsets 1 and 5. Mean grade of confidence improved from 3.31 ± 0.93 to 4.21 ± 0.69, in subsets 1 and 5.

CONCLUSION

s An interactive dedicated education program on bladder MRI and the VI-RADS score led to a significant increase in readers' diagnostic performance over time, with a general improvement observed after 100-150 cases.

CLINICAL RELEVANCE/APPLICATION

These findings may represent a useful experience to improve and shape future fellowship programs and radiology curricula.

R5A-SPGU-2 Yield of second-round targeted multi-parametric MRI (mpMRI) Ultrasound (US) guided fusion prostate biopsy after initial first-round biopsy: factors associated with second-round clinically significant prostate cancer diagnosis

Participants
Yashmin Nisha, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To determine the yield of second-round mpMRI-US fusion biopsy and factors which may predict eventual clinically significant (CS) PCa diagnosis

METHODS AND MATERIALS

The retrospective cross-sectional study identified 940 men with MRI before prostate biopsy at a single institution from Jan 1 2013 to Dec 30 2021. 106 patients with negative MRI were excluded. 85 men underwent second-round mpMRI-US fusion biopsy of 92 lesions (47.8% [44/92] peripheral zone and 52.2% [48/92] transition zone). Patient age, PSA, PSA density (PSAD), PI-RADS score, size and location of lesions were retrieved and compared to histopathological diagnosis (any PCa and CS-PCa=Gleason Score =7 on target or on template biopsy) using multi-variate logistic regression.

RESULTS

Mean patient age, PSA, PSAD were: 64±7 years, 8.5±7.0 ng/mL, 0.17±0.11. Clinical indications were: active surveillance 21.2% (18/85), previous negative biopsy 42.4% (36/85) and 36.5% (31/85) biopsy naïve. Results from first-round targeted biopsy were: 63.0% (58/92) negative and 37.0% (34/92) Gleason 6 PCa. The time interval between first-round and second-round biopsy was 42 ± 1428 days. Second-round targeted biopsy identified 25.0% (23/92) CS-PCa (Gleason score 3+4=7 N=19, Gleason score 4+3=7 N=4) and an additional eight Gleason 3+3=6 PCa on targeted biopsy. Multivariate logistic regression showed no difference in age (p=0.101), psa (p=0.381), psad (p=0.268), PI-RADS score (p=0.491), size (p=0.235) or location (p=0.293) of lesions by eventual CS-PCa diagnosis.

CONCLUSION

s Repeat second-round targeted mpMRI-US fusion biopsy yielded clinically significant PCa diagnosis in the targeted biopsy specimen in approximately one-quarter of patients in our study. There was no variable which was significantly associated with second round CS-PCa diagnosis

CLINICAL RELEVANCE/APPLICATION

Clinically significant PCa diagnosed in approximately one-quarter of patients on repeat second-round targeted mpMRI-US fusion biopsy suggest the need for repeat biopsy.

R5A-SPGU-3 CT-based preoperative risk assessment of prolonged urine leak in patients undergoing partial nephrectomy for renal tumor

Participants
Hyojeong Lee, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate risk factors of prolonged urine leak following partial nephrectomy, in order to identify objective imaging characteristics on preoperative CT.

METHODS AND MATERIALS

865 patients who underwent partial nephrectomy for renal tumor were included. The RENAL nephrometry scoring system was used to characterize the CT features of renal tumor. Perioperative findings including ischemic time during the surgery and tumor pathology were compared between the groups with or without urine leak. As we intended to identify an imaging parameters other than tumor size and location, we set two fold tumor-size matched control group without urine leak, with all tumor located =4 mm to the collecting system. Four CT parameters that depicts the relationship of tumor and collecting system were analyzed; curvilinear border length, protruding distance, margin at the interface and pelvicalyceal contact. Multivariate logistic regression analyses were performed to identify significant predictors of urine leak. The sensitivity, specificity, and accuracy of significant variables were calculated.

RESULTS

53 of 865 patients (6.1%) demonstrated urine leak. The urine leak group had significantly larger tumor size (4.75 vs. 2.88 cm) and were more likely to have close proximity to renal sinus. The curvilinear border length and protruding distance were significantly longer in urine leak group (28.32 vs. 16.82 and 12.48 vs. 6.27, respectively). The frequencies of urine leak were higher with the tumor has non-smooth contact interface (18.9%) and direct pelvicalyceal contact (71.7%). In the multivariate analysis pelvicalyceal contact was the significant predictor of urine leak (OR = 2.612). Ischemic time was longer in the urine leak group (1423.0 vs. 1105.0 sec). Ischemic time was positively correlated with curvilinear border length, protruding distance and tumor size. For diagnostic accuracy, combined the CT parameters obtained AUC of 0.70 with a sensitivity of 58.5% and a specificity of 79.2%.

CONCLUSION

s The four preoperative CT features were significantly associated with increased risk of urine leak, and should be considered as predictor of urine leak before partial nephrectomy.

CLINICAL RELEVANCE/APPLICATION

A comprehensive preoperative imaging evaluation of the relationship between the tumor and renal sinus may provide advantages to select the optimal surgical options and afford better patient counselling of complication risk.

In the multivariate analysis pelvicalyceal contact was the significant predictor of urine leak (OR = 2.612). Ischemic time was longer in the urine leak group (1423.0 vs. 1105.0 sec). Ischemic time was positively correlated with curvilinear border length, protruding distance and tumor size. For diagnostic accuracy, combined the CT parameters obtained AUC of 0.70 with a sensitivity of 58.5% and a specificity of 79.2%.

CONCLUSION

s The four preoperative CT features were significantly associated with increased risk of urine leak, and should be considered as predictor of urine leak before partial nephrectomy.

CLINICAL RELEVANCE/APPLICATION

A comprehensive preoperative imaging evaluation of the relationship between the tumor and renal sinus may provide advantages to select the optimal surgical options and afford better patient counselling of complication risk.

R5A-SPHN-1 Ultra-sonographic Prediction of Tumor Invasiveness in Follicular Thyroid Carcinoma: Based on The WHO Classification and TERT Promoter Mutation

Participants
Myoung Kyoung Kim, seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to assess the role of ultrasound (US) in predicting tumor invasiveness in follicular thyroid carcinoma (FTC) based on the World Health Organization (WHO) classification and telomerase reverse transcriptase (TERT) promoter mutation.

METHODS AND MATERIALS

This retrospective study included 54 surgically confirmed FTC patients who underwent preoperative US and TERT mutation analysis. The WHO classification consisted of minimally invasive (MI-FTC), encapsulated angioinvasive (EA-FTC), and widely invasive (WI-FTC) types. The alternative classification was composed as follows: Group 1 (MI-FTC; EA-FTC with wild type [WT]-TERT), Group 2 (WI-FTC with WT-TERT), and Group 3 (EA-FTC with mutant [M]-TERT; WI-FTC with M-TERT). Each nodule was categorized based on the US pattern according to the K-TIRADS and ACR-TIRADS. For statistical analysis, the Jonckheere-Terpstra and Cochran-Armitage tests were used.

RESULTS

Among the 54 FTCs, there were 29 (53.7%) MI-FTCs, 16 (29.6%) EA-FTCs, and 9 (16.6%) WI-FTCs. The alternative classification included 42 (77.8%) Group 1, 5 (9.3%) Group 2, and 7 (13.0%) Group3. Neither benign nor low suspicion US category was assigned to WI-FTC and alternative groups 2 and 3. In both classification groups, lobulation, irregular margin, and final assessment category showed significant differences (all ps < 0.04) and incidences of lobulation, irregular margin, and high suspicion category had a trend to increase with the increasing tumor invasiveness (all ps for trend < 0.006). In the WHO groups, hypoechogenicity differed significantly among the groups ($p = 0.0112$) and tended to increase in proportion as tumor invasiveness increased (p for trend = 0.0145). Meanwhile, in the alternative groups, so did punctate echogenic foci ($p = 0.0256$, p for trend = 0.0245).

CONCLUSION

s Increasing tumor invasiveness in FTC based on the WHO classification and TERT promoter mutation is significantly correlated with the probability of displaying malignant US features using both K-TIRADS and ACR-TIRADS.

CLINICAL RELEVANCE/APPLICATION

A recent study proposed molecular marker-based risk stratification of FTC using TERT promoter mutations and WHO classification to better predict clinical outcome. Our study suggests that US prediction of tumor invasiveness in FTC is highly correlated with the WHO morphological classification as well as newly proposed TERT promoter mutation-based risk stratification.

R5A-SPHN-3 Risk Stratification of Thyroid Nodules Initially Diagnosed as Atypia/Follicular Lesion of Undetermined Significance Cytology with Thyroid Imaging Reporting and Data System, Cytology Subcategory, and Nodule Size

Participants
Hye Shin Ahn, MD, (*Presenter*) Nothing to Disclose

PURPOSE

To stratify the malignancy risk of thyroid nodules initially diagnosed as atypia/follicular lesion of undetermined significance (AUS/FLUS) cytology with Thyroid Imaging Reporting and Data System (TIRADS), cytology subcategory, and nodule size.

METHODS AND MATERIALS

This study included 320 consecutive nodules with final diagnoses among 504 thyroid nodules (= 1 cm) initially diagnosed as AUS/FLUS from January 2010 to December 2014. The malignancy risk was assessed according to US patterns by TIRADS (ATA guideline, KSThR(KT) guideline, AACE/ACE/AME guideline, ETA guideline, and ACR guideline), cytology subtype (AUS or FLUS), and nodule size. We investigated if TIRADS guidelines could predict malignancy at each cytology subcategory of AUS/FLUS nodules.

RESULTS

The overall malignancy rate was 20.6% (AUS, 22.4% and FLUS, 14.7%, $p = 0.145$). The large nodules (= 3 cm) showed a higher malignancy rate than small nodules (< 3 cm) in overall and AUS/FLUS subcategory nodule ($p = 0.057$). The malignancy rate of all nodules was significantly different in all of TIRADS guidelines ($p = 0.004$) and there was a trend towards an increasing malignancy

rate as the score of each guideline increased (p = 0.003). The malignancy rates of AUS nodules and FLUS nodules were significantly different according to the US pattern and there was a trend towards an increasing malignancy rate as the guideline score increased in both of AUS nodules and FLUS nodules except FLUS nodules in ETA and AACE guidelines. Malignancy was not found in KT3/FLUS, ATA3/FLUS, ETA3/FLUS, ACR3/FLUS nodules less than 3 cm, and the malignancy rate of large nodules (= 3 cm) was at least 16.7% in these guidelines.

CONCLUSION

s Malignancy risk can be stratified by TIRADS guidelines in both AUS and FLUS subcategory nodules. Small nodules (< 3 cm) diagnosed as FLUS on initial cytology with mild or low suspicious US feature could be managed conservatively with US follow-up.

CLINICAL RELEVANCE/APPLICATION

AUS/FLUS is represented by cytology that is not easily classified as benign, suspicious, or malignant. In a recent Bethesda system, the estimated malignancy risk of this category is 10% to 30% and repeat FNA, molecular test, or lobectomy was recommended for management, even though the nodule was benign. According to the result of this study, small FLUS nodules can be observed by follow-up US instead of further invasive diagnostic procedure.

R5A-SPIN-1 Fully Automated Volumetry of Living Donor Liver Transplantations Incorporating the Central Hepatic Vein

Participants
Sven Koitka, Essen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

For major liver resections and living donor liver transplantations, a pre-operative calculation of the liver volume is essential. The aim of this retrospective study was to develop a fully-automated, reproducible, and quantitative 3D volumetry of the right and left liver lobes from standard CT scans of the abdomen.

METHODS AND MATERIALS

In this work, a dataset consisting of 100 in-house contrast-enhanced venous phase CT scans for training, as well as 30 ex-house contrast-enhanced venous phase CT scans for testing, were collected. All CT images were resampled to a common slice thickness of 5mm and were annotated with background, right lobe, and left lobe labels. The training images were annotated only once, but the testing images were annotated by three experienced annotators and, additionally, a standard of reference (SoR) was derived for evaluation by employing a majority voting. Voxels with tie votes were marked with an ignore label and were not included in the metrics calculation. An ensemble of 3D Multi-resolution U-Nets was trained using 5-fold cross-validation.

RESULTS

When compared against the SoR annotations, the ensemble achieves a Sørensen-Dice coefficient of 0.9726 for the liver, 0.9639 for the right lobe, and 0.9223 for the left lobe on the ex-house test dataset. The mean volume differences are 32.12ml for the liver, 22.68ml for the right lobe, and 9.44ml for the left lobe.

CONCLUSION

s The developed system implements a fully automated, reproducible, fast, and accurate volumetry of right and left liver lobes.

CLINICAL RELEVANCE/APPLICATION

The fully automated liver volumetry can reduce the workload for radiologist while increasing the standardization and reproducibility of the volumetry for liver transplantations.

R5A-SPIN-2 Data Augmentation Can Cause Class Bias in Medical Image Classification

Participants
Hansang Lee, Daejeon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Data augmentation (DA) plays an important role in preventing overfitting for classifier learning by diversifying the amount and the pattern of the training data. However, it has recently been reported that the effect of DA on the computer vision task is not only class-dependent but also shows the class bias that decreases the classifier performance for some classes. We aim to observe whether the DA exhibits the class bias characteristics in the medical image classification tasks.

METHODS AND MATERIALS

To validate whether DA causes class bias, we used a dataset of 1290 CT liver lesion images consisting of 681 training, 302 validation, and 307 test images of 3 disease classes. In DA, we applied scaling, rotation, or translation DA with various parameters. In network training, we trained ResNet-18 CNN. From these trained networks, we observed the change in test accuracy and class-wise AUCs according to the selection of DA parameter. In order to verify that our observation is not limited to a specific dataset, we also perform experiments on the public ISIC skin lesion classification dataset.

RESULTS

In experiments, we observed that the trend of the test accuracy and the trends of class-wise performances according to the DA parameter do not match. This means that the DA with the best test accuracy does not guarantee the best performances in every class. In the CT dataset, the hemangiomas show different AUC trends from those of cysts, metastases, and the test accuracy. Thus, at the “optimal” DA with the best test accuracy, the AUC of hemangiomas is degraded by 2.05% lower than the best AUC of hemangiomas. In the ISIC dataset, the melanomas and the vascular lesions show opposite class sensitivity trends according to the DA parameters and the class bias on the melanomas was also observed at the “optimal” DA settings.

CONCLUSION

s We generally optimize the DA parameters by maximizing the accuracy of the entire validation data. This is based on the assumption that the effect of the DA will appear nearly uniformly for the entire data. However, we observed that the effect of DA improved the performance of only some class data or even reinforced the class bias by decreasing the performance of other classes. Our observation suggests two future directions. First, we need to optimize DA by considering the performance of each class as well as the accuracy of the entire data. Second, it can be helpful to design a novel DA technique that applies different levels of transformation for each class. (This work was supported by the National Research Foundation of Korea grant funded by the Korea government (MSIT) (No. 2020R1A2C1102140))

CLINICAL RELEVANCE/APPLICATION

Our observation and discussions are expected to be valid for other medical image classification problems and other DA techniques.

R5A-SPIN-3 Application Of Artificial Intelligence for Evaluation Of Neuroradiology Emergencies; Clinical Workflow

Participants
Delaram Shakoor, MD, (*Presenter*) Nothing to Disclose

PURPOSE

The goal of this study was to assess the user-interface of radiologists with an artificial-intelligence (AI) algorithm to detect intracranial hematoma (ICH) and cervical spine fracture (CSFX).

METHODS AND MATERIALS

Over 12 month period, positive consecutive head and cervical spine CTs performed at our institution were reviewed and user-interaction data with our AI algorithm (AiDOC) were obtained. These interaction variables were extracted (Figure 1): Notification Image Review (NIR), representing the number of scans in which the key image of a positive notification was reviewed on the desktop application, upon receiving the prioritization notification. Panel image review (PIR) was defined as the number of positive scans which was reviewed by a reader from the main panel. Positive dictated cases (PDC) represented the number of positive notifications which were received by the readers upon interpreting the positive study. Positive reviewed cases (PRC) were the number of positive studies which dictating reader reviewed the key image of a positive case from the notification. Usage variable was defined as division of PRC over the PDC to evaluate the usage of Aidoc key images by the reader.Wilcoxon-Mann-Whitney test was used to compare median and interquartile range (IQR) of interaction variables. Linear and binary logistic regressions were performed to assess for presence of factors associated with higher usage.

RESULTS

Data from interactions of 86 residents, 19 neuroradiology fellows, 36 ED and 15 neuroradiology attendings were collected. All interactions except for usage (ICH: median: 28.8%, IQR:34.3%; CSFX: median:21.8%, IQR:62.5%, P-value=0.9) were significantly higher for head CT (Figure 2). Linear regression did not show any statistically significant association between usage and scan type (Coefficient: 2.18, 95% CI: -4.7, 9.1, P-value 0.6), trainees versus attendings (Coefficient: -1.8, 95%CI: -9.3, 5.6, P-value=0.6), ED versus neuroradiology (Coefficient: -5.8, 95% CI: -12.9, 1.3, P-value:0.1). Comparing the interactions of trainees versus attendings for head CTs, median of PDC was significantly higher for faculty (Trainee: median:16, IQR:31; Faculty: median:40, IQR:63, P-value:0.004) while the remaining interactions were not statistically significantly different. No significant difference was noted between ED and neuroradiology attendings.

CONCLUSION

s The results of our preliminary study imply that approximately two third of our readers don’t interact with Aidoc while interpreting head and cervical spine CTs.

CLINICAL RELEVANCE/APPLICATION

Further studies with survey analysis are recommended to recognize the reasons for low interactions and means to increase radiologist interface with AI in a busy radiology practice.

R5A-SPIN-4 Pretraining using Masked Image Reconstruction Improves Deep Learning Performance in Disease Classification and Segmentation

Participants
Joseph Bae, MS, BS, Chino Hills, CA (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning (DL) analysis in medical imaging suffers from the absence of large datasets for model pretraining analogous to those for natural images (eg: ImageNet). To improve computational modeling of small medical image datasets, self-supervised training can be utilized to improve feature learning. Here we analyze Masked Autoencoder (MAE) self-pretraining to improve medical segmentation and classification performance. Self-pretraining refers to the pretraining of a DL network on the same dataset studied in downstream classification/segmentation tasks. By self-pretraining a Vision Transformer (ViT) to reconstruct images after masking a subset of regions in the original image, we hypothesize that the model will learn to exploit the regional interdependencies inherent to anatomical structures and the physiological environments that they cohabitate.

METHODS AND MATERIALS

We applied MAE self-pretraining to 3 common medical imaging tasks using public datasets. The ChestX-ray14 (CXR14) dataset was studied for thoracic disease classification, the Multi-Atlas Labeling Beyond the Cranial Vault (BTCV) was studied for organ segmentation, and the Brain Tumor Segmentation (BRATS) dataset was studied for tumor segmentation. CXR14 contains 112,120 frontal CXRs, BTCV contains 30 abdominal CT scans, and BRATS contains 484 multi-sequence brain MRIs. For MAE self-pretraining, CXRs were split into 16x16 pixel patches. CTs and MRIs were split into 16x16x16 voxel patches. For each dataset, a fraction of image patches were masked and input into a ViT. A decoder was trained to reconstruct whole images from ViT outputs. After the completion of self-pretraining, the VIT was used for dataset-specific downstream tasks in either classification (CXR14) or segmentation (BTCV, BRATS). Performance was compared with state of the art (SOTA) approaches. Classification and segmentation performance were assessed using AUC and dice score (DSC), respectively.

RESULTS

A masked patch ratio of 12.5% was found to be optimal for the downstream tasks. CXR14 classification yielded an AUC of 81.5% (SOTA: 80.7%). BTCV abdominal organ segmentation resulted in a DSC of 83.5 (SOTA: 79.7). BRATS brain tumor segmentation resulted in a DSC of 78.9% (SOTA: 77.8).

CONCLUSION

s MAE self-pretraining can improve image classification and segmentation tasks for a variety of imaging modalities and anatomical sites. MAE enforces the learning of spatial relationships between anatomical regions and can improve performance on datasets as small as N=30.

CLINICAL RELEVANCE/APPLICATION

MAE self-pretraining can be leveraged for the analysis of pathologies and images that might be too rare or costly for large-scale data collection while also achieving clinically impactful performance.

R5A-SPIN-5 MAGIC: Multitask Synthesis of Contrast-free CT Perfusion Maps via Generative Adversarial Network

Participants
Garrett Fullerton, BS, Gainesville, FL (*Presenter*) Nothing to Disclose

PURPOSE

CTP is a popular imaging modality used to evaluate the micro circulatory structures of the brain and is commonly used in the detection of abnormalities in the brain parenchyma. Contrast imaging is generally safe, but it can present adverse side effects with increased procedure time and monetary cost. Here, we introduce a multi-task automated generation framework (MAGIC) model for contrast-free CTP brain imaging generation via physiology-inspired deep learning. By applying this framework, we predict contrast-free CTP maps with only non-contrast CT (NCCT) comparable to those generated by commercial software from contrast-enhanced images.

METHODS AND MATERIALS

Neuroimaging data were retrospectively retrieved from 12,186 (7.76 TB) patients at UF Health between 2013 and 2020 with Institutional Review Board approval. The perfusion studies were conducted using iodinated contrast injection, and the collected data were analyzed using RAPID CT Perfusion analysis software (iSchemaView, Menlo Park, CA., USA), termed as "RAPID" below. Subjects with both NCCT imaging and RAPID-generated perfusion maps were included, resulting in 493 subjects. 431 subjects were selected for training and the remainder were reserved for testing. Model MAGIC was implemented using PyTorch v1.5.0 in Python v3.6.10 and NVIDIA CUDA v7.6.5. Model MAGIC was trained for 50 epochs on an NVIDIA TITAN X GPU.

RESULTS

Three experienced radiologists evaluated MAGIC- and RAPID-generated CTP maps from 62 subjects in a double-blinded fashion via a 4-part questionnaire. Raters determined that there was no physiologically distinguishable difference between the synthetic and real CTP maps ($p<0.05$) and found 81% accuracy in diagnostic outcomes in the synthetic and real CTP maps. The further quantitative evaluation confirmed the high structural fidelity between the synthetic and real CTP maps It was determined that the MAGIC-generated CTP maps were both physiologically and diagnostically acceptable and consistent.

CONCLUSION

s The proposed framework MAGIC can generate contrast-free brain perfusion imaging from solely non-contrast, structural imaging that exhibits comparable analytical and diagnostic results to the ground-truth perfusion imaging, reducing the time, cost, and patient risk associated with CTP brain imaging.

CLINICAL RELEVANCE/APPLICATION

The proposed artificial intelligence (AI) model enables the diagnostically competitive synthesis of CT perfusion (CTP) maps from non-contrast-enhanced imaging alone, reducing the cost, time, and radiation dose associated with perfusion imaging.

Data Augmentation Can Cause Class Bias in Medical Image Classification

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - IN DPS

Participants
Hansang Lee, Daejeon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Data augmentation (DA) plays an important role in preventing overfitting for classifier learning by diversifying the amount and the pattern of the training data. However, it has recently been reported that the effect of DA on the computer vision task is not only class-dependent but also shows the class bias that decreases the classifier performance for some classes. We aim to observe whether the DA exhibits the class bias characteristics in the medical image classification tasks.

METHODS AND MATERIALS

To validate whether DA causes class bias, we used a dataset of 1290 CT liver lesion images consisting of 681 training, 302 validation, and 307 test images of 3 disease classes. In DA, we applied scaling, rotation, or translation DA with various parameters. In network training, we trained ResNet-18 CNN. From these trained networks, we observed the change in test accuracy and class-wise AUCs according to the selection of DA parameter. In order to verify that our observation is not limited to a specific dataset, we also perform experiments on the public ISIC skin lesion classification dataset.

RESULTS

In experiments, we observed that the trend of the test accuracy and the trends of class-wise performances according to the DA parameter do not match. This means that the DA with the best test accuracy does not guarantee the best performances in every class. In the CT dataset, the hemangiomas show different AUC trends from those of cysts, metastases, and the test accuracy. Thus, at the "optimal" DA with the best test accuracy, the AUC of hemangiomas is degraded by 2.05% lower than the best AUC of hemangiomas. In the ISIC dataset, the melanomas and the vascular lesions show opposite class sensitivity trends according to the DA parameters and the class bias on the melanomas was also observed at the "optimal" DA settings.

CONCLUSION

s We generally optimize the DA parameters by maximizing the accuracy of the entire validation data. This is based on the assumption that the effect of the DA will appear nearly uniformly for the entire data. However, we observed that the effect of DA improved the performance of only some class data or even reinforced the class bias by decreasing the performance of other classes. Our observation suggests two future directions. First, we need to optimize DA by considering the performance of each class as well as the accuracy of the entire data. Positive reviewed cases (PRC) were the number of positive studies which dictating reader reviewed the key image of a positive case from the notification. Usage variable was defined as division of PRC over the PDC to evaluate the usage of Aidoc key images by the reader.Wilcoxon-Mann-Whitney test was used to compare median and interquartile range (IQR) of interaction variables. Linear and binary logistic regressions were performed to assess for presence of factors associated with higher usage.

RESULTS

Data from interactions of 86 residents, 19 neuroradiology fellows, 36 ED and 15 neuroradiology attendings were collected. All interactions except for usage (ICH: median: 28.8%, IQR:34.3%; CSFX: median:21.8%, IQR:62.5%, P-value=0.9) were significantly higher for head CT (Figure 2). Linear regression did not show any statistically significant association between usage and scan type (Coefficient: 2.18, 95% CI: -4.7, 9.1, P-value 0.6), trainees versus attendings (Coefficient: -1.8, 95%CI: -9.3, 5.6, P-value=0.6), ED versus neuroradiology (Coefficient: -5.8, 95% CI: -12.9, 1.3, P-value:0.1). Comparing the interactions of trainees versus attendings for head CTs, median of PDC was significantly higher for faculty (Trainee: median:16, IQR:31; Faculty: median:40, IQR:63, P-value:0.004) while the remaining interactions were not statistically significantly different. No significant difference was noted between ED and neuroradiology attendings.

CONCLUSION

s The results of our preliminary study imply that approximately two third of our readers don’t interact with Aidoc while interpreting head and cervical spine CTs.

CLINICAL RELEVANCE/APPLICATION

Further studies with survey analysis are recommended to recognize the reasons for low interactions and means to increase radiologist interface with AI in a busy radiology practice.

Pretraining using Masked Image Reconstruction Improves Deep Learning Performance in Disease Classification and Segmentation

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - IN DPS

Participants
Joseph Bae, MS, BS, Chino Hills, CA (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning (DL) analysis in medical imaging suffers from the absence of large datasets for model pretraining analogous to those for natural images (eg: ImageNet). To improve computational modeling of small medical image datasets, self-supervised training can be utilized to improve feature learning. Here we analyze Masked Autoencoder (MAE) self-pretraining to improve medical segmentation and classification performance. Self-pretraining refers to the pretraining of a DL network on the same dataset studied in downstream classification/segmentation tasks. By self-pretraining a Vision Transformer (ViT) to reconstruct images after masking a subset of regions in the original image, we hypothesize that the model will learn to exploit the regional interdependencies inherent to anatomical structures and the physiological environments that they cohabitate.

METHODS AND MATERIALS

We applied MAE self-pretraining to 3 common medical imaging tasks using public datasets. The ChestX-ray14 (CXR14) dataset was studied for thoracic disease classification, the Multi-Atlas Labeling Beyond the Cranial Vault (BTCV) was studied for organ segmentation, and the Brain Tumor Segmentation (BRATS) dataset was studied for tumor segmentation. CXR14 contains 112,120 frontal CXRs, BTCV contains 30 abdominal CT scans, and BRATS contains 484 multi-sequence brain MRIs. For MAE self-pretraining, CXRs were split into 16x16 pixel patches. CTs and MRIs were split into 16x16x16 voxel patches. For each dataset, a fraction of image patches were masked and input into a ViT. A decoder was trained to reconstruct whole images from ViT outputs. After the completion of self-pretraining, the VIT was used for dataset-specific downstream tasks in either classification (CXR14) or segmentation (BTCV, BRATS). Performance was compared with state of the art (SOTA) approaches. Classification and segmentation performance were assessed using AUC and dice score (DSC), respectively.

RESULTS

A masked patch ratio of 12.5% was found to be optimal for the downstream tasks. CXR14 classification yielded an AUC of 81.5% (SOTA: 80.7%). BTCV abdominal organ segmentation resulted in a DSC of 83.5 (SOTA: 79.7). BRATS brain tumor segmentation resulted in a DSC of 78.9% (SOTA: 77.8).

CONCLUSION

s MAE self-pretraining can improve image classification and segmentation tasks for a variety of imaging modalities and anatomical sites. MAE enforces the learning of spatial relationships between anatomical regions and can improve performance on datasets as small as N=30.

CLINICAL RELEVANCE/APPLICATION

MAE self-pretraining can be leveraged for the analysis of pathologies and images that might be too rare or costly for large-scale data collection while also achieving clinically impactful performance.

R5A-SPIN-5

MAGIC: Multitask Synthesis of Contrast-free CT Perfusion Maps via Generative Adversarial Network

Thursday, Dec. 1 12:15PM - 12:45PM Room: Learning Center - IN DPS

Participants
Garrett Fullerton, BS, Gainesville, FL (*Presenter*) Nothing to Disclose

PURPOSE

CTP is a popular imaging modality used to evaluate the micro circulatory structures of the brain and is commonly used in the detection of abnormalities in the brain parenchyma. Contrast imaging is generally safe, but it can present adverse side effects with increased procedure time and monetary cost. Here, we introduce a multi-task automated generation framework (MAGIC) model for contrast-free CTP brain imaging generation via physiology-inspired deep learning. By applying this framework, we predict contrast-free CTP maps with only non-contrast CT (NCCT) comparable to those generated by commercial software from contrast-enhanced images.

METHODS AND MATERIALS

Neuroimaging data were retrospectively retrieved from 12,186 (7.76 TB) patients at UF Health between 2013 and 2020 with Institutional Review Board approval. The perfusion studies were conducted using iodinated contrast injection, and the collected data were analyzed using RAPID CT Perfusion analysis software (iSchemaView, Menlo Park, CA., USA), termed as "RAPID" below. Subjects with both NCCT imaging and RAPID-generated perfusion maps were included, resulting in 493 subjects. 431 subjects were selected for training and the remainder were reserved for testing. Model MAGIC was implemented using PyTorch v1.5.0 in Python v3.6.10 and NVIDIA CUDA v7.6.5. Model MAGIC was trained for 50 epochs on an NVIDIA TITAN X GPU.

RESULTS

Three experienced radiologists evaluated MAGIC- and RAPID-generated CTP maps from 62 subjects in a double-blinded fashion via a 4-part questionnaire. Raters determined that there was no physiologically distinguishable difference between the synthetic and real CTP maps ($p<0.05$) and found 81% accuracy in diagnostic outcomes in the synthetic and real CTP maps. The further quantitative evaluation confirmed the high structural fidelity between the synthetic and real CTP maps It was determined that the MAGIC-generated CTP maps were both physiologically and diagnostically acceptable and consistent.

CONCLUSION

s The proposed framework MAGIC can generate contrast-free brain perfusion imaging from solely non-contrast, structural imaging that exhibits comparable analytical and diagnostic results to the ground-truth perfusion imaging, reducing the time, cost, and patient risk associated with CTP brain imaging.

CLINICAL RELEVANCE/APPLICATION

The proposed artificial intelligence (AI) model enables the diagnostically competitive synthesis of CT perfusion (CTP) maps from non-contrast-enhanced imaging alone, reducing the cost, time, and radiation dose associated with perfusion imaging.

R5A-SPIR-1 Imaging Implications of Extracellular Matrix Stiffness on Liver Cancer Vascular Phenotypes

Participants
Ryosuke Taiji, MD, Kashihara, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Interplay between liver tumor stiffness and microvascular phenotypes has not been fully elucidated. The goal of this study is to characterize impact of matrix stiffness signatures on vascular histology and dynamic contrast-enhancement imaging in a rat HCC model.

METHODS AND MATERIALS

Buffalo-McA-RH7777 (n=12) and Sprague Dawley-N1S1 (n=8) tumor models were used to evaluate tumor stiffness by shear wave elastography (SWE), along with tumor perfusion by dynamic CEUS and CECT. Atomic force microscopy (AFM) was used to calculate tumor stiffness at a sub-micron scale. Computer-aided image analyses were performed using Aperio-microvessel and GENIE pattern-recognition algorithms. Arbitrary 2(au) and Hounsfield units (HU) were used for peak intensity or attenuation, respectively. Pearson product-moment correlation coefficient, linear mixed model, and Wilcoxon signed-rank were used to evaluate pairwise correlations and differences between models.

RESULTS

Results of linear mixed model showed distinct tissue signatures between models according to the distribution of the stiffness values ($P<0.05$). Higher stiffness values were attributed to SD-N1S1 tumors, with a positive coefficient for AFM ($P = 0.048$) and marginally significant for SWE ($P= 0.07$), using AFM as reference. The stiffer N1S1 model was associated with scant microvascular network and with mean % of CD34+microvessel coverage of 2.9±1.2 compared to 8.7±1.6 in McA-RH7777 ($P=0.001$). Moreover, a higher % of vessels were located on the tumor periphery compared to tumor center ($P=0.03$). Opposite results were observed in McA-RH7777 model, exhibiting richer tumor vasculature with predominantly central distribution ($P=0.02$). Consistently with these findings, tumor enhancement was significantly greater in McA-RH7777 tumors than N1S1 on both CEUS ($P=0.014$) and CECT (HU increase; $P=0.003$, AUCarterial; $P<0.001$; AUCtotal au*s; $P=0.02$ and HU*s; $P<0.001$). Significant positive correlation between tumor perfusion and % microvessel coverage was observed (CEUS;$P=0.043$ and CECT;$P=0.006$). Enhancement features were closely correlated with between CEUS and CECT; $P<0.05$

CONCLUSION

s Stiffness signatures translated into different tumor vascular phenotypes. These differences displayed unique imaging perfusion parameters with significantly greater contrast enhancement observed in softer McA-RH7777 tumors

CLINICAL RELEVANCE/APPLICATION

Matrix stiffness represents a barrier to effective drug delivery and can negatively impact the outcome of local treatments. Elastography can provide helpful information about the tumor microenvironment, particularly the matrix and its modification by stromal cells

R5A-SPIR-2 Percutaneous Combined Chemical and Mechanical Necrosectomy for Walled-Off Pancreatic Necrosis: A Retrospective Analysis

Participants
Kamyar Ghabili, MD, New Haven, CT (*Presenter*) Nothing to Disclose

PURPOSE

The management of walled-off pancreatic necrosis (WOPN) as a complication of acute necrotic pancreatitis necessitates a multidisciplinary step-up approach. However, the current level of evidence for percutaneous necrosectomy by interventional radiology in treating WOPN is limited. We aimed to study the feasibility, safety, and efficacy of percutaneous combined chemical and mechanical necrosectomy using a Malecot anchor drain and Arrow-Trerotola Percutaneous Thrombolytic device in patients with WOPN by comparing the results with a historical control group.

METHODS AND MATERIALS

In a retrospective analysis, patients with pancreatitis complicated by WOPN not amenable to endoscopic-guided cystogastrostomy were studied in case and historical control groups. Patients in the case group underwent percutaneous combined chemical (using hydrogen peroxide) and mechanical necrosectomy using the Malecot anchor drain and/or Arrow-Trerotola percutaneous thrombolytic device from December 2020 through September 2021. The controls underwent mechanical necrosectomy alone without chemical necrosectomy. Clinical success was defined as complete resolution of the cavity on follow up sinogram or noncontract CT

scans with subsequent drain removal.

RESULTS

Thirteen patients (median age, 40 years; 11 men) in the case group and 11 control patients (median age, 60 years; 10 men) underwent CT or US guided percutaneous drain placement followed by percutaneous combined chemical and mechanical necrosectomy (case group) or mechanical necrosectomy only (control group) for WOPN. Drain placement and necrosectomy were technically successful in all studied patients. One case patient developed bleeding from a small branch of the jejunal artery on post-necrosectomy day 9, which was successfully embolized by interventional radiology. No pancreaticocutaneous fistula was reported on 3-month follow-up of our patients. The clinical success rate in the case and control groups was 100% and 38.4%, respectively (p=0.002).

CONCLUSION

s Percutaneous combined chemical and mechanical necrosectomy performed by interventional radiology is a feasible, safe, and effective treatment approach of WOPN.

CLINICAL RELEVANCE/APPLICATION

Percutaneous chemical plus mechanical necrosectomy using Malecot catheter and Arrow-Trerotola thrombolytic device is a feasible, safe and effective treatment of walled-off pancreatic necrosis.

R5A-SPIR-3 The Bariatric Embolization of Arteries with Imaging Visible Embolics (BEATLES) Trial: Pilot Phase

Participants
Adham Khalil, MD, Baltimore, MD (*Presenter*) Research Grant, Siemens AG

PURPOSE

To evaluate the feasibility, safety and efficacy of bariatric artery embolization (BAE) in patients with obesity using customized tightly calibrated 100-200µm radiopaque embolic microspheres, "BTG-001933" (Biocompatibles UK Ltd).

METHODS AND MATERIALS

BEATLES is an IRB and FDA-approved physician-initiated investigational device exemption prospective clinical trial. The pilot phase of this study started in October 2020, with 10 participants currently enrolled. Key inclusion criteria include: age 21-70 years, BMI =35 kg/m2 and weight =400 lb. Absolute exclusion criteria include: taking hypoglycemic agents (except metformin), inability to undergo MRI, allergy to iodinated contrast and renal insufficiency. After initial screening, participants have a six-week "run-in" to complete pre-BAE screening for psychiatric disorders and dietary coaching. Eligible participants undergo a rapid whole-body MRI for volumetric measurement of body adiposity, and an upper endoscopy with gastric mucosal biopsy to rule out pathologies such as peptic ulcer disease or gastritis, which may exclude them from the study.Seven participants (6 women and 1 man; mean age 39.7±10.5 years) with obesity who underwent BAE were included in the preliminary analysis. Participants were followed up for 12 months after embolization. Changes in body weight and BMI at 1, 3, 6, and 12-months follow-up as well as the 30-day adverse events (AEs) were recorded. Feasibility was assessed based on ability to visualize the microspheres under fluoroscopy and extent of embolic fundal coverage on post-procedural MDCT.

RESULTS

In seven participants, the LGA (n=7), with or wiout the gastroepiploic artery (GEA; n=4), was embolized, with a 100% technical success rate. There were no major AEs. One minor AE (mucosal ulcer) was observed and healed at 5-month endoscopy. All participants were admitted for routine supportive care for <48 hours post-BAE. Pre-procedural mean weight was 124.6±21.2 kg and mean BMI 42.7±4.5 kg/m2. Table 1 shows the changes in body weight and BMI at different follow-ups.

CONCLUSION

s BAE using customized tightly calibrated radiopaque 100-200µm microspheres "BTG-001933" is feasible and appears to be well tolerated by participants with severe obesity. Preliminary analysis of weight loss outcomes demonstrates promising efficacy.

CLINICAL RELEVANCE/APPLICATION

BEATLES is the first clinical study to evaluate using "BTG-001933", a novel customized tightly caliberated radiopaque micropsheres of the 100-200µm size, for bariatric artery embolization.

R5A-SPIR-4 Ethanol Embolization Combined or Not with Surgery and Close Clinical Follow-up Can Effectively Control Extracranial Arterio-venous Malformations (AVMS)

Participants
Ke Chen, MD, (*Presenter*) Nothing to Disclose

PURPOSE

Arteriovenous malformations (AVM) are congenital high flow lesions that have a wide range of clinical manifestations, varying from asymptomatic to high-output heart failure. We looked at the long-term outcome of patients with extra-cranial AVMs following different types of treatment.

METHODS AND MATERIALS

A retrospective study was performed, collecting data on all cases of proven extracranial AVMs at two university hospitals from 1985 to 2021. We documented whether the patient received conservative, endovascular, surgical, or combined treatments. The clinical response of treatments was assessed using the Schobinger's classification. Our primary endpoint was to evaluate evolution of Schobinger class in patients of our cohort.

RESULTS

A total of 190 proven cases of extracranial AVMs were included in the study. Mean follow up time was 7.0 years [0.0-28.0 years]. The mean Schobinger stage was 2.11 at baseline and 1.32 at final follow-up (p<0.001). For the cohort, 52 patients were treated conservatively, 104 patients received endovascular treatment alone, 3 patients received surgical treatment alone, and 31 patients

received combined therapy. Overall, 71 patients (37%) achieved complete remission of the disease, 34 patients (18%) achieved improvement of symptoms, 81 patients (42%) remained stable, and 4 patients (2%) worsened. No clinical worsening was observed in the 52 patients (Schobinger stage 1-2) that did not receive any endovascular or surgical treatment.

CONCLUSION

s Ethanol embolization with or without surgery is efficient for long term control of extracranial AVMs. We observed that not all patients evolve from Schobinger stage 1-2 to a further stage, and clinical observation without treatment can be suitable and appropriate for asymptomatic patients.

CLINICAL RELEVANCE/APPLICATION

Since extracranial AVMs are rare, there is a lack of empirical evidence in the literature to assess if ethanol embolization with or without surgery can successfully and safely achieve lifelong control of extracranial AVMs. It was also thought that all these lesions inevitably progress with time. Our study is demonstrates the effectiveness and safety of ethanol embolization to treat extracranial AVMs. We also show that not all patients with AVMs evolve to a further stage.
